The clinical spectrum of gonorrhea differs substantially in men and women (Figure 30–8). In men, the primary site of infection is the urethra. Symptoms begin 2 to 7 days after infection and consist primarily of purulent urethral discharge and dysuria. Although uncommon, local extension can lead to epididymitis or prostatitis. The endocervix is the primary site in women, in whom symptoms include increased vaginal discharge, urinary frequency, dysuria, abdominal pain, and menstrual abnormalities. As mentioned previously, symptoms may be mild or absent in either sex, particularly women.

▪ Other Local Infections

Rectal, pharyngeal infections relate to sexual practices

Rectal gonorrhea occurs after rectal intercourse or, in women, after contamination with infected vaginal secretions. This condition is generally asymptomatic, but may cause tenesmus, discharge, and rectal bleeding. Pharyngeal gonorrhea is transmitted by oral–genital sex and, again, may be asymptomatic. Sore throat and cervical adenitis may occur. Infection of other structures near primary infection sites, such as Bartholin glands in women, may lead to abscess formation.

Transmission at birth causes ophthalmia neonatorum

Inoculation of gonococci into the conjunctiva produces a severe, acute, purulent conjunctivitis. Although this infection may occur at any age, the most serious form is gonococcal ophthalmia neonatorum, a disease acquired during childbirth by a newborn from an infected mother. The disease was formerly a common cause of blindness, which is now prevented by the administration of

prophylactic topical eye drops or ointment (erythromycin or tetracycline) at birth.

▪ Pelvic Inflammatory Disease

* Salpingitis, peritonitis cause scarring, infertility

The clinical syndrome of pelvic inflammatory disease (PID) develops in 10% to 20% of women with gonorrhea. The findings include fever, lower abdominal pain (usually bilateral), adnexal tenderness, and leukocytosis with or without signs of local infection. These features are caused by spread of organisms along the fallopian tubes to produce salpingitis and into the pelvic cavity to produce pelvic peritonitis and abscesses (**Figure 30–9**). PID is also known to develop when other genital pathogens ascend by the same route. These organisms include anaerobes and *Chlamydia trachomatis*, which may appear alone or mixed with gonococci. The most serious complications of PID are infertility and ectopic pregnancy secondary to scarring of the fallopian tubes.

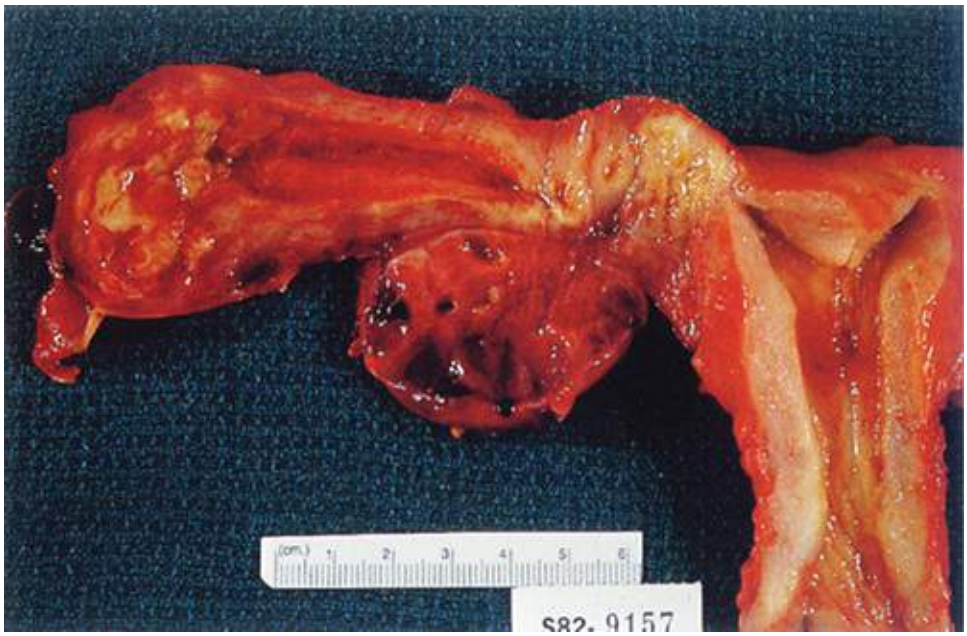

FIGURE 30–9. Tubo-ovarian abscess. This large abscess in the fallopian tube is part of the spectrum of pelvic inflammatory disease (PID) of which *Neisseria gonorrhoeae* is a major cause. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Think ▸▸ Apply 30-2: The primary culprit is antigenic variation of

the primary virulence factors. Whatever immune response is mounted finds a changed pathogen even during the course of a single infection. Any effective vaccine would have to use a highly conserved pilin or OMP epitope.

▪ Disseminated Gonococcal Infection

Skin rash, arthralgia, and arthritis with bacteremia

Purulent arthritis in large joints

Any of the local forms of gonorrhea or their extensions such as PID may lead to bacteremia. In the bacteremic DGI phase, the primary features are fever, migratory polyarthralgia, and a petechial, maculopapular, or pustular rash. Some of these features may be immunologically mediated. Gonococci are infrequently isolated from the skin or joints at this stage despite their presence in the blood. The bacteremia may lead to metastatic infections such as endocarditis and meningitis, but the most common is purulent arthritis. The arthritis typically follows the bacteremia and involves large joints such as elbows and knees. Gonococci are readily cultured from the pus.

DIAGNOSIS

▪ Gram Smear

*** Smear diagnostic in men**

The presence of multiple pairs of bean-shaped, Gram-negative diplococci within a neutrophil is highly characteristic of gonorrhea when the smear is from a genital site (Figure 30–1). The direct Gram smear is more than 95% sensitive and specific in symptomatic men. Unfortunately, it is only 50% to 70% sensitive in women, and its specificity is complicated by the presence of other bacteria in the female genital flora that have similar morphology. A positive Gram smear is generally accepted as diagnostic in men. It should not be used as the sole source for diagnosis in women or when the findings have social (divorce) or legal (rape, child abuse) implications.

▪ Culture

Urethra, cervix preferred culture sites

ML agar inhibits competing flora

Attention to detail is necessary for isolation of the gonococcus because it is a fragile organism that is often mixed with hardier members of the genital flora. In men, the best specimen is urethral exudate or urethral scrapings (obtained with a loop or special swab). In women, cervical swabs are preferred over urethral or vaginal specimens. Rectal cultures in men and throat cultures are needed only when indicated by sexual practices. The selective medium (eg, Martin-Lewis agar) is an enriched selective chocolate agar with antibiotics active against Gram-positive bacteria (vancomycin), Gram-negative bacteria (colistin, trimethoprim), and fungi (nystatin).

▪ Direct Detection

NAA methods sensitive and specific

Gonococci and *Chlamydia* combined

Much effort has been directed at developing immunoassay and NAA methods that detect gonococci in genital and urine specimens without culture. Such methods have particular importance for screening populations in which culture is impractical. After a series of improvements NAA methods are now considered the diagnostic standard. NAA results are considered diagnostic from genital sites (including urine) but may need to be confirmed by culture from other sites. The cost/benefit ratio of NAA tests has been improved by combining them with *Chlamydia* detection (see Chapter 39), which targets the same clinical population.

TREATMENT

GC and Chlamydia treated together

IM ceftriaxone

Penicillin, which once was active against all known gonococci at extremely low concentrations (less than 0.1 μg/mL), is no longer used due to the development of multiple mechanisms of resistance. Third-generation cephalosporins resistant

to the β-lactamases prevalent in gonococci are now the standard. In addition, it is now recommended that all patients treated for gonorrhea also be treated for *Chlamydia* infection. For gonorrhea, ceftriaxone is given in a single intramuscular injection. Until late 2020, oral azithromycin, which is also effective against *Chlamydia*, was added to follow the ceftriaxone dose but has now been dropped in favor of a higher dose of ceftriaxone. Resistance rates up to 25% have taken fluoroquinolones out of the picture.

PREVENTION

Condoms block transmission

Condoms provide a high degree of protection against both infection with *N gonorrhoeae* and transmission to a sexual partner. Spermicides and other vaginal foams and douches are not reliable protection. The classic public health methods of case–contact tracing and treatment are important but difficult because of the size of the infected population. The availability of a good serologic test would greatly aid control, as it has for syphilis. Although candidate immunogens continue to be studied, the development of a vaccine is a high but distant goal.

KEY CONCLUSIONS

- *Neisseria gonorrhoeae* is more fastidious than *N meningitis* and lacks a capsule.
- Gonorrhea is sexually transmitted.
- Pili and outer membrane proteins (OMPs) mediate attachment and invasion of urethral and cervical epithelial cells.
- Intense inflammation typically extends only locally (fallopian tubes, epididymis) not systemically.
- Pelvic inflammatory disease (PID), ectopic pregnancy and sterility are consequences in women.
- Antigenic variation of pili and OMPs confounds lasting immunity, vaccine strategies.
- Nucleic acid amplification methods have replaced culture for definitive diagnosis.
- Emergence of β-lactamase-mediated resistance requires treatment with ceftriaxone.

CASE STUDY

Recruit with Fever, Backache, and Rash

A 20-year-old man presented to the emergency room because of fever and backache. A basic trainee on leave from a naval training station, he was perfectly well until the day of admission when he awakened with fever, malaise, and lumbar backache, all of which gradually worsened over the ensuing 6 hours.

Examination revealed an acutely ill man with blood pressure of 105/65 mm Hg, pulse rate 120/min, and temperature 104°F. A few small petechiae were on the volar surfaces of each forearm. The muscles of the back, arms, and legs were tender to palpation. The remainder of the examination was normal. A lumbar puncture showed 1500 white blood cells/mL, 95% of which were PMNs. CSF cultures were obtained.

QUESTIONS

1. Which factor would most influence the likely etiologic agents?

A. Height of fever
B. Number of PMNs in CSF
C. Immunization status
D. Extent of petechiae
E. Prior antibiotics

2. What is the primary cause of the patient's petechiae?

A. Superantigen production
B. Pore-forming toxin
C. Endotoxin
D. Pili
E. OMPs

3. In addition to culture of the CSF, culture of what other site would be most valuable?

A. Throat
B. Sputum
C. Petechiae
D. Blood

4. If the CSF cultures are positive for *N meningitidis*, is any preventive action appropriate for the man's contacts?

A. Conjugate vaccine for family
B. Conjugate vaccine for healthcare workers
C. Chemoprophylaxis for family
D. Chemoprophylaxis for healthcare workers
E. No action required

ANSWERS

chapter 31

Haemophilus and *Bordetella*

Haemophilus influenzae • *Haemophilus ducreyi* • *Bordetella pertussis*

Whooping cough—why, he nearly whooped himself to death.

—Rosa Nouchette Carey: *Uncle Max* (1887)

OVERVIEW

Haemophilus and *Bordetella* are small, Gram-negative rods that tend to assume a coccobacillary shape. Members of both genera contain species exclusively found in humans and cause respiratory tract infections. The major species are *Haemophilus influenzae*, the cause of acute purulent meningitis, and *Bordetella pertussis*, the cause of whooping cough. *H influenzae* type b (Hib) produces acute, life-threatening infections of the central nervous system, epiglottis, and soft tissues, primarily in children. Disease begins with fever and lethargy, and in the case of acute meningitis, can progress to coma and death in less than 1 day. In affluent countries, Hib disease has been controlled by immunization. *H influenzae* also produces common but less fulminant infections of the bronchi, respiratory sinuses, and middle ear; the latter are usually associated with nonencapsulated strains. Pertussis is a prolonged illness caused by toxins produced by *Bordetella pertussis* bacteria attached to the cilia of respiratory epithelial cells. It progresses in stages over many weeks, beginning with rhinorrhea (runny nose), and evolving into a persistent paroxysmal cough lasting weeks more. The term “whooping cough” comes the inspiratory “whoop” made by children after an exhausting series of retching coughs. Pertussis vaccine has reduced disease incidence in developed countries, but vaccine modifications to reduce febrile seizures have led to important reductions in effectiveness.

HAEMOPHILUS

Tiny Gram-negative coccobacilli

Haemophilus are among the smallest of bacteria. The curved ends of the short (1.0-1.5 µm) bacilli make many appear nearly round; hence the term coccobacilli (**Figure 31–1**). The cell wall has a structure similar to that of other Gram-negative bacteria. The most virulent strains of *H influenzae* have a

polysaccharide capsule, but other species of *Haemophilus* are not encapsulated.

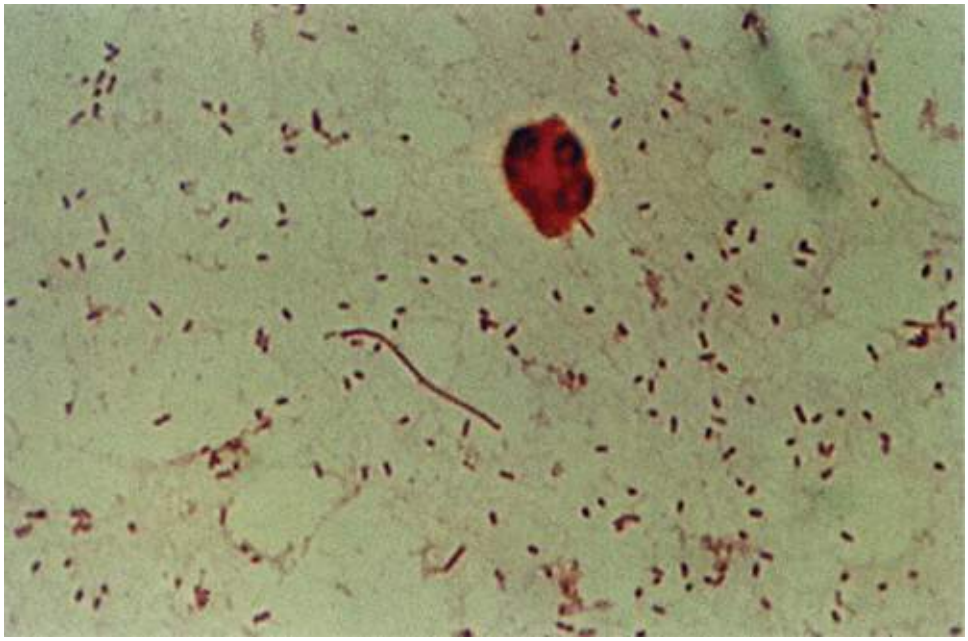

FIGURE 31–1. *Haemophilus influenzae* Gram stain. The Gram-negative bacilli are small and so short that some appear almost round. This is the basis of the term coccobacilli. The morphology of *Bordetella pertussis* is the same. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

*** Require hematin and/or NAD**

***Staphylococcus aureus* may provide NAD**

Non-*influenzae Haemophilus* species similar to nonencapsulated *H influenzae*

Cultivation of *Haemophilus* (Greek *haema*, blood, and *philos*, loving) species requires the use of culture media enriched with blood or blood products for optimal growth. This requirement reflects bacterial need for exogenous hematin and/or nicotinamide adenine dinucleotide (NAD). These growth factors, also termed X factor (hematin) and V factor (NAD), are present in erythrocytes. In culture media, optimal concentrations are not available unless the red blood cells are lysed by gentle heat (chocolate agar) or added separately as a supplement. Although erythrocytes are the only convenient source of hematin, sufficient amounts of NAD may be provided by certain other bacteria and yeasts. This is responsible for the "satellite phenomenon," in which colonies of *Haemophilus* have been observed to grow only in the vicinity of a colony of *Staphylococcus aureus.* The several species of *Haemophilus* are defined by their

requirement for hematin and/or NAD, dependence on CO_2, and other growth-related characteristics (**Table 31-1**). Species of *Haemophilus* other than *H influenzae* (eg, *H parainfluenzae*, associated with some cases of endocarditis) have the same biology described below for the nonencapsulated strains of *H influenzae.*

TABLE 31–1 Features of *Haemophilus* and *Bordetella*

SPECIES	TYPE	GROWTH REQUIREMENT	CAPSULE	ADHERENCE FACTORS	TOXINS	EPIDEMIOLOGY	DISEASE
Haemophilus							
H influenzae	a–f	Hematin and NAD	Polysaccharide	Pili, HMW	—	Microbiota, respiratory droplet spread	Meningitis, epiglottitis, arthritis, sepsis, otitis media
H influenzae	—	Hematin and NAD	—	Pili, HMW	—	Microbiota, respiratory droplet spread	Otitis media, bronchitis, sinusitis
H ducreyi	—	Hematin	—	Pili	Cytolethal distending toxin	Sexual contact	Chancroid
Other species[a]	—	Hematin or NAD	—	—	—	Microbiota	Bronchitis, endocarditis
Bordetella							
B pertussis	—	Nicotinamide[b]	—	Pili, FHA, PT, pertactin	PT, AC, TCT	Strict pathogen, respiratory droplet spread	Whooping cough
B bronchiseptica	—	Nicotinamide	—	Pili, FHA	AC, TCT	Dogs, rabbits, swine	Kennel cough, rhinitis
B parapertussis	—	Nicotinamide	—	Pili, FHA	AC, TCT	Minor cause of pertussis	Whooping cough (mild)

HMW, high-molecular-weight proteins (HMW1, HMW2); FHA, filamentous hemagglutinin; PT, pertussis toxin; AC, adenylate cyclase; TCT, tracheal cytotoxin
[a]*H parainfluenzae, H aphrophilus, H hemolyticus.*
[b]Also requires additives such as charcoal to neutralize toxicity in standard media.

• *Haemophilus influenzae*

BACTERIOLOGY

Six serotypes based on capsular polysaccharide

*** Hib capsule is PRP**

Haemophilus that meets the species requirements for *H influenzae* may or may not have a capsule. Those that do are divided into six serotypes, a through f, based on the capsular polysaccharide antigen. The type b capsule comprises a

polymer of ribose, ribitol, and phosphate, called **polyribitol phosphate (PRP)**. These surface polysaccharides are strongly associated with virulence, particularly in *H influenzae* type b (**Hib**). The surface of *H influenzae* features pili and an outer membrane similar to the structure of other Gram-negative bacteria. The outer membrane includes high molecular weight proteins (HMW1, HMW2), lipopolysaccharide (LPS), and lipooligosaccharides (LOS). The nonencapsulated, and thus nontypable, *H influenzae* (NTHi) can be classified by various typing schemes based on outer membrane proteins (OMPs) and other factors. *H influenzae* produces no known exotoxins.

HAEMOPHILUS INFLUENZAE DISEASE

EPIDEMIOLOGY

*** Nasopharyngeal colonization common**

*** Meningitis in children under 2 years**

H influenzae is a strictly human pathogen and has no known animal or environmental sources. It can be found in the nasopharyngeal flora of 20% to 80% of healthy persons, depending on age, season, and other factors. Most of these are NTHi, but encapsulated strains (including Hib) are not rare. Spread is by respiratory droplets, as with streptococci. Before the introduction of effective vaccines, approximately 1 in every 200 children developed invasive disease by the age of 5 years; meningitis was the most common invasive form and most often attacked those under 2 years of age. Cases of epiglottitis and pneumonia tended to peak in the 2- to 5-year age group. More than 90% of these cases were due to a single serotype, Hib.

*** Immunization (where implemented) has dramatically reduced disease**

The introduction of universal immunization with the Hib protein conjugate vaccine (see Prevention) has reduced invasive disease rates by 99%. Most of the cases in immunized populations are now caused either by serotypes other than b or nonencapsulated strains. Evidence suggests a steady increase in infections

worldwide due to nonencapsulated strains, primarily targeting perinatal infants, young children, and the elderly. And as before, in countries and populations unable to afford the vaccine, Hib disease continues.

Prophylaxis limits person-to-person spread

At one point in time, *H influenzae* that caused meningitis were believed to be isolated, endogenous infections, but reports of outbreaks in closed populations and careful epidemiologic studies of secondary spread in families have changed this view. The risk of serious infection for unimmunized children younger than 4 years of age living with an index case is more than 500-fold than for unexposed children. This risk indicates a need for protection of susceptible contacts with postexposure antibiotic prophylaxis (see Prevention).

PATHOGENESIS

▪ Invasive Disease

* Encapsulated strains more invasive

Certain clones account for most disease

For unknown reasons, *H influenzae* strains commonly found in the microbiota of the nasopharynx occasionally invade deeper tissues. Bacteremia then enables spread to the central nervous system and metastatic infections at distant sites, such as bones and joints (**Figure 31–2**). These events seem to take place within a short period (<3 days) after an encounter with a new virulent strain. Systemic spread is typical only for encapsulated *H influenzae* strains, and more than 90% of invasive strains exhibit type b capsule. Even among Hib strains there are distinct clones, which account for approximately 80% of all invasive disease worldwide.

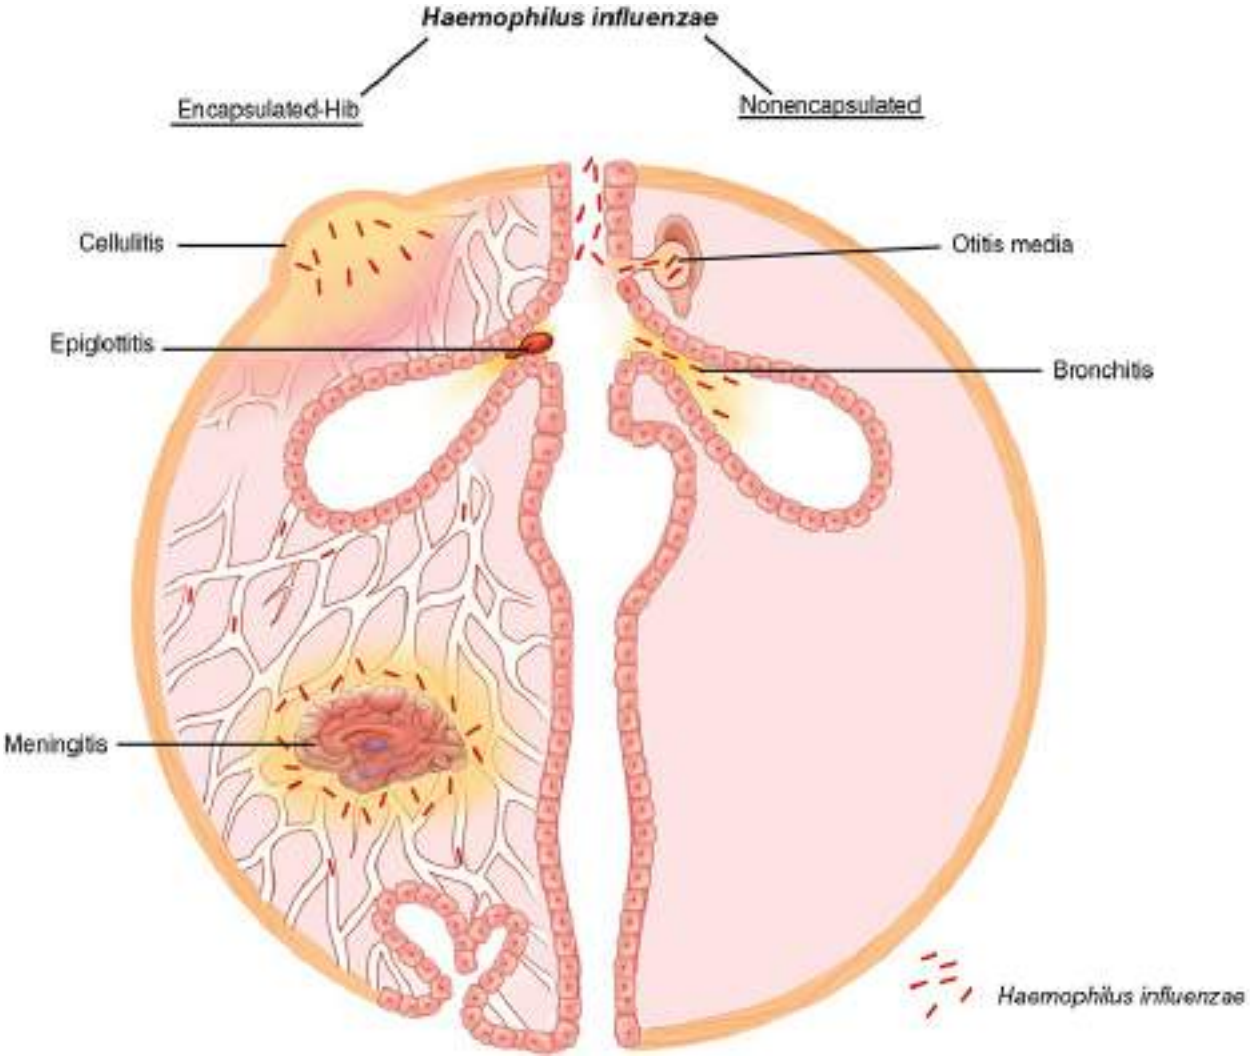

FIGURE 31–2. *Haemophilus* disease overview. (*Left*) Invasive disease is caused by encapsulated strains, mostly type b (Hib). From a nasopharyngeal colonization site, the organisms invade locally to produce cellulitis or epiglottitis. Invasion of the blood occurs in all Hib diseases and can lead to meningitis. (*Right*) Localized disease is produced when nonencapsulated strains from the nasopharynx are trapped in the middle ear, paranasal sinuses or compromised bronchi.

*** Capsule prevents phagocytosis**

Pili, other adhesins bind to epithelial cells

Invasion goes between cells

Attachment to respiratory epithelial cells is mediated by pili and OMPs. Evidence suggests that this depends on a complex regulatory cascade, coordinating capsular biosynthesis and adherence factors that act cooperatively in establishing the microbe within susceptible hosts. *H influenzae* can be seen to

invade between the cells of the respiratory epithelium (**Figure 31–3**), and for a time resides between and below them. Once past the mucosal barrier, the antiphagocytic capsule confers resistance to C3b deposition in the same manner as it does for other encapsulated bacteria. As with pathogenic *Neisseria*, there is evidence that *H influenzae* LOS may provide an antiphagocytic effect by binding host components such as sialic acid. Outer membrane LOS is toxic to ciliated respiratory cells, and when circulating in the bloodstream, produces all the features of endotoxemia.

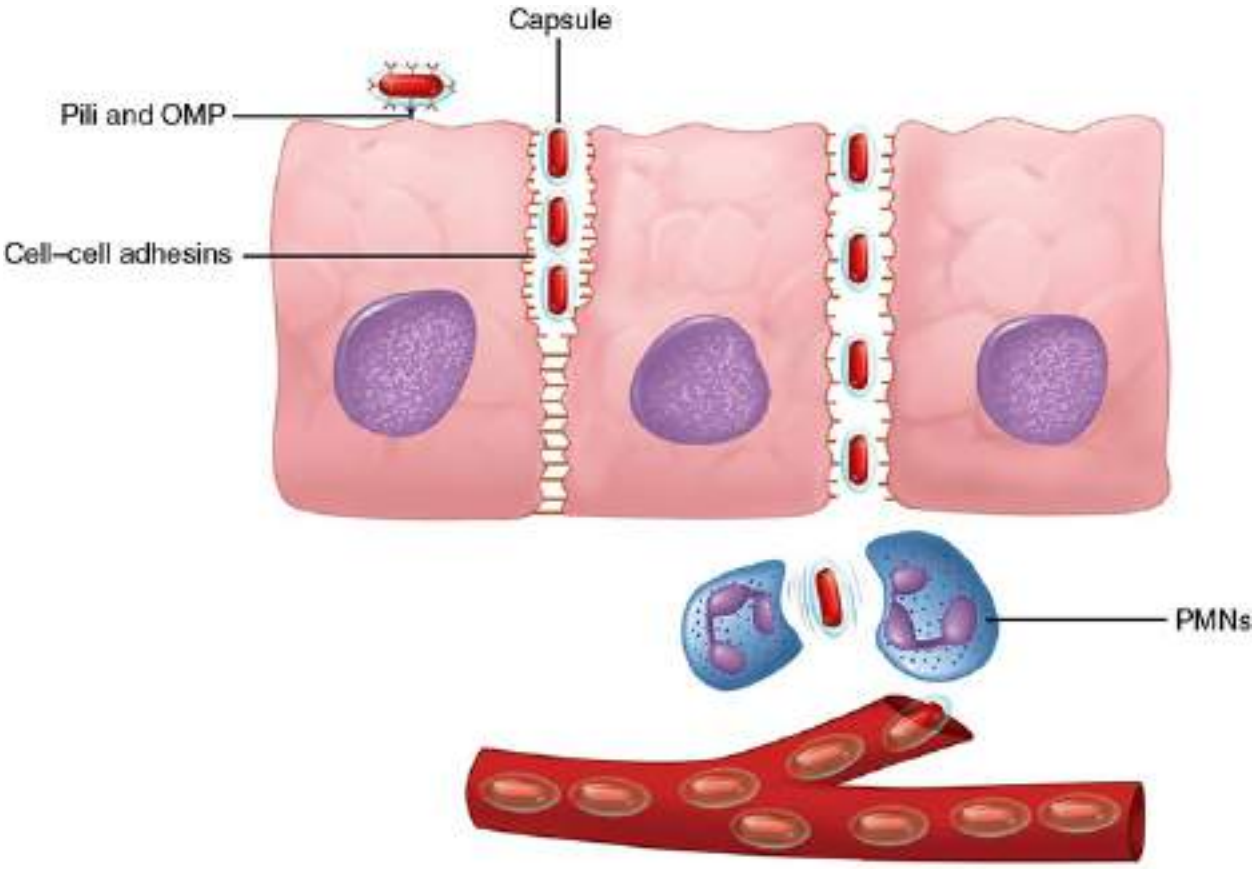

FIGURE 31–3. ***Haemophilus influenzae*** **disease, cellular view.** Organisms attach to epithelial cells using pili and outer membrane proteins (OMP). Invasion takes place between cells by disruption of cell–cell adhesion molecules. In the submucosa, the capsule allows the bacteria to evade phagocytosis and enter the bloodstream. PMNs, polymorphonuclear neutrophils.

▪ Localized Disease

NTHi trapped in middle ear, sinuses, bronchi produce localized infections

Adherence by pili, OMPs, other proteins

NTHi produce disease under circumstances in which they are entrapped at a luminal site adjacent to the respiratory microbiota, such as the middle ear, sinuses, or bronchi (Figure 31–2), usually when normal clearing mechanisms have been disrupted, for example by a viral infection or structural damage. NTHi attach to bronchial epithelial cells and laminin using pili, OMPs, and other proteins. Consistent with their relative prevalence in the respiratory tract, NTHi account for more than 90% of localized *H influenzae* disease, particularly otitis media, sinusitis, and exacerbations of chronic bronchitis.

IMMUNITY

*** Anticapsular antibody is bactericidal and protective**

*** Hib infections occur at ages when antibody is absent**

Immunity to Hib infections has long been associated with the presence of anticapsular (PRP) antibodies, which are bactericidal in the presence of complement. The infant is usually protected by passively acquired maternal antibody for the first few months of life. Thereafter, actively acquired antibody increases with age; it is present in the serum of most children by 10 years of age. The peak incidence of Hib infections in unimmunized populations occurs at 6 to 18 months of age, when serum antibody is least likely to be present. This inverse relationship between infection and serum antibody is similar to that for *Neisseria meningitidis* (see Figure 30–4). The major difference is that substantial immune protection is provided by antibody directed against a single serotype (Hib) rather than the multiple types of other encapsulated bacteria, such as *N meningitidis* and *S pneumoniae*. Thus, systemic *H influenzae* infections (meningitis, epiglottitis, cellulitis) are rare in adults, but where such infections develop, the immunologic deficit is typically the same as that with meningococci—lack of type-specific circulating antibody.

FIGURE 31–4. The swollen epiglottis characteristic of *Haemophilus influenzae* acute epiglottitis. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

*** T-cell–independent PRP response poor at less than 18 months**

*** Protein conjugate vaccines elicit protective T-cell responses**

Like other polysaccharides, Hib PRP behaves as a T-cell–independent antigen. Antibody responses to immunization are poor in children younger than 18 months of age, and boosters do not elicit significant secondary responses. The conjugation of PRP to protein dramatically improved immunogenicity by eliciting T-cell–dependent responses while preserving the specificity for PRP, and this maneuver represented a significant breakthrough in vaccine immunology in the 1980s.

HAEMOPHILUS INFLUENZAE DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

Of the major acute Hib infections, meningitis accounts for just over 50% of cases; the remaining cases involve pneumonia, epiglottitis, septicemia, cellulitis,

and septic arthritis. Localized infections can be caused by encapsulated strains including Hib, but most are caused by NTHi.

▪ Meningitis

Acute purulent meningitis follows sinusitis, otitis media

Mortality, neurologic sequelae significant

Hib meningitis follows the same pattern as other causes of acute purulent bacterial meningitis. The initial signs and symptoms may be those of an upper respiratory infection, such as pharyngitis, sinusitis, or otitis media; whether these represent a predisposing viral infection or early invasion by the organism is not known. Just as often, meningitis is preceded by vague malaise, lethargy, irritability, and fever. Mortality is 3% to 6% despite appropriate therapy, and roughly one-third of all survivors have significant neurologic sequelae.

▪ Acute Epiglottitis

*** Cherry-red, swollen epiglottis and stridor are hallmarks**

*** Attention to airway maintenance critical**

Acute epiglottitis is a dramatic infection in which the inflamed epiglottis and surrounding tissues obstruct the airway; Hib is one of several causes. Onset is sudden, with fever, sore throat, hoarseness, an often muffled cough, and rapid progression to severe prostration within 24 hours. Affected children have air hunger, inspiratory stridor, and retraction of the soft tissues of the chest with each inspiration. The hallmark of the disease is an inflamed, swollen, cherry-red epiglottis that protrudes into the airway (**Figure 31–4**) and can be visualized on lateral X-rays. As with meningitis, this infection must be treated as a medical emergency, with primary emphasis on maintenance of a patent airway (by tracheostomy or endotracheal intubation) and antimicrobial therapy. Clinical maneuvers such as direct examination or attempting to take a throat swab may trigger acute obstruction and fatal laryngospasm.

▪ Cellulitis and Arthritis

*** Cellulitis is usually facial**

Arthritis involves large joints

A tender, reddish-blue swelling in the cheek or periorbital areas is the usual presentation of Hib cellulitis. This picture may follow an upper respiratory infection or otitis media; fever and a moderately toxic state are usually present. Joint infection begins with fever, irritability, and local signs of inflammation, often in a single large joint. *Haemophilus* arthritis is occasionally the cause of a more subtle set of findings in which fever occurs without clear clinical evidence of joint involvement. Bacteremia is often present in both cellulitis and arthritis.

▪ Other Infections

*** Nonencapsulated strains are common in otitis media, sinusitis, and bronchitis**

Pneumonia may arise in damaged airways

Haemophilus influenzae is an important cause of conjunctivitis, otitis media, and acute and chronic sinusitis. It is also one of several common respiratory organisms that can cause and exacerbate chronic bronchitis. Most of these infections are caused by NTHi strains and remain localized without bacteremia. Disease may be acute or chronic, depending on the anatomic site and underlying pathology. For example, otitis media is acute and painful because of the small, closed space involved, but after antimicrobial therapy and reopening of the eustachian tube, the condition usually clears without sequelae. The association of *H influenzae* with chronic bronchitis is more complex. There is evidence to suggest that *H influenzae* and other bacteria play a role in inflammatory exacerbations, but a direct cause-and-effect relationship has been difficult to prove. The underlying cause of the bronchitis is usually related to chronic damage resulting from factors such as smoking. *Haemophilus* pneumonia may be caused by either encapsulated or nonencapsulated organisms. Encapsulated strains have been observed to produce a disease much like pneumococcal pneumonia; however, NTHi strains may also produce pneumonia, particularly in patients with chronic bronchitis. The closely related *H parainfluenzae* belongs to the so-called HACEK group of fastidious Gram-negative bacteria (*Haemophilus*, *Aggregatibacter*, *Cardiobacterium*, *Eikenella*, *Kingella kingae*) that are known to produce up to 3% of all infective endocarditis cases, typically in patients with prosthetic valves or underlying heart disease.

Is *Haemophilus* otitis media the event preceding systemic infections like meningitis?

DIAGNOSIS

*** X and V factor requirements distinguish species**

Blood cultures useful in systemic infections

The combination of clinical findings and a typical Gram smear may be sufficient to make a presumptive diagnosis of *Haemophilus* infection. The tiny cells are usually of uniform shape except in cerebrospinal fluid, where some may be elongated to several times their usual length (Figure 31–1). The diagnosis is usually confirmed by isolation of the organism from the site of infection or from the blood. Blood cultures are particularly useful in systemic *H influenzae* infections because it is often difficult to obtain an adequate specimen directly from the site of infection. Bacteriologically, small coccobacillary Gram-negative rods that grow on chocolate agar but not blood agar strongly suggest *Haemophilus*. Confirmation and speciation depend on demonstration of the requirement for hematin (X factor) and/or NAD (V factor) and/or biochemical tests. Serotyping is unnecessary for clinical purposes, but important in epidemiologic and vaccine studies.

TREATMENT

*** β-lactamase-producing strains ampicillin-resistant**

*** Third-generation cephalosporin treatment**

All forms of *H influenzae* disease were effectively treated with ampicillin until the 1970s, when resistance emerged, in a pattern similar to that of *Neisseria gonorrhoeae*. The major mechanism was production of a β-lactamase identical to that found in *Escherichia coli.* The frequency of β-lactamase–producing strains varies between 5% and 50% in different geographic areas, with rates of 20% to 30% appearing in recent North American isolate collections. More recently, ampicillin resistance has emerged in β-lactamase–negative strains due

to alterations in the transpeptidase site of the penicillin-binding protein, PBP3. Current practice is to start empiric therapy with a third-generation cephalosporin (eg, ceftriaxone), which can be narrowed to ampicillin if laboratory testing indicates that the infecting strain is susceptible.

PREVENTION

*** PRP vaccine missed peak age of disease**

*** Vaccines conjugating PRP to bacterial proteins stimulate T cells**

*** Dramatic reductions in Hib disease have been sustained**

Purified PRP vaccines became available in 1985; however, owing to the typically poor immune response of infants to polysaccharide antigens, their use was limited to children 24 months of age and older. Because immunization at this age failed to protect those most susceptible to Hib invasive disease, a new vaccine strategy was needed to evoke the improved stimulation of T-cell–dependent immune responses in infants. To achieve this, the first protein conjugate vaccines were developed by linking PRP to proteins derived from bacteria (diphtheria toxoid, *N meningitidis* OMP). The first PRP–protein conjugate vaccines were licensed in 1989; by late 1990, they were recommended for universal immunization in children, beginning at 2 months of age. As illustrated in **Figure 31–5,** the impact has been dramatic. This 99% reduction in what was once one of the most feared diseases of childhood is one of the greatest achievements in medical history. Fortunately, the decline in Hib has not been accompanied by compensatory rise in the numbers of non-b cases or in the other causes of acute purulent meningitis. An unexpected concomitant finding has been a dramatic drop in *H influenzae* colonization rates in immunized populations. Under the direction of the World Health Organization, government and philanthropic efforts like those of the Gates Foundation continue to implement Hib immunization in children across the globe.

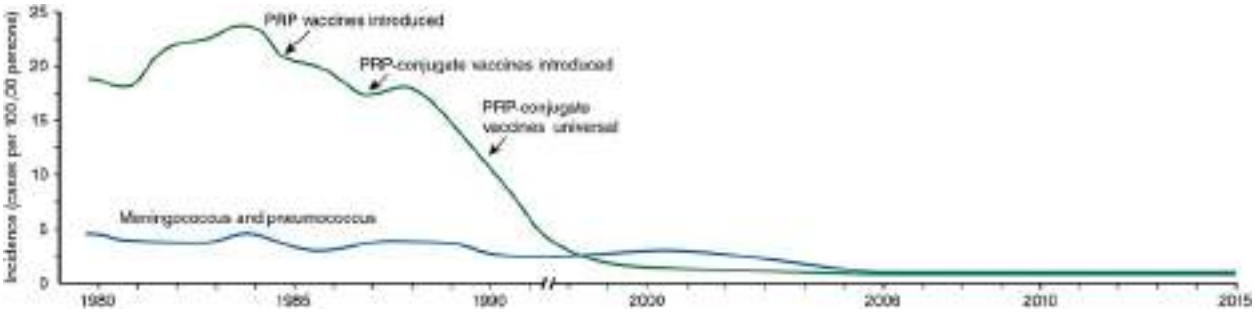

FIGURE 31–5. The decline in *Haemophilus influenzae* type b (Hib) meningitis in association with the introduction of new vaccines is shown. Note also the steady state of the other major causes of childhood meningitis; they did not increase to "fill in the gap" nor did *H influenzae* invasive disease caused by other serotypes.

Rifampin prophylaxis indicated

As with *N meningitidis*, rifampin chemoprophylaxis is indicated for unimmunized close contacts of cases for children and adults alike.

Think ▸▸ Apply 31-1: If so, this would only happen with encapsulated strains, which are the minority in OM. Although probable because of the high prevalence of OM, the specific epidemiologic evidence is lacking for this connection.

• *Haemophilus ducreyi*

*** Soft chancre: a nonindurated genital ulcer with satellite lesions**

May contribute to spread of HIV in Africa

Haemophilus ducreyi causes chancroid, a common cause of genital ulcer that has been found in Africa, Southeast Asia, India, and Latin America. Occasional outbreaks in North America have most often been associated with the exchange of sex for drugs or money. The typical lesion is a tender papule on the genitalia that develops into a painful ulcer with sharp margins (**Figure 31–6**). Satellite lesions may develop by autoinfection, and regional lymphadenitis is common. The incubation period is usually short (2-5 days). The lack of induration around the ulcer has caused the primary lesion to be called "soft chancre" to distinguish it from the primary syphilitic chancre, which is typically indurated and painless.

The presence of open genital sores due to *H ducreyi* greatly enhances the risk of transmission of HIV by providing a portal of entry and/or by the recruitment of CD4+ cells to the site. This may contribute to the heterosexual spread of HIV on the African continent, where chancroid is common. However, determination of the true global incidence of chancroid has been obviated by widespread practice of syndromic management for bacterial genital ulcer disease—that is, empiric treatment with agents effective against both syphilis and chancroid. *H ducreyi* has also recently been identified as a causative agent of nongenital cutaneous ulcers in children in tropical regions where yaws is endemic (eg, Papua New Guinea, the Solomon Islands).

FIGURE 31–6. Chancroid. These penile ulcers are caused by *Haemophilus ducreyi*. In contrast to the ulcers of syphilis, they are soft and painful. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

Candidate *H ducreyi* virulence factors include pili and an OMP (DsrA) which mediates attachment to epithelial cells and resistance to complement-mediated killing. In the lesion, *H ducreyi* localizes with neutrophils and macrophages but remains extracellular. There is evidence to suggest that the organism may gain an advantage by secreting antiphagocytic proteins and by resisting antimicrobial peptides that are part of the innate immune response. Host immunity may be dampened by the action of cytolethal distending toxin on T cells.

*** Culture requires selective medium**

The specific diagnosis of *H ducreyi* infection is difficult. Although the organism grows on chocolate agar, it does so slowly, and other organisms in the genital flora are apt to over-grow the plates. Incorporating antibiotics (usually vancomycin) in the agar overcomes this problem, but few laboratory suppliers in the United States produce this selective medium. Preferred treatments for chancroid include single doses of either azithromycin or ceftriaxone; alternative agents include multiple-dose regimens of ciprofloxacin or erythromycin. Condoms are effective in blocking transmission.

• *BORDETELLA*

*** Species similar to *B pertussis* may cause mild whooping cough**

The genus *Bordetella* contains seven species; *Bordetella pertussis* is by far the most important because it is the cause of classic pertussis (whooping cough). Nucleic acid homology and other analyses indicate that *Bordetella parapertussis* and *B bronchiseptica* are almost similar enough to *B pertussis* to be considered variants of the same species. *B parapertussis* occasionally causes a disease similar to, but milder than, pertussis and has appeared together with *B pertussis* in outbreaks. This mild phenotype is probably due to its lack of pertussis toxin (PT) production, even though a silent copy of the toxin gene is present. The remainder of this section focuses on *B pertussis.*

• *BORDETELLA PERTUSSIS*

BACTERIOLOGY

GROWTH AND STRUCTURE

Morphologically similar to *Haemophilus*

*** Growth slow, requires nicotinamide**

Bordetella pertussis is a tiny (0.5-1.0 µm), Gram-negative coccobacillus morphologically similar to *Haemophilus*. Growth requires a special medium with nutritional supplements (nicotinamide), additives (charcoal) to neutralize

the inhibitory effect of compounds in standard bacteriologic media, and antibiotics to inhibit other respiratory flora. Under the best conditions, growth is still slow, requiring 3 to 7 days for isolation. The organism is also very susceptible to environmental changes and survives only briefly outside the human respiratory tract.

*** FHA binds amino acid sequences found on host cells**

*** Pili and pertactin are adhesins**

The cell wall of *B pertussis* has the structure typical of Gram-negative bacteria, although the outer membrane lipopolysaccharide differs significantly in structure and biologic activity from that of the Enterobacteriaceae. The surface exhibits a rod-like protein called the **filamentous hemagglutinin (FHA)** because of its ability to bind to and agglutinate erythrocytes. FHA has strong adherence qualities, based on domains in its structure that interact with an amino acid sequence present in host integrins, epithelial cells, and macrophages. FHA also stimulates cytokine release and interferes with T_H1 immune responses. The organism surface also contains other adhesive structures including **pili** and an OMP called **pertactin.**

EXTRACELLULAR PRODUCTS

▪ Pertussis Toxin

*** A-B toxin ADP-ribosylates G protein**

*** Adenylate cyclase and cell regulation are disrupted**

PT is the major virulence factor of *B pertussis*. It is an A-B toxin produced from a single operon as an enzymatic subunit and five binding subunits that are assembled into the complete toxin on the bacterial surface. The binding subunits mediate attachment of the toxin to carbohydrate moieties on the host cell surface. The enzymatic subunit is then internalized and ADP-ribosylates a G protein that affects adenylate cyclase (AC) activity. Unlike cholera toxin, which keeps cyclase activity switched on, PT freezes the opposite side of the regulatory circuit and cripples the capacity of the host cell to inactivate cyclase activity. Multiple intracellular signaling pathways are disrupted by this G protein modification. Among the results of this action are lymphocytosis, insulinemia,

and histamine sensitization.

- **Other Toxins**

*** Toxin adenylate cyclase disrupts immune cell function**

*** Peptidoglycan fragments injure ciliated tracheal cells**

Another potent toxin, a pore-forming **adenylate cyclase**, enters host cells and catalyzes the conversion of host cell ATP to cyclic AMP at levels far above what can be achieved by normal mechanisms. This activity interferes with cellular signaling, chemotaxis, superoxide generation, and function of immune effector cells, including PMNs, lymphocytes, macrophages, and dendritic cells. AC can also induce programmed cell death (apoptosis). **Tracheal cytotoxin (TCT)** is a monomer of *B pertussis* peptidoglycan generated during cell wall synthesis. The fragments are released into the environment by multiplying bacterial cells because *B pertussis* lacks mechanisms present in other bacteria for recycling these monomers. TCT is directly toxic to ciliated tracheal epithelial cells, causing their extrusion from the mucosa and eventual death; there is little or no effect on the nonciliated cells.

PERTUSSIS (WHOOPING COUGH)

EPIDEMIOLOGY

*** Highly contagious, spread by airborne droplet nuclei**

*** Immunization reduces disease but outbreaks continue**

Pertussis is a major health problem worldwide, with an estimated 50 million cases and 300,000 deaths annually. More than 90% of the cases are in developing nations and most of the deaths are among infants. *Bordetella pertussis* is spread by airborne droplet nuclei and remains localized to the tracheobronchial tree. It is highly contagious, infecting more than 90% of exposed susceptible persons. Secondary spread in families, schools, and hospitals is rapid. Sporadic epidemics occur, but there is no strong seasonal pattern. *B pertussis* is a strictly human pathogen. It is not found in animals and

survives poorly in the environment. Asymptomatic carriers are rare except in outbreak situations. The introduction of immunization in the 1940s produced a dramatic reduction in disease, but outbreaks persisted in 3- to 5-year cycles. Large outbreaks have occurred in populations where the immunization rates fell, for example, as a result of concerns about febrile reactions to the original pertussis vaccine.

*** Undiagnosed adult disease facilitates spread**

*** Infants have high mortality**

*** Waning immunity needs boosting**

Immunization also produced a change in the age distribution of the residual cases. Previously a disease of toddlers and young children, pertussis began to appear in infants and—due to the relatively short duration (10-12 years) of immunity—adults, beginning in late adolescence. Upon exposure, susceptible adults usually have a milder form of the disease, which is often not recognized as pertussis. These unwitting adults then are the major source for outbreaks in highly susceptible populations, such as infants. In the preimmunization era, newborns were usually protected by maternal transplacental IgG stimulated by the almost universal exposure to *B pertussis* in the general population. In an immunized population with waning immunity, this antibody has frequently dropped below protective levels by the childbearing years. In a cruel twist, infants have the most severe form of the disease; more than 70% of fatal cases occur in children younger than 1 year of age. These problems appear to have worsened with the switch to an acellular vaccine whose protection is of even shorter duration. (See Prevention)

PATHOGENESIS

*** Attachment to cilia provides site for toxin production**

*** Mucosa becomes devoid of ciliated cells**

When introduced into the respiratory tract, *B pertussis* has a remarkable tropism for ciliated bronchial epithelium, attaching to the cilia themselves. This adherence is mediated by FHA, pili, pertactin, and the binding subunits of PT. Once attached, the bacteria immobilize the cilia and begin a sequence in which

the ciliated cells are progressively destroyed and extruded from the epithelial border (**Figures 31–7** and **31–8**). This local injury is caused primarily by the action of TCT. This toxicity eventually produces an epithelium devoid of the ciliary blanket, needed to move foreign matter away from the lower airways. Persistent coughing is the clinical correlate of this ciliary defect. Although considerable local inflammation and exudate are produced in the bronchi, *B pertussis* does not directly invade the cells of the respiratory tract or spread to deeper tissue sites.

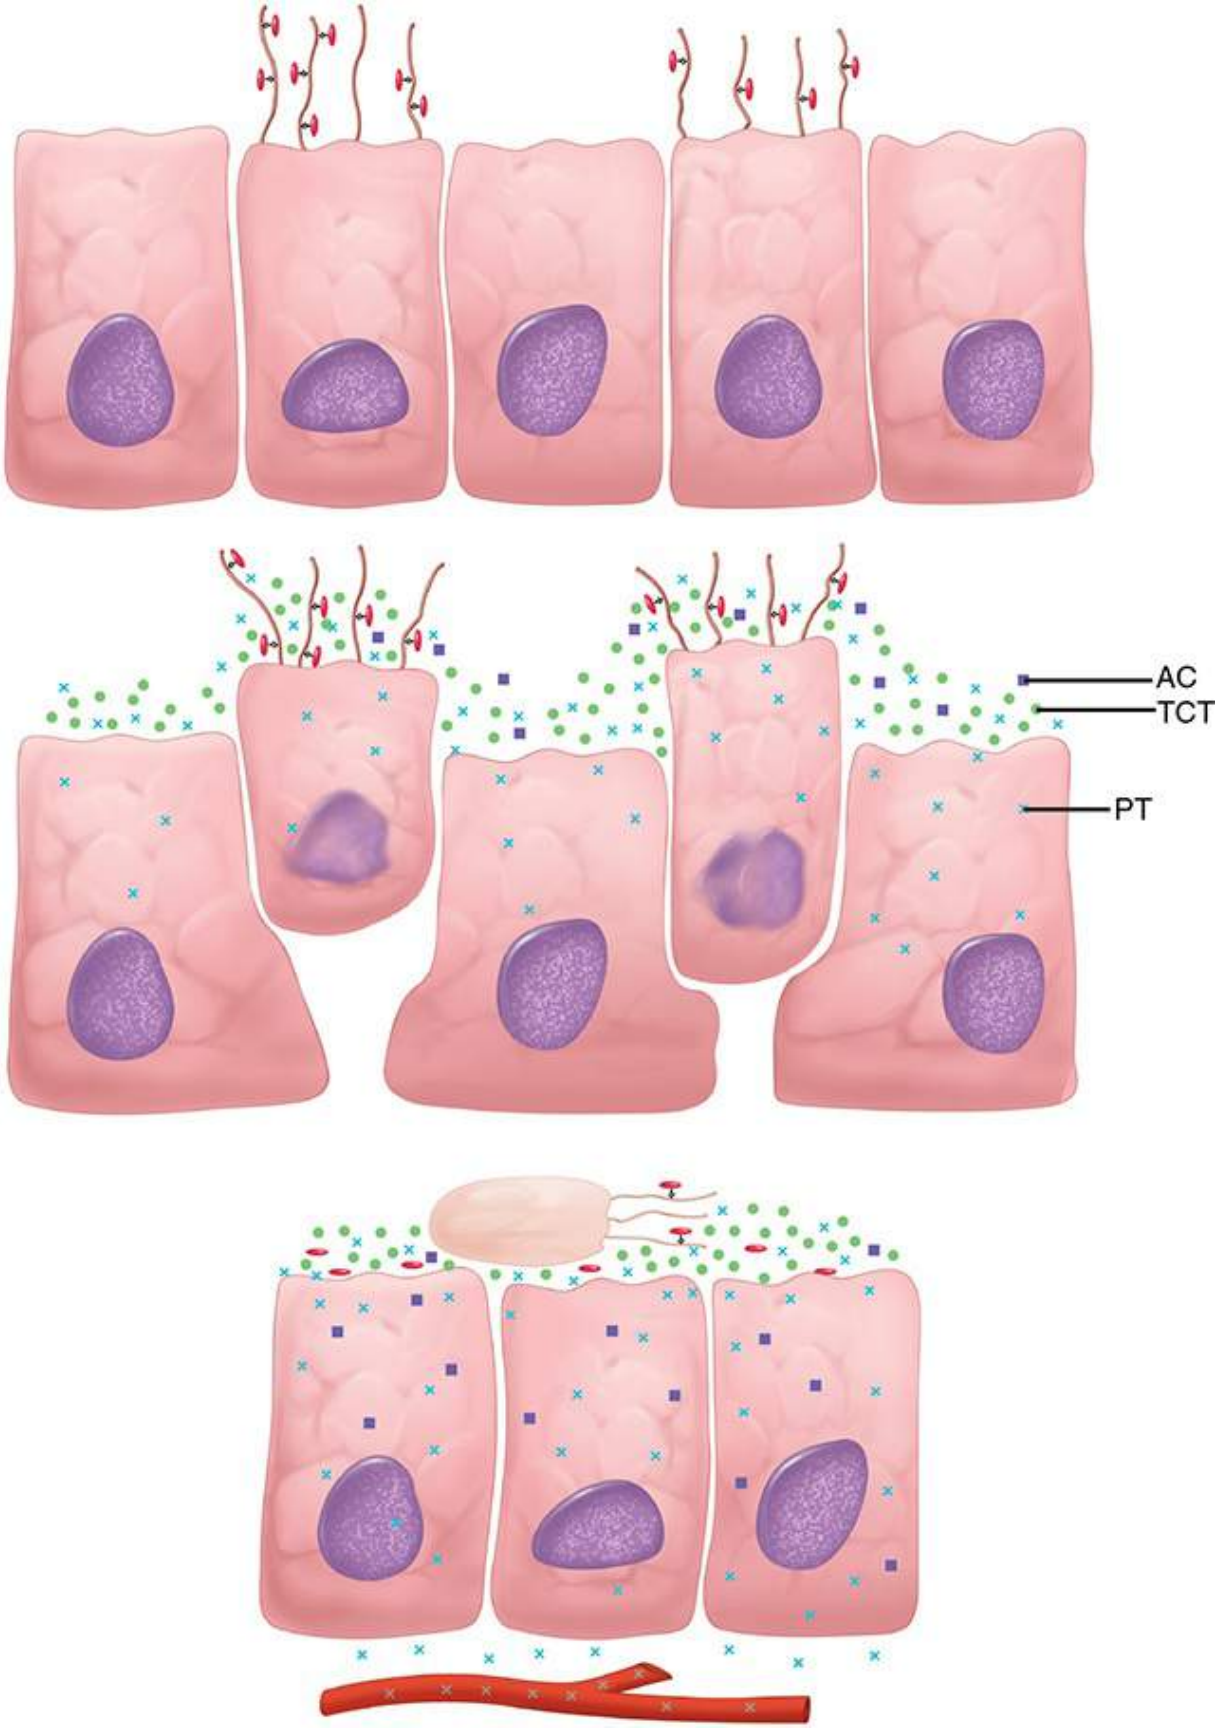

FIGURE 31–7. Whooping cough, cellular view. (*Top*) *Bordetella pertussis* attaches to the cilia of cells in the respiratory epithelium. Attachment is mediated by pili, filamentous hemagglutinin, and pertactin. (*Middle*) Regulatory systems initiate production of pertussis toxin (PT) and adenylate cyclase (AC), which injure the cells and they begin to be extruded. Additional injury is from the peptidoglycan fragments of tracheal cytotoxin (TCT). (*Bottom*) The ciliated cells are destroyed, leaving a denuded mucosa without protective cilia. PT is absorbed into the bloodstream to act throughout the body.

FIGURE 31–8. A tracheal organ culture 72 hours after infection with *Bordetella pertussis*. The organisms have attached to the cilia of some cells and killed them. These balloon-like cells with attached bacteria are extruded from the epithelium. The large arrow shows the *Bordetella*, and the small arrow shows cilia. Note the background of uninfected ciliated cells and denuded epithelium where nonciliated cells remain. (Reproduced with permission from Muse KE, Collier AM, Baseman JB: Scanning electron microscopic study of hamster tracheal organ cultures infected with Bordetella pertussis, *J Infect Dis* Dec;136(6):768-777.)

▪ Virulence Factors

PT and AC attack immune cells

Absorbed PT acts on multiple cell types

In addition to the local effects on bronchial epithelium, other virulence factors of *B pertussis* contribute to the disease in diverse ways. The combined action of PT and AC on neutrophils, macrophages, and lymphocytes creates paralysis and even death of these crucial effector cells of the immune system. Many of the systemic manifestations of the disease, such as lymphocytosis, histamine sensitization, and insulin secretion, are due to the action of circulating PT absorbed at the primary infection site. The specific biologic effect depends on how disruption of G-protein regulation by PT is manifested by the host cell type that the toxin reaches. Pertussis is the result of a well-orchestrated delivery by *B pertussis* of toxic and adhesive factors to host cells at local and distant sites to produce a disease that persists for many weeks.

▪ Genetic Regulation of Pathogenicity

Multiple virulence genes respond to temperature, ionic changes

Virulence genes regulated in two-component model

Adherence factors precede injury products

How *B pertussis* deploys its repertoire of virulence genes is a model for the regulation of bacterial pathogenicity. *B pertussis* regulates the synthesis of PT, AC, FHA, pili, and many other genes through genetic loci that control the expression of at least 20 unlinked chromosomal genes at the transcriptional level. Expression is modulated in a two-component system by changes in specific environmental parameters, including temperature. The induction of virulence factors in *B pertussis* is sequential, with expression of adhesins (FHA and pili) preceding expression of factors involved in tissue injury (PT, AC). The finely honed responses of *B pertussis* virulence factors to changes in temperature and ionic conditions presumably play a role in the pathogenesis of infection and help the organism adapt in a stepwise fashion to the diverse local conditions throughout the human respiratory tract. Details of the genetic mechanisms involved are discussed in Chapter 22 and illustrated in Figure 22–8.

IMMUNITY

*** Immunity is not lifelong**

Although IgG antibodies are produced to PT, pili, and pertactin during the

course of natural infection and by immunization, they are not long-lasting, and their role in immunity is not well understood. Although naturally acquired immunity is not lifelong, second attacks (when recognized) tend to be mild.

PERTUSSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Catarrhal phase most communicable**

*** Paroxysmal coughing lasts for weeks**

After an incubation period of 7-10 days, pertussis follows a prolonged course consisting of three overlapping stages: (1) catarrhal, (2) paroxysmal, and (3) convalescent. In the catarrhal stage, the primary feature is profuse mucoid rhinorrhea, which persists for 1 to 2 weeks. Nonspecific findings such as fever, malaise, sneezing, and anorexia may also be present. The disease is most communicable at this stage because large numbers of organisms are present in the nasopharynx and the mucoid secretions.

*** Inspiratory whoop, coughing may lead to apnea**

*** Marked lymphocytosis**

The appearance of a persistent cough marks the transition from the catarrhal to the paroxysmal coughing stage. At this time, episodes of paroxysmal coughing occur up to 50 times a day for 2 to 4 weeks. The characteristic inspiratory whoop follows a series of coughs as air is rapidly drawn in through the narrowed glottis; vomiting may follow the whoop. The combination of mucoid secretions, whooping cough, and vomiting produces a miserable, exhausted child barely able to breathe. Apnea may follow such episodes, particularly in infants. Marked lymphocytosis reaches its peak at this time, with absolute lymphocyte counts of up to 40,000/mm^3.

*** Convalescent phase a gradual fading**

During the 3- to 4-week convalescent stage, the frequency and severity of

paroxysmal coughing and other features of the disease gradually fade. Partially immune persons and infants younger than 6 months of age may not show all the typical features of pertussis. Some evolution through the three stages is usually seen, but paroxysmal coughing and lymphocytosis may be absent.

Atelectasis and superinfection are major complications

The most common complication of pertussis is pneumonia caused by a superinfecting organism such as *Streptococcus pneumoniae*. Atelectasis is also common but may be recognized only by radiologic examination. Other complications, including convulsions and subconjunctival—or even intracerebral—bleeding, are related to the venous pressure effects of the paroxysmal coughing and the anoxia produced by inadequate ventilation and apneic spells.

DIAGNOSIS

*** Nasopharyngeal swab is plated on charcoal blood agar**

Organisms are often gone by later paroxysmal phase

A clinical diagnosis of pertussis is best confirmed by detection of *B pertussis* in nasopharyngeal secretions or swabs. Throat swabs are not suitable because the cilia to which the organism attaches are not found there. Specimens collected early in the course of disease (during the catarrhal or early paroxysmal stage) provide the greatest chance of successful isolation. Unfortunately, the diagnosis is frequently not considered until paroxysmal coughing has been present for some time, by which point the number of organisms has decreased significantly. Usually, the nasopharyngeal specimens are plated onto a special charcoal blood agar medium made selective by the addition of a cephalosporin; this allows the slow-growing *B pertussis* to be isolated in the presence of more rapidly growing members of the normal upper respiratory flora. The characteristic colonies appear after 3 to 7 days of incubation and look like tiny drops of mercury. Immunologic methods (agglutination, immunofluorescence) are required for specific identification.

*** DFA and/or PCR allow rapid diagnosis**

A direct immunofluorescent antibody (DFA) technique has been successfully applied to nasopharyngeal smears for rapid diagnosis of pertussis. DFA is

particularly helpful in pertussis because of the many days required for culture results. Nucleic acid amplification tests are now replacing both culture and DFA as they have proven to be more timely and sensitive than the classic methods. However, culture confirmation should be considered before declaring an epidemic. Serologic tests are widely used for epidemiologic studies but not diagnosis of individual clinical cases.

TREATMENT

*** Macrolide antibiotics most effective in catarrhal phase**

Once the paroxysmal coughing stage has been reached, the treatment of pertussis is primarily supportive. Antimicrobial therapy is useful at earlier stages and for limiting the spread to other susceptible individuals. Of a number of antimicrobial agents active *in vitro* against *B pertussis*, macrolides are preferred for both treatment and prophylaxis. Erythromycin has the greatest clinical experience, but azithromycin and clarithromycin are equally effective.

PREVENTION

*** Whole cell vaccine effective but had side effects**

*** Acellular vaccines are purified**

Active immunization is the primary method of preventing pertussis. The original vaccine, which produced a dramatic reduction in disease (Figure 31–9), was prepared from inactivated whole cell suspensions and given together with diphtheria and tetanus toxoids as DTP. The undoubted efficacy of this vaccine was colored by a high rate of side effects due to the crude nature of the whole cell preparation. These included local inflammation, fever and, rarely, febrile seizures. Although permanent neurologic sequelae were never convincingly linked to pertussis immunization, some argued that the vaccine was worse than the disease. This led to the development of acellular vaccines containing virulence factors purified from inactivated whole cell preparations.

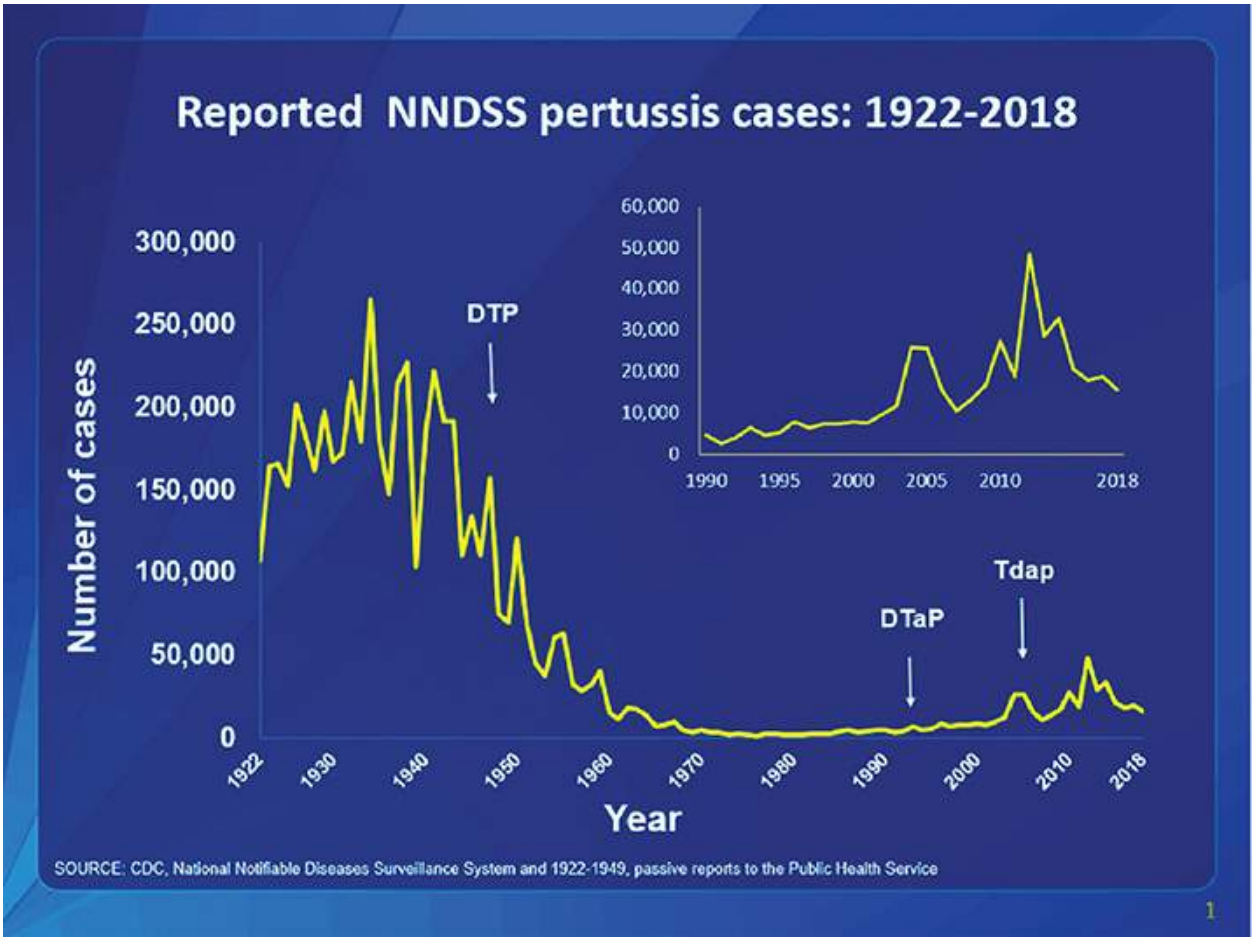

FIGURE 31–9. Impact of pertussis vaccines 1922-2018. The changes in pertussis incidence produced by diphtheria/tetanus/pertussis (DTP [whole cell]) and the acellular (DTaP, Tdap) vaccines are shown. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. Pertussis [Whooping Cough]. December, 2019.)

*** Vaccines include PT, FHA, and other virulence factors**

*** DTaP has replaced DTP**

*** Duration of immunity from acellular vaccine in question**

The multiple acellular vaccine products have different combinations of virulence factors. All contain PT and FHA, and some add pertactin or pili (vaccine manufacturers use the term fimbriae). In combination with diphtheria and tetanus toxoids, the acellular vaccine has now replaced the whole cell DTP as DTaP (“a” for acellular). This vaccine is now recommended for the full primary immunization series (at 2, 4, and 6 months) and boosters (at 15-18 months, 4-6 years). The safety and efficacy of these vaccines have now been extensively evaluated. All have dramatically less frequent side effects compared

with the whole cell preparations, but their efficacy is increasingly in question. In the United States, major pertussis outbreaks in 2005, 2010, and 2012 have been traced to vaccine failures in fully immunized adolescents and even preadolescent children. Clearly, the acellular vaccine does not provide immunity for as long as the product it replaced. The concern for transmission to newborns (Figure 31–10) has led to a strategy called cocooning, in which all family members are newly immunized or boosted before the baby comes home. There appears to be no going back to the whole cell vaccine, but adjustments in booster schedules and vaccine formulation are ahead.

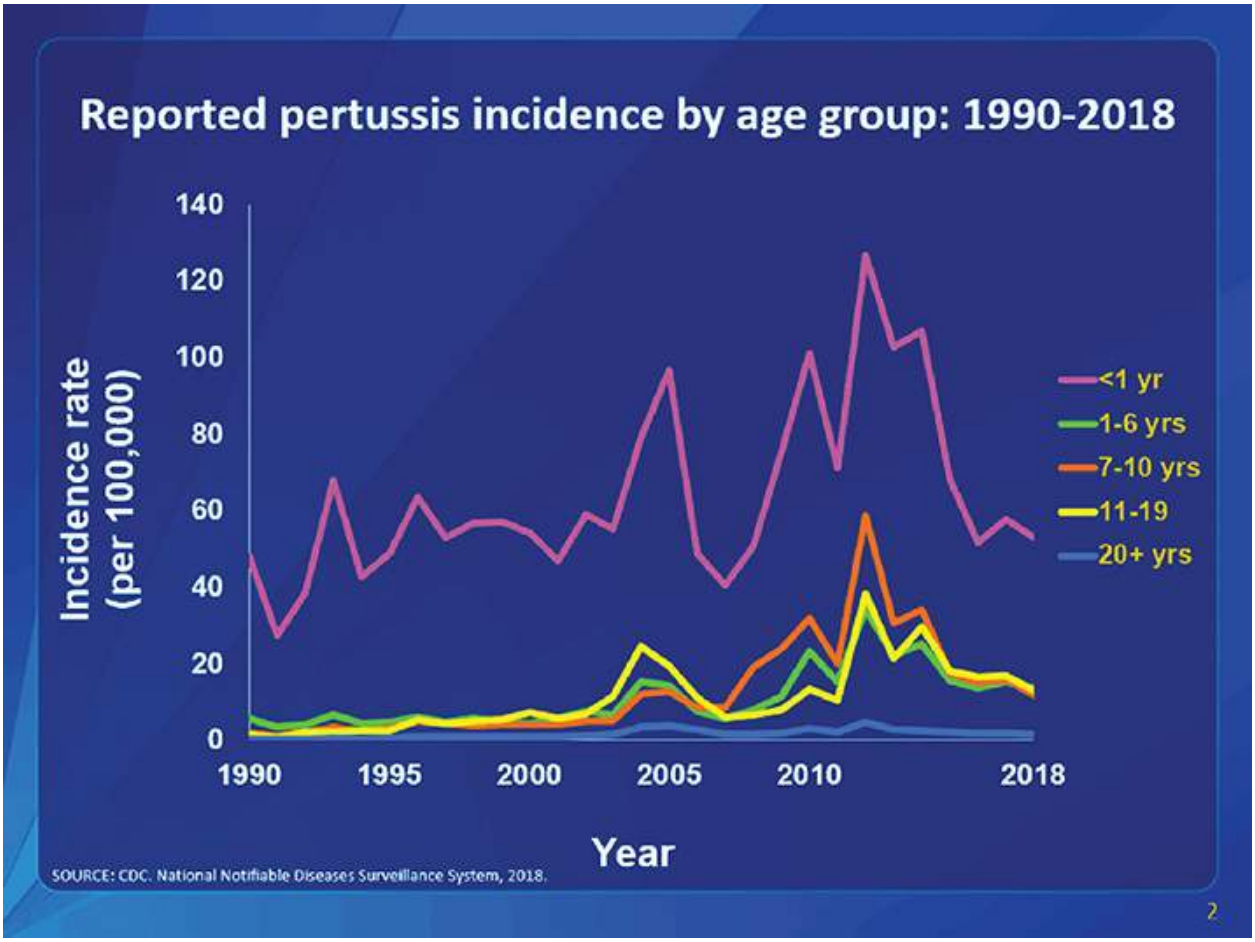

FIGURE 31–10. Impact of acellular pertussis vaccines by age group 1990-2018. Note the predominance of cases in infants less than 1 year of age. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. Pertussis [Whooping Cough]. December, 2019.)

Do we need a new vaccine?

Think ▸▸ Apply 31-2: It looks more and more like this is the case, but there are big problems. The scientific evidence for new immunogens is lacking and activities of antivaccine groups discourage commercial development.

*** Duration of immunity from acellular vaccine in question**

*** DTaP has replaced DTP**

*** Vaccines include PT, FHA, and other virulence factors**

KEY CONCLUSIONS

- *Bordetella pertussis* is slow growing and requires a special selective medium for growth.
- *B pertussis* pili and filamentous hemagglutinin attach directly to respiratory cilia. The organism does not invade tissues.
- Pertussis toxin stimulates regulatory G-proteins disrupting cell functions locally and systemically.
- Peptidoglycan fragments called tracheal cytotoxin cause direct injury to tracheobronchial epithelium.
- High infectivity and waning immunity have shifted pertussis incidence to highly vulnerable infants.
- Absolute lymphocytosis is a unique diagnostic finding.
- Nucleic acid amplification methods provide the most rapid and specific means of laboratory diagnosis.
- The new acellular vaccine is less toxic but has a shorter duration of protection than the old whole cell vaccine.

CASE STUDY

A Choking, Coughing Infant

A male infant born prematurely was still in the pediatric intensive care unit at 12 days old. On the eighth day, he began to exhibit repetitive coughing,

which progressed to his turning red, choking, and gasping for breath. The episodes were sometimes followed by vomiting. On the tenth day, he suffered apnea and then required ventilatory assistance. His physical examination was significant for a pulse of 160 bpm and respiratory rate of 72/min (both highly elevated). The child's chest radiograph was clear. There was no evidence of tracheal abnormalities. The infant's white cell count was 15,500/mm^3 with 70% lymphocytes.

QUESTIONS

1. Which of this patient's findings are most unique for pertussis?

A. Cough
B. Choking
C. Vomiting
D. Leukocytosis
E. Lymphocytosis

2. Which of the following would yield the most rapid confirmation of a whooping cough diagnosis?

A. Throat culture
B. Nasopharyngeal culture
C. Nasopharyngeal direct fluorescent antibody smear
D. Throat direct fluorescent antibody smear
E. *B pertussis* serology

3. What is the most likely source of this child's infection?

A. Sibling
B. Parent
C. Delivery room environment
D. Healthcare worker carrier
E. Healthcare worker with disease

ANSWERS

1. **(E)**
2. **(C)**
3. **(E)**

chapter 32

Vibrio, Campylobacter, and *Helicobacter*

Vibrio cholerae • *Campylobacter jejuni* • *Helicobacter pylori*

I am poured out like water, and all my bones are out of joint: my heart is like wax; it is melted in the midst of my bowels.

—The Bible: *Psalms* 22:14

OVERVIEW

Vibrio cholerae is a motile (flagellated), comma-shaped oxidase-positive Gram-negative rod that grows best on specialized media. Although many infections are asymptomatic, epidemic cholera produces the most dramatic watery diarrhea known. Intestinal fluids pour out in voluminous bowel movements, which untreated rapidly leads to dehydration and electrolyte imbalance. The pathogenesis is solely due to the action of cholera enterotoxin secreted by *V cholerae* in the bowel lumen. Despite the profound physiologic effects, there is no fever, inflammation, or direct injury to the bowel mucosa.

Campylobacter jejuni is the most common of the pathogenic *Campylobacter* species all of which are curved, motile Gram-negative rods. Clinical disease with *C jejuni* typically begins with lower abdominal pain, which evolves into diarrhea over a matter of hours. The diarrhea may be watery or dysenteric, with blood and pus in the stool. Most patients are febrile. The illness resolves spontaneously after a few days to 1 week.

Helicobacter pylori is also a curved, flagellated, small Gram-negative rod that is distinguished by being catalase, oxidase, and urease positive. Infections are limited to the mucosa of the stomach in which urease production enables survival in the acid milieu. Most are asymptomatic even after many years. Burning pain in the upper abdomen, accompanied by nausea and sometimes vomiting, is a symptom of gastritis, but peptic gastric or duodenal ulcers may ensue with additional symptoms and complications including bleeding and perforation.

This group of curved Gram-negative rods includes *Vibrio cholerae*, the cause of cholera and one of the first proven infectious diseases, along with *Campylobacter jejuni* and *Helicobacter pylori*, which were incriminated as pathogens late in the 20th century (**Table 32-1**). Cholera has undergone

resurgence in recent decades and has now spread from its historic roots in South Asia to Africa and the Americas, including the coastline of the United States. *C jejuni* is one of the most common causes of diarrhea in virtually every country of the world. The peptic ulcer disease now known to be caused by *H pylori* had been long accepted to be due to stress and disturbed gastric acid secretion.

TABLE 32–1 **Features of *Vibrio, Campylobacter, and Helicobacter*[a]**

BACTERIOLOGY			PATHOGENESIS			
ORGANISM	GROWTH	UREASE	EPIDEMIOLOGY	ADHERENCE	TOXINS	DISEASE
Vibrio cholerae	Facultative	–	Fecal–oral, water-borne, pandemics	Surface protein[b], pili	CT[c]	Watery diarrhea (cholera)
Campylobacter jejuni	Microaerophilic	–	Animals, unpasteurized milk	Unknown	Unknown	Dysentery, watery diarrhea
Helicobacter pylori	Microaerophilic	+	Human, gastric secretions	OMPs[d]	Urease,[e] VacA,[f] CagA[g]	Chronic gastritis, ulcers, adenocarcinoma, lymphoma

[a]All are curved Gram-negative rods with similar morphology.
[b]Surface protein able to bind to chitin and human intestine.
[c]Cholera toxin.
[d]OMPs, outer membrane proteins (especially BabA, which binds to Lewis b blood group antigen)
[e]Urease enables survival in acid milieu of stomach by producing ammonia.
[f]Vacuolating cytotoxin (VacA).
[g]Cytotoxin associated gene A (CagA) is strongly associated with virulence.

• *VIBRIO*

* Motile curved rods found in seawater

Vibrios are curved, Gram-negative rods commonly found in saltwater. Cells may be linked end to end, forming S shapes and spirals. They are highly motile with a single polar flagellum, non–spore-forming, and oxidase-positive, and they can grow under aerobic or anaerobic conditions. The cell envelope structure is similar to that of other Gram-negative bacteria. *V cholerae* is the prototype cause of a water-loss diarrhea called **cholera.** Other species causing diarrhea, wound infections, and, rarely, systemic infection are listed in **Table 32-2.**

TABLE 32–2 **Features of Less Common *Vibrio* and *Campylobacter* Species**

ORGANISM	FEATURES	EPIDEMIOLOGY	DISEASE
Vibrio			
V mimicus	Closely related to *V cholerae*; cholera-like enterotoxin; sucrose-negative	Ingestion of raw seafood	Watery diarrhea
V parahaemolyticus	Produces two enterotoxins; sucrose-negative	Coastal seawater; ingesting raw seafood; outbreaks on cruise ships; common in Japan	Watery diarrhea, occasionally dysentery
V vulnificus	Siderophores scavenge iron from host transferrin and lactoferrin; two cytotoxins include pore-forming activity	Coastal seawater, particularly when water temperatures rise; ingesting raw seafood or contamination of wound with seawater	Fulminant bacteremia following ingestion, cellulitis from wound contamination, high fatality rate in those with iron-storage disease or cirrhosis
V alginolyticus		Wounds contaminated by seawater	Cellulitis
Campylobacter			
C fetus	Fails to grow on selective medium used for *C jejuni*	Cause of abortion in cattle and sheep	Bacteremia, thrombophlebitis
C upsaliensis	Fails to grow on selective medium used for *C jejuni*	Associated with dogs and cats	Diarrhea similar to *C jejuni*
C hyointestinalis		Enteritis in swine	Diarrhea in immunocompromised and homosexual men
C lari		Associated with birds	Diarrhea, bacteremia in immunocompromised

• *VIBRIO CHOLERAE*

BACTERIOLOGY

GROWTH AND STRUCTURE

*** Grow in alkaline conditions**

*** Cholera limited to O1, O139 serotypes**

*** Biofilm produced in environment**

V cholerae has a low tolerance for acid, but grows readily under alkaline (pH 8.0-9.5) conditions that inhibit many other Gram-negative bacteria. It is distinguished from other vibrios by biochemical reactions, lipopolysaccharide (LPS) O antigenic structure, and production of cholera toxin (CT). There are over 200 O antigen serotypes, only two of which (O1 and O139) cause cholera. *V cholerae* biogroup El Tor, an O1 variant, is a biotype of the classic strain. The O139 strains phenotypically resemble O1 El Tor strains but also produce a polysaccharide capsule. *V cholerae* possess long filamentous pili that form

bundles on the bacterial surface and belong to a family of pili whose chemical structure is similar to those of the gonococcus and a number of other bacterial pathogens. All strains capable of causing cholera produce a colonizing factor known as the toxin-coregulated pilus (TCP) because its expression is regulated together with CT. In aquatic environments, *V cholerae* produces polysaccharide biofilms, which contain carbohydrate moieties mediating cell–cell adhesion and attachment to surfaces.

CHOLERA TOXIN

*** B subunit receptor surface ganglioside**

*** A1 ADPRs G-protein**

*** Adenylate cyclase locked in active state**

*** cAMP accumulation causes water, electrolyte hypersecretion**

The structure and mechanism of action of CT have been studied extensively (**Figure 32–1**). CT is an A–B type ADP-ribosylating (ADPR) toxin. Its molecule is an aggregate of multiple polypeptide chains organized into two toxic subunits (A1, A2) and five binding (B) units. The B units bind to a GM1-ganglioside receptor found on the surface of many types of cells. Once bound, the A1 subunit is released from the toxin molecule by reduction of the disulfide bond that binds it to the A2 subunit, and it enters the cell by translocation. In the cell, it exerts its effect on the membrane-associated adenylate cyclase system at the basolateral membrane surface. The target of the toxic A1 subunit is a guanine nucleotide (G) protein, Gsα, which regulates activation of the adenylate cyclase system. CT catalyzes the ADPR (Figure 21–16) of the G-protein, rendering it unable to dissociate from the active adenylate cyclase complex. This causes persistent activation of intracellular adenylate cyclase, which in turn stimulates the conversion of adenosine triphosphate to cyclic adenosine 3′,5′-monophosphate (cAMP). The net effect is excessive accumulation of cAMP at the cell membrane, which causes hypersecretion of chloride, potassium, bicarbonate, and associated water molecules out of the cell. Strains of *V cholerae* other than the two epidemic serotypes may or may not produce CT.

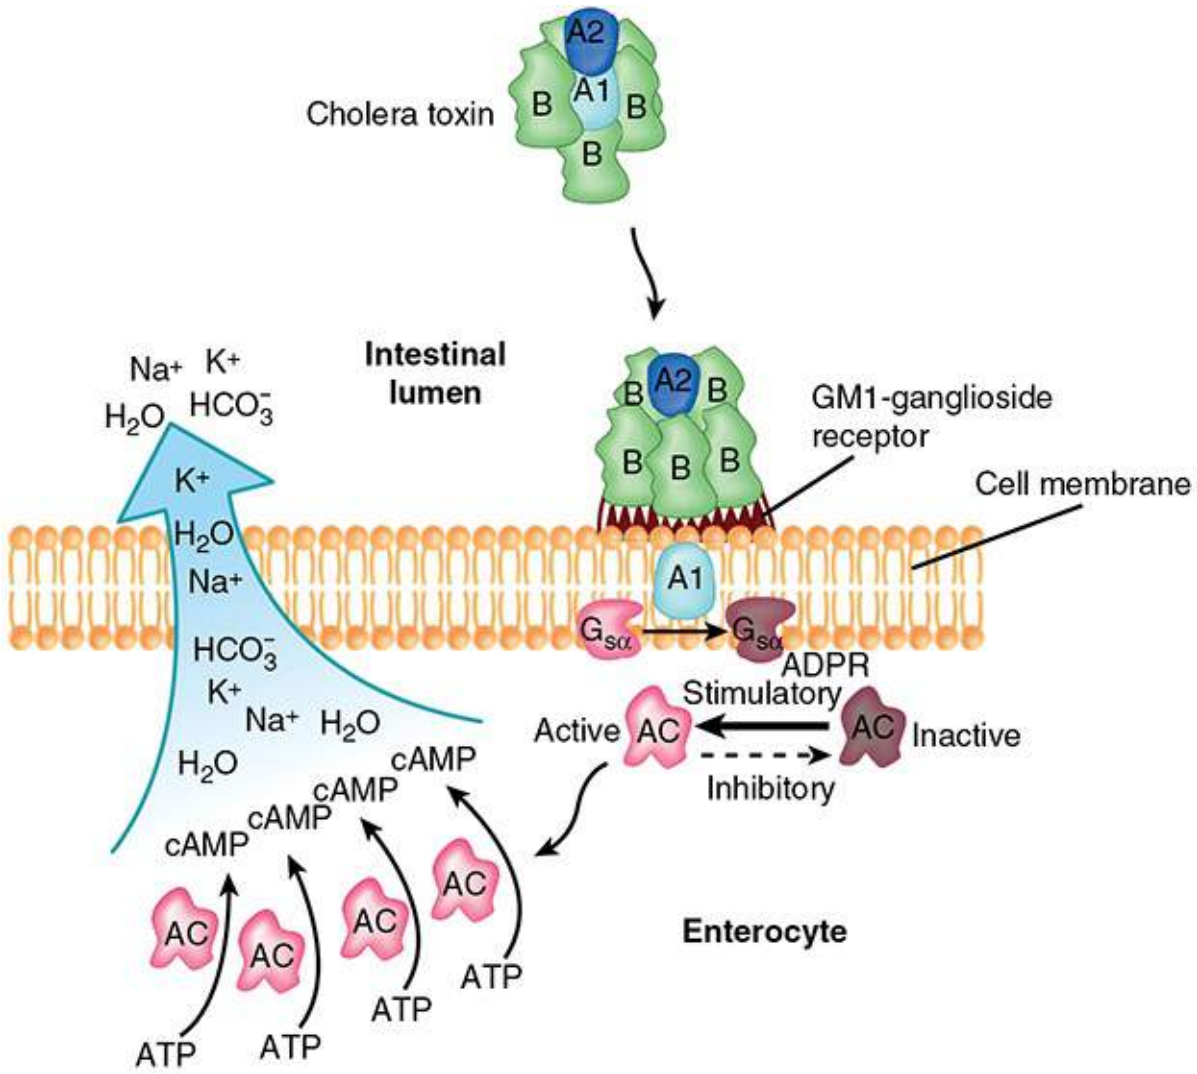

FIGURE 32–1. The action of cholera toxin. The complete toxin is shown binding to the GM1-ganglioside receptor on the cell membrane via the binding (B) subunits. The active portion (A1) of the A subunit catalyzes the ADP-ribosylation (ADPR) of the G_S (stimulatory) regulatory protein, "locking" it in the active state. Because the G_S protein acts to return adenylate cyclase from its inactive to active form, the net effect is persistent activation of adenylate cyclase. The increased adenylate cyclase (AC) activity results in accumulation of cyclic adenosine 3',5'-monophosphate (cAMP) along the cell membrane. The cAMP causes the active secretion of sodium (Na^+), chloride (Cl^-), potassium (K^+), bicarbonate (HCO_3^-), and water out of the cell into the intestinal lumen.

CHOLERA

EPIDEMIOLOGY

*** Transmission through untreated water**

*** Incubation period 2 days**

Epidemic cholera is spread primarily by contaminated water under conditions of poor sanitation, particularly where sewage treatment is absent or defective. Even though convalescent human carriage is brief, if the numerous vibrios purged from the intestines of those infected with cholera are able to reach the primary water supply, the conditions for spread are established. The short incubation period (2 days) ensures that organisms ingested by others quickly enter the epidemic cycle. Even so, modern travel makes imported cases of cholera possible. For instance, one man developed diarrhea in Florida after eating ceviche (marinated uncooked fish) just before departure from an airport in Ecuador.

*** Endemic on Indian subcontinent, East Africa**

*** Pandemics span decades**

*** Gulf Coast cases from undercooked shellfish**

*** Latin American epidemics widespread**

Cholera is endemic in the Indian subcontinent and now in Africa. Over the last two centuries, cholera has periodically spread beyond its historic locale to other parts of Asia, Indonesia, and even Europe in the 1800s during successive pandemics, each lasting 5 to 25 years. The current pandemic has brought cholera to the Western Hemisphere for the first time since 1911. Sporadic cases of cholera in the United States first appeared in the early 1970s and were traced to inadequately cooked crabs and shrimp caught off the Gulf Coast of Louisiana and Texas. In 1991, Latin America was hit with epidemic cholera with cases reported from 21 countries from Peru to northern Mexico. A massive epidemic of cholera followed the devastating earthquake of 2010 in Haiti. *V cholerae* O1, biotype El Tor was reintroduced into East Africa between 2015 and 2016 and is now endemic with tens of thousands of cases and thousands of deaths being reported. Currently, war-torn Yemen is experiencing the largest outbreak in recent history of O1, biotype El Tor cholera with over a million cases as a consequence of disrupted sanitation and water supplies.

*** *V cholerae* O1, biotype El Tor dominated 20th century**

* New O139 serotype spreading

The dominant strain of the 20th century was the El Tor biotype, first isolated from pilgrims to Mecca at the El Tor quarantine camp in Egypt in 1905 by Koch. This strain survives slightly longer in nature and is more likely to produce subclinical cases of cholera, both of which facilitate its spread. In 1992, the first cases of cholera due to a serotype other than O1 were detected in India and Bangladesh. The new serotype (O139 Bengal) is fully virulent with the additional threat of enhanced ability to produce disease in persons whose immunity is due to exposure to the old serotype. Genomic analysis of the clonal Haitian epidemic strains showed them to be nearly identical to variant *V cholera* El Tor O1 strains isolated from Bangladesh in 2002 and 2008, likely introduced into Haiti by asymptomatic UN peacekeepers from South Asia, and quite different from earlier Peruvian isolates. These realities illustrate the potential for the global spread of cholera and the challenges for the vaccine strategies designed to prevent it.

Cholera was unknown in Haiti before 2010. How could an earthquake cause an epidemic there?

* Survival in shellfish and plankton facilitates epidemics

The epidemic potential of *V cholerae* depends on its ability to survive in both aquatic environments and human hosts. In the environment, it persists in a dormant state in association with shellfish and plankton by attaching to their chitinous exoskeleton in the biofilms formed in the dormant seawater state but not during infection. This dual life is facilitated by a surface protein able to bind a constituent of chitin as well as glycoproteins and lipids on the intestinal epithelium. Satellite tracking has linked periodic climate changes (warming seawater), plankton blooms, and cholera epidemics along the coast of South America. Otherwise, the organism is fragile, surviving only a few days in the environment outside its human or crustacean hosts.

PATHOGENESIS

* Large doses pass stomach acid barrier

*** Pili, proteins mediate adherence**

*** CT-stimulated hypersecretion causes diarrhea**

To produce cholera, *V cholerae* must reach the small intestine, swim to the intestinal crypts, multiply, and produce virulence factors. In healthy people, ingestion of large numbers of bacteria is required to offset the acid barrier of the stomach. Colonization of the entire intestinal tract from the jejunum to the colon by *V cholerae* requires adherence to the epithelial surface by the abovementioned protein and surface pili. Bacteria recently passed from cholera cases are hyperinfectious by virtue of chemotactic motility facilitating colonization of the small intestine. The outstanding feature of *V cholerae* pathogenicity is the ability of virulent strains to secrete CT, which is responsible for the disease cholera. The water and electrolyte shift from the cell to the intestinal lumen is the fundamental cause of the watery diarrhea of cholera. Non-O1, non-O139 strains have been sporadically isolated from cases of gastroenteritis but do not produce CT, and thus not the disease cholera.

Think ▸▸ Apply 32-1: The sanitary infrastructure disruptions caused by earthquakes can contribute to epidemics but only if the pathogen is already present. Ironically, in this case, it was the aid workers flown in to help who brought the *V cholerae* with them. The absent immunity in the Haitian population accelerated spread and heightened morbidity.

*** Small intestine loses fluid**

*** K^+ plus bicarbonate loss causes hypokalemia, acidosis**

The fluid loss that results from the adenylate cyclase stimulation of cells depends on the balance between the amount of bacterial growth, toxin production, fluid secretion, and fluid absorption in the entire gastrointestinal tract. The outpouring of fluid and electrolytes is greatest in the small intestine, where the secretory capacity is high and absorptive capacity is low. The diarrheal fluid can amount to many liters per day, with approximately the same NaCl content as plasma, but also significant potassium and bicarbonate. The result is dehydration (isotonic fluid loss), hypokalemia (potassium loss), and

metabolic acidosis (bicarbonate loss). The intestinal mucosa remains unaltered except for some hyperemia because *V cholerae* does not invade or otherwise injure the enterocyte.

▪ Genetic Regulation of Virulence

*** ToxR controls CT and TCP genes**

*** Biofilm formation expressed in environmental crustaceans**

The expression of the multiple virulence factors of *V cholerae* is controlled in a coordinated two-component systems involving environmental sensors and as many as 20 chromosomal genes divided between a pathogenicity island (PAI) containing CT and one containing TCP. The chief regulator is a transmembrane protein (ToxR) that “senses” environmental changes in pH, osmolarity, and temperature, which convert it to an active form. In the active state, ToxR can directly turn on CT genes as well as activate transcription of a second regulatory protein, ToxT. ToxT, whose natural effector may be bile, then activates transcription of virulence genes in both PAIs, including TCP and CT. Another set of environmental sensors switch *V cholerae* from free-swimming forms to the sessile, biofilm-forming state associated with environmental persistence in crustaceans. Quorum-sensing systems deploy expression of these virulence genes at a time when a critical mass of *V cholerae* is present to sustain it.

IMMUNITY

*** Rate higher with achlorhydria**

*** sIgA associated**

Nonspecific defenses such as gastric acidity, gut motility, and intestinal mucus are important in preventing colonization with *V cholerae*. For example, in persons who lack gastric acidity (gastrectomy or achlorhydria from malnutrition), the attack rate of clinical cholera is higher. The immune state has been most strongly associated with sIgA directed against O-antigen LPS, CT (B subunit), and TCP. The precise protective mechanisms remain to be established.

CHOLERA: CLINICAL ASPECTS

MANIFESTATIONS

*** Watery diarrhea causes large fluid loss**

*** Dehydration and electrolyte imbalance**

Typical cholera has a rapid onset, beginning with abdominal fullness and discomfort, rushes of peristalsis, and loose stools. Vomiting may also occur. The stools quickly become watery, voluminous, almost odorless, and contain mucus flecks, giving it an appearance called **rice-water stools.** Neither white blood cells nor blood are in the stools, and the patient is afebrile. Clinical features of cholera result from the extensive fluid loss and electrolyte imbalance, which can lead to extreme dehydration, hypotension, and death within hours if untreated. No other disease produces dehydration as rapidly as cholera.

DIAGNOSIS

Stool culture uses TCBS selective agar

The initial suspicion of cholera depends on recognition of the typical clinical features in an appropriate epidemiologic setting. A bacteriologic diagnosis is accomplished by isolation of *V cholerae* from the stool. The organism grows on common clinical laboratory media such as blood agar and MacConkey agar, but its isolation is enhanced with a selective medium that contains thiosulfate–citrate–bile salt–sucrose (TCBS agar). Once isolated, *V cholerae* (sucrose-fermenting yellow colonies on green background) is readily identified by biochemical reactions. Outside cholera-endemic areas, the TCBS agar is not routinely used for stool cultures, so clinical laboratories must be alerted to the suspicion of cholera.

TREATMENT

*** Oral or IV fluid and electrolyte replacement**

*** Antimicrobials reduce duration, severity**

The outcome of cholera depends on balancing the diarrheal fluid and ionic losses with adequate fluid and electrolyte replacement. This is accomplished by oral and/or intravenous administration of solutions of glucose with near physiologic concentrations of sodium and chloride and higher than physiologic concentrations of potassium and bicarbonate. Exact formulas are available as dried packets to which a given volume of water is added. Oral replacement, particularly if begun early, is sufficient for all but the most severe cases and has substantially reduced the mortality from cholera. Antimicrobial therapy plays a secondary role in fluid replacement by shortening the duration of diarrhea and magnitude of fluid loss. A single dose of azithromycin provides optimal antimicrobial therapy, but doxycycline, a fluoroquinolone, or trimethoprim-sulfamethoxazole also are effective agents.

PREVENTION

*** Water sanitation, cooking shellfish**

Killed vaccines disappointing

*** Live oral vaccine approved**

Epidemic cholera, a disease of poor sanitation, does not persist where treatment and disposal of human waste are adequate. Because good sanitary conditions do not exist in much of the world, secondary local measures such as boiling and chlorination of water during epidemics are required. Cholera associated with ingestion of crabs and shrimp can be prevented by adequate cooking (10 minutes) and avoidance of recontamination from containers and surfaces. Vaccines prepared from whole cells, lipopolysaccharide, and CT B subunit have been disappointing providing protection that is not long-lasting. Live attenuated strains of *V cholerae* have garnered the most research interest because of their potential to stimulate a sIgA immune response in the gut. In 2016, the FDA first approved such a vaccine, for use in adults 18 through 64 years of age traveling to cholera-affected areas, based on challenge studies in nonimmune individuals of whom 91% seroconverted with a fourfold rise in serum vibriocidal antibody. The active component of this vaccine is lyophilized *V cholerae* CVD 103-HgR. There are caveats: efficacy has not been established in persons with any preexisting immunity due to exposure to *V cholerae* (as in endemic or epidemic

areas) or receipt of a cholera vaccine and it has not been shown to protect against V cholera serogroup O139 or other non-O1 serogroups.

OTHER *VIBRIOS*

*** *V parahaemolyticus* diarrhea from undercooked seafood**

***V vulnificus* sepsis, wound infections linked to raw oysters, iron overload**

Species of *Vibrio* other than *V cholerae* may still produce disease, but are uncommon and typically restricted to seacoast locales. *Vibrio parahaemolyticus* produces a diarrheal illness after ingestion of raw or inadequately cooked seafood due to the production of a pair of its own enterotoxins. For virulence *Vibrio vulnificus* stands out because it can produce a rapidly progressive cellulitis in wounds sustained in seawater as well as a fatal bacteremic infection after ingestion of raw seafood. The latter has been common enough in Florida to threaten the local oyster trade. Cases were also seen in the area devastated by hurricane Katrina. *V vulnificus* is also a spectacular scavenger of host iron stores and produces particularly fulminant disease in persons with iron-overload states (eg, thalassemia and hemochromatosis) and those with cirrhosis of the liver. Features of these and other less common vibrios are shown in Table 32-2.

KEY CONCLUSIONS

- *Vibrio cholerae* produces an enterotoxin that activates the adenylate cyclase system.
- Cholera reemerges when public health infrastructure breaks down.
- *V cholerae* survives and persists in saltwater plankton and crustaceans.
- Accumulations of cAMP in enterocytes result in massive outpouring of intestinal fluid.
- Voluminous diarrhea leads to dehydration, acidosis, and death swiftly unless replaced.
- Effective therapy (single dose of azithromycin) halts toxin production and thereby shortens duration.
- *Vibrio parahaemolyticus* causes diarrhea after seafood ingestion.
- *Vibrio vulnificus* and other halophilic species cause soft tissue infections and sepsis in patients with cirrhosis or iron overload.

• *CAMPYLOBACTER*

Campylobacters are motile, curved, oxidase-positive, Gram-negative rods similar in morphology to vibrios. The cells have polar flagella and are often attached at their ends giving pairs “S” shapes or a “seagull” appearance. More than a dozen *Campylobacter* species have been associated with human disease. Of these, *C jejuni* is by far the most common and is discussed here as the prototype for intestinal disease. The features of other species are summarized in Table 32-2.

BACTERIOLOGY: *CAMPYLOBACTER JEJUNI*

*** Microaerophilic atmosphere for growth**

*** CDT is cytotoxin**

Before 1973, *C jejuni* was not recognized as a cause of human disease. Not until selective methods for its isolation were developed was it recognized as one of the most common causes of infectious diarrhea. Like other campylobacters, *C jejuni* grows well only on enriched media at 42°C under microaerophilic conditions. That is, it requires oxygen at reduced tension (5-10%), presumably because of the vulnerability of some of its enzyme systems to superoxides. Growth usually requires 2 to 4 days, sometimes as much as 1 week. *C jejuni* has the structural components found in other Gram-negative bacteria (eg, outer membrane, LPS, and LOS). The cells are actively motile through the action of a polar flagellum. In contrast to the vibrios, *C jejuni* does not break down carbohydrates but uses amino acids and metabolic intermediates for energy. It is one of a number of pathogens that produce a membrane-bound protein called cytolethal-distending toxin (CDT). CDT has an A/B toxin structure in which the A subunit is able to cause cell cycle arrest.

CAMPYLOBACTER ENTERITIS

EPIDEMIOLOGY

*** Diarrhea worldwide**

*** Infecting dose low**

It is humbling to consider how a pathogen as common as *C jejuni* could have been missed for decades. Rates of campylobacteriosis vary widely around the world but at 4% to 30% of diarrheal stools, it is the leading cause of gastrointestinal infection in developed countries. Over 2 million cases occur each year in the United States at a rate roughly double that of *Salmonella*, the second most common bacterial enteric pathogen. This high rate of disease is facilitated by the low infecting dose of *C jejuni*—only a few hundred cells.

*** Reservoir in animals**

*** Undercooked poultry, unpasteurized milk major sources**

The primary reservoir is in animals, and the bacteria are transmitted to humans by ingestion of contaminated food or by direct contact with pets. Campylobacters are commonly found in the normal gastrointestinal and genitourinary flora of warm-blooded animals, including sheep, cattle, chickens, wild birds, and many others. The most common source of human infection is undercooked poultry, but outbreaks have been caused by contaminated rural water supplies and unpasteurized milk often consumed as a “natural” food. Sometimes a direct association can be made with a household pet, particularly a new puppy just brought home from a kennel.

PATHOGENESIS

Intracellular microtubule movement

*** Invasion, CDT, LOS vesicles cause injury**

Infection is established by oral ingestion, followed by colonization of the intestinal mucosa. Adherence to enterocytes is facilitated by action of the flagellum followed by entrance into cells in endocytotic vacuoles. Once inside, they move in association with the cell’s microtubule structure, rather than the actin microfilaments associated with some other invasive bacteria. Candidate

injury mechanisms include the cytotoxic CDT and the action of lipooligosaccharides (LOS) released in outer membrane vesicles. The intestinal pathology is that of an invasive pathogen with acute inflammation, crypt abscesses, and occasional seeding of the bloodstream.

*** GBS may follow infection**

*** Anti-LOS antibodies cross-react with neural gangliosides**

There is an association between *C jejuni* infection and **Guillain-Barré syndrome (GBS),** an acute demyelinating neuropathy that is frequently preceded by an infection. Although *C jejuni* is not the only antecedent to this syndrome, it is the most common of identifiable causes. Up to 40% of patients have culture or serologic evidence of *Campylobacter* infection at the time the neurologic symptoms occur. The mechanism is a type II hypersensitivity involving antibody elicited by epitopes in the *C jejuni* outer membrane LOS that cross-react with host peripheral nerve myelin gangliosides. These antiganglioside antibodies are found in the serum of patients with GBS motor neuropathies. This molecular mimicry is similar to the mechanism of group A streptococcal rheumatic fever. Reactive arthritis may also occur following infection.

IMMUNITY

*** Immune mechanisms unclear**

Acquired immunity after natural infection with *C jejuni* has been demonstrated in volunteer studies, but the mechanisms involved are unknown. Secretory and serum IgA are formed in the weeks after infection but decline thereafter. The high rate of *Campylobacter* infection in patients with AIDS suggests the importance of cellular immune mechanisms.

CAMPYLOBACTERIOSIS: CLINICAL ASPECTS

MANIFESTATIONS AND DIAGNOSIS

Abdominal pain and dysentery

Culture on selective medium in microaerophilic atmosphere

The illness typically begins 1 to 7 days after ingestion, with fever and lower abdominal pain that may be severe enough to mimic acute appendicitis. These are followed within hours by dysenteric stools that usually contain blood and pus. The illness is typically self-limiting after 3 to 5 days but may last 1 to 2 weeks. The diagnosis is confirmed by isolation of the organism from the stool. This requires a special medium made selective for *Campylobacter* by inclusion of antimicrobials that inhibit the normal facultative microbiota of the bowel. Plates must be incubated in a microaerophilic atmosphere, which can now be conveniently generated in a sealed jar by hydration of commercial packs similar to those used for anaerobes.

TREATMENT

*** Azithromycin drug of choice**

Since less than 50% of patients clearly benefit from antimicrobial therapy, cases of *Campylobacter* infection are usually not treated unless the disease is severe or prolonged (lasting longer than 1 week). *Campylobacter jejuni* is typically susceptible to macrolides and fluoroquinolones but resistant to β-lactams. Azithromycin is the therapy of choice but must be given early for maximal effect; erythromycin is an alternative. Fluoroquinolones are also effective, but resistance is becoming more common, especially in patients with HIV infection who have difficulty clearing the organism despite treatment.

KEY CONCLUSIONS

- *Campylobacter jejuni* causes diarrhea by invasion and cytotoxin production.
- Found in the intestine of many animals, especially poultry, it is a foodborne pathogen.
- The disease is self-limited, but excretion and transmission are halted by macrolide therapy.
- Carriage after infection is transient except in HIV-infected patients.
- Guillian-Barré syndrome can follow infection by virtue of molecular mimicry.

• *HELICOBACTER*

Almost everything we once knew about ulcers was wrong

In 1983 an Australian internist and pathologist (Warren and Marshall) postulated that gastritis and peptic ulcers were infectious diseases. Subsequently, they fulfilled Koch's postulates by self-experimentation with Warren's ingestion of a broth slurry of *H pylori*, his development of gastritis, and the recovery of *H pylori* in pure culture from his gastric mucosa. Later the 2005 Nobel Prize in Medicine was awarded to the pair for their scientific contradiction of long-held beliefs. Ironically, the 10th edition of *Harrison's Principles of Internal Medicine* published in 1983 described peptic ulcers as due to an unfavorable balance between gastric acid–pepsin secretion and gastric or duodenal mucosal resistance. Underlying causes cited included genetic and lifestyle (smoking) as well as psychologic factors (anxiety, stress). Treatment with bismuth salts, antacids, and inhibitors of acid secretion gave relief but not cure. Relapsing patients (50-80%) were subjected to surgical treatments (vagotomy, partial gastrectomy), which had their own set of complications (reflux, afferent loop, and dumping syndromes). All of this seemed logical and supported by clinical observations and research studies but was simply incorrect. The bacteria now called *Helicobacter* had been observed but dismissed because they were so common and their urease was once considered a secretory product of the stomach itself. The Nobel Prize-winning studies that stimulated the reversal of this dogma have led to cures with antibacterial agents and new ideas linking *Helicobacter* infection to cancer. This experience has also left us with a sense that we can never be smug about what we "know" in medicine.

BACTERIOLOGY: *HELICOBACTER PYLORI*

*** Similar to *Campylobacter***

H pylori has morphologic and growth similarities to the campylobacters, with which they were originally classified. The cells are slender, curved rods with polar flagella. The cell wall structure is typical of other Gram-negative bacteria. Growth requires a microaerophilic atmosphere and is slow (3-5 days). The cells are rapidly motile due to the action of multiple polar flagella.

*** Urease raises pH**

*** VacA injures lysosomal, endosomal membranes**

*** CagA induces multiple changes**

A number of unique bacteriologic features have been found in *H pylori.* The most distinctive is a **urease** whose action allows the organism to persist in low pH environments by the generation of ammonia. The urease is produced in amounts so great (6% of bacterial protein) that its action can be demonstrated within minutes of placing *H pylori* in the presence of urea. Another secreted protein called the **vacuolating cytotoxin** (VacA) causes apoptosis in eukaryotic cells it enters generating multiple large cytoplasmic vacuoles (**Figure 32–2**). The vacuoles are felt to be generated by the toxin's formation of channels in lysosomal and endosomal membranes. Another protein, CagA, induces changes in multiple cellular proteins and has a strong association with virulence. Both VacA and CagA are delivered to cells by injection secretion systems (type IV). The genes for CagA and the components of its secretion system are located in a large PAI.

HELICOBACTER GASTRITIS

EPIDEMIOLOGY

*** Transmitted by human fecal, gastric secretions**

*** Gastric colonization prevalent worldwide**

Infection with *H pylori* causes what is perhaps the most prevalent disease in the world. The organism is found in the stomachs of 30% to 50% of adults in developed countries, and it is almost universal in developing countries. The exact mode of transmission is not known, but is presumed to be person to person by the fecal–oral route or by contact with gastric secretions in some way. Colonization increases progressively with age, and children are believed to be the major amplifiers of *H pylori* in human populations. A declining prevalence in developed countries may be due to decreased transmission because of less crowding and frequent exposure to antimicrobial agents.

*** Colonization persists**

*** Ethnic links strong**

Once established, the same strain persists for years, decades, even for life. Molecular epidemiologic analysis indicates the strains themselves have strong linkages to ethnic origins that can be traced back to the earliest known patterns of human migration. *H pylori* has been called an “accidental tourist,” which was established in the stomachs of humans thousands of years ago and remained bound to the original population as it dispersed from continent to continent.

*** Sole nondrug cause of gastritis, ulcers**

*** Adenocarcinoma, lymphoma preceded by infection**

H pylori is the most common precursor of gastritis, gastric ulcer, and duodenal ulcer cases which are not due to drugs. In addition, *Helicobacter* gastritis caused by Cag^+ strains is acknowledged to be an antecedent of gastric adenocarcinoma, one of the most common causes of cancer death in the world. It is also linked to a gastric mucosa-associated lymphoid tissue (MALT) lymphoma, which is less common but shows the striking property of regressing with antimicrobial therapy. *H pylori* gained the dubious distinction of being the first bacterium declared a class I carcinogen by the World Health Organization.

Other helicobacters in animals

H pylori is exclusive to humans, but other species have been found in the stomachs of a wide range of animals, where they are also associated with gastritis. It is difficult to imagine the old "stress ulcer" theories surviving the discovery of a cheetah with *Helicobacter* gastritis. Speculation that domestic animals may serve as a reservoir for human infection has not been confirmed.

PATHOGENESIS

*** Urease neutralizes gastric acid**

*** Motility facilitates microenvironment survival**

To persist in the hostile environs of the stomach, *H pylori* uses many mechanisms to adhere to the gastric mucosa and survive the acid milieu of the stomach (**Figure 32–3**). Motility provided by the flagella allows the organisms to swim to the less acidic locale beneath the gastric mucus, where the urease further creates a more neutral microenvironment by ammonia production. Urease production is regulated in response to changes in the gastric acidity such as rises to a pH as high as 6.0 following the buffering effect of meals. At the mucosa, adherence is mediated by multiple outer membrane proteins which bind to the surface of gastric epithelial cells and certain erythrocyte antigens (Lewis b).

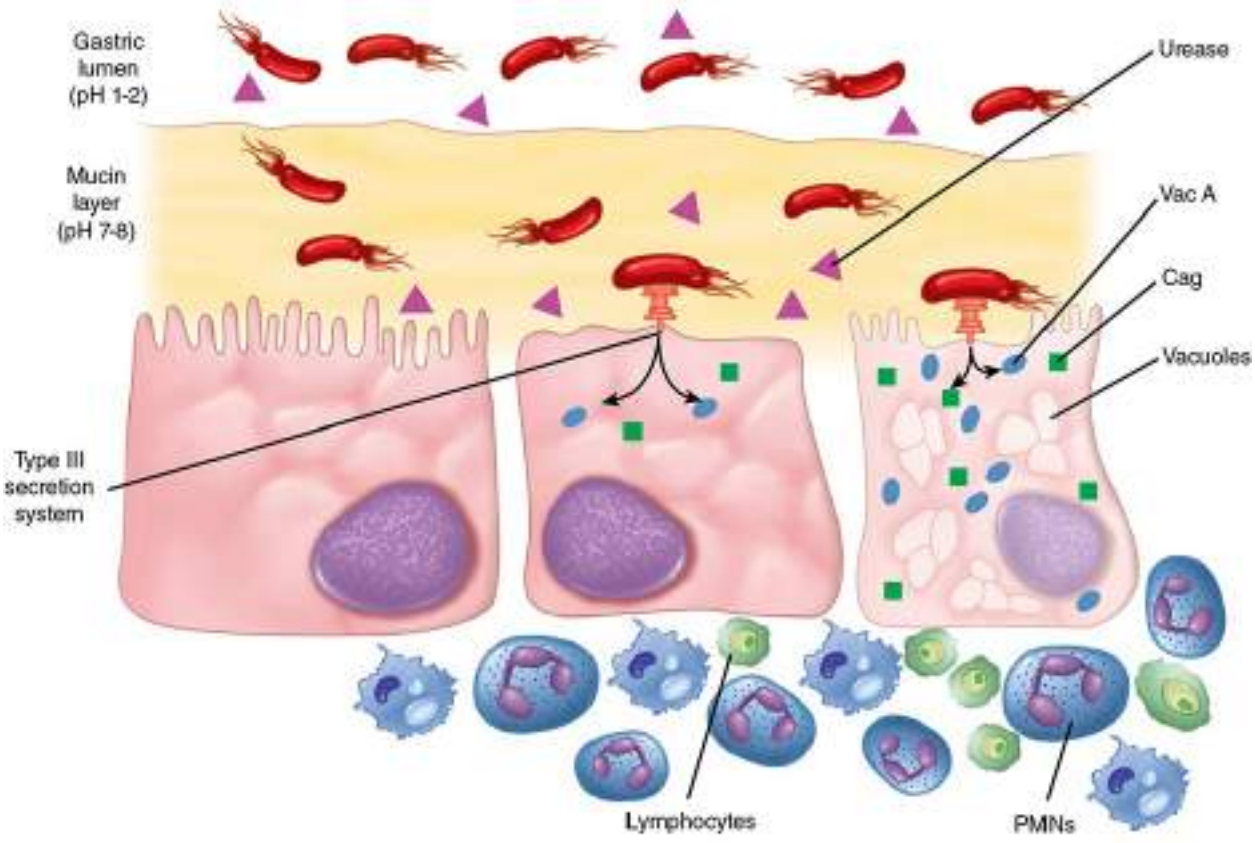

FIGURE 32–3. ***Helicobacter*** **gastritis, cellular view.** From the low pH gastric lumen *H pylori* swims beneath the mucus layer, produces urease, and persists in a more physiologic environment. A type III secretion system injects the vacuolating cytotoxin (VacA), and Cag, into the gastric cells. Acute and chronic inflammatory cells gather in the submucosa. PMNs, polymorphonuclear neutrophils.

Multiple inflammation factors

*** VacA induces cellular changes, death**

*** CagA alters cytoskeleton**

H pylori colonization is almost always accompanied by a cellular infiltrate ranging from minimal mononuclear infiltration of the lamina propria to extensive inflammation with neutrophils, lymphocytes, and microabscess formation. Both gastritis and duodenal ulcers are most strongly associated with colonization of the antrum area of the stomach. The inflammation may be due to toxic effects of the urease or the VacA transported into the gastric epithelial cells by the secretion system. Inside the cell, VacA causes vacuolization of the endosomal compartment and has other effects including altered T-cell function. The CagA protein is injected into the gastric epithelial cell by the secretion

system, where it triggers multiple enzymatic reactions including those that cause reorganization of the actin cytoskeleton and stimulation of cytokines. Variations in the genes contained in the PAI generate a mixed population of *H pylori* cells particularly in relation to the multiple properties of CagA. Added together urease, CagA, and VacA provide ample explanation for the gastritis that is universal in *H pylori* infection. This prolonged and aggressive inflammatory response could lead to epithelial cell death and ulcers. The progression from gastritis to ulcer remains to be explained although a duodenal ulcer-promoting gene has been identified.

*** Chronic inflammation leads to metaplasia**

*** CagA triggers oncogenic signals**

That decades of inflammation and assault by the virulence factors just described could cause metaplasia, and eventually cancer seems logical, but the specific mechanisms of carcinogenesis have only recently been explored. CagA, for example, has been shown to trigger a cascade of interactions leading to growth-promoting oncogenic signals. The gastric lymphomas may represent neoplastic transformation of B-lymphocyte clones proliferating in response to chronic antigenic stimulation. The discovery that *H pylori* colonization may affect hormones involved in glucose homeostasis has led to other hypotheses involving type 2 diabetes.

IMMUNITY

There is obviously little evidence of natural immunity in an infection that typically lasts for decades. The immunosuppressive effect of virulence factors such as VacA may be responsible in combination with yet to be discovered mechanisms.

HELICOBACTER DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

*** Epigastric pain, nausea signs of gastritis**

Primary infection with *H pylori* is either silent or causes an illness with nausea and upper abdominal pain lasting up to 2 weeks. Years later, the findings of gastritis and peptic ulcer disease include nausea, anorexia, vomiting, epigastric pain, and even less specific symptoms such as belching. Many patients are asymptomatic for decades, even up to perforation of an ulcer. Perforation can lead to extensive bleeding and peritonitis due to the leakage of gastric contents into the peritoneal cavity.

DIAGNOSIS

*** Culture, urease, or antigen detection**

*** Serology demonstrates chronic infection**

The most sensitive means of diagnosis is endoscopic examination, with biopsy and culture of the gastric mucosa. The *H pylori* urease is so potent that its activity can be directly demonstrated in biopsies in less than an hour. Noninvasive methods include serology and a urea breath test. For the breath test, the patient ingests ^{13}C- or ^{14}C-labeled urea, from which the urease in the stomach produces products that appear as labeled CO_2 in the breath. A number of methods for the detection of antibody directed against *H pylori* are now available. Because IgG or IgA remains elevated as long as the infection persists, these tests are valuable both for screening and for evaluation of therapy. The advantage of direct detection of the organism is that culture is the most sensitive indicator of cure following therapy. A stool antigen detection test is also a sensitive indicator of colonization.

TREATMENT AND PREVENTION

*** Combination therapies achieve cures**

*** Regimen difficult to tolerate**

H pylori is susceptible to a wide variety of antimicrobial agents. Bismuth subsalicylate (eg, Pepto-Bismol), which in the past was believed to act by coating the stomach, also has antimicrobial activity. Cure rates approaching 90% have been achieved with a quadruple regimen (14 days) of bismuth subsalicylate, a protein pump inhibitor (PPI) (omeprazole), tetracycline, and

metronidazole. Triple therapy with a PPI, clarithromycin, and amoxicillin is less effective. These combination regimens must be continued for at least 2 weeks and may be difficult for some patients to tolerate. Prevention of *H pylori* disease awaits further understanding of transmission and immune mechanisms. Prophylactic treatment of asymptomatic persons colonized with *H pylori* is not yet recommended.

Should everyone be screened for *H pylori* colonization?

KEY CONCLUSIONS

- *Helicobacter pylori* is found worldwide as a common inhabitant of the stomach.
- *H pylori* is also the sole nondrug cause of gastritis and gastric and duodenal ulcers.
- Its toxins VacA and CagA cause chronic inflammation that can lead to gastric adenocarcinoma.
- Diagnosis of active disease is done by endoscopic biopsy, the breath test for urease, or stool antigen detection.
- Quadruple therapy with bismuth, omeprazole, tetracycline, and metronidazole is optimal.

CASE STUDY

Raw Oysters in Rifle

On August 17, 1988, a 42-year-old man was treated for profuse, watery diarrhea, vomiting, and dehydration at an emergency room in Rifle, Colorado. On August 15, he had eaten approximately 12 raw oysters from a new oyster-processing plant in Rifle. Approximately 36 hours after eating the oysters, he had sudden onset of symptoms and passed 20 stools during the day before seeking medical attention. Stool culture subsequently yielded toxigenic *Vibrio cholerae* O1, El Tor biotype. The patient had no underlying illness, was not taking medications, and had not traveled outside the region during the month before onset.

The oysters had been harvested on August 8, 1988, in a bay off the coast of Louisiana. Approximately 1000 bushels (200,000 oysters) arrived by refrigerator truck at the plant in Rifle on August 11. The patient purchased three dozen of these oysters on August 15. During a 6-day period, eight other persons shared the oysters purchased by the patient. None became ill. Although one of seven tested had a vibriocidal antibody titer of 1:640, none had elevated antitoxic antibody titers, and none had *V cholerae* isolated from stool. Physicians and local health departments were asked to notify the Colorado Department of Health about similar cases, but no cases were reported.

Think ▸▸ Apply 32-2: Widespread screening to prevent ulcers remains controversial in asymptomatic persons. In parts of the world with high *H pylori* prevalence and gastric adenocarcinoma rates, screening followed by treatment of positives is under study as a means of cancer prevention. The diversity of regimes used worldwide and the paucity of controlled trials with adequate follow-up, however, have hampered definitive conclusions.

QUESTIONS

1. What is the probable source of this patient's *V cholerae* infection?

A. Oyster bar employee
B. An imported case from Asia
C. Gulf of Mexico
D. Rifle groundwater
E. South America

2. What would you expect a biopsy of this patient's small intestine to show?

A. Hyperemia
B. Pseudomembrane
C. Flask-shaped ulcers
D. Enterocyte necrosis
E. Focal hemorrhage

3. Which of the following measures would be the *least effective* in preventing a recurrence of this outbreak?

A. Disinfecting the plant
B. A new source for oysters
C. Prophylactic rifampin
D. Cooking the oysters

ANSWERS

1. **(C)**
2. **(A)**
3. **(C)**

chapter 33

Enterobacteriaceae

Escherichia coli • *Shigella species* • *Salmonella enterica* • *Yersinia* • *Klebsiella* • *Enterobacter* • *Serratia* • *Proteus* • *Morganella* • *Providencia*

She died of a fever / And no one could save her / And that was the end of sweet Molly Malone / But her ghost wheels her barrow / Through streets broad and narrow / Crying cockles and mussels alive, alive o!

—James Yorkston: Irish Ballad

OVERVIEW

The Enterobacteriaceae are a large and diverse family of Gram-negative rods, members of which are both free-living and part of the indigenous flora of humans and animals; a few are adapted strictly to humans. The Enterobacteriaceae grow rapidly under aerobic or anaerobic conditions and are metabolically active. They are by far the most common cause of urinary tract infections (UTIs), and a limited number of species are also important etiologic agents of diarrhea. Entry into the bloodstream may cause Gram-negative endotoxin shock, a dreaded and often fatal complication. Historically, dying "of a fever" usually meant typhoid fever (*Salmonella* ser. Typhi), which because of its prolonged course and lack of localizing signs, caused unfortunates like Molly Malone to appear to be dying of fever alone. The term UTI encompasses a range of infections from simple cystitis involving the bladder to full-blown infection of the entire urinary tract, including the renal pelvis and kidney (pyelonephritis). The primary feature of cystitis is frequent urination, which often has a painful burning quality. In pyelonephritis, symptoms include fever, general malaise, and flank pain in addition to frequent urination. Cystitis is usually self-limiting, but infection of the upper urinary tract carries a risk of spread to the bloodstream. It is the leading cause of Gram-negative sepsis and septic shock. Diarrhea is the universal finding with *Escherichia coli* strains that are able to cause intestinal disease; the nature of the diarrhea varies depending on the pathogenic mechanism. Enterotoxigenic and enteropathogenic strains produce a watery diarrhea, the enterohemorrhagic strains produce a bloody diarrhea, and the enteroinvasive strains may cause dysentery with blood and pus in the stool. The diarrhea is usually self-limiting after only 1-3 days. The enterohemorrhagic *E coli* are an exception, with life-threatening manifestations outside the gastrointestinal tract due to Shiga toxin production. *Shigella* is the classic cause of dysentery, which is typically spread person to person under poor sanitary conditions. The illness begins as a watery diarrhea but evolves into an intense colitis with fever and frequent small-volume stools that contain blood and pus. Despite the invasive properties of the causal organism, the infection usually does not spread outside the intestinal tract. Typhoid fever has a slow, insidious onset and, if untreated, lasts for weeks. The primary symptom is a slowly rising fever, often accompanied by abdominal pain but little else. It ends either by

gradual resolution or in death due to complications (eg, rupture of the intestine or spleen). Family members may note only the extended fever, although physicians may observe a subtle rash or feel an enlarged spleen. Diarrhea may occur sporadically during the course but is not a consistent feature.

• GENERAL CHARACTERISTICS

BACTERIOLOGY

Rods are large

The Enterobacteriaceae are among the largest bacteria, measuring 2 to 4 μm in length with parallel sides and rounded ends. Forms range from large coccobacilli to elongated, filamentous rods. The organisms do not form spores or demonstrate acid-fastness.

O = LPS

K = polysaccharide capsule

H = flagellar protein

The cell wall, cell membrane, and internal structures are morphologically similar for all Enterobacteriaceae, and follow the cell plan described in Chapter 21 for Gram-negative bacteria. Components of the cell wall and surface, which are antigenic, have been extensively studied in some genera and form the basis of systems dividing species into serotypes. The outer membrane lipopolysaccharide (LPS) is called the **O antigen.** Its antigenic specificity is determined by variation in the sugars that form the long terminal polysaccharide side chains linked to the core polysaccharide and lipid A. Cell surface polysaccharides may form a well-defined capsule or an amorphous slime layer and are termed the **K antigen** (from the Danish *kapsel*, capsule). Motile strains have protein peritrichous flagella, which extend well beyond the cell wall and are called the **H antigen.** Many Enterobacteriaceae have adhesive surface pili (fimbriae), which are antigenic proteins, but not part of traditional typing systems.

Facultative growth is rapid

Enterobacteriaceae grow readily on simple media, often with only a single carbon energy source. Growth is rapid under both aerobic and anaerobic conditions, producing 2 to 5 mm colonies on agar media and diffuse turbidity in broth after 12 to 18 hours of incubation. All Enterobacteriaceae ferment glucose, reduce nitrates to nitrites, and are oxidase-negative.

CLASSIFICATION

*** Biochemical characteristics establish species**

*** Antigenic features define serotypes within species**

Genus and species designations are based on phenotypic characteristics such as patterns of carbohydrate fermentation and amino acid breakdown. The O, K, and H antigens are used to further divide some species into multiple **serotypes**. These types are expressed with letter and number of the specific antigen, such as *Escherichia coli* O157:H7, the cause of numerous foodborne outbreaks. These antigenic designations have been established only for the most important species and are limited to known antigenic structures. For example, many species lack capsules and/or flagella. In recent years, DNA and rRNA homology comparisons have been used to validate these relationships and establish new ones. The genera containing the species most virulent for humans are *Escherichia, Shigella, Salmonella, Klebsiella,* and *Yersinia.* Other less common but medically important genera are *Enterobacter, Serratia, Proteus, Morganella,* and *Providencia*. Multiple locus sequence typing (MLST) schemes have been developed in order to facilitate identification of and communication about important clones within these key pathogenic species.

TOXINS

All have LPS

Cytotoxins kill host cells

Enterotoxins cause secretion and diarrhea

In addition to the **LPS endotoxin** common to all Gram-negative bacteria, some Enterobacteriaceae also produce **protein exotoxins,** which act on host cells by

damaging membranes, inhibiting protein synthesis, or altering metabolic pathways. The end result of these actions may be cell death (cytotoxins) or a physiologic alteration, the net effect of which depends on the function of the affected cell. For example, enterotoxins act on intestinal enterocytes, causing the net secretion of water and electrolytes into the gut to produce diarrhea. Although these toxins are most strongly associated with *E coli*, *Shigella*, and *Yersinia*, others with the same or very similar actions have now been discovered in other species. Toxins found in another species may differ slightly in protein structure and genetic regulation, but still have the same biologic action on host cells. Details of these toxins are discussed later in this chapter in relation to their prototype species.

DISEASES CAUSED BY ENTEROBACTERIACEAE

EPIDEMIOLOGY

Present in nature and the intestinal tract

* *Shigella* and *S* Typhi are found only in humans

Most Enterobacteriaceae are primarily colonizers of the lower gastrointestinal tract of humans and animals. Many species survive readily in nature and live freely anywhere that water and minimal energy sources are available. In humans, they are the major facultative components of the colonic bacterial flora but are also found in the female genital tract and as transient colonizers of the skin. Enterobacteriaceae are scant in the respiratory tract of healthy individuals; however, their numbers may increase in hospitalized patients with intensive antibiotic exposure. *E coli* is the most common species of Enterobacteriaceae found among the indigenous flora, followed by *Klebsiella, Proteus,* and *Enterobacter* species. *Salmonella* and *Shigella* species are not considered members of the resident microbiota, although carrier states can exist. *Shigella* and *Salmonella* serovar Typhi are strict human pathogens with no animal reservoir. An overview of these infections is illustrated in **Figure 33–1**.

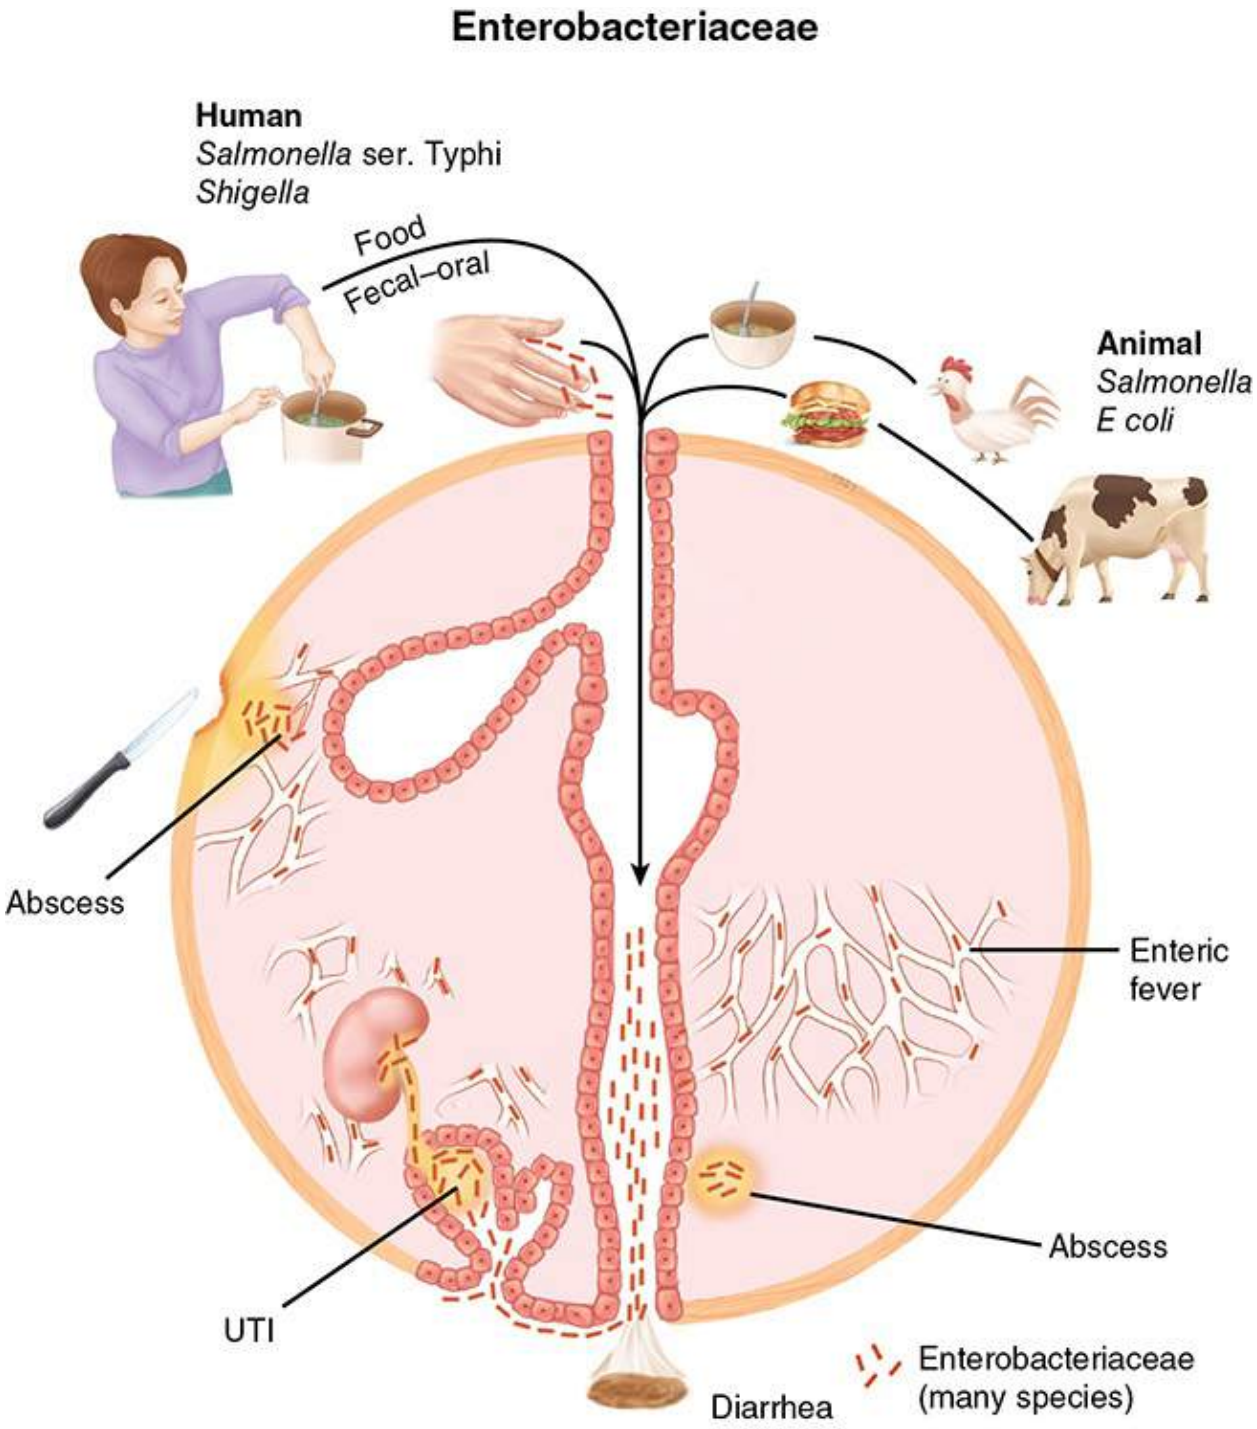

FIGURE 33–1. Enterobacteriaceae disease overview. The external sources of infection are frequently animal sources, but some pathogens are strictly human (*Shigella*, *Salmonella* ser. Typhi). Endogenous flora are the source of opportunistic infection, particularly urinary tract infection (UTI). Bacteria of any source entering the blood may cause endotoxic shock.

PATHOGENESIS

▪ Opportunistic Infections

*** Colonization presents opportunity when defense barriers open**

*** Access and adherence to bladder mucosa may lead to UTI**

Enterobacteriaceae are often poised to take advantage of their presence in the environment and among human microbiota to produce disease whenever they gain access to normally sterile body sites. Surface structures such as pili have been proven to aid this process for some species, and likely do so for many others as well. Once in deeper tissues, bacteria may persist and cause injury using strategies that, with the exception of LPS endotoxin and production of exotoxins or capsules, are still not well understood. The prototype infectious syndrome is the UTI, in which Enterobacteriaceae gain access to the urinary bladder due to minor trauma or instrumentation. Strains able to adhere to uroepithelial cells can persist and multiply in the nutrient-rich urine, sometimes ascending by way of the ureters to the renal pelvis and kidney, producing pyelonephritis. Likewise, mucosal or skin trauma can allow access to underlying soft tissue, and aspiration can provide access to the lung when the relevant sites are colonized with Enterobacteriaceae.

▪ Intestinal Infections

*** Cell destruction causes dysentery**

*** Enterotoxins cause watery diarrhea**

*** Enteric fever is a systemic illness**

Salmonella, *Shigella*, *Yersinia enterocolitica*, and certain strains of *E coli* are able to produce disease in the intestinal tract. These intestinal pathogens have invasive properties or virulence factors such as cytotoxins and enterotoxins, which correlate with the type of diarrhea they produce. In general, the invasive and cytotoxic strains produce an inflammatory diarrhea called **dysentery** with white blood cells (WBCs) and/or blood in the stool. The enterotoxin-producing strains cause a **watery diarrhea** in which fluid loss is the primary pathophysiologic feature. For a few species, the intestinal tract may be the original portal of entry, but the disease ultimately becomes systemic as a result of spread of bacteria to multiple organs. **Enteric (typhoid) fever** caused by *Salmonella enterica* ser. Typhi is the prototype of this form of infection.

▪ Regulation of Virulence

* Secretion systems inject virulence factors

In addition to adhesive pili, LPS, and exotoxins, the Enterobacteriaceae produce a myriad of other virulence factors to cause disease. Many of them are deployed in complex and sequential fashion, in response to environmental signals (temperature, iron, calcium) or as-yet unknown factors. Some members have **injection (type III or IV) secretion systems** that target human cells by delivering a syringe-like injection of multiple virulence factors into the cytoplasm of host cells.

Virulence genes are organized into gene clusters

PAIs contain multiple genes

* Expression stimulated by environmental cues

The genes for these factors, located on the chromosome, plasmids, or both, are controlled by interactive regulators that seem to produce each virulence factor exactly when it is needed. The genes themselves are often organized into clusters, which include the genes for the effector molecules as well as their regulatory proteins. This is particularly true for complex characteristics such as invasiveness, which involve multiple sequential steps. Some of these gene clusters reside within **pathogenicity islands (PAIs)** acquired *en bloc* from another bacterium in the genetically distant past. In particular, PAIs are associated with injection secretion systems, where they contain the structural genes for the injection apparatus, as well as the virulence factors injected.

IMMUNITY

* Immunity is short-lived

Little is understood about immunity to the broad range of opportunistic infections caused by Enterobacteriaceae. Antibody directed against an LPS core antigen has been shown to provide a degree of protection against Gram-negative endotoxemia, but the diversity of antigens and virulence factors among the Enterobacteriaceae is too great to expect broad immunity in any given host. Immunity to intestinal infection is generally short-lived and will be discussed

where relevant to specific intestinal pathogens.

ENTEROBACTERIACEAE: CLINICAL ASPECTS

MANIFESTATIONS

*** UTI and acute diarrhea are most common**

The Enterobacteriaceae produce the widest variety of infections of any group of microbial agents, including two of the most common infectious states, UTI and acute diarrhea. Urinary tract infections are manifested by dysuria and urinary frequency when infection is limited to the bladder, with the addition of fever and flank pain when the infection spreads to the kidney. Enterobacteriaceae are by far the most common cause of UTIs, and the most common species involved is *E coli.*

DIAGNOSIS

*** MacConkey agar demonstrates lactose fermentation**

*** Selective media required for *Salmonella* and *Shigella* in stools**

Gene probes allow direct detection

Culture is the primary method of diagnosis; all Enterobacteriaceae are readily isolated on routine media under almost any incubation conditions. Special indicator media such as MacConkey agar are commonly used in primary isolation to promote rapid identification of the pathogen from many possible species. For example, the common pathogens *E coli* and *Klebsiella* typically ferment lactose rapidly, producing acid (pink) colonies on MacConkey agar, whereas the intestinal pathogens *Salmonella* and *Shigella* do not. Separation of the intestinal pathogens from all the other Enterobacteriaceae in stool requires highly selective media designed solely for this purpose. (These are discussed as they relate to individual pathogens.) Improved understanding of the genetic and molecular basis for virulence has led to the development of direct nucleic acid and immunodiagnostic techniques for direct detection of toxin, adhesin, and invasin proteins or their genes in clinical materials, such as stool. Once too

expensive for use in clinical laboratories, these methods are emerging as primary diagnostic tools.

TREATMENT

* Susceptibility to antimicrobials is highly variable

Antimicrobial therapy is crucial to the outcome of certain infections caused by Enterobacteriaceae. Unfortunately, combinations of chromosomal and plasmid-determined resistance render them the most variable of all bacteria in susceptibility to antimicrobial agents. They are intrinsically resistant to penicillin G, erythromycin, and clindamycin, but may be susceptible to the extended-spectrum β-lactams, carbapenems, aminoglycosides, tetracyclines, chloramphenicol, sulfonamides, quinolones, nitrofurantoin, and the polypeptide antibiotics. The emergence and spread of multidrug resistance plasmids featuring hydrolytic enzymes such as extended-spectrum cephalosporinases or carbapenemases have fundamentally altered the empiric treatment of Gram-negative infections. Because the probability of resistance varies among genera and in different epidemiologic settings, the susceptibility of any individual strain must be determined by antimicrobial susceptibility tests. Typical patterns of resistance for some of the more common Enterobacteriaceae appear in **Appendix 23–1**.

• *ESCHERICHIA COLI*

BACTERIOLOGY

* Serotypes use O, K, H antigens

Most strains of *E coli* ferment lactose rapidly and produce indole. These and other biochemical reactions are sufficient to separate it from the other pathogenic Enterobacteriaceae. There are over 150 distinct O antigens and a large number of K and H antigens, all of which are designated by number. The antigenic formula for serotypes is described by linking the letter (O, K, or H) and the assigned number of the antigen(s) present (eg, O18:K1:H7). In the sequencing era, the emergence of multidrug-resistant clones has led to the use of

alternative nomenclature (eg, *E coli* Sequence Type 131, *Klebsiella pneumoniae* Sequence Type 258).

PILI

Type 1 pili bind mannose

P pili bind kidney cells

Pili of diarrhea strains bind enterocytes

Pili play a role in virulence as mediators of attachment to human epithelial surfaces. They show marked tropism for different epithelial cell types, which is determined by the availability of their specific receptor on the host cell surface. Most *E coli* express **type 1,** or common, **pili**. Type 1 pili bind to the D-mannose residues commonly present on epithelial cell surfaces and thus mediate binding to a wide variety of cell types. More specialized pili are found in select clones of *E coli*. **P pili** bind to digalactoside (Gal–Gal) moieties particularly common on kidney cells and erythrocytes of the P blood group. Pili that mediate binding to enterocytes are found among the diarrhea-causing *E coli* and are specific to the pathogenic type, as shown in **Figure 33–2** and listed in **Table 33-1**. *E coli* also causes diarrhea in animals, and different sets of pili exist with host-specific tropism for their enterocytes. The receptor(s) for the enteric pili are not known in detail but include glycolipids and glycoproteins on the enterocyte surface.

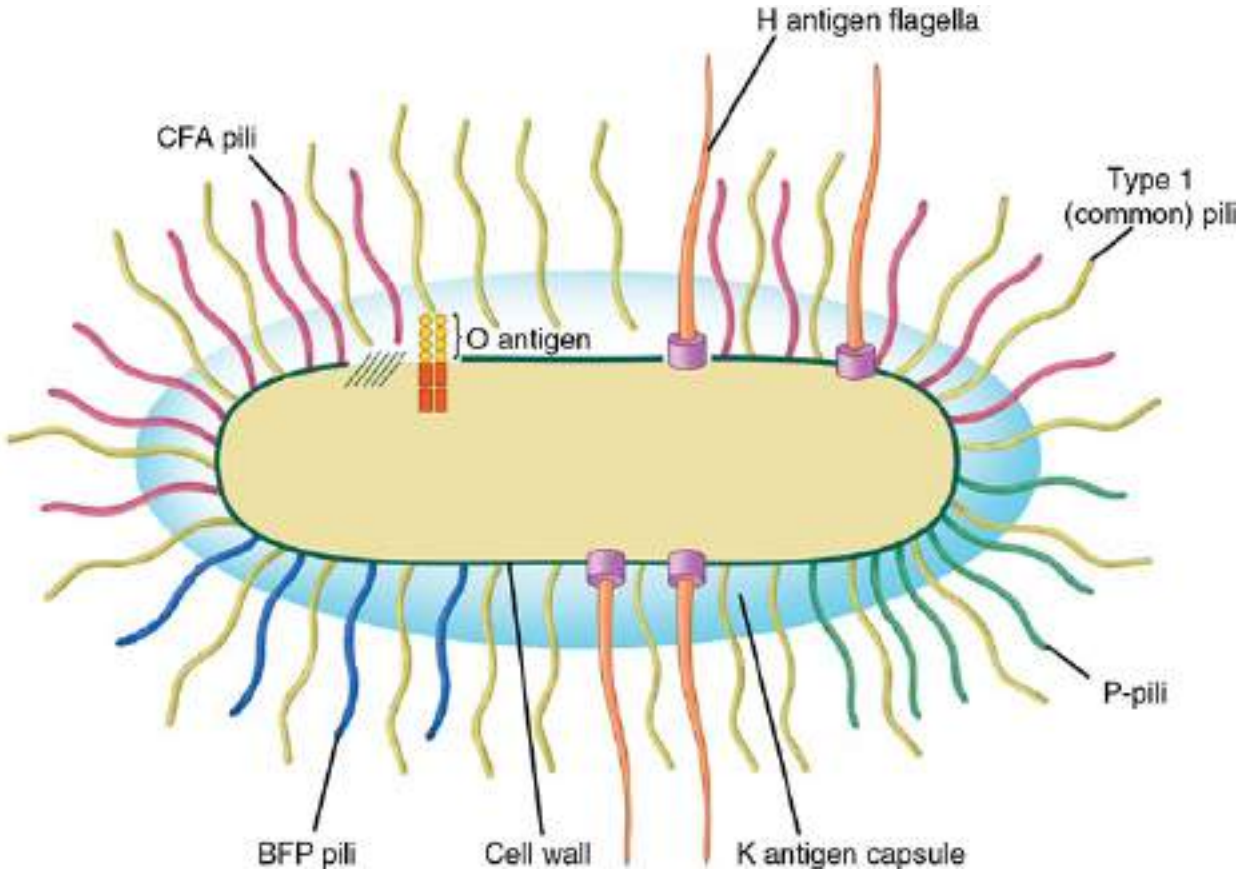

FIGURE 33–2. Antigenic structure of *Escherichia coli*. The O antigen is contained in the repeating polysaccharide units of the lipopolysaccharide (LPS) in the outer membrane of the cell wall. The H antigen is the flagellar protein. The K antigen is the polysaccharide capsule present in some strains. Most *E coli* have type 1 (common) hair-like pili extending from the surface. Some *E coli* have specialized P pili, colonization factor antigens (CFAs), or bundle-forming pili (Bfp), as well as type 1 pili.

TABLE 33–1 Characteristics of Pathogenic Enterobacteriaceae

	DIAGNOSTIC ANTIGENS	PILI	ADHESIN OR CAPSULE	EXOTOXIN	PATHOGENIC LESIONS	SECRETED PROTEINS[a]	GENETICS	TRANSMISSION	DISEASE
Escherichia coli	**O, H, K**								
Newborn meningitic (NMEC)	O18:K1:H7, O1:K1, O2:K1	Type 1[b]	K1 polysaccharide	α-Hemolysin	Inflammation		PAI	Intestinal flora	Opportunistic, newborn meningitis
Uropathogenic (UPEC)		Type 1[b], P (Gal-Gal)		α-Hemolysin	Inflammation		PAI	Fecal flora, ascending	UTI
Enterotoxigenic (ETEC)		CFs		LT, ST	Hypersecretion		Plasmid (CF, LT, ST)	Fecal–oral	Watery diarrhea (travelers)
Enteropathogenic (EPEC)		Bfp	Intimin		A/E, small intestine	Esps	PAI	Fecal–oral	Watery diarrhea
Enteroinvasive (EIEC)			Ipas		Invasion, inflammation, ulcers	Ipas	Large plasmid, PAI	Fecal–oral	Dysentery
Enterohemorrhagic (EHEC)	O157:H7	Lpf	Intimin	Stx	A/E, colon, hemorrhage	Esps	Prophage, PAI	Fecal–oral direct, low dose, cattle	Bloody diarrhea, HUS
Enteroaggregative (EAEC)		AAFs		Stx[c]	Adherent biofilm				Watery diarrhea; bloody diarrhea and HUS[d]
Shigella	**O serogroups**								
S dysenteriae	A (10 types)		Ipas	Stx (serotype A1 most potent)	Invasion, inflammation, colonic ulcers	Ipas	Large plasmid, PAI	Fecal–oral, direct, low dose	Dysentery (severe), HUS
S flexneri	B (6 types)		Ipas	Stx (variable)	Invasion, inflammation, colonic ulcers	Ipas	Large plasmid, PAI	Fecal–oral, direct, low dose	Dysentery, HUS
S boydii	C (15 types)		Ipas	Stx (variable)	Invasion, inflammation, colonic ulcers	Ipas	Large plasmid, PAI	Fecal–oral, direct, low dose	Dysentery, HUS
S sonnei	D		Ipas	Stx (variable)	Invasion, inflammation, colonic ulcers	Ipas	Large plasmid, PAI	Fecal–oral, direct, low dose	Dysentery, HUS
Salmonella enterica	**O, H_1, H_2, K**								
Serotypes	>2000 serovars	Type 1[b]			Ruffles, invasion, inflammation	Inv, Spa, others	PAI	Fecal–oral, animals, and humans	Gastroenteritis, sepsis
Typhi	O group D	Type 1[b]	Vi polysaccharide		Macrophage survival, RES growth	As in serotypes[e]	PAI	Fecal–oral, moderate dose, humans only	Enteric (typhoid) fever
Yersinia	**O, H**								
Y pestis			Invasin	Protease, fibrinolysin	RES growth, bacteremia, pneumonia	Yops	PAI	Rats, flea bite, aerosol (human)	Plague
Y pseudotuberculosis	10 types		Invasin		RES growth, microabscesses	Yops	PAI	Fecal–oral, animal	Mesenteric adenitis
Y enterocolitica	>50 types		Invasin		RES growth, microabscesses	Yops	PAI	Fecal–oral, animals	Mesenteric adenitis, enteric fever
Klebsiella	70 capsular types	Pili	Polysaccharide					Intestinal flora	Opportunistic, pneumonia, UTI
K pneumoniae		Pili	K1, K2 polysaccharide		Abscesses			Intestinal flora	Liver abscess, endophthalmitis
Enterobacter, Serratia, Citrobacter								Intestinal flora	Opportunistic, UTI
Proteus						Urease		Intestinal flora	UTI

A/E, attaching and effacing lesion; Bfp, bundle-forming pili; CFs, colonizing factor antigens; Esps, *E coli*-secreted proteins; HUS, hemolytic uremic syndrome; Ipas, invasion protein antigens; LT, labile toxin; Lpf, long polar fimbriae; PAI, pathogenicity island; RES, reticuloendothelial system; ST, stable toxin; UTI, urinary tract infection; Yops, *Yersinia* outer membrane proteins.
[a]Delivered by injection (type III) secretion system.
[b]Bind to mannose.
[c]No animal model, presumed to be similar to *S enterica* serotypes.
[d]Major outbreak in 2011 due to EAEC serotype O104:H4 that acquired shiga toxin stx$_2$.

Type 1 has on–off switch

The genetics of pilin expression are complex. The genes are organized into multicistronic clusters that encode structural pilin subunits and regulatory functions. Pili of different types may coexist on the same bacterium, and their expression may vary under different environmental conditions. Type 1 pilin expression can be turned on or off by inversion of a chromosomal DNA sequence containing the promoter responsible for initiating transcription of the pilin gene. Other genes control the orientation of this switch.

TOXINS

α-Hemolysin is pore-forming cytotoxin

CNF disrupts intracellular signaling

As a single species, *E coli* can produce every kind of protein exotoxin found among the Enterobacteriaceae. These include a pore-forming cytotoxin, inhibitors of protein synthesis, and a number of toxins that alter messenger pathways in host cells. The **α-hemolysin** is a pore-forming cytotoxin that inserts into the plasma membrane of a wide range of host cells in a manner similar to streptolysin O (Chapter 25) and *Staphylococcus aureus* α-toxin (Chapter 24). The toxin causes leakage of cytoplasmic contents and eventually cell death. The more recently discovered **cytotoxic necrotizing factor (CNF)** is often produced in concert with α-hemolysin. CNF is an A-B toxin that disrupts G proteins regulating signaling pathways in the cell cytoplasm with multiple effects including cytoskeleton rearrangement and apoptosis.

* Shiga toxin is produced by *Shigella* and *E coli*

* Inhibits protein synthesis by ribosomal modification

Shiga toxin (Stx) is named for the microbiologist who discovered *Shigella dysenteriae*, and this toxin was once believed to be limited to that species. It is now recognized to exist in at least two molecular forms released upon bacterial lysis by multiple *E coli* and *Shigella* strains. In the years after the discovery of this toxin, the term Shiga toxin was reserved for the original toxin, while others were called Shiga-like. In this book, the term Stx is used for all molecular variants that have the same mode of action regardless of the species under consideration. Stx is an A–B type toxin. The B unit directs binding to a specific glycolipid receptor (Gb_3) present on eukaryotic cells and leads to internalization by an endocytotic vacuole. Inside the cell, the A subunit crosses the vacuolar membrane in the trans-Golgi network, exits to the cytoplasm, and enzymatically modifies the ribosome site (28S-RNA of 60S subunit) where amino-acyl tRNA binds. This alteration blocks protein synthesis, leading to cell death (**Figure 33–3**). This action is very similar to the plant toxin ricin.

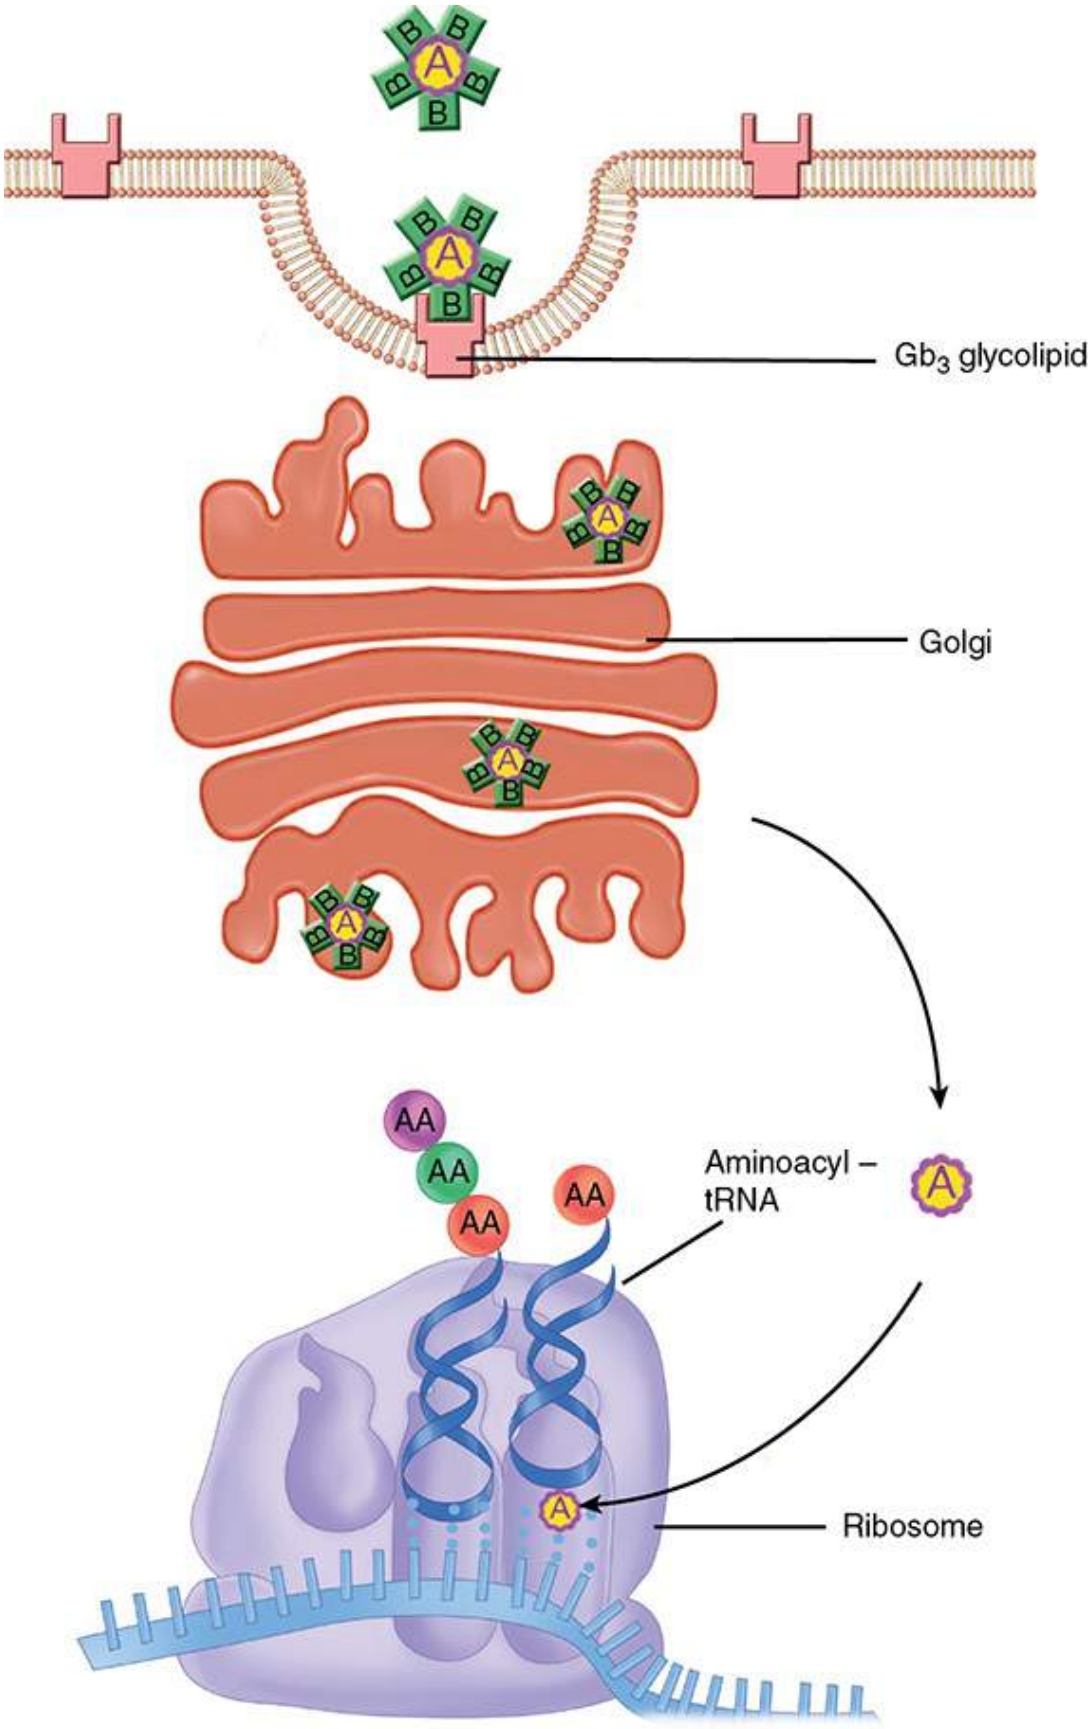

FIGURE 33–3. Stx (Shiga) toxin. The A–B toxin binds to the cytoplasmic membrane, enters in an endocytotic vacuole, and enters the Golgi network. Exiting to the cytoplasm, it combines at ribosome sites involved with tRNA binding. The result is interference with protein synthesis.

*** LT ADP-ribosylates G protein**

*** Adenylate cyclase stimulation similar to cholera**

Labile toxin (LT) is also an A–B toxin. Its name relates to the physical property of heat lability, which was important in its discovery, and contrasts with the heat-stable toxin (ST) also produced by *E coli*. The B subunit binds to the cell membrane, and the A subunit catalyzes the ADP-ribosylation of a regulatory G protein located in the membrane of the intestinal epithelial cell. This inactivation of part of the G protein complex causes permanent activation of the membrane-associated adenylate cyclase system and a cascade of events, the net effect of which depends on the biologic function of the stimulated cell. If the cell is an enterocyte, the result is the stimulation of chloride secretion out of the cell and the blockage of NaCl absorption; the net effect is the secretion of water and electrolytes into the bowel lumen. The structure and action of LT are nearly identical with that already described for cholera toxin (CT), but LT is less potent than CT.

*** ST stimulates guanylate cyclase**

Stable toxin is a small peptide that binds to a glycoprotein receptor, resulting in the activation of a membrane-bound guanylate cyclase. The subsequent increase in cyclic GMP concentration causes an LT-like net secretion of fluid and electrolytes into the bowel lumen.

E COLI EXTRAINTESTINAL INFECTIONS

URINARY TRACT INFECTION

▪ Epidemiology

Perineal flora is reservoir of common cystitis

E coli accounts for more than 90% of the more than 7 million cases of cystitis

and 250,000 of pyelonephritis estimated to occur in otherwise healthy individuals every year in the United States. Urinary tract infections are much more common in women, 40% of whom have an episode in their lifetime, usually when they are sexually active. The reservoir for these infections is the patient's own intestinal *E coli* flora, which colonize the perineal and urethral area. In individuals with urinary tract obstruction or instrumentation, exogenous sources assume greater importance.

▪ Pathogenesis

Minor trauma admits *E coli* to the bladder

UPEC cause most UTIs

Relatively minor trauma or mechanical disruptions can allow bacteria colonizing the periurethral area brief access to the urinary bladder. These bacteria originally derived from the intestinal flora are frequently present in the bladder of women immediately after sexual intercourse. In most instances, they are purged by the flushing action of voiding, but may persist to cause a UTI, depending on host and bacterial factors. Although most UTIs occur in otherwise healthy women, host situations that violate bladder integrity (urinary catheters) or that obstruct urine outflow (in men, enlarged prostate) may allow the bacteria more time to attach, multiply, and cause injury. Here, bacterial virulence factors are important, and *E coli* is the prototype UTI pathogen. Fewer than 10 *E coli* clones (whether characterized as serotypes or sequence types) account for the majority of UTI cases, and these UTI clones are not the most common ones in the fecal flora. These *E coli* with enhanced potential to produce UTI are called **uropathogenic** ***E coli*** **(UPEC)**.

*** Type 1 pili adhere to periurethral and bladder cells**

P pili prominent in pyelonephritis

The ability of UPEC to produce UTI begins with type 1 pili, which are the most important for both periurethral and bladder colonization. The tips of such pili attach to mannose moieties presented by membrane proteins (uroplakins) in the transitional epithelium of the bladder. Other pili such as P pili may add to the strength of this attachment; however, because their cognate Gal–Gal receptor is most abundant in the renal pelvis and kidney, P pili are more important for upper urinary tract disease. Strains possessing P pili are a minor percentage of fecal *E*

coli (<20%), but the proportion of P^+ strains progressively rises with the severity of UTI, reaching 70% among pyelonephritis isolates. Motility driven by flagellar motors also plays a role both in access to the bladder and swimming up the ureter to the kidney. Because adherence and motility operate at cross purposes, UPEC reciprocally regulate these features with on/off switching of fimbrial expression. But even with type 1 fimbriae switched on, UPEC can alternate between swimming and adherent phases due to the catch-bond properties of the tip adhesin. Another pathogenic feature of UPEC is the ability to invade superficial epithelial cells. The raft-like clusters formed by this maneuver have been proposed to aid persistence against the periodic flushing of the bladder. Once bacteria are established, LPS and the production of other virulence factors such as α-hemolysin and CNF cause injury. Spread to the bloodstream leads to LPS-induced septic shock. The adherence aspects of UPEC are illustrated in **Figure 33–4.**

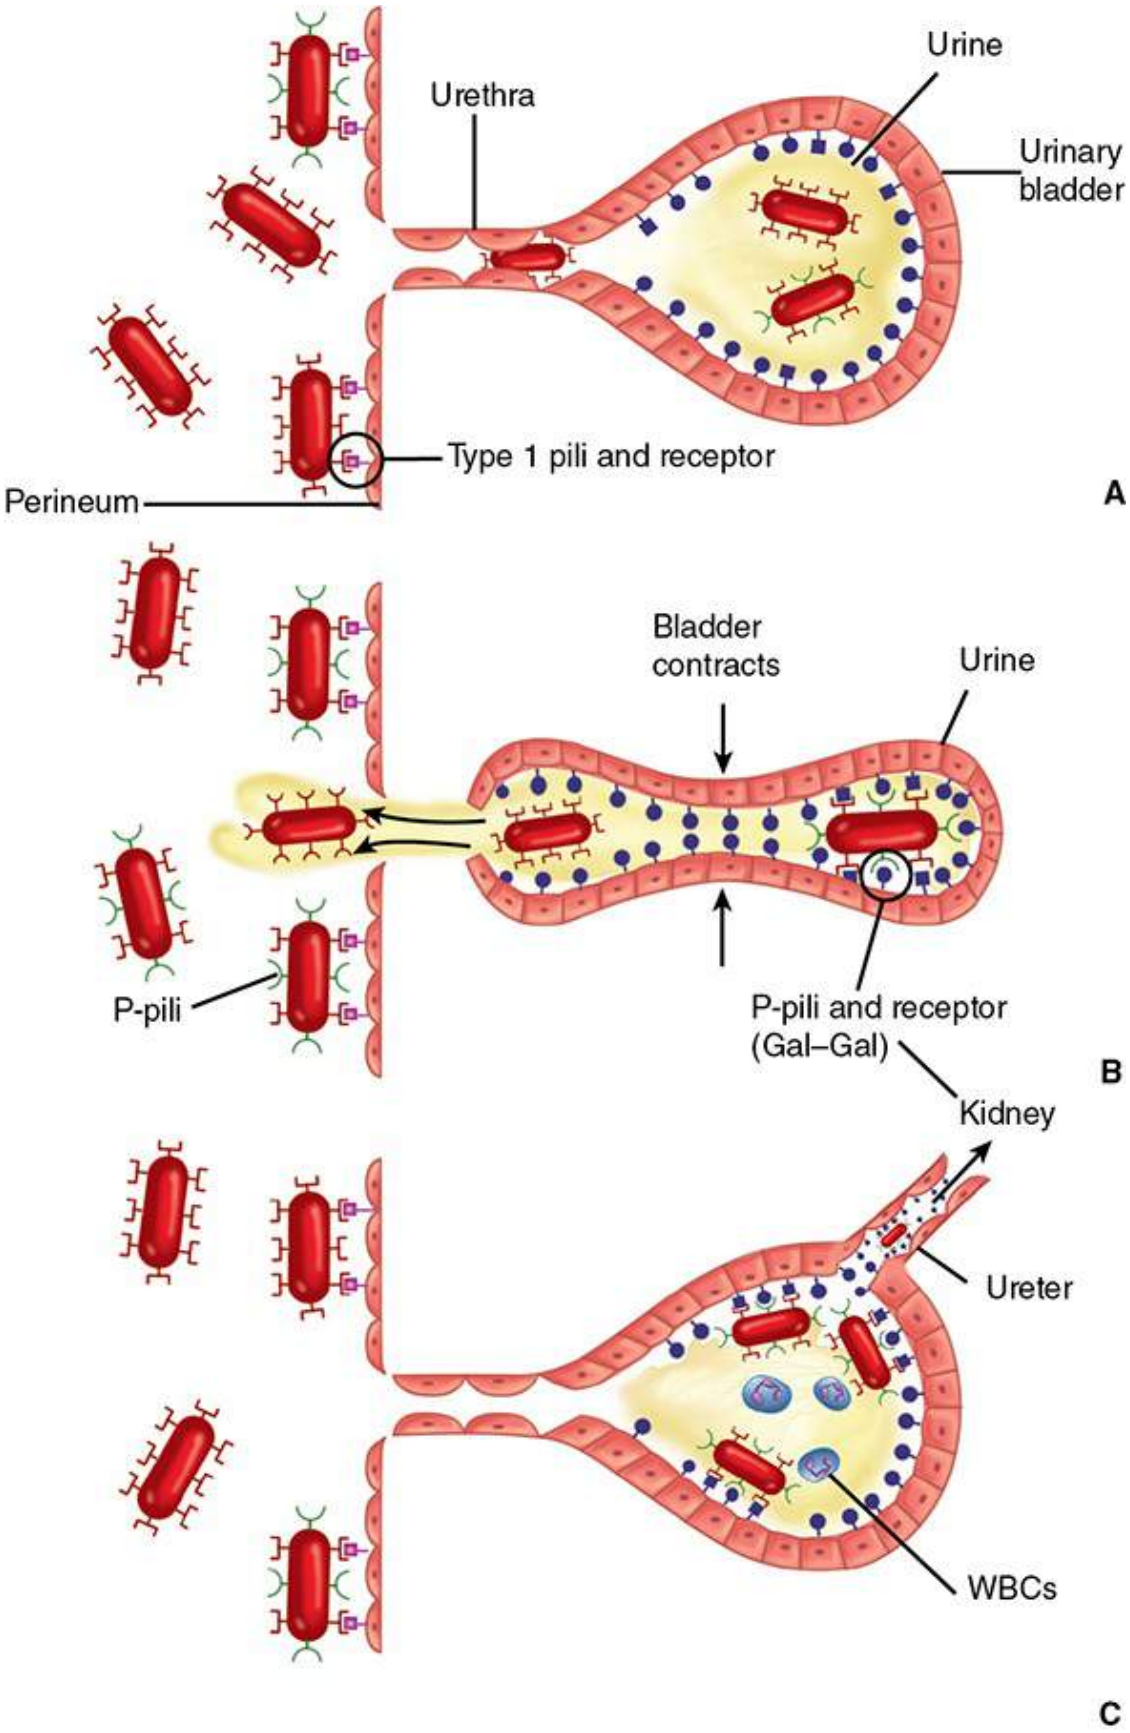

FIGURE 33–4. Urinary tract infection due to *Escherichia coli*. Features of the lower female urinary tract, including the bladder, perineal mucosa, and urethra, are shown. *E coli* from the nearby rectal flora have colonized the perineum, utilizing binding by type 1 (common) pili. Also present are *E coli* with P pili, though these adhesins are of no use at this site. **A.** A few *E coli* have gained access to the bladder owing to mechanical disruptions, such as sexual intercourse or instrumentation (catheters). Note that receptors for the P pili, absent on the perineal mucosa, are found on the surface of bladder mucosal cells. **B.** During voiding, the bladder has expelled the *E coli*, which have only type 1 pili. The P pili-containing bacteria remain behind due to the strong binding to the P (Gal–Gal) receptor. **C.** The remaining *E coli* have multiplied and are causing a UTI (cystitis) with inflammation and hemorrhage. In some cases, the bacteria ascend the ureter to cause pyelonephritis in the kidney, where the P (Gal–Gal) receptor is most abundant. WBCs, white blood cells.

OTHER EXTRAINTESTINAL INFECTIONS

▪ Meningitis

*** From vaginal flora-like group B strep**

*** K1 capsule identical to meningococcus**

E coli is one of the most common causes of neonatal meningitis, producing many features similar to group B streptococcal disease. The pathogenesis involves colonization of the infant with maternal *E coli* via ruptured amniotic membranes or during childbirth. Failure of protective maternal IgM antibodies to cross the placenta and the immunologic immaturity of newborns surely play a role. Fully 75% of cases of newborn meningitis are caused by strains possessing the sialic acid-containing K1 capsular polysaccharide, which is structurally identical to the group B polysaccharide of *Neisseria meningitidis*, another cause of meningitis.

*** Non-UTI infections require breach of defenses**

With the exception of UTIs, extraintestinal *E coli* infections are uncommon unless there is a significant breach in host defenses. Opportunistic infection may follow mechanical damage, such as trauma or a ruptured intestinal diverticulum, or involve a generalized impairment of immune function. The virulence factors involved are likely the same as with UTI (eg, pili, α-hemolysin), but have been less specifically studied. Host failure to control local infection can lead to spread and eventually Gram-negative septic shock. A significant proportion of blood isolates have the K1 surface polysaccharide. The particular diseases that result depend on the sites involved.

E COLI INTESTINAL INFECTIONS

*** Several pathogenic mechanisms have distinctive epidemiologic and clinical features**

Diarrheal illnesses continue to produce a tremendous mortality burden worldwide, particularly in children under 5 years of age, with the largest numbers of deaths occurring in sub-Saharan Africa and South Asia. *E coli* and *Shigella* (which are specialized *E coli*) are among the top causes of moderate-to-severe diarrhea among children in these areas. Diarrhea-causing *E coli* are classified according to their virulence properties as **enterotoxigenic (ETEC), enteropathogenic (EPEC), enteroinvasive (EIEC), enterohemorrhagic (EHEC),** or **enteroaggregative (EAEC).** Each group causes disease by a different mechanism, and the resulting syndromes usually differ clinically and epidemiologically. For example, ETEC and EIEC strains infect only humans. Food and water contaminated with human waste and person-to-person contact are the principal means of infection. A summary of the pathogenesis of infection, clinical syndromes, and epidemiology of infection for each enteropathogen is shown in Table 33-1.

ENTEROTOXIGENIC *E COLI*

▪ Epidemiology

*** Traveler's diarrhea affects children in developing countries**

Enterotoxigenic *E coli* (ETEC) produce diarrhea in infants in developing countries, where they are a leading cause of morbidity and mortality during the first 2 years of life. ETEC is also the most important cause of traveler's diarrhea in visitors to these countries. Repeated bouts of diarrhea caused by ETEC and other infectious agents are an important cause of growth retardation, malnutrition, and developmental delay in developing countries where ETEC are endemic. ETEC disease is rare in industrialized nations, although recent outbreaks suggest that it may be underestimated.

High dose in uncooked foods required

Transmission is by consumption of food and water contaminated by infected human or convalescent carriers. Uncooked foods such as salads or marinated meats and vegetables are associated with the greatest risk. Direct person-to-person transmission is unusual because the infecting dose is high. Animals are not involved in ETEC disease.

▪ Pathogenesis

*** LT and/or ST cause fluid outpouring in small intestine**

CF pili are required

ETEC diarrhea is caused by strains of *E coli* that produce LT and/or ST enterotoxins in the proximal small intestine. ST seems to be more potent than LT, and strains that elaborate both cause the most severe illness. Adherence to surface microvilli, mediated by multiple variants of colonizing factor (CF) pili, is essential for the efficient delivery of toxin to the target enterocytes. The genes encoding the ST, LT, and the CF pili are borne on plasmids; a single plasmid can carry all three sets of genes. The bacteria remain on the epithelial surface, where the adenylate cyclase-stimulating action of the toxin(s) creates the flow of water and electrolytes from the enterocyte into the intestinal lumen. The mucosa becomes hyperemic but is not injured in the process. There is no invasion or inflammation.

▪ Immunity

sIgA to LT and CFs may provide some protection

Although infections with ETEC do stimulate immunity, individuals may experience more than one episode of ETEC diarrhea. Travelers from industrialized nations have a much higher attack rate than adults living in the endemic area. This natural immunity is presumably mediated by sIgA specific for LT and CFs; the small ST peptides are nonimmunogenic. The disease is of very low incidence in breastfed infants, underscoring the protective effect of maternal antibody and the importance of transmission by contaminated food and water.

ENTEROPATHOGENIC *E COLI*

Epidemiology

Nursery outbreaks and endemic diarrheas in developing world

Enteropathogenic *E coli* (EPEC) strains were first identified as the cause of explosive outbreaks of diarrhea in hospital nurseries in the United States and Great Britain during the 1950s. The link to *E coli* was established on epidemiologic grounds alone, using serotyping of stool isolates—no small task. In 1987, the World Health Organization recognized a group of 12 EPEC serotypes that remain of epidemiologic significance. The disease seems to have disappeared in industrialized nations, although it may be underestimated because of the diagnostic challenges. In developing countries throughout the world, EPEC account for up to 20% of diarrheal illnesses in bottle-fed infants younger than 1 year of age. The reservoir is infant cases and adult carriers, with transmission by the fecal–oral route. Nursery outbreaks demonstrate the importance of spread by fomites, suggesting that the infecting dose for infants is low. Adult cases are felt to require a very high infecting dose (10^8 to 10^{10} bacteria).

Pathogenesis

*** Intimin receptor and Esps are injected**

*** Cytoskeleton modification produces A/E lesion**

Enteropathogenic *E coli* initially attach to small intestine enterocytes using **bundle-forming pili (Bfp)** to form clustered microcolonies on the enterocyte cell surface. The lesion then progresses with localized degeneration of the brush border, loss of the microvilli, and changes in the cell morphology including the production of dramatic “pedestals” with the EPEC bacterium at their apex. These actions in combination result in the **attachment and effacing (A/E)** lesion (**Figure 33–5**). The many steps involved in the formation of the A/E lesion are genetically controlled in a PAI, which includes the genes for the major EPEC attachment protein, **intimin,** and an injection (type III) secretion system. The secretion system injects over 30 ***E coli* secretion proteins (Esps)** into the host cell cytoplasm, including—remarkably—the surface receptor (Tir) for intimin, which migrates to the surface after its injection. The other *E coli* secretion proteins perturb intracellular signal transduction pathways, one effect of which is the induction of modifications in enterocyte cytoskeleton proteins actin and talin.

The cytoskeleton accumulates beneath the attached bacteria to form the pedestals and complete the actin-rich A/E lesion (**Figure 33–6**). The Esps cause a host of other intracellular disruptions, including mitochondrial injury and induction of apoptosis. The link between the morphologic changes of the A/E lesion and diarrhea is not known, but the injected Esps have been shown to change electrolyte transport across the luminal membrane.

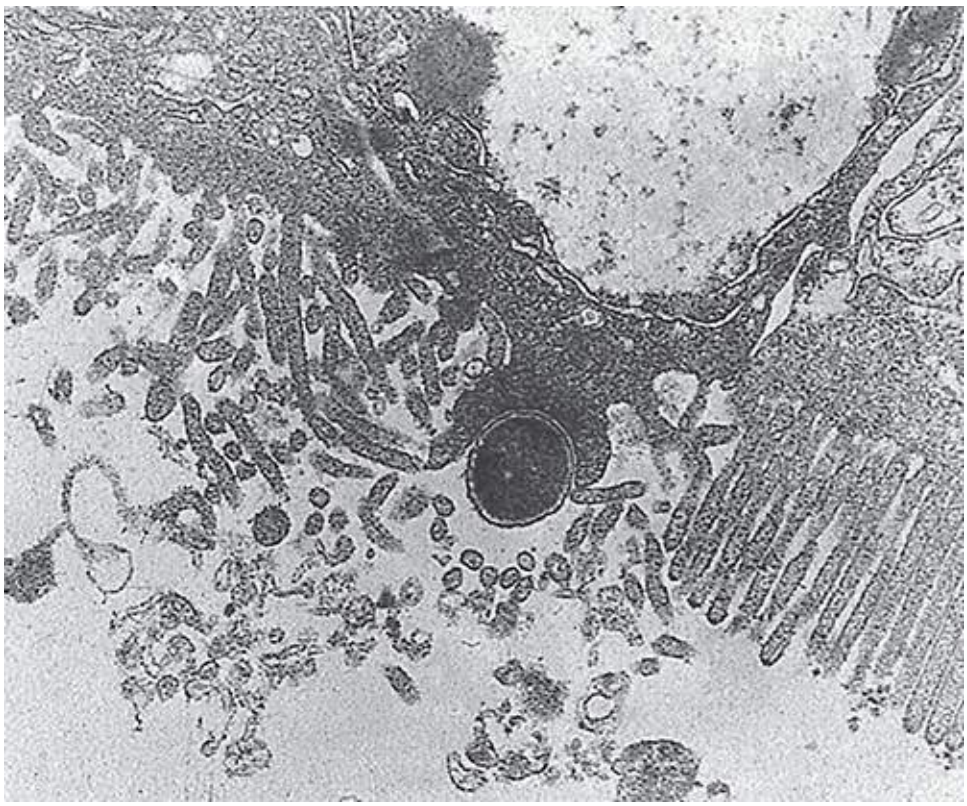

FIGURE 33–5. Enteropathogenic *Escherichia coli* (EPEC) attachment to epithelial cells. The EPEC are attaching to and effacing the microvilli on the epithelial cell surface. The cell's filamentous actin is rearranged at the attachment point. Note the pedestal below the EPEC cell.

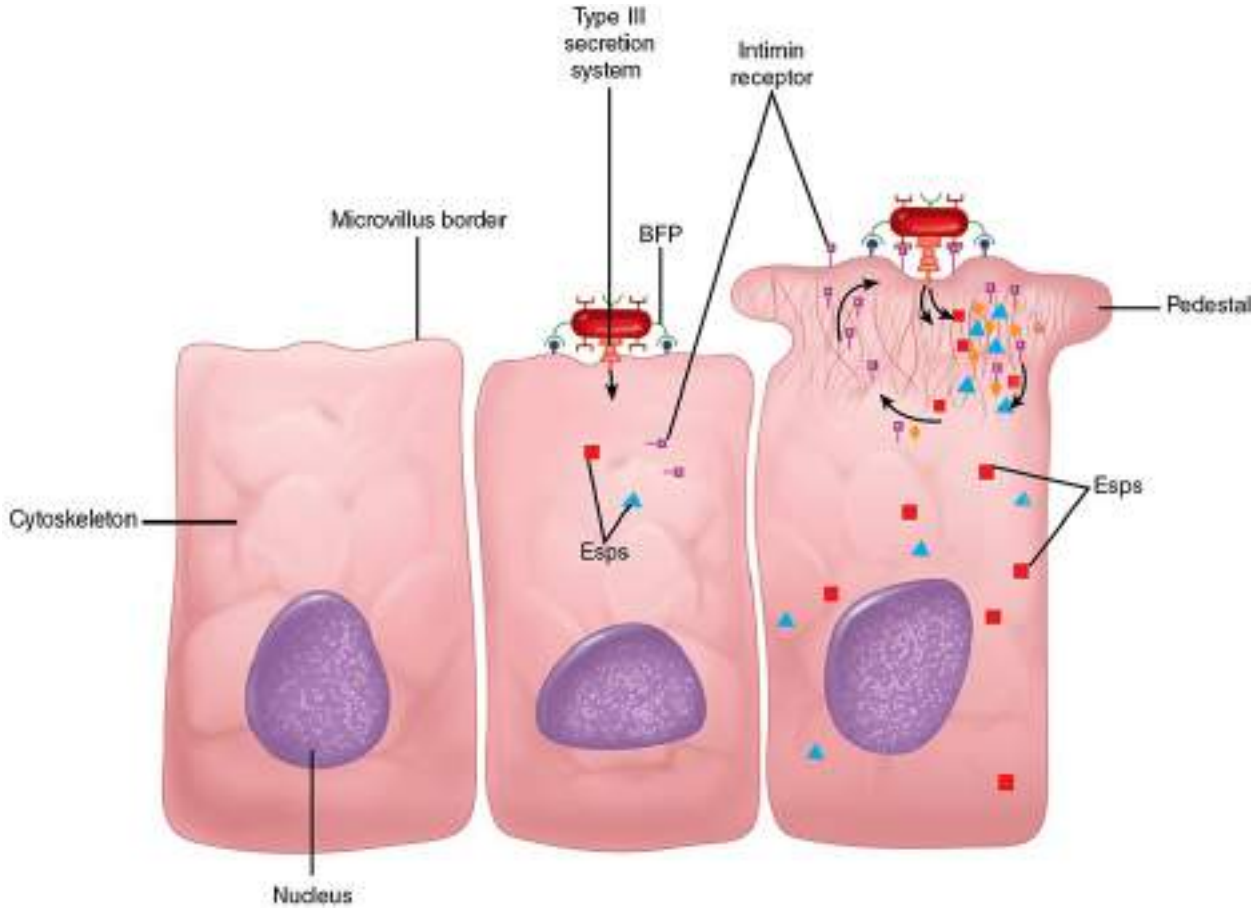

FIGURE 33–6. Enteropathogenic *Escherichia coli* (EPEC) contact secretion system. (*Left*) An enterocyte is shown with a microvillus border and a delicate supporting cytoskeleton. (*Middle*) An EPEC has attached to the cell surface by binding of the bundle-forming pili to receptors on the host cell surface. A type III secretion system apparatus has been inserted into the cell and is exporting secretion proteins (Esps) into the cytoplasm. One of these is the receptor for intimin. (*Right*) The intimin receptor has been inserted below the host cell membrane and is now mediating tight binding to the surface. The other Esps have disrupted multiple cellular functions, including the structure of the cytoskeleton. Cytoskeleton elements have been concentrated to form a pedestal cradling the EPEC (Figure 33–5). Bfp, bundle-forming pili.

▪ Immunity

Little evidence for immunity

In endemic areas, EPEC can be isolated often from the stool of asymptomatic adults, but unlike ETEC, these strains do not seem to cause traveler's diarrhea in individuals new to the area. This observation obscures whether adults have acquired immunity or resistance based on physiologic factors.

ENTEROHEMORRHAGIC *E COLI*

Epidemiology

Consumption of contaminated animal products the main source

Enterohemorrhagic *E coli* (EHEC) disease and the associated **hemolytic uremic syndrome (HUS)** result from the consumption of products from animals colonized with EHEC strains. It is also clear from secondary cases in families during outbreaks that person-to-person transmission also occurs. This disease occurs more in developed than developing countries.

*** Bloody diarrhea and HUS linked to O157:H7**

EHEC was first recognized when outbreaks of HUS (hemolytic anemia, renal failure, and thrombocytopenia) were linked to a single *E coli* serotype, O157:H7. Since then, EHEC disease has emerged as an important cause of **bloody diarrhea** in industrialized nations and retained a remarkable, though not exclusive, relationship with the O157:H7 serotype. Regional and national outbreaks associated with ground beef, unpasteurized juices, and fresh vegetables often catch the attention of the public, the press, and the government, and at times bring renewed scrutiny to food safety policies and practices in public and private sectors.

*** Low infecting dose facilitates transmission**

*** Modern meat processing facilitates outbreaks**

*** Unpasteurized beverages another risk**

The emergence of EHEC is related to its virulence, low infecting dose, common reservoir (cattle), and changes in the modern food processing industry that provide fresher meat (and bacteria) over wider distribution networks. The infecting dose, estimated to be as low as 100 organisms, is particularly important. This is a level at which food need not come directly from the infected animal, but only be contaminated by it. For example, large modern meat-processing plants can mix EHEC from colonized cattle at one ranch into beef from hundreds of other farms and quickly ship it all over the country. Therefore, the worst outbreaks have been seen in countries with the most advanced food production and distribution systems. If the organisms are ground into hamburger meat, an infecting dose of EHEC may remain even after cooking if the meat is left rare in the middle. Unpasteurized milk carries an obvious risk, but fruits and

vegetables have also been the source for EHEC infection. In these instances, the EHEC from the manure of cattle grazing nearby has contaminated fruit in the field. The bacterial dose from a few “drop” apples (those picked up from the ground) included in a batch of cider has been enough to cause disease.

▪ Pathogenesis

*** Produce both A/E lesions and Stx**

*** Quorum-sensing regulates Stx**

Lesions are in colon

EHEC strains cause the A/E lesions previously described for EPEC, but also produce the Stx toxin. The EHEC pathotype, which was first described in O157:H7 strains in 1982, is proposed to have evolved by an EPEC acquiring the genes for Stx via prophage. Apparently, the injection secretion system which creates the A/E pedestals also facilitates delivery of Stx to the enterocyte. Stx secretion is regulated through a quorum-sensing system which awaits a critical EHEC population to activate. The interaction of EHEC with enterocytes is much the same as that of EPEC, except that EHEC strains do not form localized microcolonies on the mucosa and have their own adhesive pili (long polar fimbriae [Lpf]), which mediate attachment in the colon rather than the small intestine. The outer membrane protein intimin mediates tight adherence, and the injection secretion system introduces the *E coli* secretion proteins, which cause alterations in the host cytoskeleton. The genes for these properties are also found in a PAI. The multiple extraintestinal features such as HUS are the result of circulating Stx.

*** Stx causes capillary thrombosis and inflammation**

*** Circulating Stx leads to HUS**

The A/E features alone are sufficient to cause nonbloody diarrhea. On top of this, Stx production causes capillary thrombosis and inflammation of the colonic mucosa, leading to a hemorrhagic colitis. (The distinctive association between shiga toxin and bloody diarrhea has given rise to the term STEC, or shiga toxin-producing *E coli*, as an alternate pathotype descriptor for EHEC.) Although it has not been detected in the blood of human cases, Stx is presumed to be absorbed across denuded intestinal mucosa. Circulating Stx binds to renal tissue,

where its glycoprotein receptor globotriaosylceramide (Gb3) is particularly abundant, causing glomerular swelling and the deposition of fibrin and platelets in the microvasculature. How Stx causes hemolysis is less clear; perhaps the erythrocytes are simply damaged as they attempt to traverse the occluded capillaries. Cases and outbreaks caused by Stx-producing *E coli* of other serotypes are common in many countries.

ENTEROINVASIVE *E COLI*

*** EIEC closely resemble *Shigella***

The biochemistry, genetics, and pathogenesis of enteroinvasive *E coli* (EIEC) strains are so close to those of *Shigella* that our understanding of EIEC disease is generally extrapolated from that genus—EIEC disease is essentially a mild version of shigellosis. Epidemiologically, EIEC infections are primarily seen in children younger than 5 years living in developing countries. The occasional documented outbreaks in industrialized nations are usually linked to contaminated food or water. There is a lower incidence of person-to-person transmission of EIEC, which correlates with the observation that the infecting dose is higher than it is for *Shigella.* Humans are the only known reservoir.

ENTEROAGGREGATIVE *E COLI*

Enteroaggregative *E coli* (EAEC) is associated with a protracted (>14 days) watery diarrhea that occasionally features blood and mucus. First recognized in infants and children in developing countries, EAEC is increasingly diagnosed in a variety of community settings. EAEC strains are identified by the “stacked brick” pattern the bacteria make when adhering to cultured mammalian cells. The EAEC pili (aggregative adherence fimbriae [AAF]) mediate tight adherence to the intestinal mucosa, but the A/E lesions of the EPEC and EHEC are not present. The pathogenesis of diarrhea involves formation of a thick mucus–bacteria biofilm on the intestinal surface.

Adherence and biofilm cause diarrhea

*** Outbreak strain acquired Stx genes**

This view of EAEC was dramatically altered by a 2011 German outbreak of serotype O104:H4 initially thought to be caused by EHEC based on clinical

features. There were a thousand cases of bloody diarrhea and 53 deaths due to HUS, but the rate of HUS development was twice that typical for EHEC disease. It turned out that the responsible strain had all the essential features of EAEC, but with the addition of Stx genes. There was no injection secretion system or A/E lesions. Apparently, the tight adherence of EAEC provided a particularly effective mechanism for delivery of Stx to the intestinal mucosa.

E COLI INFECTIONS: CLINICAL ASPECTS

MANIFESTATIONS

- **Extraintestinal Infections**

*** Dysuria and frequency are features of UTIs**

The most common symptoms of *E coli* UTI are dysuria and urinary frequency – as they are for UTI produced by the other, less common Gram-negative urinary pathogens. If the infecting bacteria ascend the ureters to produce pyelonephritis, fever and flank pain are common and bacteremia may develop. Although *E coli* may have enhanced virulence in the production of pneumonia as well as soft tissue and other infections, no clinical features distinguish these cases from those caused by other members of the Enterobacteriaceae.

If the EHEC diarrhea is bloody, why would fever not be more prominent?

- **Intestinal Infections**

*** ETEC and EPEC diarrhea is watery**

*** EIEC and EHEC diarrhea is bloody**

Infection caused by any *E coli* intestinal pathotype usually begins with a mild watery diarrhea starting 2 to 4 days after ingestion of an infectious dose. In most instances, the duration of diarrhea is limited to a few days, with the exception of

EAEC diarrhea, which can last for weeks. With ETEC and EPEC, the diarrhea remains watery, but with EIEC and EHEC, a dysenteric illness follows. Some EPEC cases may also become chronic. EHEC disease begins like the others but often also includes vomiting; in 90% of cases, this is followed in 1 to 2 days by intense abdominal pain and bloody diarrhea, but fever is not prominent. Some EHEC cases develop into a dysentery illness that is less severe than that seen in shigellosis. Colonoscopy reveals edema, hemorrhage, and pseudomembrane formation. Resolution usually takes place over a 3- to 10-day period, with few residual effects on the bowel mucosa.

*** HUS begins as oliguria and may progress to renal failure**

HUS develops as a complication in 5% to 10% of cases of EHEC hemorrhagic colitis, primarily in children under 10 years of age. The disease begins with decreased urine output, edema, and pallor, progressing to the triad of microangiopathic hemolytic anemia, thrombocytopenia, and renal failure. The systemic effects are often life-threatening, requiring transfusion and hemodialysis for survival. The mortality rate is 5%, and up to 30% of those who survive suffer sequelae such as renal impairment or hypertension.

DIAGNOSIS

Bacterial counts in urine are high

Diarrhea requires immunoassay or gene probe

*** Sorbitol agar screens for O157:H7**

Like the rest of the Enterobacteriaceae, *E coli* is readily isolated in culture. In UTIs, the bacteria typically reach high numbers (>10^5/mL), which makes them readily detectable by Gram stain even in an unspun urine specimen (**Figure 33–7**). For the diagnosis of intestinal disease, separating the virulent types discussed previously from the numerous other *E coli* strains universally found in stool presents a special problem. A myriad of immunoassay and nucleic acid amplification methods have been described that are able to detect the toxins (LT, ST, Stx) or genes associated with virulence. These methods work but their clinical use is hampered by limited positive predictive value—healthy persons may also have positive test results with these methods—and high cost, especially in developing countries where ETEC, EIEC, EPEC, and EAEC are prevalent. A

screening test for EHEC takes advantage of the observation that the O157:H7 serotype typically fails to ferment sorbitol. Incorporating sorbitol in place of lactose in MacConkey agar provides an indicator medium from which suspect (colorless) colonies can be selected and then confirmed with O157 antisera. This procedure has become routine in areas where EHEC is endemic but does not detect the non-O157 EHEC strains.

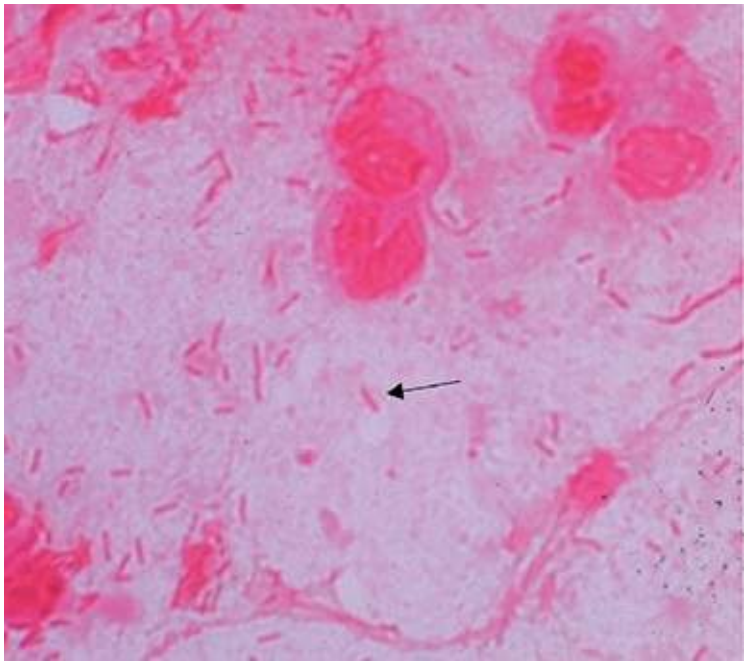

FIGURE 33–7. ***Escherichia coli*** **urinary tract infection.** The ready observation of the large Gram-negative bacilli (such as that indicated by the arrow) and WBCs in a drop of unspun urine indicates the number of bacteria in the urine is high. (Used with permission from Professor Shirley Lowe, University of California, San Francisco School of Medicine.)

Think ▸▸ Apply 33-1: The blood in the stool in EHEC is due to the action of Stx and not due to destruction of enterocytes. It usually takes cellular destruction to cause inflammation and thus fever. This is a feature of shigellosis (see below).

TREATMENT

Resistance patterns influence antimicrobial selection

Acute uncomplicated UTIs are often treated empirically. Because of widespread

resistance to earlier agents like ampicillin, use of trimethoprim/sulfamethoxazole (TMP-SMX) and fluoroquinolones for this purpose rose steadily. In turn, use of these agents set the stage for the rise of international multidrug-resistant clones like *E coli* Sequence Type 131, which wields chromosome-encoded fluoroquinolone resistance and plasmid-borne resistance to TMP-SMX, gentamicin and, not infrequently, extended-spectrum cephalosporins. Thus, in many clinical settings domestically and abroad, *E coli* resistance to these latter agents has now exceeded the 20% level used to indicate the suitability of antibiotics for empiric use. In cases of empiric treatment failure, selection of other antimicrobials must be guided by antimicrobial susceptibility testing of the patient's isolate.

Antibiotics may shorten symptoms for ETEC, EIEC, and EPEC

*** Antibiotics may increase risk of HUS in EHEC**

Because most *E coli* diarrheas are mild and self-limiting, treatment is usually not required. When it is, rehydration and supportive measures are the mainstays of therapy, regardless of the causative agent. In the case of EHEC with hemorrhagic colitis and HUS, heroic supportive measures such as hemodialysis or plasmapheresis may be required. Treatment with TMP-SMX or fluoroquinolones reduces the duration of diarrhea in ETEC, EIEC, and EPEC infection. However, because the risk of HUS may be increased by the use of antimicrobial agents, their use is contraindicated when EHEC is even suspected. Antimotility agents are not helpful and are contraindicated when EIEC or EHEC could be the etiologic agent.

PREVENTION

*** Avoid uncooked foods**

*** Chemoprophylaxis works for defined periods**

Traveler's diarrhea is usually little more than an inconvenience. Because the infecting dose is high, the incidence of the disease can be greatly reduced by eating only cooked foods and peeled fruits and drinking hot or carbonated beverages. Avoiding nonbottled water, ice, salads, and raw vegetables is a wise precaution when traveling in developing countries. High-priced hotel accommodations have no protective effect. Chemoprophylaxis against traveler's

diarrhea is not routinely recommended, and in fact may increase risk of intestinal colonization with multidrug-resistant Enterobacteriaceae encountered abroad. Short courses of TMP-SMX or ciprofloxacin (<2 weeks) have been recommended for those at high risk for disease resulting from such chronic conditions as achlorhydria, gastric resection, prolonged use of H_2 blockers or antacids, and underlying immunosuppressive diseases.

*** Rare hamburgers carry risk for EHEC**

These public health measures apply equally to EHEC, but here prevention is more difficult because the infecting dose is so low. Cooking hamburgers all the way through is sensible, but abstinence from salads at home has only been recommended in defined outbreak scenarios associated with romaine lettuce. Recent U.S. recommendations for the irradiation of meats and the extension of pasteurization requirements to fruit juices are designed largely to stem the spread of EHEC.

• SHIGELLA

BACTERIOLOGY

*** O antigens and biochemicals define four species**

*** Invasiveness and Stx production are virulence factors**

Shigella species may be considered specialized *E coli*. Their antigenic makeup has been characterized in a manner similar to that of *E coli*, with the exception that they lack flagella (and thus H antigens). All *Shigella* species are nonmotile. The genus is divided into four species, which are defined by biochemical reactions and specific O antigens organized into serogroups. The species are *Shigella dysenteriae* (serogroup A), *Shigella flexneri* (serogroup B), *Shigella boydii* (serogroup C), and *Shigella sonnei* (serogroup D). All but *S sonnei* are further subdivided, producing a total of 38 individual O antigen serotypes specified by numbers. *Shigella* is the prototype invasive bacterial pathogen. All species are able to invade and multiply inside a wide variety of epithelial cells, including their natural target, the enterocyte. *Shigella dysenteriae* type 1, the

Shiga bacillus, is the most potent producer of Stx. Other *Shigella* species produce various molecular forms and quantities of Stx.

SHIGELLOSIS

EPIDEMIOLOGY

*** Strictly human disease**

*** Low infecting dose facilitates fecal–oral spread**

Shigellosis is a strictly human disease with no animal reservoirs. Worldwide, it is consistently one of the most common causes of infectious diarrhea, with over 150 million cases and 600,000 deaths per year. As with almost all infectious diarrheas, the incidence is related to general levels of sanitation, but *Shigella* disease remains important in both developed and developing countries. This high prevalence despite lack of a nonhuman reservoir is primarily due to highly efficient transmission by the fecal–oral route. This spread by person-to-person contact is so effective because the infecting dose is extremely low, as few as 10 organisms in some studies. The secondary attack rates among family members are as high as 40%. *Shigella* is also spread by food or water contaminated by human waste products.

*** Individual behaviors or community sanitary practices determine incidence**

*** Wars and disasters enable outbreaks**

The incidence and spread of shigellosis are directly related to individual- and community-level behaviors and practices. In developed countries, shigellosis has often been seen as a pediatric disease producing daycare-associated outbreaks, as well as an adult syndrome in men who have sex with men. In countries where the sanitary infrastructure is inadequate and in institutions plagued by crowding and poor hygienic conditions, the disease may be more widespread; wartime and natural disasters create similar circumstances. The most common species are *S flexneri* and *S sonnei*, with *S dysenteriae* largely limited to underdeveloped tropical areas. *S dysenteriae* type 1 produces the most severe disease, historically

known as “bacillary dysentery.” This condition slowed the march of many an army; it was the leading cause of death in the notorious Andersonville prison camp during the American Civil War.

PATHOGENESIS

* *Shigella* pass stomach acid and invade colon

Shigella, unlike *Vibrio cholerae* and most *Salmonella* species, is acid-resistant and survives passage through the stomach to reach the intestine. Once there, the fundamental pathogenic event is invasion and destruction of the human colonic mucosa. This triggers an intense acute inflammatory response with mucosal ulceration and abscess formation. The steps involved in this process constitute one of the richest tales in bacterial pathogenesis (**Figure 33–8**). Most pathogenesis research has been done with *S flexneri*, but there is no reason to believe it does not apply equally to the three other species and to EIEC.

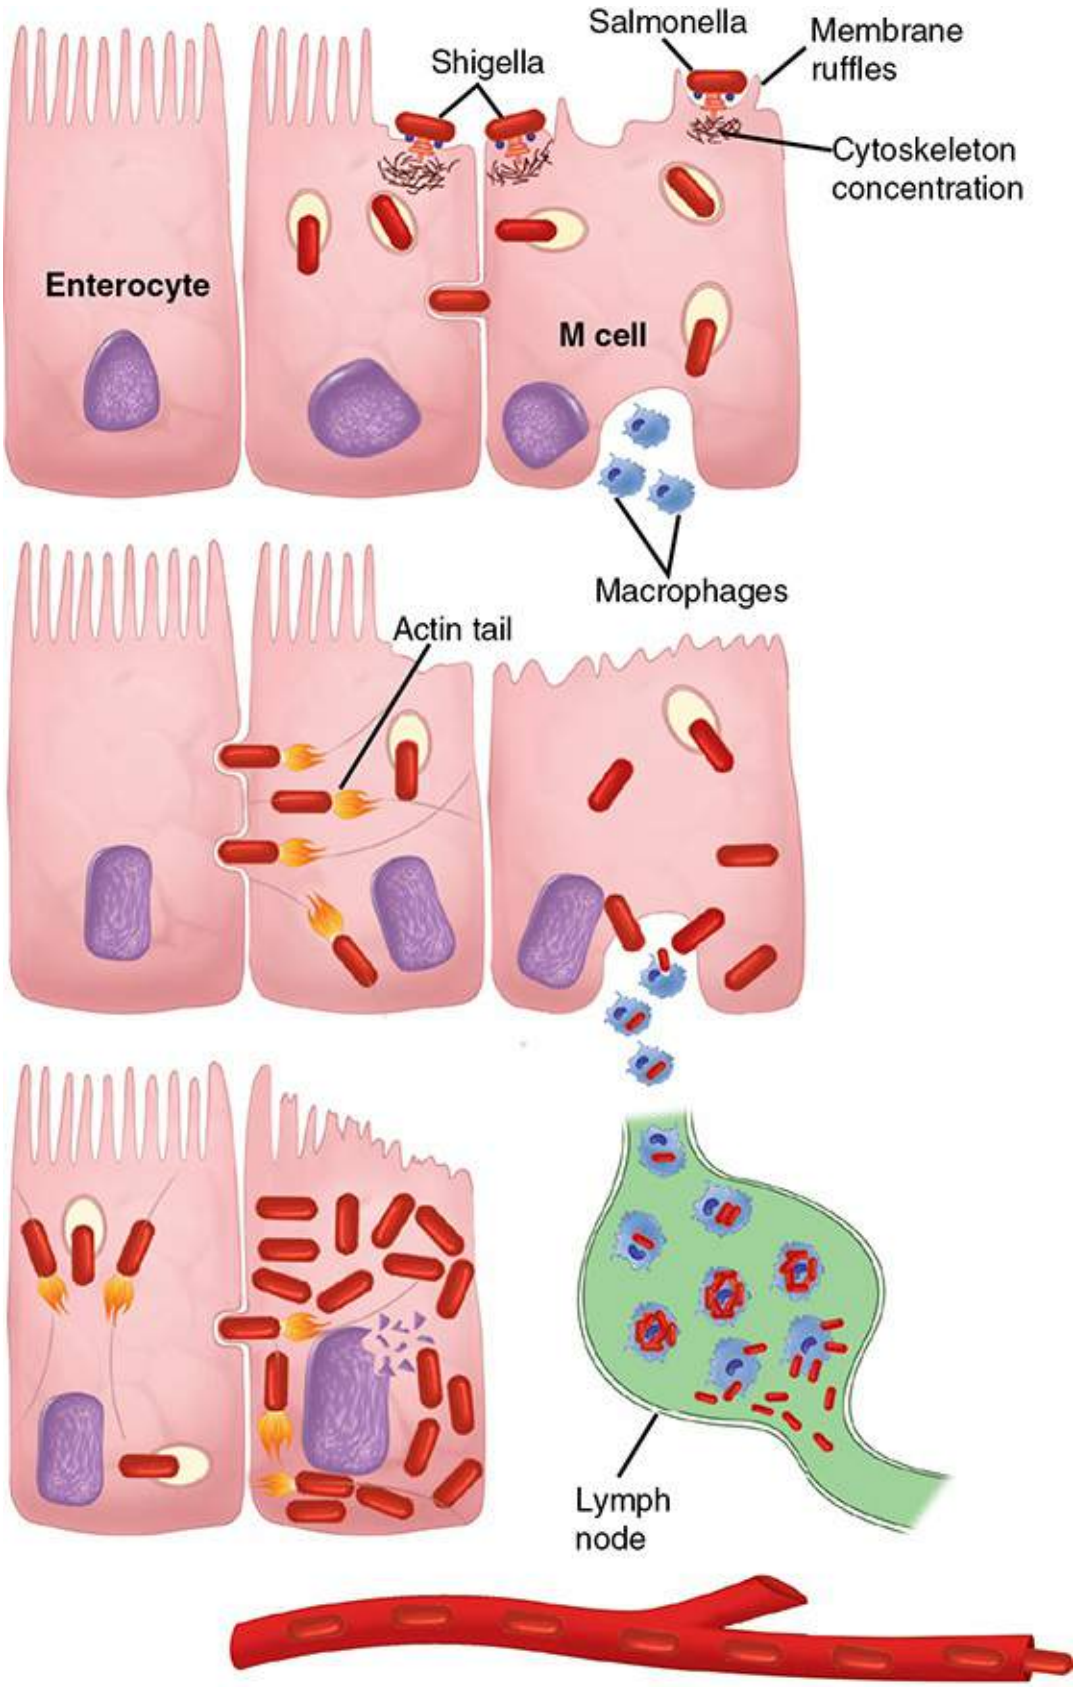

FIGURE 33–8. Invasion by *Shigella flexneri* and *Salmonella* serotype Typhi. *Shigella* and *Salmonella* are shown invading the intestinal M cells but taking different paths after escaping the endocytotic vacuole. The *Shigella* multiplies in the cell and propels itself through the cytoplasm to invade adjacent cells, and the *Salmonella* passes through the cell to the submucosa, where it is taken up by macrophages. Serovar Typhi is able to multiply in the macrophages in the lymph node and other reticuloendothelial sites. Both organisms induce apoptosis in their host cells. In the case of *Shigella*, this produces a mucosal ulcer; in the case of Typhi, it leads to seeding of the bloodstream and typhoid fever.

*** Transcytose M cells to macrophages**

Invade enterocytes from dead macrophages

Injected Ipa proteins induce endocytosis

Shigella initially cross the mucosal membrane by entering the follicle-associated M cells of the intestine, which lack the highly organized brush borders of absorptive enterocytes. *Shigella* adhere selectively to M cells, enter, and then transcytose through them into the underlying collection of macrophages. Inside macrophages, the organisms escape from the phagosome to the cytoplasm and activate programmed cell death (apoptosis) in the macrophage. Bacteria released from the dead macrophage contact the basolateral side of enterocytes and initiate a multistep invasion process mediated by a set of **invasion plasmid antigens** (IpaA–IpaD). On contact with the enterocyte, these proteins are injected by an injection (type III) secretion system and induce cytoskeleton reorganization, actin polymerization, and other changes, particularly at the cell surface. Rather than create the A/E lesions of the EPEC and EHEC, this cytoskeleton modification process induces engulfment and internalization of *Shigella* into the host cell by endocytosis.

*** Escape phagosome to cytoplasm**

*** Polymerization of cytoskeletal actin propels bacteria**

Microtubules are digested

Shigella are highly adapted to the intracellular environment and make unique use of it to continue the infection. Although initially the bacteria are surrounded by a phagocytic vacuole, they quickly escape and enter the cytoplasmic compartment of the host cell. Almost immediately, they orient in parallel with the filaments of the cell's actin cytoskeleton and initiate a process in which they control polymerization of the monomers that make up the actin fibrils. This process creates an actin "tail" at one end of the microbe, which appears to propel

it through the cytoplasm like a comet. This exploitation of the cytoskeletal apparatus allows nonmotile *Shigella* to not only replicate in the cell but to move efficiently through it. Apparently, the cell's microtubule network is an obstruction, so the bacteria produce an enzyme that digests this. One microbiologist called this strategy "bushwhacking through a microtubule jungle."

Adjacent enterocytes are invaded directly

Double-membrane lysis restarts process

Eventually, the bacteria encounter the host cell membrane, much of which is adjacent to the neighboring enterocytes. At this point, some *Shigella* rebound but others push the membrane as much as 20 μm into the adjacent cell; this invasion of the neighboring enterocyte forms finger-like projections, which eventually pinch off, placing the bacterium within a new cell but surrounded by a double membrane. The organisms then lyse both membranes and are released into the cytoplasm, free to begin their relentless invasion anew.

*** Enterocyte invasion creates ulcers**

*** Diarrhea + WBCs + RBCs = dysentery**

The cell-by-cell extension of this process radially destroys enterocytes and creates focal ulcers in the mucosa, particularly in the colon. The ulcers add a hemorrhagic component and allow *Shigella* to reach the lamina propria, where they evoke an intense acute inflammatory response. Extension of the infection beyond the lamina (for example, to the bloodstream) is unusual in healthy individuals. The diarrhea created by this process is almost purely inflammatory, consisting of small-volume stools containing WBCs, RBCs, bacteria, and little else—this is classic dysentery.

*** Stx increases severity of disease**

Some *Shigella* also produce Stx, which is not essential for disease but does contribute to the severity of the illness. The original and most potent producer of Stx, *S dysenteriae* type 1, is the only *Shigella* with a significant mortality rate in previously healthy individuals. This is probably due to systemic effects of the toxin, which can be the same as previously described for the EHEC, including HUS. The role, if any, of Stx in enterocyte injury and diarrhea is uncertain.

*** Large plasmid containing Ipa genes required for virulence**

All virulent *Shigella* and EIEC carry a very large plasmid that has several genes essential for the attachment and entry process, including the Ipa genes. The characteristics of *Shigella* entry and interaction with cellular elements are very similar to those observed with *Listeria monocytogenes*, which is Gram-positive and motile and prefers livestock to humans. Finding that such dissimilar bacteria use such similar tactics to infect their preferred host suggests commonality among the selective pressures on a microbe to become a "successful" enteric pathogen (convergent evolution).

IMMUNITY

Immunity is brief

Episodes of *Shigella* infection produce modest immunologic protection against infection by homologous serotypes, but do not significantly protect against other serotypes. Recently, large-scale epidemiologic studies have elucidated the predominant *Shigella* serogroups responsible for the major burden of disease, invigorating the prospects for design of a multivalent vaccine.

SHIGELLOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Watery diarrhea followed by fever, bloody mucoid stools, and cramping**

*** Mortality significant with *S dysenteriae* type 1**

*** Most infections self-limiting**

Shigella organisms cause an acute inflammatory colitis and bloody diarrhea, which in the most characteristic state presents as a dysentery syndrome—a clinical triad consisting of cramps, painful straining to pass stools (tenesmus), and a frequent, small-volume, bloody, mucoid fecal discharge. However, most clinical shigellosis due to *S sonnei* is a watery diarrhea that is often

indistinguishable from that of other bacterial or viral diarrheal illness. The disease usually begins with fever and systemic manifestations of malaise, anorexia, and sometimes myalgia. These nondescript symptoms are followed by the onset of watery diarrhea containing the large numbers of leukocytes detectable by light microscopy. The diarrhea may turn bloody with or without the other classic signs of dysentery. The manifestations may be more severe when *S flexneri*, the species that predominates in the developing world, is involved and most severe with *S dysenteriae* type 1 (Shiga bacillus). Although most cases of shigellosis resolve spontaneously after 2 to 5 days, the mortality rate in Shiga epidemics in Asia, Latin America, and Africa has been as high as 20%.

Why is *Shigella* so potent in producing epidemics in conditions of poor sanitation or natural disaster?

DIAGNOSIS

*** Selective media routinely used**

*** O antigens confirm species**

All *Shigella* species are readily isolated using selective media (eg, Hektoen enteric agar) that are part of the routine stool culture protocol in all clinical laboratories. These media contain chemical additives shown to inhibit facultative flora (eg, *E coli*, *Klebsiella*) with relatively little effect on *Shigella* (or *Salmonella*). They also contain indicator systems that use typical biochemical reactions to mark suspect *Shigella* colonies among the other flora. Isolates are identified with further biochemical tests. Slide agglutination tests using O group-specific antisera (A, B, C, D) confirm both the species and the *Shigella* genus.

Think ▸▸ Apply 33-2: Epidemics with most enteric pathogens require widespread distribution in food (*Listeria*, EHEC). This also occurs with *Shigella*, but in addition, its resistance to gastric acid and low infecting dose facilitates human-to-human

transmission by direct contact. This is magnified when basic sanitation is compromised (war, natural disaster) or nonexistent.

TREATMENT

*** Treatment shortens illness and excretion**

*** Antibiotic resistance continues to emerge and spread**

Though hydration and maintenance or restoration of electrolyte balance remain the cornerstones of management, various antimicrobial agents have been used in the treatment of shigellosis over time. Because the disease is usually self-limiting, the beneficial effect of treatment is in shortening the duration of the illness and the period of excretion of organisms. Ampicillin was once the treatment of choice, but resistance rates as high as 50% have caused a shift to other agents; in recent years, increasing rates of nonsusceptibility to ciprofloxacin, ceftriaxone, and azithromycin have raised grave concerns about the continued effectiveness of these agents. Antispasmodic agents may aggravate the condition and are contraindicated in shigellosis and other invasive diarrheas.

PREVENTION

*** Sanitation, insect control, handwashing, cooking block transmission**

Vaccine strategies under investigation

Standard sanitation practices such as sewage disposal and water chlorination are important in preventing the spread of shigellosis. In certain circumstances, insect control may also be important, because flies can serve as passive vectors when open sewage is present. Good individual sanitary practices, such as handwashing and proper cooking of food, are highly protective. Parenteral vaccines have proved disappointing thus far, particularly in infants. Ongoing efforts encompass development and testing of a wide range of formulations, including live attenuated, formalin-killed whole cell, glycoconjugate, subunit and novel antigen (such as Type III secretion systems and outer membrane protein) vaccines.

• *SALMONELLA*

BACTERIOLOGY

*** Complexity of O, K, and H antigens leads to many serotypes**

*** Historic names persist as serotypes of *S enterica***

More than any other genus, *Salmonella* has been a favorite of those who love to subdivide and name biologic entities. At one time, there were over 2000 names for various members of this genus, many colorfully reflecting aspects of place or circumstances of the original isolation (eg, *S budapest, S seminole, S tamale, S oysterbeds*). This rich nomenclature has now been streamlined to a single species —*S enterica*—with the previous species names relegated to the status of serovars. Adding to this robust picture is a large number of lipopolysaccharide O antigens, a few capsular K antigens, and flagellar H antigens that undergo phase variation (thus doubling the possible H antigenic states for each strain). As in *Shigella*, the specific O antigens are organized into serogroups (eg, A, B, K, and so on), to which the two H and K (if present) antigen designations are appended to achieve the full antigenic formula. It is not difficult to understand why microbiologists—confronted by a salmonella with the antigenic formula O:group B [1,4,12] H:I;1,2—still prefer to call it *Salmonella typhimurium.* The proper name for this organism is *S enterica* serovar Typhimurium, but indulging in the convenience of elevating the serotype to species status is still common.

*** *Salmonella* serotypes vary in preferred host**

*** *S* Typhi infects only humans**

Another feature distinguishing *Salmonella* serotypes is their host range. Some are highly adapted to particular mammals or amphibians while others infect a broad range of hosts. Of interest for medical microbiology are those strictly adapted to humans and those that infect humans and other animals. *S enterica* serovar Typhi is the prototype for the former, and *S enterica* serovar Typhimurium the prototype for the latter. In the following discussions, the Typhi descriptor is used for the strictly human species that produce enteric (typhoid) fever. Unless otherwise specified, *S enterica* is used for serotypes such as

Typhimurium, which are able to infect animals or humans and typically cause gastroenteritis in the latter.

Type 1 pili and flagella present

Salmonellae possess multiple types of pili, one of which is morphologically and functionally similar to *E coli* type 1 pili and binds D-mannose receptors on various eukaryotic cell types. Most strains are motile through the action of their flagella. *S* Typhi has a surface polysaccharide called the Vi antigen, but capsules have not been as important in the other *Salmonella*.

SALMONELLA GASTROENTERITIS (*S ENTERICA*)

CLINICAL CAPSULE

The typical example of *Salmonella* "food poisoning" is the community picnic, in which participants prepare poultry, salads, and other potential culture media to be eaten later in the day. Because the refrigerators are filled with beer and soda, the food is left out in covered pans. A near-physiologic incubation temperature is provided by the still-warm contents and the afternoon sun. This allows the organisms to enter logarithmic growth during the softball game. The bacteria usually produce no noticeable change in the food. One to two days after the feast, a significant proportion of the revelers develop abdominal pain, nausea, vomiting, and diarrhea lasting for 3 or 4 days. An investigation points to a particular food, such as potato salad or turkey dressing, exposure to which correlates with both attack rate and severity of illness.

EPIDEMIOLOGY

*** Infecting dose is higher than *Shigella***

S enterica gastroenteritis is predominantly a disease of industrialized societies and improper food handling, which allows the transmission from the animal reservoir to humans. The infecting dose of *S enterica* infection varies widely

with serotype (from 200 to 10^6 bacteria) but is generally considerably higher than *Shigella*. This makes human-to-human transmission by direct contact unlikely, so these infections are transmitted under conditions in which the bacteria increase their numbers by growth in contaminated foods before ingestion. Achlorhydric individuals or those taking antacids can be infected with smaller inocula. Consistently, salmonellae are a leading cause of foodborne intestinal infection in circumstances like those described in the preceding capsule.

*** Poultry products are common source**

Poultry products, including eggs (infected transovarially), are most often implicated as the vehicle of infection of *Salmonella* gastroenteritis. Food storage and preparation practices that permit growth of bacteria to an infecting dose before ingestion are commonly involved. The incidence in the United States is estimated at 1.35 million illnesses annually (compared to 450,000 illnesses due to *Shigella*), leading to 26,500 hospitalizations and over 400 deaths each year. The number of cases varies seasonally, with peak incidence in summer and fall.

*** Outbreaks in institutions common**

*** Human carriers a source**

The highest rates of infection are in children under 5 years of age, persons aged 20 to 30, and those older than 70. If one household member becomes infected, the probability that another will become infected approaches 60%. Nearly one-third of all *Salmonella* epidemics occur in nursing homes, hospitals, mental health facilities, and other institutional settings. Increases in the popularity of raw milk have been associated with outbreaks of *Salmonella* (and *Campylobacter*) infection. Exotic pets, including turtles, bearded dragons, and hedgehogs, have also been the source of infection. Humans can also be the source of disease: fully 5% of patients recovering from gastroenteritis still shed the organisms 20 weeks later. Chronic carriers who are food handlers are an important reservoir in the epidemiology of foodborne disease.

*** Modern food production and delivery systems can spread disease efficiently**

In recent years, the number of multistate outbreaks has increased, often

through the contamination of foodstuffs during large-scale production at a single plant, as in a 2009 U.S. outbreak involving peanut products and encompassing over 700 cases in 48 states. Efficient interstate and international distribution systems that deliver large amounts of the contaminated food over a wide area facilitate spread, as with a 2013 U.S. outbreak involving chicken products that infected over 600 persons across 29 states and Puerto Rico. Under these conditions, an attack rate as low as 0.5% can still produce many infections because of the large number of persons at risk. It is of concern that relatively small numbers of cases sprinkled over a massive area will be missed by local surveillance systems hampered by chronic budgetary cutbacks.

PATHOGENESIS

* **Adherence triggers surface ruffles**

* **Secretion system genes are in PAIs**

Ingested *S enterica* cells that surmount the stomach acid and swim through the intestinal mucous layer eventually reach the small bowel, where they must compete with indigenous host flora and evade enteric defenses. Though it is not clear whether the initial host cell contact there may be with M (microfold) cells, enterocytes, or columnar epithelial cells, the initial adherence is probably mediated by pili. Upon engagement of *S enterica* injection (type III) secretion systems, formation of membrane “ruffles” dramatically alters the normal host cell architecture within minutes (**Figure 33–9**). These ruffles are specialized plasma membrane sites of filamentous actin cytoskeletal rearrangement, normally induced by physiologic molecules such as growth factors. The bacterial secretion systems inject multiple other effectors coded by genes located within PAIs in the *Salmonella* genome; the virulence factors coded by PAI genes are either components of the injection system apparatus itself or the effector proteins it injects.

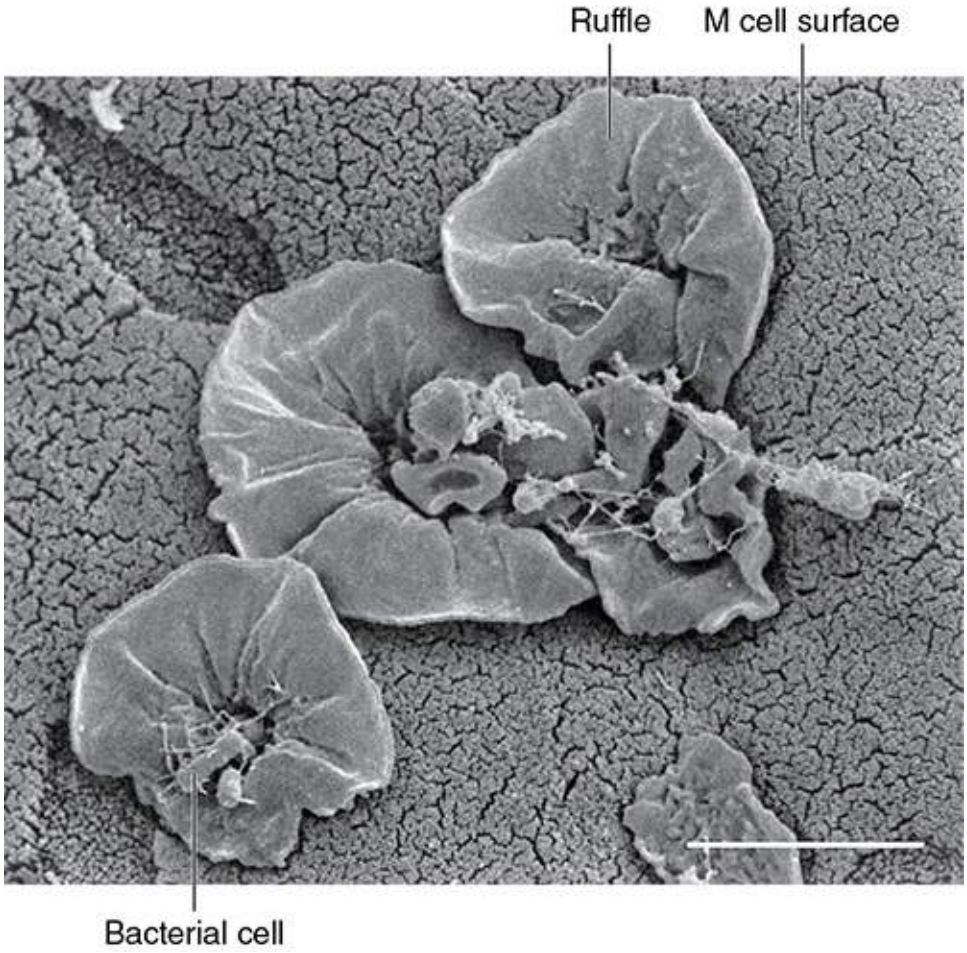

FIGURE 33–9. Salmonella ruffles. *S* serovar Typhimurium is shown inducing wave-like ruffles on an intestinal M cell. This leads to induction of uptake of the bacteria by the M cell. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: Microbiology: *A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

*** Ruffles induce endocytosis**

*** Macrophage apoptosis aids survival**

Persisters may lead to relapse

The ruffles seem to engulf the organism in an endocytic vacuole, permitting it to transcytose from the apical surface to the basolateral membrane. Once in the cell, *S enterica* multiplies in the vacuole and continues on through the cell, entering the lamina propria; there the bacteria typically induce a profound inflammatory response and are phagocytosed by neutrophils and macrophages. Then, by deploying a second injection secretion system from inside the host macrophage, bacteria induce apoptosis, killing the macrophages and thus

persisting in the lamina propria. This process contrasts with *Shigella*, which escapes the endocytic vacuole (and double vacuole) to the cytoplasm and prefers to invade adjacent enterocytes rather than move through to the submucosa. Alternatively, *Salmonella* may become nonreplicating persisters within host cells, enacting survival programs induced by vacuolar acidification and nutritional deprivation; subsequent resumption of intracellular growth by these persisters may be the basis for relapsing infection.

*** Invasion and inflammation cause diarrhea**

Enterotoxin role is unclear

The joint impact of invasion and transcytosis of enterocytes, together with the associated increased vascular permeability and inflammatory response, may account in aggregate for diarrhea. The release of prostaglandins and chemotactic factors may trigger inflammation and biochemical changes in enterocytes. Although the process remains localized to the mucosa and submucosa with most *S enterica* strains, some invade more deeply, reaching the bloodstream and distant organs; some serotypes (eg, *S* ser. Choleraesuis) invade so rapidly that they produce minimal diarrhea and are isolated more frequently from the blood than stool. Although various enterotoxins have been described in *Salmonella*, their role in diarrhea is unclear.

IMMUNITY

Immune mechanisms may benefit as well as harm *Salmonella*

Evidence that both humoral and cell-mediated immune responses are stimulated by infection with *S enterica* is ample. *Salmonella* pathogens are also able to exploit some of these responses to compete successfully with resident microbiota and promote their own survival within the host. While several of these host-pathogen interactions have been characterized in great detail, the key determinants in the outcome of infectious episodes (resolution, dissemination, chronic infection) remain to be determined.

ENTERIC (TYPHOID) FEVER (*SALMONELLA* SEROVAR TYPHI)

EPIDEMIOLOGY

* Fecal–oral transmission requires moderate dose

Typhoid fever is a strictly human disease; chronic carriers of *S* Typhi are the primary reservoir. Some patients become carriers for years (witness the infamous “Typhoid Mary” Mallon), usually because of chronic infection of a biliary tract where gallstones are present. All cases can and should be traced back to their human source; if a patient with typhoid has not traveled to an endemic area, the source must be a visitor or someone else who prepared food. The pathogen can be transmitted in the water supply in endemic areas or anywhere that structural defects allow sewage from carriers to contaminate drinking water. Transmission is by the fecal–oral route. The infecting dose of 10^5 to 10^6 bacteria is intermediate between *Shigella* and most *S enterica*, and Typhi’s Vi capsule may further reduce the number of organisms needed to infect. Three serotypes called Paratyphi (A, B, C) have features similar to *S* Typhi, including the production of an enteric fever syndrome; cases are likewise traceable to a human source.

* Prevalence is linked to sanitation infrastructure

Typhoid fever is still an important cause of morbidity and mortality worldwide, producing 16 million cases and 600,000 deaths a year. In developed countries, it is mostly seen in travelers returning from endemic areas in Latin America, Asia, and India. Visitors from these areas who are carriers are often the source of isolated cases. The decline in disease in industrialized nations largely reflects the availability of clean water supplies and improved disposal of human waste.

PATHOGENESIS

* Typhi invades M cells and macrophages

*** Vi polysaccharide limits PMN (neutrophil) phagocytosis**

There is no animal model for the strictly human *S* Typhi. The details of the cellular events are inferred from studies of Typhimurium, which in mice produces a disease similar to typhoid (thus the name). The invasion and killing of intestinal M cells and macrophages are presumed to follow the same pattern as that of *S enterica*, with two key differences: the Vi surface polysaccharide and the extensive multiplication of Typhi in macrophages. In the submucosa, Vi (for virulence) blocks neutrophil phagocytosis by interfering with complement deposition in a manner similar to that of other bacterial surface polysaccharides. This may favor uptake by macrophages, where at least some Typhi cells establish a privileged niche, and the Vi^+ phenotype in turn favors intracellular multiplication. Like other serotypes of *Salmonella*, Typhi remains within a membrane-bound vacuole, but unlike them, it enters a stage of extended replication rather than killing the macrophage.

*** Macrophage oxidative burst inhibited**

*** Infection spreads through RES**

The primary feature distinguishing Typhi from the other serotypes—the prolonged intracellular survival in macrophages—is due to Typhi's ability to inhibit the oxidative metabolic burst and thus continue to multiply. As they proliferate in macrophages, Typhi bacteria are carried through the lymphatic circulation to the mesenteric nodes, spleen, liver, and bone marrow, all elements of the reticuloendothelial system (RES). At the RES sites, Typhi continue to multiply, infecting new host macrophages. Rather than the acute inflammatory response seen with *S enterica*, *S* Typhi generates a mononuclear response so mild as to spare the host from diarrhea; this may be due to the downregulation of innate toll-like receptor responses in the intestinal mucosa by the Vi antigen.

*** RES sites seed the bloodstream and other organs**

*** Endotoxin produces the fever**

Eventually, the burgeoning bacterial population begins to reach the bloodstream (Figure 33–8). The entry of Gram-negative bacteria and their LPS endotoxin into the blood triggers fever that increases slowly. Continued seeding of *S* Typhi into the blood feeds the fever and sometimes leads to metastatic

infection of other organs including the urinary tract and the biliary tree; the latter may ultimately cause reinfection of the bowel. This cycle, beginning and ending in the small intestine, takes approximately 2 weeks to complete.

IMMUNITY

*** Immunity follows natural infection**

Natural infection with *S* Typhi confers immunity; reinfection is rare unless the course was shortened by early administration of antimicrobials. The immune response is both T_H1- and T_H2-mediated. In nonfatal cases, antibody and activated macrophages eventually subdue untreated infection over a period of about 3 weeks. Which antigens stimulate this immunity is not clearly understood; the Vi antigen is usually credited, but various surface proteins are also candidates.

SALMONELLOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** *S enterica* = gastroenteritis**

*** Typhi = enteric fever**

The clinical patterns of salmonellosis can be divided into gastroenteritis, bacteremia with or without focal extraintestinal infection, enteric fever, and the asymptomatic carrier state. In principle any *Salmonella* serotype may cause any of these clinical manifestations under appropriate conditions, but in practice the *S enterica* serotypes are mainly associated with gastroenteritis, and Typhi and related serotypes (Paratyphi) cause enteric fever.

▪ Gastroenteritis

*** Diarrhea, vomiting, and cramps are common**

Typically, the episode begins 24 to 48 hours after ingestion, with nausea and vomiting followed by, or concomitant with, abdominal cramps and diarrhea.

Diarrhea persists as the predominant symptom for 3 to 4 days and usually resolves spontaneously within 7 days. Fever (39°C) is present in about 50% of the patients. The spectrum of disease ranges from a few loose stools to a severe dysentery-like syndrome.

▪ Bacteremia and Metastatic Infection

*** Bacteremia is most common and severe in the immunocompromised**

*** Metastatic sites linked to previous injury, particularly sickle cell anemia**

The acute gastroenteritis caused by *S enterica* can be associated with transient or persistent bacteremia. Frank sepsis is uncommon, except in those with compromised cell-mediated immunity; *Salmonella* infection in patients with acquired immunodeficiency syndrome (AIDS) is common and often severe. Bacteremia occurs in 70% of these patients and can cause septic shock and death. Despite adequate antimicrobial coverage, relapses are common. Patients with T-cell defects, such as lymphoproliferative diseases, or those receiving immune-suppressive agents after organ transplant are also highly susceptible to disseminated salmonellosis. Metastatic spread by salmonellae is a significant risk when bacteremia occurs. These organisms have a unique ability to colonize sites of preexisting structural abnormality, including atherosclerotic plaques, sites of malignancy, and the meninges (especially in infants). *Salmonella* infection of the bone typically involves the long bones; in particular, sites of trauma, sickle cell injury, and skeletal prosthetics are at risk.

▪ Enteric Fever

*** Slowly increasing fever lasts for weeks**

*** Diarrhea is intermittent or absent**

Enteric fever is a multiorgan *Salmonella* infection characterized by prolonged fever, sustained bacteremia, and profound involvement of the mesenteric lymph nodes, liver, and spleen. The manifestations of typhoid (**Figure 33–10**) have been well documented in human volunteer studies conducted during vaccine trials. The mean incubation period is 13 days, and the first sign of disease is fever associated with a headache. The fever rises in stepwise fashion over the

next 72 hours; a slow pulse, rather than the quickened pulse typical of fever, is pathognomonic for typhoid fever. In untreated patients, elevated temperature persists for weeks. Many patients are constipated, but up to one-third of patients have mild diarrhea; as untreated disease progresses, diarrhea may become more prominent. A faint rash (rose spots) appears during the first few days on the abdomen and chest; few in number, these spots may be missed by clinicians on the skin of people of color.

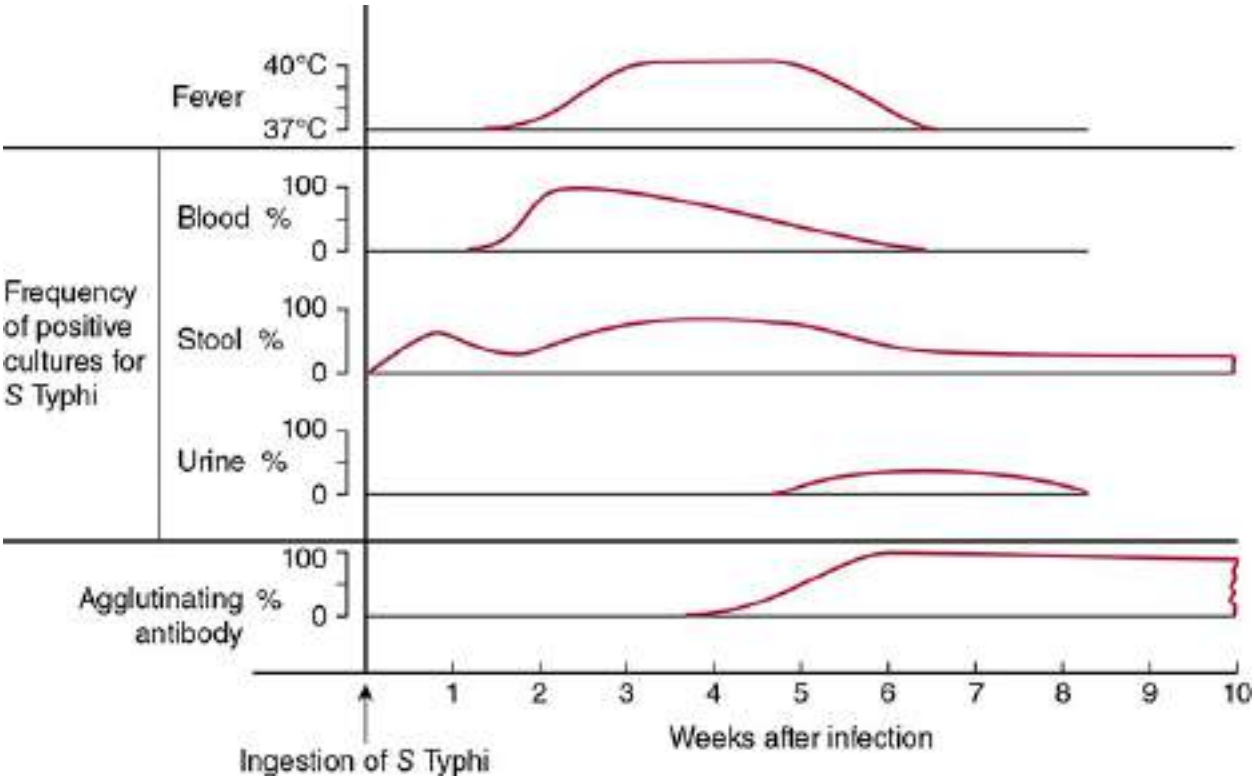

FIGURE 33–10. Natural history of enteric (typhoid) fever. The course of disease without antimicrobial therapy. Fever chart shows time course for typical patient. Culture and agglutinating antibody show timing and probability of positive results in a group of typhoid fever patients.

Why does it take so long? Why is there no diarrhea?

*** Biliary tree infection reseeds intestine**

*** Urinary tract, bone, and joints are metastatic sites**

Obviously, prolonged infection of the bloodstream is serious, and the effects of endotoxin can lead to myocarditis, encephalopathy, or disseminated

intravascular coagulation. Moreover, the persistent bacteremia can lead to infection at other sites. Of particular importance is the biliary tree, with reinfection of the intestinal tract and diarrhea late in the disease. Urinary tract infection and metastatic lesions in bone, joint, liver, and meninges may also occur. However, the most important complication of typhoid fever is intestinal perforation (through the wall of the terminal ileum or proximal colon at the site of necrotic Peyer patches) and hemorrhage; these occur in patients whose disease has been progressing for 2 weeks or more.

DIAGNOSIS

*** Stool and blood culture are routine**

*** Typhi has characteristic features**

Culture of *Salmonella* from the blood or stool is the primary diagnostic method. Early in the course of enteric fever, blood is far more likely to give a positive culture result than culture from any other site. The media used for stool culture are the same as those used for *Shigella.* Failure to ferment lactose and the production of hydrogen sulfides from sulfur-containing amino acids are characteristic features used to identify suspect colonies on the selective isolation media. Characteristic results of biochemical tests are used to identify the genus, though an isolate may also be subjected to O serogroup antisera for confirmation in larger laboratories. Typhi has a pattern of biochemical reactions distinctive enough to permit identification without reliance on serotype. All isolates should be referred to public health laboratories for confirmation and epidemiologic tracing; whole genome sequencing and other molecular typing methods have continued to gain prominence in these settings.

TREATMENT

*** Antimicrobials are of limited use in gastroenteritis**

The primary therapeutic approach to *Salmonella* gastroenteritis consists of fluid and electrolyte replacement and the control of nausea and vomiting. Antibiotic therapy is not indicated in most cases because it may promote and prolong the carrier state. When used to eradicate the carrier state, antibiotics produce only erratic success and may fail altogether in the presence of biliary tract disease.

Therefore, the use of antimicrobial agents in *S enterica* gastroenteritis is restricted to those with severe infections or underlying risk factors (such as immunosuppressive illnesses or therapies) and to infants less than 3 months old; in these instances, antimicrobial use is intended to prevent systemic spread.

Antibiotics effective but multidrug resistance is increasing

In typhoid fever, antimicrobial therapy is clearly indicated. Chloramphenicol (no longer in use) and then ampicillin were the first antibiotics used and reduced the mortality rate from 20% to less than 2%. Use of ampicillin is now limited by widespread resistance, leaving the extended-spectrum cephalosporins (ceftriaxone, cefixime) and ciprofloxacin as preferred first-line agents. As seen in other pathogenic enteric species (*E coli*, *K pneumoniae*), global patterns of antimicrobial resistance in *S* Typhi have been reshaped by the recent emergence of a single multidrug resistant clone. Nonetheless, with effective antimicrobial therapy, patients feel better in 24 to 48 hours, their temperature returns to normal in 3 to 5 days, and they are generally well in 10 to 14 days.

Think ▸▸ Apply 33-3: In the 2 weeks before the onset of fever, *S* Typhi is multiplying in macrophages and spreading to lymph nodes, spleen, and other elements of the RES. There may be a transient diarrhea but too mild for most to seek medical attention and have a culture taken. The disease is due to circulating LPS, not enterocyte dysfunction or destruction.

PREVENTION

*** Typhoid vaccines are only moderately effective**

*** Sanitation and public health measures can eliminate Typhi**

Killed whole bacterial vaccines have been available for typhoid since the late 19th century, with protection in the range of 50% to 70%. Newer vaccines—one that uses a live attenuated Typhi strain, the other a polysaccharide vaccine containing the Vi antigen—give slightly higher protection, but none lasting more than a few years. The newest vaccine contains Vi antigen conjugated to a

bacterial protein in the manner of Hib, meningococcal, and pneumococcal vaccines. It shows promise for both higher efficacy and use in children less than 5 years of age. No human vaccine is available for the other *Salmonella* serotypes. When all is said and done, the provision of clean water supplies and the treatment of carriers would still go a long way toward eradicating typhoid. The importance of carriers and sanitation was emphasized by a 1973 typhoid outbreak among migrant workers in Florida; the source was traced to leakage of sewage into the water supply, failure of chlorination, and a chronic carrier. All three are required to sustain an outbreak when adequate sanitary infrastructure is in place.

• YERSINIA

BACTERIOLOGY

*** Coccobacillary and grow at variable temperatures**

*** Human pathogens linked to animals**

Morphologically, *Yersinia* tend to be coccobacillary and to retain staining at the ends of the cells (bipolar staining). Growth and metabolic characteristics are the same as those of other Enterobacteriaceae, although some strains grow more slowly or have optimal growth temperatures lower than 37°C. The genus includes 11 species, of which *Yersinia pestis*, *Yersinia pseudotuberculosis*, and *Yersinia enterocolitica* are pathogenic for humans. *Yersinia pestis* is antigenically homogenous, but *Y pseudotuberculosis* and *Y enterocolitica* have multiple O and H antigen serotypes. *Yersinia* are primarily animal pathogens, with occasional transmission to humans through direct or indirect contact. *Yersinia pestis*, the cause of plague, is discussed in Chapter 36, although features of its pathogenesis common to other *Yersinia* are included below.

YERSINIA DISEASES (*Y PSEUDOTUBERCULOSIS* AND *Y ENTEROCOLITICA*)

EPIDEMIOLOGY

*** Transmitted by ingestion from animal source**

Geographic variation is great

In animals, *Y pseudotuberculosis* causes pseudotuberculosis, a disease characterized by local necrosis and granulomatous inflammation in the lymph nodes, spleen, and liver. In humans, the portal of entry is the gastrointestinal tract, presumably by consumption of contaminated food or water; farm animals and wild rodents are among the most likely source of infection. Rates of *Y enterocolitica* infection vary markedly by geographic region, with the highest rates reported in Scandinavian and other European countries, and much lower rates in the United Kingdom and the United States. However, *Y enterocolitica* infection may be underdiagnosed due to lack of routine testing by many laboratories.

PATHOGENESIS

*** Intestinal M cells are invaded**

*** Secreted Yops disrupt cellular function**

Enteropathogenic *Yersinia* enter the human host in contaminated food and invade the M cells of the Peyer patch. The invasive process and its effects on the host cell are driven by a large array of virulence factors that are deployed under complex genetic and environmental regulation. These proteins include **invasin,** which binds to integrins on the surface of host cells, and the major effector proteins called Yersinia outer membrane proteins (**Yops**). The Yops are delivered by yet another injection (type III) secretion system; when injected into the host cell, they trigger cytotoxic events, including disruption of biochemical pathways (dephosphorylation, serine kinase), sensor functions, and the actin cytoskeleton.

Ca^{2+} and temperature regulate virulence factor expression

Plasmid and PAI contain virulence genes

Some of the virulence factors produced by *Yersinia* are regulated in response

to either temperature or free calcium (Ca^{2+}) concentration. The physiologic temperature in a mammalian host is different from that in an insect or the environment, and the intracellular calcium concentration is markedly different from that of extracellular fluids; by sensing the environment, *Yersinia* are able to express or suppress virulence factors at different stages of the pathogenic process. The results seem timed to support the pathogenic strategy of *Yersinia*, which is to paralyze the phagocytic activity of defending macrophages and neutrophils and thus nullify the host cellular immune response. The virulence determinants are encoded both on the bacterial chromosome and on a plasmid that contains genes for the secretion apparatus as well as the Yops. Another genetic component is a PAI, which is found only in the three pathogenic species and not other *Yersinia*.

*** Spread leads to microabscesses in lymph nodes**

The biological outcome of this extraordinary multifactorial process is the enhanced capacity of the pathogenic *Yersinia* to enter and replicate within the RES and to delay the cellular immune response. This leads to the formation of microabscesses and destruction of the cytoarchitecture of Peyer patches and the mesenteric lymph nodes. The systemic symptoms seen with dissemination can largely be attributed to the effects of endotoxin.

*** *Y pestis* has capsule, plasminogen activator, and fibrinolysin**

Yersinia pestis is a specialized variant closely related to *Y pseudotuberculosis*. Instead of entering the intestinal tract, *Y pestis* reaches the dermal lymphatics by the bite of an infected flea. It has its own invasin-like adhesin as well as two plasmids not found in the enteropathogenic *Yersinia*. Unique virulence factors for *Y pestis* include a capsular protein antigen with antiphagocytic properties, a plasminogen activator protease that promotes adherence to basement membranes, and a fibrinolysin that may play a survival role in the flea.

YERSINIA INFECTIONS: CLINICAL ASPECTS

*** Mesenteric lymphadenitis creates abdominal pain**

Not routinely sought in stools

Both *Y enterocolitica* and *Y pseudotuberculosis* cause acute mesenteric lymphadenitis, a syndrome involving fever and abdominal pain that often mimics acute appendicitis. *Y enterocolitica* produces a wider variety of manifestations as well. The most common of these is enterocolitis, which usually occurs in children and is characterized by fever, diarrhea, and abdominal pain. *Y enterocolitica* also causes enteric fever, terminal ileitis, and an immune-mediated polyarthritic syndrome occurring after acute infection. Few laboratories in the United States routinely screen stools for *Yersinia* because yield has been low and good selective media are not available.

Antimicrobials not needed for self-limited disease

Resistance patterns vary by species

The role of antimicrobial therapy in enteric *Yersinia* infections is uncertain as the episodes are usually self-limiting. *Y pseudotuberculosis* is susceptible to ampicillin, cephalosporins, aminoglycosides, and tetracyclines, but *Y enterocolitica* is usually resistant to penicillins and cephalosporins through the production of β-lactamases.

• OTHER ENTEROBACTERIACEAE

All Enterobacteriaceae described here are capable of producing opportunistic infections of the type discussed under *E coli*; none is considered a primary cause of enteric disease in the normal host. The genera isolated in at least moderate frequency are discussed briefly below. There are many other less common species.

KLEBSIELLA

*** Polysaccharide capsule blocks complement deposition**

The most distinctive bacteriologic features of the genus *Klebsiella* are the absence of motility and the presence of a polysaccharide capsule; the latter gives colonies a glistening, mucoid character and forms the basis of a serotyping system. Over 70 capsular types have been defined, including some that cross-

react with those of other encapsulated pathogens, such as *Streptococcus pneumoniae* and *Haemophilus influenzae*. Limited studies suggest that the capsule interferes with complement activation as it does in other encapsulated pathogens. *Klebsiella* also express several types of pili on the cell surface which probably aid in adherence to respiratory and urinary epithelium.

*** Often multidrug resistant**

Klebsiella pneumoniae, the most common species, is able to cause classic lobar pneumonia, a characteristic of other encapsulated bacteria; most *Klebsiella* pneumonias are indistinguishable from those produced by other members of the Enterobacteriaceae. Highly mucoid *K pneumoniae* bearing K1 or K2 capsule have been associated with distinctive clinical syndromes featuring liver abscess and endophthalmitis, particularly in Southeast Asian countries. Of all the Enterobacteriaceae, *Klebsiella* species are now among the most resistant to antimicrobial agents. In the early 2000s, a single *K pneumoniae* clone (Sequence Type 258), now notorious for its near pan-resistant properties, emerged as a devastating cause of hospital-acquired infection (bloodstream, respiratory tract, urinary tract) in the northeastern United States and spread rapidly around the globe. The rise and spread of this and other highly resistant "superbugs" have led to concerns about a postantibiotic era.

ENTEROBACTER

*** Resistance can emerge during treatment**

Modest virulence but are linked to hospital acquisition

Enterobacter species generally ferment lactose promptly and produce colonies similar to those of *Klebsiella*, though not as mucoid. A differential feature is motility by peritrichous flagella, which are generally present in *Enterobacter* species but uniformly absent in *Klebsiella*. *Enterobacter* species, which are generally less virulent than *Klebsiella*, have attracted increasing attention as a cause of infections acquired in the hospital, where their intrinsic antibiotic resistance properties undoubtedly confer a selective advantage. In addition to ampicillin, most isolates are resistant to first-generation cephalosporins. Though *Enterobacter* may appear susceptible to later-generation cephalosporins, resistance to these agents may emerge during treatment via derepression of β-lactamase production in patients with inadequate source control, such as those

with incompletely drained abscesses or devitalized/necrotic tissue where bacteria may persist.

SERRATIA

*** Red pigment and multidrug resistance are characteristic**

Serratia strains ferment lactose slowly (3-4 days), if at all. Some produce distinctive brick-red colonies. Although less common, this genus produces the same range of opportunistic infections seen with other Enterobacteriaceae. *Serratia* strains show consistent intrinsic resistance to ampicillin and cephalothin/cefazolin, and like Enterobacter, may become further resistant to later generation cephalosporins during treatment. Circulating hospital strains may acquire plasmids conferring resistance to other antimicrobial classes including the aminoglycosides. Sporadic infections and nosocomial outbreaks with multiresistant strains have often been difficult to control.

CITROBACTER

*** Opportunistic infection and brain abscess are uncommon**

Though biochemically and serologically similar to *Salmonella*, the genus *Citrobacter* is an uncommon cause of opportunistic infection. Like many other Enterobacteriaceae, *Citrobacter* strains may be present in the intestinal microbiota and cause opportunistic infections. Despite reports of association with diarrheal disease, present evidence does not indicate that *Citrobacter* should be considered an enteric pathogen of humans. *Citrobacter freundii* has been associated with neonatal meningitis and brain abscess.

PROTEUS, PROVIDENCIA, AND *MORGANELLA*

*** Swarming is a feature of some species**

*** Urease production is linked to urinary stones**

Proteus, Morganella, and *Providencia* are also opportunistic pathogens found with varying frequencies in the intestinal microbiota. *Proteus mirabilis,* the most commonly isolated member of the group, is one of the most susceptible of the

Enterobacteriaceae to the penicillins. Other Proteae (typically, indole-positive species like *P vulgaris*) are intrinsically resistant to ampicillin and the cephalosporins. *Proteus mirabilis* and *P vulgaris* share the ability to swarm over the surface of microbiologic media, rather than remaining confined to discrete colonies; this characteristic makes them readily recognizable in the laboratory—often to the microbiologist's dismay, as this spreading growth covers other organisms in the culture and thus delays their isolation. Swarming coupled with motility could facilitate the production of UTI by propelling *Proteus* up urinary catheters. *Proteus* and *Morganella* differ from other Enterobacteriaceae in the production of a very potent **urease**, which allows for their rapid identification; it also contributes to the formation of urinary stones and produces alkalinity and an ammoniac odor to the urine. *Providencia* species do not produce urease, are the least frequently isolated, and are generally the most resistant of the group to antimicrobials.

CASE STUDY

Hamburgers and Hemorrhage

A 24-year-old woman was seen in a hospital emergency department with a history of nausea, vomiting, and nonbloody diarrhea, which progressed to bloody diarrhea. Four days earlier, she had eaten a hamburger at a fast-food restaurant. To replace fluid lost from diarrhea, she was given 2 liters of IV fluid. She felt better and was sent home with antinausea medication.

After 2 days, the vomiting, nausea, and bloody diarrhea persisted, along with abdominal cramps and orthostatic dizziness. She returned to the emergency department, was admitted, again given IV fluids, and discharged after 2 days of hospitalization. A stool sample was taken for culture.

Three days later, the patient awoke with vomiting and contacted her private physician. Laboratory tests were done with the following results: blood urea nitrogen 67.0 mg/dL (ref. 7-19); white blood cells 13 100/mL; hemoglobin 7.0 g/dL (ref. 11.5-15.5); platelet count 75 000/µL (ref. >150 000). The stool culture taken earlier was positive for *E coli* O157:H7.

The patient was transferred to the ICU the same day and was described as severely ill. She was fatigued, very dehydrated, with abdominal tenderness and back pain but no neurologic problems. Steroids were the only additional medication given in addition to plasmapheresis, which was done five times during her hospitalization. She gradually recovered and was discharged.

QUESTIONS

1. Which of the following is probably the source of this patient's infection?

A. Colonized cow
B. Colonized restaurant worker
C. Contaminated restaurant water
D. Family member
E. Restaurant air

2. What bacterial product was primarily responsible for the hemorrhage and renal injury?

A. Endotoxin
B. α-Toxin
C. Labile toxin (LT)
D. Stable toxin (ST)
E. Shiga toxin (Stx)

3. If hamburger is the source, this infection could have been prevented by which of the following?

A. Screening the restaurant workers
B. Handwashing
C. Disinfectants
D. Complete cooking
E. Antibiotic prophylaxis

ANSWERS

1. **(A)**
2. **(E)**
3. **(D)**

chapter 34

Legionella and *Coxiella*

Legionella pneumophila • *Coxiella burnetii*

The death toll in the outbreak of the mysterious respiratory disease in Philadelphia rose by two to 25 as medical detectives accelerated efforts today to seek a chemical or poison as the possible cause.

—*The New York Times*, August 7, 1976

OVERVIEW

Legionella are thin, pleomorphic, long, Gram-negative rods that stain poorly and require special media for isolation. They are ubiquitous and persistent in the environment, especially in water and soil. When inhaled into the lung, *Legionella* enter alveolar macrophages, escape host defenses, and produce a destructive pneumonia marked by headache, fever, chills, dry cough, and chest pain. There may be multiple foci in both lungs and extension to the pleura, but spread outside the respiratory tract is very rare.

Coxiella (agent of Q fever) are tiny Gram-negative coccobacilli that when inhaled from animal and soil environmental sources cause pneumonia. In addition to the lung, *Coxiella* also have a tropism for the liver where they reside in macrophages and cause granulomatous hepatitis. Less commonly, *Coxiella* causes infective endocarditis not detected by culturing blood.

Legionella is a genus of Gram-negative bacilli that takes its name from the outbreak at the American Legion convention where it was first discovered. The name of the type species, *Legionella pneumophila*, reflects its propensity to cause the necrotizing pneumonia known as Legionnaires disease. *Legionella* species are now known to be widespread in the environment in ponds, amoebas, and the plumbing of large buildings. *Coxiella*, a cause of pneumonia known long before *Legionella*, shares many pathogenic, epidemiologic, and clinical features with it.

• *LEGIONELLA*

BACTERIOLOGY

STRUCTURE

*** Gram negative rods stain with difficulty**

L pneumophila is a thin, pleomorphic, Gram-negative rod that may show elongated, filamentous forms up to 20 μm long. In clinical specimens, the organism stains poorly or not at all by Gram stain or the usual histologic stains; however, it can be demonstrated by silver impregnation methods (Dieterle stain). Polar, subpolar, and lateral flagella may be present and most species of *Legionella* are motile. Spores are not found.

*** LPS less toxic than other Gram negatives**

Side chains hydrophobic

Structurally, *L pneumophila* has features similar to those of Gram-negative bacteria with a typical outer membrane, thin peptidoglycan layer, and cytoplasmic membrane. The toxicity of *L pneumophila* lipopolysaccharide (LPS) is significantly less than that of other Gram-negative bacteria such as *Neisseria* and the Enterobacteriaceae. This has been attributed to chemical makeup of the LPS side chains that renders the cell surface highly hydrophobic, a property which may promote distribution in aerosols.

METABOLISM

*** Intracellular parasite of protozoa**

*** Biofilms in water systems**

*** Requires L-cysteine, ferric ions, low pH**

Legionella is a facultative intracellular pathogen multiplying to high numbers inside free-living amoebas, other protozoa, and macrophages. In human-made water systems the organisms persist in a low metabolic state imbedded in biofilms. *In vitro L pneumophila* fails to grow on common enriched

bacteriologic media such as blood agar due to requirements for certain amino acids (L-cysteine), ferric ions, and slightly acidic conditions (optimal pH 6.9). Even when these requirements are met, growth under aerobic conditions is slow, requiring 2 to 5 days to produce colonies that have a distinctive surface resembling ground glass. Although a few enzymatic actions (catalase, oxidase, β-lactamase) are demonstrable, the classification of *Legionella* depends largely on antigenic features, chemical analysis, and nucleic acid homology comparisons. The closest relative among pathogenic bacteria is *Coxiella burnettii* (see later).

Multiple serogroups, other species

L pneumophila has multiple serogroups (16) and there are over 50 other *Legionella* species (eg, *Legionella longbeachae*, *Legionella bozemanii*, *Legionella dumoffii*, *Legionella micdadei*). The original Philadelphia strain (serogroup 1) is still the most common, and a limited number of *L pneumophila* serogroups account for 80% to 90% of cases. This suggests enhanced virulence for humans, since the frequency of *L pneumophila* among species found in the environment is below 30%. Less than half of the non–*L pneumophila* species have been isolated from human infections.

LEGIONNAIRES DISEASE

EPIDEMIOLOGY

1976 outbreak led to discovery

Earlier outbreaks solved

The widely publicized outbreak of pneumonia among attendees of the 1976 American Legion convention in Philadelphia led to the isolation of a previously unrecognized infectious agent, *L pneumophila*. The event was unique in medical history. For months, the American public entertained theories of its cause that ranged from chemical sabotage to viroids and fears that something like Michael Crichton's 1969 novel *The Andromeda Strain* was ahead. It was almost a letdown to find that a Gram-negative rod that could not be stained or grown by

the common methods was responsible. The Centers for Disease Control investigation was an outstanding example of the benefits of pursuing sound epidemiologic evidence until it is explained by equally sound microbiologic findings. We now know the disease had occurred for many years. Specific antibodies and organisms have been detected in material preserved from the 1950s, and a mysterious hospital outbreak in 1965 has been solved retrospectively by examination of preserved specimens. Today, most cases of Legionnaires disease in the United States are caused by just a few *L pneumophila* serogroups, including the original Philadelphia strain, but there is considerable variation worldwide. In Australia, New Zealand, and Japan *L longbeachae* and *L pneumophila* are found with similar frequency.

*** Freshwater amoebas are reservoir**

*** Aerosols distributed by humidifying and cooling systems**

In nature, *Legionella* species are ubiquitous in freshwater lakes, streams, and subterrestrial groundwater sediments. They are also found in moist potting soil, mud, and riverbanks. In these sites, they also exist as parasites of protozoa including numerous species of amoebas, which appear to be the environmental reservoir. Transmission to humans occurs when aerosols are created in manmade water supplies that harbor *Legionella*. Most outbreaks have occurred in or around large buildings such as hotels, factories, and hospitals with cooling towers or some other part of an air-conditioning system as the dispersal mechanism. Some hospital outbreaks have implicated respiratory devices and potable water coming from parts of the hot water system such as faucets and showerheads. Even the mists used in supermarkets to make the vegetables look fresh have been the source of outbreaks. *Legionella* can persist in a water supply despite standard disinfection procedures, particularly when the water is warm and the pipes contain scale or low-flow areas that compromise the effectiveness of chlorine compounds.

*** Person-to-person transmission, carriers unknown**

*** Disease rate low**

It is difficult to ascertain the overall incidence of *Legionella* infections because most information has been from outbreaks that constitute only a small part of the total cases. Estimates based on seroconversions suggest

approximately 25,000 cases in the United States each year. The attack rate among those exposed is estimated at less than 5% and serious cases are generally limited to immunocompromised persons. Person-to-person transmission has not been documented, and the organisms have not been isolated from healthy individuals. Growth in free-living amoebas produces *Legionella* cells that are more resistant to environmental stress (acid, heat, osmotic) and have enhanced infectivity.

PATHOGENESIS

*** Tropism for lung**

*** Pneumonia with intracellular bacteria**

L pneumophila is striking in its propensity to attack the lung, producing a necrotizing multifocal pneumonia. Microscopically, the process involves the alveoli and terminal bronchioles, with relative sparing of the larger bronchioles and bronchi (**Figure 34–1**). The inflammatory exudate contains fibrin, neutrophils, macrophages, and erythrocytes. A striking feature is the preponderance of bacteria within phagocytes and the lytic destruction of inflammatory cells.

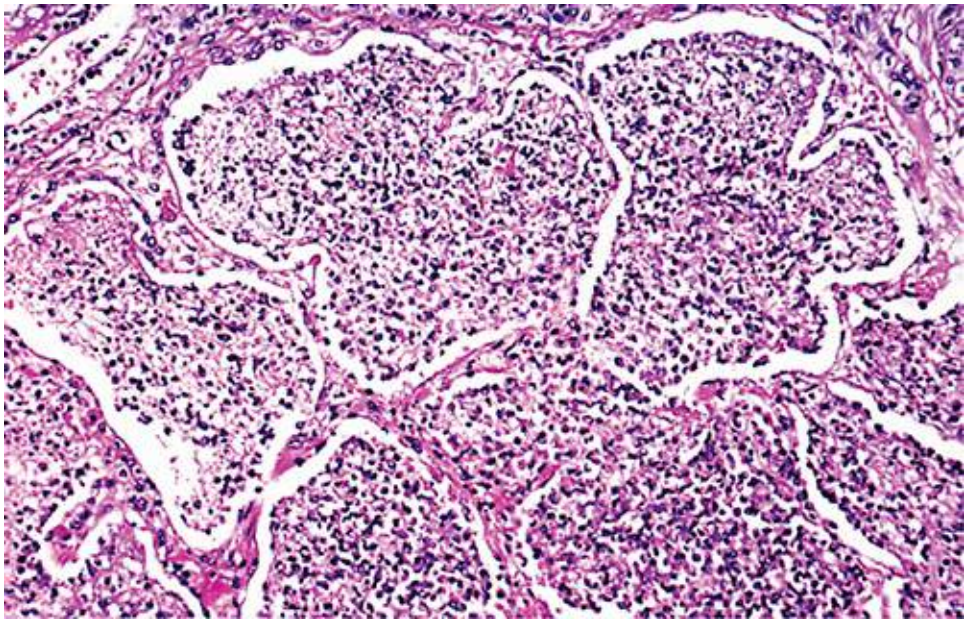

FIGURE 34–1. *Legionella pneumonia.* Note the filling of alveoli with exudate. Some of the alveolar septa are starting to degenerate. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases.* Stamford CT: Appleton & Lange; 1997.)

*** Host ER incorporated into LCV**

*** Lysosomal fusion blocked**

*** Invades alveolar macrophages**

Inhaled *Legionella* bacteria reach the alveoli, where they attach to their pathogenic target the alveolar macrophage. In this process, they are aided by flagella, pili, and a variety of other proteins. Following attachment the bacteria enter the macrophage in an endocytic vacuole. Inside the cell *L pneumophila* initiates a process which prevents fusion with the lysosome and instead recruits ribosomes, mitochondria, and elements of the host cell endoplasmic reticulum (ER) into its own phagosome called the Legionella-containing vacuole (LCV). In the LCV niche protected from lysosomal digestion, the organisms multiply to high numbers (**Figure 34-2**). They eventually kill the macrophage releasing new cells to repeat the cycle. The multiple enzymes released in this process lead to inflammation, destructive lesions in the lung, and a systemic toxicity that may be related to cytokine release.

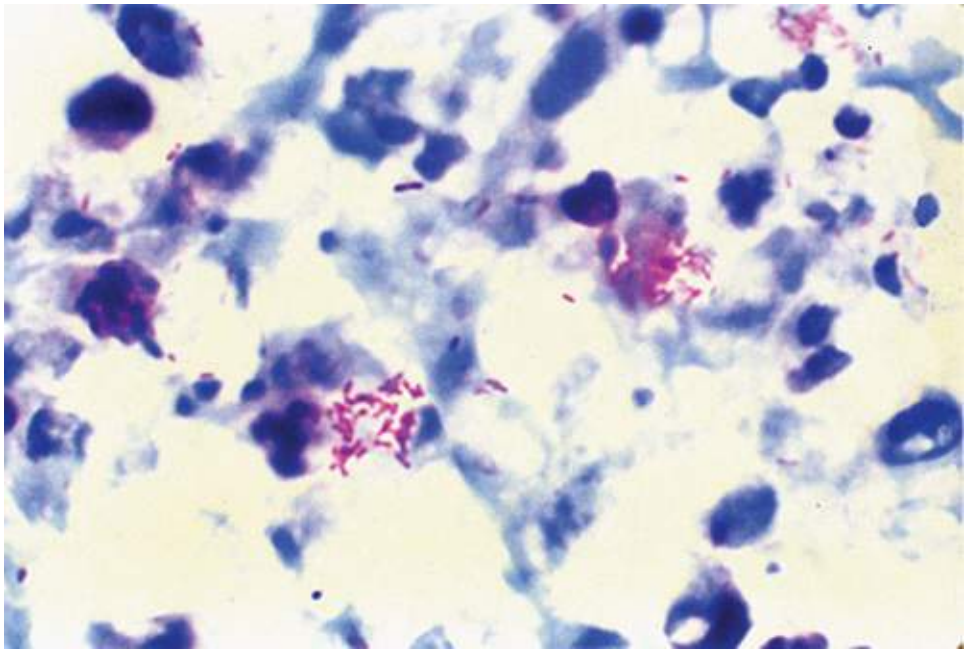

FIGURE 34–2. Legionnaires disease. Imprint smear of lung shows *L pneumophila* (*stained red*) mostly inside alveolar macrophages. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Protein secretion system inside host cell

*** Macrophage, amoeba replication similar**

*** Nutrient-restriction facilitates survival, infectivity**

L pneumophila accomplishes this control of the phagocyte through the complex deployment of over 200 proteins. Only a few of these proteins have functions which are known or have been inferred by genomic analysis. It is known that the majority of these proteins are produced by an injection secretion system (type IV) which in contrast to those described in other Gram-negative pathogens operates from *inside* the unfortunate macrophage. As the intracellular population grows, the virulence protein deployment shifts to products facilitating egress from the LCV and macrophage with some causing pore-forming membrane lysis. The entire process in environmental protozoa is similar to that in the macrophage. In both amoebas and humans this rapid growth takes place under nutrient-rich conditions. Similar to other intracellular bacterial pathogens (*Chlamydia*, *Chlamydophila*, and *Coxiella*), *L pneumophila* also has a nutrient-restricted phase in which elements that mediate resistance to environmental stress and facilitate future infectivity are produced. This appears to be the situation in the low metabolic state of biofilm-imbedded cells, which lurk in the pipes of human-constructed water systems.

IMMUNITY

Innate defenses triggered by TLRs

*** Cytokine-activated macrophages limit intracellular growth**

Antibody less important

Just as intracellular multiplication is the key to *L pneumophila* virulence, its arrest by innate and adaptive mechanisms is the most important aspect of immunity. The high level of innate immunity to *Legionella* infection in most persons is related to brisk pattern recognition responses triggered by toll-like receptors (TLRs) in macrophages and dendritic cells that recognize *Legionella* LPS. The activation of the T_H1 adaptive immune response and its associated cytokines (IFN-γ, IL-12, IL-18) completes the process of macrophage activation and intracellular killing of the invading *Legionella.* Failure of this aspect of the immune response is the primary reason for most cases of progressive Legionnaires disease in the immunocompromised. Antibodies formed in the

course of *Legionella* infection are useful for diagnosis, but do not appear to be important in immunity. It is unknown whether humans who have had Legionnaires disease are immune to reinfection and disease.

LEGIONNAIRES DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

*** Toxic pneumonia in 5% of exposed**

*** Mortality high in immunocompromised**

Legionnaires disease is a severe toxic pneumonia that begins with myalgia and headache, followed by a rapidly rising fever. A dry cough may develop and later become productive, but sputum production is not a prominent feature. Chills, pleuritic chest pain, vomiting, diarrhea, confusion, and delirium may all be seen. Radiologically, patchy or interstitial infiltrates with a tendency to progress toward nodular consolidation are present unilaterally or bilaterally. Liver function tests often indicate some hepatic dysfunction. In the more serious cases, the patient becomes progressively ill and toxic over the first 3 to 6 days, and the disease terminates in shock, respiratory failure, or both. The overall mortality rate is about 15%, but it has been higher than 50% in some hospital outbreaks. Mortality is particularly high in patients with serious underlying disease or suppression of cell-mediated immunity.

A less common form of disease called **Pontiac fever** (named for a 1968 Michigan outbreak), is a nonpneumonic illness that resembles influenza with fever, myalgia, dry cough, and a short incubation period (6-48 hours). Pontiac fever is a self-limiting illness and may represent a reaction to endotoxin or hypersensitivity to components of the *Legionella* or their protozoan hosts.

DIAGNOSIS

*** Lung specimens needed**

*** DFA only 50% sensitive**

The diagnosis of *Legionella* pneumonia requires a high-quality specimen. Lung aspirates, bronchoalveolar lavage, or biopsies are preferred, because the organism may not be found in sputum. Typically, the Gram smear fails to show bacteria owing to poor staining, but organisms may be seen by DFA based on *L pneumophila*-specific conjugates. Non-*L pneumophila* species are not detected and DFA yields a positive result in only 25% to 50% of culture-proved cases. Multiplex PCR platforms for *L pneumophila* are increasingly being used for diagnosis; however, non-*L pneumophila* species require culture.

*** Culture on BCYE**

Other species isolated

Cultures must be made on buffered charcoal yeast extract (BCYE) agar medium that includes supplements (amino acids, vitamins, L-cysteine, ferric pyrophosphate), which meets the growth requirements of *Legionella*. It is buffered to meet the acidic conditions—optimal for *Legionella* growth. The isolation of large Gram-negative rods on BCYE after 2 to 5 days that have failed to grow on routine media (blood agar, chocolate agar) is presumptive evidence for *Legionella*. The BCYE also allows isolation of species of *Legionella* species other than *L pneumophila.*

PCR rapid and sensitive

*** Antigenuria detects serogroup 1**

The difficulty and slow speed of culture together with the low sensitivity of DFA have spurned searches for other methods. This has led to the development of nucleic acid amplification (NAA) procedures for use in respiratory specimens and immunoassay methods for the detection of antigen in urine. NAA methods such as the polymerase chain reaction (PCR) have proved to be rapid and much more sensitive than DFA. A simple card-based antigenuria detection test has also proved to be sensitive for the common *L pneumophila* serogroup 1 but does not detect other serogroups or other *Legionella* species. The primary barrier to making these methods more widely used is that Legionnaires disease is uncommon except in immunocompromised populations. This tends to limit their availability to reference laboratories and hospitals serving immunocompromised patients. Demonstrating a significant rise in serum antibody is used primarily for retrospective diagnosis and in epidemiologic studies.

TREATMENT

Fluoroquinolone, azithromycin treatments of choice

The best information on antimicrobial therapy is still provided by the original Philadelphia outbreak. Because the cause of Legionnaires disease was completely obscure at the time, the cases were treated with many different regimens. Patients treated with erythromycin clearly did better than those given the penicillins, cephalosporins, or aminoglycosides. Subsequently, it was shown that most *Legionella* produce β-lactamases. Currently, therapy with levofloxacin (or moxifloxacin) or azithromycin is preferred.

PREVENTION

*** Preventing aerosols primary goal**

*** Heat, hyperchlorination, metal ions in institutional water systems**

The prevention of legionellosis involves minimizing production of aerosols in public places from water that may be contaminated with *Legionella*. Prevention is complicated by the fact that, compared with other environmental bacteria, *Legionella* bacteria are relatively resistant to chlorine and heat. The bacteria have been isolated from hot water tanks held at over 50°C. Methods for decontaminating water systems are still under evaluation. Some outbreaks have been terminated by hyperchlorination, by correcting malfunctions in water systems, or by temporarily elevating the system temperature above 70°C. The installation of silver and copper ionization systems similar to those used in large swimming pools has been effective as a last resort in hospitals plagued with recurrent nosocomial legionellosis. An outbreak reported from a neonatal intensive care unit in Cyprus was traced to free-standing humidifiers which had been filled with tap water. This underscores both the ubiquity of *Legionella* and the need to at least start with sterile water wherever possible.

• *COXIELLA*

BACTERIOLOGY

*** Multiplies in alveolar macrophage**

*** Resists acid and enzymes of phagolysosome**

*** Spore-like forms survive in environment**

C burnetii is a Gram-negative bacillus and the cause of **Q fever.** Its intracellular growth has caused it to be discussed with the rickettsiae; however, it is now known to be most closely related to *Legionella*. Previously thought to be an obligate intracellular parasite, *C burnetii* does not suffer the metabolic deficits of the *Rickettsia* and has now been grown in a cell-free environment. The primary growth niche of *C burnetii* in humans is the alveolar macrophage where it deploys the same secretion system (type IV) used by *L pneumophila*. *C burnetii* continues to multiply even following phagosome/lysosome fusion, because it is adapted to growth at low pH and resists lysosomal enzymes. In its growth cycle *Coxiella* includes a form that is resistant to drying and other environmental conditions much like a bacterial spore. These forms do not have the chemical composition of *Bacillus* or *Clostridium* spores but do survive prolonged periods in the environment. It is felt that this accounts for the ability of *C burnetii* to produce infection by aerosol inhalation, often at considerable distance from the presumed source.

COXIELLA INFECTION: Q FEVER

*** Transmission by inhalation; occasionally ingestion**

*** Exposure in abattoirs, research facilities**

Q fever is primarily a zoonosis transmitted from animals to humans by inhalation rather than by arthropod bite. Its distribution is worldwide among a wide range of mammals, of which cattle, sheep, and goats are most associated with transmission to humans. *C burnetii* grows particularly well in placental tissue, attaining huge numbers (less than 10^{10} per gram), which at the time of parturition contaminate the soil and fomites, where it may survive for years. Q fever occurs in those who are exposed to infected animals or their products, particularly farmers, veterinarians, and workers involved in slaughtering.

Another high-risk environment is animal research facilities that have not provided adequate protection for personnel. Infection in all of these circumstances is believed to result from inhalation, which may be at some distance from the site of generation of the infectious aerosols. Infection can also occur from ingestion of animal products such as unpasteurized milk.

Q FEVER: CLINICAL ASPECTS

*** Systemic infection without rash**

*** Pneumonia and endocarditis**

C burnetii has an affinity for the reticuloendothelial system, but little is known of the pathology, because fatal cases are rare. As in livestock, most human infections are unapparent. When clinically evident, Q fever usually begins at an average of 20 days after inhalation, with abrupt onset of fever, chills, and headache. A mild, dry, hacking cough and patchy interstitial pneumonia may or may not be present. There is no rash. Hepatosplenomegaly and abnormal liver function tests are common. Complications such as myocarditis, pericarditis, and encephalitis are rare. Chronic infection is also rare, but particularly important when it takes the form of endocarditis. There is evidence that the strains associated with endocarditis constitute an antigenic subgroup of *C burnetii.*

Diagnosis serologic or PCR

Diagnosis of Q fever is usually made by demonstrating high or rising titers of antibody to Q fever antigen by complement fixation, IFA, or enzyme immunoassay procedures or by PCR. Although most infections resolve spontaneously, doxycycline therapy is believed to shorten the duration of fever and reduce the risk of chronic infection. Vaccines have been shown to stimulate antibodies, and some studies have suggested a protective effect for heavily exposed workers.

KEY CONCLUSIONS

- *Legionella pneumophila* is acquired by inhalation and multiplies within

pulmonary alveolar macrophages.

- *Legionella* are found widely in the environment persisting in amoebas in standing water. Biofilm formation and dormancy facilitate survival in the pipes of large buildings.
- *L pneumophila* serogroup 1 can be diagnosed with a specific urinary antigen test. Other diagnostics include immunofluorescent staining, specialized culture, and NAA methods.
- Levofloxacin or azithromycin are preferred for treatment.
- *Coxiella burnetii* causes Q fever after inhalation of aerosols from animal or soil sources.
- *Coxiella* survives in macrophages and causes pneumonia and granulomatous hepatitis.
- Q fever is underrecognized as cause of culture-negative endocarditis

CASE STUDY

Fatal Pneumonia with Mystery Gram-Negative Bacillus

A 54-year-old man with multiple myeloma was admitted with a 2-day history of fever, nausea, and diarrhea. His lungs were initially clear, but during the first 3 days of his hospitalization he developed a progressive right lower lobe pneumonia and pleural effusion. Initial antibiotic therapy included cephalothin, tobramycin, and ticarcillin. On day 3, intravenous erythromycin was added.

Initial cultures of blood, sputum, urine, cerebrospinal fluid, and stool failed to reveal an etiologic agent. A transtracheal aspirate was also obtained with negative results, including a *Legionella* DFA. There was no resolution of the pneumonia, and spiking fevers continued. On day 13, his respiratory difficulties increased, with frank bleeding from the upper respiratory tract, and he died.

At autopsy, the most prominent findings were bronchopneumonia with focal organization and hemorrhage in the right lung. Stains of the lung tissue were negative by Gram, methenamine silver, and acid-fast methods, but Dieterle silver stains revealed short bacilli. Lung cultures yielded Gram-negative bacilli, which grew aerobically on buffered charcoal–yeast extract, but not on blood or chocolate agar. The organisms resembled *Legionella*, but failed to stain with immunofluorescence conjugates for *Legionella*

pneumophila and multiple other species (*L micdadei, L longbeachae, L gormanii, L dumoffii,* and *L bozemanae*). The organism was sent to the Centers for Disease Control and Prevention, where it was eventually identified as a new species of *Legionella*.

QUESTIONS

1. What is the most probable source of this man's infection?

A. Family member
B. Water
C. Food
D. Insect
E. Bioterrorism

2. What cell type did the organism initially infect in this patient?

A. Ciliated epithelial cell
B. Squamous epithelial
C. Microvillous cell
D. M cell
E. Alveolar macrophage

3. Which of the following contributes most to the ability of *Legionella* to multiply in host phagocytes?

A. Pore-forming toxin
B. Superantigen action
C. Cytokine stimulation
D. Inhibition of lysosome fusion
E. Inhibition of protein synthesis

ANSWERS

1. **(B)**
2. **(E)**
3. **(D)**

chapter 35

Pseudomonas and Other Opportunistic Gram-negative Bacilli

Pseudomonas aeruginosa • *Burkholderia pseudomallei* • *Burkholderia cepacia* • *Acinetobacter* *Moraxella* • *Aeromonas* and *Plesiomonas*

OVERVIEW

A number of opportunistic Gram-negative rods of several genera not considered in other chapters are included here. With the exception of *Pseudomonas aeruginosa*, they rarely cause true disease, and all are frequently encountered as superficial colonizers or contaminants; the significance of their isolation from clinical material thus depends on the circumstance and site of culture and on the clinical situation of the patient. *P aeruginosa* produces infection at a wide range of pulmonary, urinary, and soft tissue sites, much like the Enterobacteriaceae. The clinical manifestations of these infections reflect the organ system involved and are not unique for *Pseudomonas*. However, once established, infections are particularly virulent and difficult to treat, likely because affected patients almost always have some form of debilitation or compromise of immune defenses and the bacteria themselves may be highly resistant to antibiotics.

• *PSEUDOMONAS*

*** *P aeruginosa* most important pathogen**

*** Other *Pseudomonas* species cause opportunistic infection**

There is a large number of *Pseudomonas* species, the most important of which is *Pseudomonas aeruginosa. Pseudomonas* species are most frequently seen as colonizers and contaminants but are able to cause opportunistic infections; however, the number of human infections produced by the other species together is far lower than that produced by *P aeruginosa* alone. The assignment of species names has little clinical importance beyond differentiation from *P aeruginosa*. Reports vary regarding the frequency of their isolation from cases of

bacteremia, arthritis, abscesses, wounds, conjunctivitis, and urinary tract infections. In general, unless isolated in pure culture from a high-quality (direct) specimen, particularly from a normally sterile site, it is difficult to attach pathogenic significance to any of the miscellaneous *Pseudomonas* species.

PSEUDOMONAS AERUGINOSA

BACTERIOLOGY

*** Pigment-producing rod resistant to many antimicrobials**

P aeruginosa is an aerobic, motile, Gram-negative rod that is slimmer and more pale-staining than members of the Enterobacteriaceae. Its most striking bacteriologic feature is the production of vivid and colorful water-soluble pigments. Of all the medically important bacteria, *P aeruginosa* also demonstrates the most consistent resistance to antimicrobial agents of all the medically important bacteria.

Grows aerobically with minimal requirements

*** Colonies are oxidase-positive**

P aeruginosa is sufficiently versatile in its growth and energy requirements to use simple molecules such as ammonia and carbon dioxide as sole nitrogen and carbon sources. Thus, it does not require enriched media for growth and can survive and multiply over a wide temperature range (20–42°C) in almost any environment, including those with high salt content. The organism uses oxidative energy-producing mechanisms and has high levels of cytochrome oxidase (“oxidase-positive”). Although an aerobic atmosphere is necessary for optimal growth and metabolism, most strains multiply slowly in an anaerobic environment if nitrate is present as an electron acceptor.

*** Blue pyocyanin produced only by *P aeruginosa***

*** Yellow fluorescein and pyocyanin combine for green color**

Growth on all common isolation media is luxurious, and colonies have a

delicate, fringed edge. Confluent growth often has a characteristic metallic sheen and emits an intense fruity odor. Hemolysis is usually produced on blood agar. The positive oxidase reaction of *P aeruginosa* differentiates it from the Enterobacteriaceae, and its production of blue, yellow, or rust-colored pigments differentiates it from most other Gram-negative bacteria. The blue pigment, **pyocyanin,** is produced only by *P aeruginosa*. **Fluorescein,** a yellow pigment that fluoresces under ultraviolet light, is produced by *P aeruginosa* and other free-living, less pathogenic *Pseudomonas* species. Pyocyanin and fluorescein combined to produce a bright green color that diffuses throughout the medium.

*** Outer membrane porins are relatively impermeable**

Lipopolysaccharide (LPS) is present in the outer membrane, as are porin proteins, which differ from those of the Enterobacteriaceae family in offering much less permeability to molecules including antibiotics. Pili composed of repeating monomers of the pilin structural subunit extend from the cell surface. A single polar flagellum rapidly propels the organism and assists in binding to host tissues.

*** Secreted alginate forms a slime layer**

*** Overproduction due to regulatory mutations**

A mucoid exopolysaccharide slime layer is present outside the cell wall in some strains. This layer is created by secretion of **alginate,** a copolymer of D-mannuronic and L-guluronic acids. It is created by the action of several enzymes that effectively channel carbohydrate intermediates into the alginate polymer. All *P aeruginosa* produce moderate amounts of alginate, but those with mutations in regulatory genes overproduce the polymer; such mutants appear as striking mucoid colonies in cultures from the respiratory tract of patients with cystic fibrosis (CF).

*** Multiple extracellular enzymes produced**

*** ExoA action same as diphtheria toxin**

*** ExoS or ExoU injected by secretion system**

Most strains of *P aeruginosa* produce multiple extracellular products, including **exotoxin A (ExoA)** and other enzymes with phospholipase,

collagenase, adenylate cyclase, or elastase activity. ExoA is a secreted protein that inactivates eukaryotic elongation factor 2 (EF-2) by ADP ribosylation (ADPr). This arrests translation, leading to shutdown of protein synthesis and cell death. Although this action is the same as diphtheria toxin, the two toxins are otherwise unrelated. The **elastase** acts on a variety of biologically important substrates, including elastin, human IgA and IgG, complement components, and some collagens. Then, the vast majority of *P aeruginosa* strains encode a type III secretion system (T3SS) that injects virulent effector proteins—exoenzymes T (**ExoT**), along with either **ExoS** for most strains or **ExoU** for a small minority—directly into host cells. Inside the cell, ExoT and ExoS disrupt formation of reactive oxygen species and promote apoptosis, while the phospholipase ExoU functions as a cytotoxin.

P AERUGINOSA DISEASE

EPIDEMIOLOGY

*** Primary habitat environmental**

*** Occasionally colonizes humans**

The primary habitat of *P aeruginosa* is the environment; it is found in water, soil, and various types of vegetation throughout the world. *P aeruginosa* has been isolated from the throat and stool of 2% to 10% of healthy persons, but colonization rates are quite likely higher in hospitalized patients. *P aeruginosa* rarely infects previously healthy persons, but represents one of the most dreaded causes of invasive infection in hospitalized patients with serious underlying disease, such as leukemia, CF, and extensive burns (**Figure 35–1**).

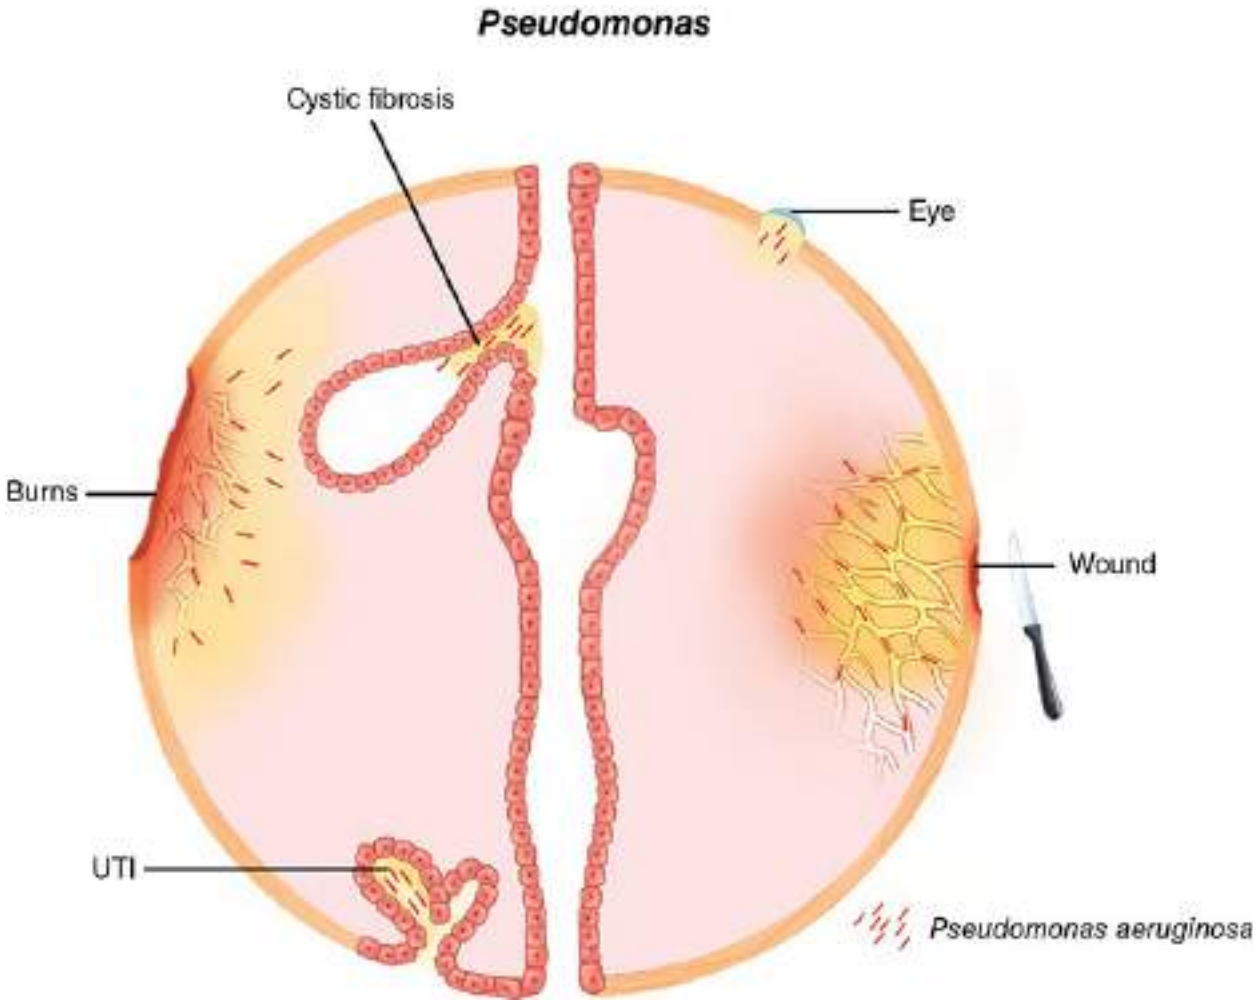

FIGURE 35–1. Pseudomonas disease overview. *P aeruginosa* is a leading cause of opportunistic infection in the eye (contact lenses), wounds, urinary tract, and burns. In a special case, it colonizes the respiratory tract of persons with cystic fibrosis by formation of a biofilm (see Figure 35–4). UTI, urinary tract infection.

*** Multiplies in humidifiers, solutions, medications**

*** Risk highest for immunocompromised persons**

The ability of *P aeruginosa* to survive and proliferate in water with minimal nutrients can lead to heavy contamination of any nonsterile fluid, such as that in the humidifiers of ventilator circuits. Inhalation of aerosols from such sources can bypass the normal respiratory defense mechanisms and initiate pulmonary infection. Infections have resulted from the growth of *Pseudomonas* in medications, contact lens solutions, and even some disinfectants. Sinks and faucet aerators may be heavily contaminated and serve as the environmental source for contamination of other items. The presence of *P aeruginosa* in

drinking water or food is not a cause for alarm; the risk lies in the access of materials susceptible to contamination to portals of entry in persons uniquely predisposed to infection.

*** Respiratory colonization of CF patients becomes chronic**

P aeruginosa is now the most common bacterial pathogen to complicate the management of patients with CF, an inherited defect in chloride ion transport that leads to a buildup of thick mucus in ducts and the tracheobronchial tree. In a high percentage of patients, the respiratory tract eventually becomes colonized with *P aeruginosa*; once established, the organism may evolve in complex ways but remains essentially impossible to eradicate. This infection is a leading cause of morbidity and eventual death of these patients.

PATHOGENESIS

*** Needs break in first-line defenses**

Pili, flagella, and slime mediate adherence

Although *P aeruginosa* is an opportunistic pathogen, it is one of particular virulence. The organism usually requires a significant break in first-line defenses (such as a wound) or a route past them (such as a contaminated solution or endotracheal tube) to initiate infection. Attachment to epithelial cells is the first step in infection and is likely mediated by pili, flagella, and the extracellular polysaccharide slime. The receptors include sialic acid and *N*-acetyl glucosamine borne by cell surface glycolipids. Attachment is favored by loss of surface fibronectin, which may in part explain the propensity for debilitated persons.

*** ExoA secretion triggered by quorum sensing**

*** ExoA correlates with invasion, destruction**

Given the proper susceptible host, the virulence of *P aeruginosa* is not unexpected, given its myriad enzymes and other factors (**Figure 35–2**). The importance of ExoA is supported by studies in humans and animals, which correlate its presence with a fatal outcome and antibody against it with survival. The effect of ExoA is not immediate, since it is one of a number of virulence factors activated through a gene-regulating system called **quorum sensing.**

Under these conditions, lactones and/or quinolones secreted by *P aeruginosa* signal their presence to the other bacterial cells. The system is quantitative so when the *Pseudomonas* cell population reaches a certain threshold, the signals direct the cytotoxin gene to be transcribed, and the toxin is then produced by the entire population at once. No diphtheria-like systemic effect of ExoA has been demonstrated, but its action correlates with the primarily invasive and locally destructive lesions seen in *P aeruginosa* infections.

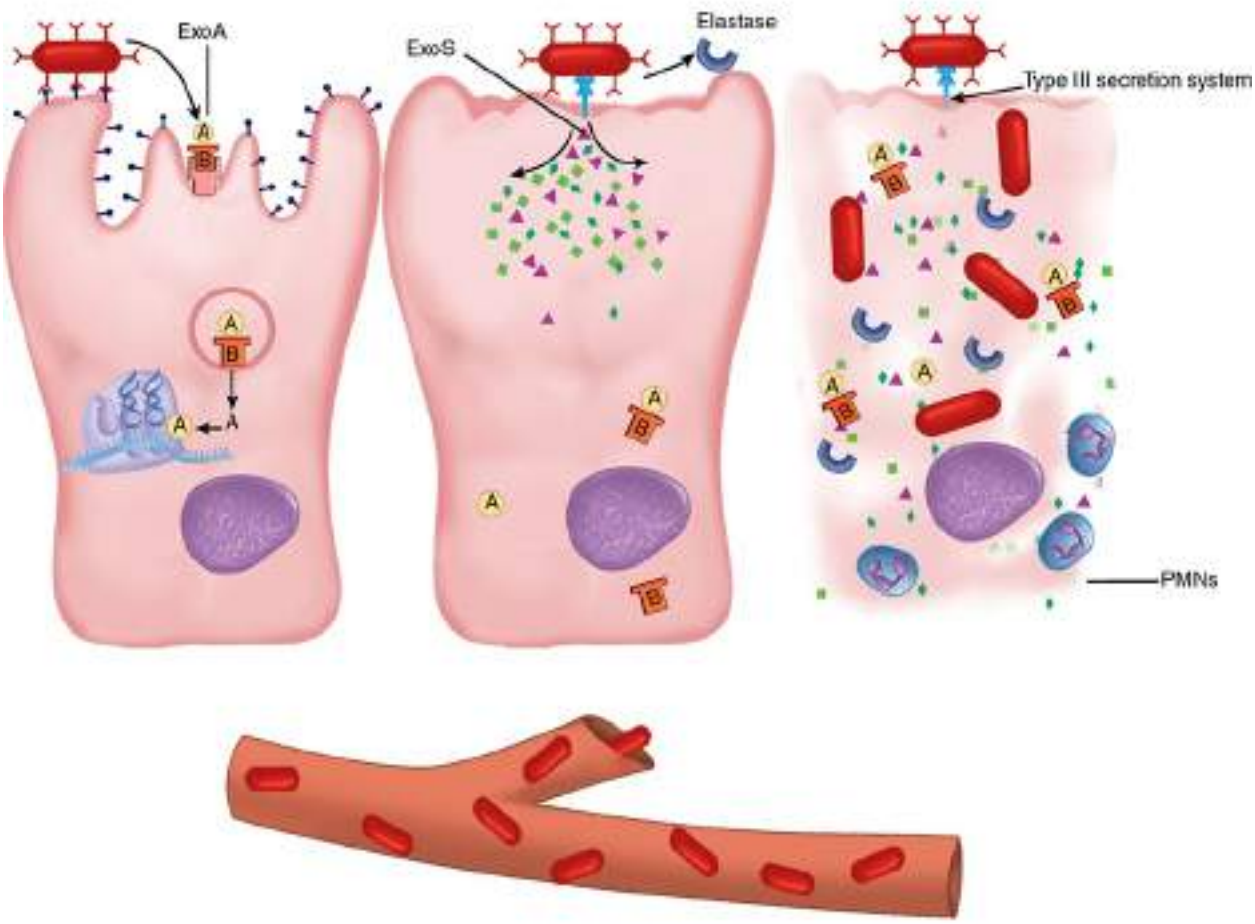

FIGURE 35–2. Pseudomonas disease, cellular view. (*Left*) *P aeruginosa* binds and secretes the A–B exotoxin A (ExoA), which acts on protein synthesis by the same mechanism as diphtheria toxin. (*Middle*) A type III injection secretion system delivers exoenzyme S (ExoS) to the cell cytoplasm. Elastase is secreted extracellularly. (*Right*) All toxins act to destroy the cell and the bacteria may enter the blood.

*** Elastase attacks lung and blood vessels**

*** Injected ExoS disrupts cells**

Elastase and phospholipase degrade proteins and lipids, respectively,

allowing the organism to acquire nutrients from the host and disseminate from the local site. The many biologically important substrates of **elastase—** particularly its namesake, elastin—argue for its importance. Elastin is found at some sites that *P aeruginosa* preferentially attacks, such as the lung and blood vessels. Elastase-mediated hemorrhagic destruction, including the walls of blood vessels (**Figure 35–3**), is the histologic hallmark of *Pseudomonas* infection. The intracellular dysfunction caused by ExoS and other factors injected by the secretion system begin immediately upon contact with the host cell. ExoS is associated with dissemination from burn wounds and with actions destructive to cells, including its action on the cytoskeleton. The blue pigment pyocyanin has been detected in human lesions and shown to have a toxic effect on respiratory ciliary function.

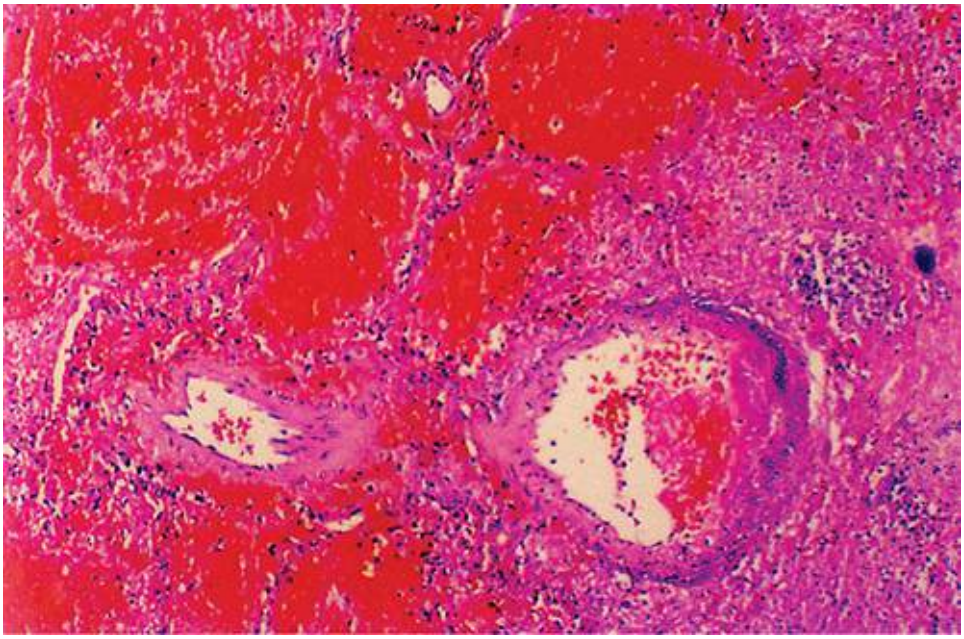

FIGURE 35–3. Pseudomonas aeruginosa pneumonia. This blood vessel in the lung of a fatal case is infected with *P aeruginosa* and is undergoing destruction. A thrombus is forming in the lumen as well. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

▪ *Pseudomonas aeruginosa* and Cystic Fibrosis

*** Mutants overproduce alginate polymer**

*** Biofilm protects bacteria**

P aeruginosa is the most persistent of the infectious agents that complicate the course of CF. Initial colonization may be aided by the fact that cells from CF

patients are less highly sialylated than normal epithelial cells, providing improved access to receptors suitable for *P aeruginosa* attachment; defects in the epithelia of CF patients may also impede bacterial clearance by desquamation. The most striking feature of this host-pathogen relationship is the appearance of strains with multiple mutations in regulatory genes, causing overproduction of the thick alginate polymer. The colonization of the bronchi then becomes a **biofilm** with microcolonies of bacteria and debris embedded in the alginate (**Figure 35–4**). The high osmolarity of characteristically thick CF secretions facilitates expression of these alginate-hyperproducing mutants. For *P aeruginosa*, biofilm confers highly advantageous protection from the immune system (complement, antibody, phagocytes) and antimicrobial agents. The global regulatory networks responsible for quorum sensing, and their effects on alginate production and other virulence-related behaviors, remain a central focus in the search for novel therapeutics.

IMMUNITY

*** Humoral and cellular immune responses both important**

Immune system balance between benefit and harm

Human immunity to *Pseudomonas* infection is not well understood. Inferences from animal studies and clinical observations suggest that both cell-mediated and humoral immunity are important. The strong propensity of *P aeruginosa* to infect those with defective cell-mediated immunity indicates that these responses are important, while provocative studies on the **host interleukin IL-17** have highlighted the humoral response. The versatile IL-17 cytokine recruits inflammatory cells to sites of infection and promotes release of neutrophilic cytokines at epithelial surfaces. While this cytokine appears critical to prevention of chronic infection, experimental deficiency has also been protective against an acute lethal response; in aggregate, these findings demonstrate the delicate balance that the immune system must strike between harmful and beneficial responses.

P AERUGINOSA DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

*** Infects burns and environmentally contaminated wounds**

P aeruginosa can produce any of the opportunistic extraintestinal infections caused by members of the Enterobacteriaceae. Burn, wound, urinary tract, skin, eye, ear, and respiratory infections all occur and may give rise to bacteremia. *P aeruginosa* is also one of the most common causes of infection in environmentally contaminated wounds (eg, osteomyelitis after compound fractures or nail puncture wounds of the foot).

*** Pneumonia aggressive in immunocompromised, chronic in CF**

Particularly in patients with neutropenia, *P aeruginosa* pneumonia is a rapid, destructive infection associated with alveolar necrosis, vascular invasion, infarcts, and bacteremia. Pulmonary infection in CF patients is different; it is a chronic infection that alternates between a state of colonization and more overt bronchitis or pneumonia (**Figure 35–5**). Although the more aggressive features of *Pseudomonas* infection in the immunocompromised are not common in CF, the infection is still serious enough to be a leading cause of death in CF patients.

FIGURE 35–5. Pseudomonas aeruginosa and cystic fibrosis. The lungs of a young adult are shown at autopsy. There is both extensive inflammation and thick biofilm throughout. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

*** Common cause of otitis externa**

*** Contact lens contamination leads to keratitis**

*** Bacteremia may cause ecthyma gangrenosum**

P aeruginosa is also a common cause of otitis externa, including "swimmer's ear" and a rare but life-threatening **malignant otitis externa** seen in patients with diabetes. Folliculitis of the skin may follow soaking in hot tubs that have become heavily contaminated with the organism. *P aeruginosa* can cause conjunctivitis, keratitis, or endophthalmitis when introduced into the eye by trauma or contaminated medication or contact lens solution. Keratitis can progress rapidly and destroy the cornea within 24 to 48 hours. In some cases of

P aeruginosa bacteremia, cutaneous papules develop which progress to black, necrotic ulcers—a condition called **ecthyma gangrenosum**. The lesions are the result of direct invasion and destruction of blood vessel walls by the organism.

DIAGNOSIS

* Pigments produced in culture

P aeruginosa is readily grown in culture. The combination of characteristic oxidase-positive colonies, pyocyanin production (**Figure 35–6**), and the ability to grow at 42°C is sufficient to distinguish *P aeruginosa* from other *Pseudomonas* species. Although biochemical tests can identify other species, such tests are usually not done unless the clinical evidence for infection is very strong.

FIGURE 35–6. ***Pseudomonas aeruginosa*** **pigment production.** The blue color of pyocyanin when mixed with yellow tissue or media components typically produces a green discoloration. This is sometimes seen in clinical cases **A.** and regularly seen on culture plates **B.** (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

TREATMENT

*** Multidrug resistance due to restricted permeability**

*** Resistance to penicillins and aminoglycosides is common**

*** Ceftazidime and cefepime (third- and fourth-generation cephalosporins) often active**

Of the pathogenic bacteria, *P aeruginosa* is the organism most consistently resistant to many antimicrobials. Inherent resistance is due to the porins that restrict entry of antibiotic compounds to the periplasmic space. *P aeruginosa* strains are uniformly resistant to penicillin, ampicillin, cephalothin, tetracycline, chloramphenicol, sulfonamides, and the earlier aminoglycosides (streptomycin, kanamycin). Much effort has been directed toward the development of antimicrobials with anti-*Pseudomonas* activity. All treatment must be guided by antimicrobial susceptibility testing as resistance patterns are highly variable. The aminoglycosides in current use—gentamicin, tobramycin, and amikacin—all are still active against most strains. Among β-lactams, clinicians have relied on the anti-pseudomonal workhorses (piperacillin/tazobactam, cefepime, ceftazidime, imipenem/cilastatin, meropenem, doripenem), but may have additional options with more recently developed β-lactam/β-lactam inhibitor combinations. In general, urinary infections may be treated with a single drug, but more serious systemic *P aeruginosa* infections are initially treated with a combination of an anti-pseudomonal β-lactam and an aminoglycoside, particularly in neutropenic patients; fluoroquinolones may also be used as monotherapy or in combination against susceptible strains. Long simmering interest in phage therapy has risen in recent years, with sporadic reports of experimental use for treatment of extensively resistant *P aeruginosa* infections, but remains under study.

*** Effective oral agents scarce**

*** Inhaled tobramycin provides benefit**

The treatment for *P aeruginosa* infection in CF presents special problems because most of the effective antimicrobials are only given intravenously. To avoid hospitalization, oral agents are often used to manage mild exacerbations. Patients that have persistent or progressive symptoms will then be admitted for “cleanout” with multiple intravenous antibiotics. The chronic nature of *P aeruginosa* colonization leads to progressive development of resistance over the course of patients’ disease. Aerosolized tobramycin has been used in many CF

patients, with evidence of clinical effectiveness in improving pulmonary function and decreasing risk of hospitalization.

PREVENTION

Vaccines are experimental

Vaccines incorporating somatic antigens from multiple *P aeruginosa* serotypes have been developed and proved immunogenic in humans. The primary candidates for such preparations are patients with burn injuries, CF, or immunosuppression. Although some protection has been demonstrated, these preparations have generally proven disappointing.

Why would aerosolized tobramycin be used in this situation?

• *BURKHOLDERIA*

*** Melioidosis is a tropical pneumonia that relapses**

*** *B cepacia* infects CF patients and hospitalized patients**

Burkholderia pseudomallei is a saprophyte in soil, ponds, rice paddies, and vegetables found in Southeast Asia, the Philippines, Indonesia, and other tropical areas. Infection is acquired by direct inoculation or by inhalation of aerosols or dust containing the bacteria. The resultant disease, **melioidosis,** is usually an acute pneumonia; however, it is sufficiently variable that subacute, chronic, and even relapsing infections may follow systemic spread. Some American soldiers relapsed years after their return from Vietnam. The clinical and radiologic features may resemble tuberculosis. In fulminant cases of melioidosis, rapid respiratory failure may ensue and metastatic abscesses develop in the skin or other sites. Though intrinsically resistant to a wide range of antibacterials, *B pseudomallei* may be susceptible to tetracycline, sulfonamides, and trimethoprim-sulfamethoxazole (as well as chloramphenicol, though its toxicity precludes its use in many developed countries). *Burkholderia cepacia* complex is a group of opportunistic species that has been found to contaminate laboratory

reagents, disinfectants, and medical devices in much the same manner as *P aeruginosa*. They have also complicated the course of CF, even producing a life-threatening necrotizing pneumonia ("cepacia syndrome"), but do not produce the mucoid polymer seen with *P aeruginosa*.

• *ACINETOBACTER*

*** Respiratory and urinary infections come from soil and water**

The genus *Acinetobacter* comprises Gram-negative coccobacilli that occasionally appear sufficiently round on Gram smears to be confused with *Neisseria*. On primary isolation, they closely resemble Enterobacteriaceae in growth pattern and colonial morphology but are distinguished by their failure to ferment carbohydrates or reduce nitrates. As with most of the organisms discussed in this chapter, the isolation of *Acinetobacter* from specimens other than normally sterile sites (blood, bronchoalveolar lavage fluid) does not define infection because these bacteria appear frequently as skin and respiratory colonizers. They are most frequently found as contaminants of almost anything wet, including soaps and some disinfectant solutions. Pneumonia is the most common infection, followed by urinary tract and soft tissue infections. Nosocomial respiratory infections have been traced to contaminated inhalation therapy equipment, and bacteremia to infected intravenous catheters. While treatment is frequently complicated by resistance to penicillins, cephalosporins, and occasionally aminoglycosides, virtually pan-resistant *Acinetobacter* isolates have produced outbreaks in intensive care units and military hospitals abroad.

• *MORAXELLA*

*** Bronchitis and otitis arise from respiratory flora**

*** *M catarrhalis* diplococci may be confused with *Neisseria***

Moraxella is another genus of Gram-negative organisms that are usually paired end-to-end. Though many *Moraxella* species exhibit coccobacillary morphology, *Moraxella catarrhalis* isolates appear as diplococci; indeed, the morphology, fastidious growth (some species require enriched media, such as blood or chocolate agar), and positive oxidase reaction of *Moraxella* species can result in

confusion with *Neisseria* in the laboratory. *M catarrhalis* is found in the normal oropharyngeal flora, and it is an occasional cause of lower respiratory tract infection and otitis media. In otitis media cases, *M catarrhalis* has been detected in mixed culture with pathogens like *Haemophilus influenzae* and *Streptococcus pneumoniae*; because *M catarrhalis* frequently produces β-lactamase, it has been blamed for "protecting" the other pathogens when β-lactam treatment fails.

• *AEROMONAS* AND *PLESIOMONAS*

Resemble other enteric bacteria

The genera *Aeromonas* and *Plesiomonas* have bacteriologic features similar to those of the Enterobacteriaceae, *Vibrio*, and *Pseudomonas*. They are aerobic and facultatively anaerobic, attack carbohydrates fermentatively, and demonstrate various other biochemical reactions. *Aeromonas* colonies are typically β-hemolytic. The resemblance of *Aeromonas* and *Plesiomonas* to *Pseudomonas* arises from their shared oxidase positivity and polar flagella. Their habitat is basically environmental (water and soil), but they can occasionally be found in the human intestinal tract.

Think ▸▸ Apply 35-1: There is no oral form of tobramycin. CF patients infected with *P aeruginosa* infected alginate biofilms need to be treated outside the hospital often for long periods. Aerosolization provides this safety and convenience and may also enhance delivery of the drug directly to biofilms at effective concentrations.

* Rapid cellulitis follows injury in water

* Diarrheal illnesses relate to enterotoxin production

Acquired in fresh or salt water, *Aeromonas* is an uncommon but highly virulent cause of wound infections. The onset can be as rapid as 8 hours after the injury, and the cellulitis can progress rapidly to fasciitis, myonecrosis, and bacteremia in less than a day. *Aeromonas* is also the leading cause of infections associated with the medical use of leeches, owing to its regular presence in the

leech foregut. In addition to opportunistic infection, some evidence suggests an occasional role for *Aeromonas* in gastroenteritis through production of toxins with enterotoxic and cytotoxic properties. *Plesiomonas* is also associated with an enterotoxic diarrhea. These associations have not been strong enough to warrant routine efforts to isolate *Aeromonas* and *Plesiomonas* from diarrheal stools, but newer molecular tests may raise clinical awareness of their prevalence in the community. Resistance to penicillins and first-generation cephalosporins is typical. Most strains show susceptibility to fluoroquinolones and tetracyclines, with variable susceptibility to aminoglycosides, including gentamicin.

"HACEK" GROUP

The HACEK acronym denotes species from the genera *Haemophilus*, *Aggregatibacter*, *Cardiobacterium*, *Eikenella*, and *Kingella* that have been implicated in up to 3% of all cases of infective endocarditis. These pathogens typically produce infection in individuals with prosthetic heart valves or other underlying heart disease. These species are part of the microbiota of the oral cavity and upper respiratory tract in humans and tend to produce syndromes that are insidious in onset and challenging to diagnose. Treatment with third-generation cephalosporins produces a favorable outcome in 80% to 90% of cases.

OTHER GRAM-NEGATIVE RODS

*** Rare species interpreted based on their clinical setting**

There are many other Gram-negative rods that rarely cause disease in humans. Some are members of the microbiota, and others come from the environment. Because many of these do not ferment carbohydrates or react in many of the tests routinely used to characterize bacteria, their identification is frequently delayed while additional tests are performed or the organism is sent to a reference laboratory. The clinical significance of all these organisms is essentially the same: the clinician usually receives report of a "non-fermenter" (or other descriptive term) and a susceptibility test result, and the significance of the isolate must then be determined on clinical grounds. The major characteristics of some of these organisms are shown in **Table 35-1**. The types of infection listed represent the most common among scattered case reports and should not be interpreted as typical for each organism.

TABLE 35–1 ***Pseudomonas*** **and Other Opportunistic Gram-negative Rods**

	BACTERIOLOGIC FEATURES						
SPECIES	MACCONKEY GROWTH	CO_2 REQUIRED	PIGMENTS	ADHERENCE	VIRULENCE FACTORS	EPIDEMIOLOGY	DISEASE
Pseudomonas							
P aeruginosa	+	–	Pyocyanin, fluorescein	Pili, flagella, alginate slime	Exotoxin A, exoenzyme S, elastase, alginate slime	Environmental, normal flora, mucosal breaks, nosocomial	Wounds, pneumonia, burns, otitis externa, cystic fibrosis
P fluorescens	+	–	Fluorescein			Environmental	Opportunistic
Other species	+	–	Fluorescein			Environmental	Opportunistic
Stenotrophomonas maltophilia	+	–	–		Protease	Environmental, mucosal breaks, water, nosocomial	Pneumonia, bacteremia
Acinetobacter	+	–	–		Capsule	Environmental, skin colonization, water, nosocomial	Respiratory, urinary catheter bacteremia
Burkholderia							
B mallei	+	–	–			Contact with horses	Glanders
B pseudomallei	+	–	–		Facultative intracellular growth	Environmental in Southeast Asia and tropical regions	Melioidosis
B cepacia	+	–	–	Pili	Invasion, elastase, biofilm	Environmental, mucosal breaks, water, nosocomial	Wounds, pneumonia, cystic fibrosis
Aeromonas	+	–	–		Enterotoxin, cytotoxin	Environmental, fresh and salt water, leeches, intestinal flora	Wounds, diarrhea
Plesiomonas	+	–	–		Enterotoxin	Water, seafood, soil	Diarrhea
Aggregatibacter*	+	+	–			Respiratory flora	Endocarditis, periodontal disease
Cardiobacterium*	+	+	–			Nasopharyngeal, intestinal flora	Endocarditis
Eikenella*	+	+	–			Periodontal flora	Endocarditis, oropharyngeal abscess, draining sinuses
Alcaligenes	+	–	–			Respiratory, intestinal flora	Blood, urine, wounds
Chromobacterium	+	+	Violet			Water, soil (tropical)	Cellulitis, bacteremia
Flavobacterium	+	+	Yellow			Environmental, nosocomial	Meningitis
Moraxella	+	+	–	Pili		Respiratory flora	Bronchitis, pneumonia

*Along with *Haemophilus* and *Kingella* species, these species constitute the HACEK group of pathogens that produce endocarditis of insidious onset.

Some bacteria remain unnamed for years

Some Gram-negative bacilli fail to conform to any of the species currently recognized. If clinically important, such strains are sent to reference centers, such as the Centers for Disease Control and Prevention (CDC) in Atlanta, Georgia. Eventually, some are given designations such as “CDC group IIF,” which may appear in clinical reports. Much later, a new genus and/or species name may be issued if agreement among taxonomists is sufficient.

CASE STUDY

Leukemia and Black Skin Ulcers

An 8-year-old boy with recently diagnosed acute leukemia was treated with potent cytotoxic drugs in an effort to induce remission. Within 5 days of starting chemotherapy, his total white blood cell count had fallen from 60,000/mm^3 pretreatment to 300/mm^3, with no granulocytes present. On the sixth day, the boy developed a high fever (40.1°C) with no focal findings

except for the appearance of several faintly erythematous nodules on the thighs.

Over the next 2 days, his skin lesions became purple, then black, and necrotic, eventually forming multiple deep ulcers. Chest radiographs taken at the onset of fever were clear, but the following day showed diffuse infiltrates in both lungs. All blood cultures taken on day 6 were positive for an oxidase-positive, Gram-negative rod that produced blue-green discoloration of the culture plates.

QUESTIONS

1. This infection is most likely due to which of the following:

A. *Pseudomonas aeruginosa*
B. *Burkholderia pseudomallei*
C. *Burkholderia cepacia*
D. *Aeromonas*
E. *Acinetobacter*

2. Which is the most important predisposing feature for this infection?

A. Hospital environment
B. Antibiotic treatment
C. Neutropenia
D. Age

3. The skin lesions are most likely due to the action of:

A. Alginate
B. Pyocyanin
C. Oxidase
D. Elastase
E. Flagella

ANSWERS

1. **(A)**
2. **(C)**
3. **(D)**

chapter 36

Plague and Other Bacterial Zoonotic Diseases

Brucella abortus • *Yersinia pestis* • *Francisella tularensis* • *Pasteurella multocida*

Dr. Rieux resolved to compile this chronicle…to state quite simply what we learn in a time of pestilence: that there are more things to admire in men than to despise.

—Albert Camus: *The Plague*

OVERVIEW

Zoonoses are infections in humans acquired by direct or indirect contact with animals. There are many zoonoses and more are being recognized (**Table 36-1**), but those covered herein are of great importance historically and still occur. The three principle species/variants of *Brucella* and their associated animals are *abortus* (cattle), *melitensis* (sheep and goats), and *suis* (pigs) in whom they cause genitourinary tract disease. Humans such as farmers, slaughterhouse workers, and veterinarians become infected directly by occupational contact or indirectly by consumption of contaminated animal products such as milk. In humans *Brucella* evade toll-like receptors (TLRs) and innate immunity, survive in macrophages by inhibiting myeloperoxidase and lysosome fusion, and produce a chronic illness characterized by fever, night sweats, and weight loss lasting weeks to months. Because the infection is localized in reticuloendothelial organs, there are few physical findings unless the liver or spleen becomes enlarged. When patients develop a cycling pattern of nocturnal fevers, the disease has been called undulant fever. The diagnosis is made by culturing blood or retrospectively by serology.

TABLE 36–1 Some Important Bacterial Zoonotic Infections

DISEASE	ETIOLOGIC AGENT	USUAL RESERVOIR	USUAL MODE OF TRANSMISSION TO HUMANS	TRANSMISSION BETWEEN HUMANS	MODE OF TRANSMISSION BETWEEN HUMANS	SPECIAL CHARACTERISTICS
Anthrax	*Bacillus anthracis*	Cattle, sheep, goats	Infected animals or products	No		Resistant spores
Bovine tuberculosis	*Mycobacterium bovis*	Cattle	Milk	No		
Brucellosis	*Brucella abortus*	Cattle, swine, goats	Milk, infected carcasses	No		
Campylobacter infection	*Campylobacter jejuni*	Wild mammals, cattle, sheep, pets	Contaminated food and water	Yes	Fecal–oral	
Leptospirosis	*Leptospira* spp.	Cattle, rodents	Water contaminated with urine	No		
Lyme disease	*Borrelia burgdorferi*	Deer, rodents	Ticks, transplacentally	No		Late sequelae
Pasteurellosis	*Pasteurella multocida*	Animal oral cavities	Bites, scratches	No		
Plague	*Yersinia pestis*	Rodents	Fleas	Yes	Droplet (pneumonic) spread	Great epidemic potential
Other *Yersinia* infections	*Y enterocolitica*, *Y pseudotuberculosis*	Wild mammals, pigs, cattle, pets	Fecal–oral	Yes	Fecal–oral	
Relapsing fever	*Borrelia* spp.	Rodents, ticks	Ticks	No	Tick	
Salmonellosis	*Salmonella* serotypes	Poultry, livestock	Contaminated food	Yes	Fecal contamination of food	
Rickettsial spotted fevers	*Rickettsia rickettsii*[a]	Rodents, ticks, mites	Ticks, mites	No		
Epidemic typhus	*R prowazeki*	Humans	Body louse	Yes	Body louse	Epidemic potential
Murine typhus	*Rickettsia typhi*	Rodents	Fleas	No		
Q fever	*Coxiella burnetii*	Cattle, sheep, goats	Contaminated dust and aerosols	No		

[a]One of several etiologic agents.

Yersinia pestis causes plague, an infection of rodents that is transmitted to humans by the bite of infected fleas and is the most explosively virulent disease known owing to its complex array of mechanisms to avoid host defenses. Most cases begin with a painful swollen lymph node (bubo) from which the bacteria rapidly spread to the bloodstream. Pneumonic plague (Black Death) is produced by pulmonary seeding from the bloodstream or is acquired directly from another patient with hemorrhagic pneumonia. All forms cause a toxic picture with shock and death within a few days. No other disease regularly kills previously healthy persons so rapidly. *Y pestis* is readily recovered on media used for other Enterobacteriaceae from aspirates of lymph nodes, blood cultures, and sputum in patients with pneumonia.

Tularemia is a disease of wild mammals caused by *Francisella tularensis.* Humans usually become infected by direct contact with infected animals or through the bite of a vector (tick or deer fly). Contact with water contaminated by ill animals has also been well documented. The illness is characterized by a local ulcer with high fever and severe constitutional symptoms. Typhoid-like illness with systemic symptoms only has been described. The epidemiology of tularemia and many features of the clinical infection are similar to those of plague.

Pasteurella multocida is found normally in the respiratory tract of many companion and other domestic and wild animals. When humans sustain a penetrating bite or scratch, most often by a cat, a rapidly destructive local soft tissue infection results.

Many bacterial, rickettsial, and viral diseases are classified as zoonoses, because they are acquired by humans either directly or indirectly from animals. This chapter considers bacteria that cause four zoonotic infections not covered in other chapters. All four etiologic agents, *Brucella abortus, Yersinia pestis, Francisella tularensis,* and *Pasteurella multocida*, are Gram-negative bacilli that are primarily animal pathogens. The diseases they cause, brucellosis, plague, tularemia, and pasteurellosis, are now mostly rare in humans and develop only after unique animal contact. The full range of zoonoses considered in this and other chapters is shown in Table 36-1.

• *BRUCELLA*

BACTERIOLOGY

Coccobacilli resemble *Haemophilus*

*** Variants infect cattle, sheep, goats, swine**

Brucella species are small, coccobacillary, Gram-negative rods that morphologically resemble *Haemophilus* and *Bordetella*. They are nonmotile, non–acid-fast, and non–spore-forming. The cells have a typical Gram-negative structure, and the outer membrane contains proteins. The genus *Brucella* contains nine closely related variants that differ primarily in their preferred terrestrial or marine hosts. Taxonomists vacillate as to whether they should be called species or something else. The three most commonly infecting humans, *B abortus* (cattle), *B melitensis* (sheep, goats), and *B suis* (swine), will all be referred to here as *B abortus* or simply *Brucella*. Their growth is relatively slow, requiring at least 2 to 3 days of aerobic incubation in enriched broth or on blood agar. They produce catalase, oxidase, and urease, but do not ferment carbohydrates. The lipid composition of the *Brucella* envelope is unusual in that the dominant phospholipid component (phosphatidylcholine) is more typical of eukaryotic than bacterial cells.

BRUCELLOSIS

EPIDEMIOLOGY

Abortion in cattle, goats, pigs

Brucellosis, a chronic infection that persists for life in animals, is an important cause of abortion, sterility, and decreased milk production in cattle, goats, and hogs. It spreads among animals by direct contact with infected tissues and ingestion of contaminated feed. It causes chronic infection of the mammary glands, uterus, placenta, seminal vesicles, and epididymis.

*** Occupational disease for veterinarians**

*** Unpasteurized dairy products a risk**

Humans acquire brucellosis by occupational exposure or consumption of unpasteurized dairy products. The bacteria may gain access through cuts in the skin, contact with mucous membranes, inhalation, or ingestion. In the United States, the number of cases has dropped steadily from a maximum of more than 6000 per year in the 1940s to the current level of fewer than 100 per year. Of these cases, 50% to 60% are in abattoir employees, government meat inspectors, veterinarians, and others who handle livestock or meat products. Consumption of unpasteurized dairy products, which accounts for 8% to 10% of infections, is the leading source in persons who have no connection with the meat-processing or livestock industries. The distribution of human cases of brucellosis in the United States includes virtually every state, but is concentrated in states with large livestock industries or the populous states bordering Mexico (California, Arizona, Texas). An outbreak in Texas was traced to unpasteurized goat cheese brought in from Mexico.

PATHOGENESIS

*** Inhibits myeloperoxidase, lysosome fusion, apoptosis**

Animal placental erythritol stimulates growth

* Evades TLRs, multiplies in macrophages

All *Brucella* are facultative intracellular parasites of epithelial cells and professional phagocytes. After they penetrate the skin or mucous membranes, they are able to evade aspects of the innate immune system, particularly Toll-like receptors (TLRs). This may be due to the more eukaryotic than prokaryotic nature of their outer membrane lipids. Once past the epithelial and innate immune barriers they enter and multiply in macrophages in the liver sinusoids, spleen, bone marrow, and other components of the reticuloendothelial system and eventually form granulomas (**Figure 36–1**). Intracellular survival is facilitated by inhibition of both the myeloperoxidase system and of phagosome–lysosome fusion. This is accompanied by multiplication in their own replicative compartment in association with the endoplasmic reticulum (ER). This intracellular strategy includes a contact secretion system (type IV) and is similar to that of *Legionella pneumophila* (see Chapter 34). *Brucella* is also able to inhibit apoptosis, thus prolonging the life of the host cell where it is replicating. In cows, sheep, pigs, and goats, erythritol, a four-carbon alcohol present in chorionic tissue, markedly stimulates growth of *Brucella*. This stimulation probably accounts for the tendency of the organism to locate in these sites. The human placenta does not contain erythritol.

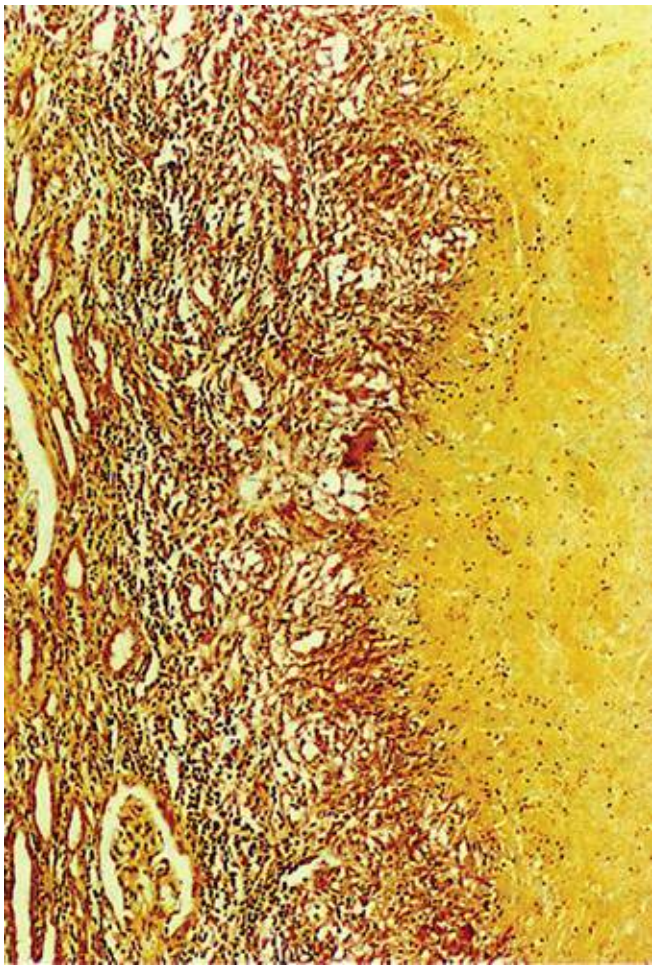

FIGURE 36–1. Brucellosis. Caseating granuloma in the kidney of a midwestern cattle farmer. The giant and epithelioid cells are pallisaded around the caseating area on the right. Glomeruli are compressed on the left. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

If not controlled locally, infection progresses with the formation of small granulomas in the reticuloendothelial sites of bacterial multiplication and with release of bacteria back into the systemic circulation. These bacteremic episodes are largely responsible for the recurrent chills and fever of the clinical illness. These events resemble the pathogenesis of typhoid fever (see Chapter 33).

IMMUNITY

* Macrophage killing requires T_H1 responses

Although antibodies are formed in the course of brucellosis, there is little evidence that they are protective. Control of disease is due to T-cell–mediated

cellular immune responses. Development of T_H1-type responses with the production of cytokines (tumor necrosis factors [TNF-α, TNF-γ, IL-1] and interleukin [IL-12]) are associated with the elimination of *Brucella* from macrophages.

BRUCELLOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Recurrent bacteremia from reticuloendothelial sites**

*** Night sweats, periodic fevers without a focus**

Brucellosis starts with malaise, chills, and fever 7 to 21 days after infection. Drenching sweats in the late afternoon or evening are common, as are temperatures in the range of 39.4°C to 40°C. The pattern of periodic nocturnal fever (undulant fever) typically continues for weeks, months, or even 1 to 2 years. Patients become chronically ill with associated body aches, headache, and anorexia. Weight loss of up to 20 kg may occur during prolonged illness. Despite these dramatic effects, physical findings and localizing signs are few. Less than 25% of patients show detectable enlargement of the fixed macrophage or reticuloendothelial organs, the primary site of infection. Of such findings, splenomegaly is most common, followed by lymphadenopathy and hepatomegaly. Occasionally, localized infection develops in the lung, bone, brain, heart, or genitourinary system. These cases usually lack the pronounced systemic symptoms of the typical illness.

DIAGNOSIS

*** Blood culture primary**

*** Serologic tests may be useful**

Definitive diagnosis of brucellosis requires isolation of *Brucella* from the blood or from biopsy specimens of the liver, bone marrow, or lymph nodes. The slower growth of *Brucella* may require longer incubation of agar plates than for most

bacteria; however, blood cultures are positive in 2 to 5 days with newer automated systems and improved media. The diagnosis is often made serologically, but is subject to the same interpretive constraints as are all serologic tests. Antibodies that agglutinate suspensions of heat-killed organisms typically reach titers of 1:640 or more in acute disease. Lower titers may reflect previous disease or cross-reacting antibodies. Titers return to the normal range within 1 year of successful therapy.

TREATMENT AND PREVENTION

*** Doxycycline plus rifampin**

*** Pasteurization primary prevention**

Doxycycline in combination with rifampin or gentamicin is the primary treatment for brucellosis. Ciprofloxacin, and trimethoprim-sulfamethoxazole are also used in combinations. Although β-lactams may be active *in vitro*, clinical response is poor, probably as a result of failure to penetrate the intracellular location of the bacteria. The therapeutic response is not rapid; 2 to 7 days may pass before patients become afebrile. Up to 10% of patients have relapses in the first 3 months after therapy. Prevention is primarily by measures that minimize occupational exposure and by the pasteurization of dairy products. Control of brucellosis in animals involves a combination of immunization with an attenuated strain of *B abortus* and eradication of infected stock. No human vaccine is in use.

• *YERSINIA PESTIS*

BACTERIOLOGY

Member of Enterobacteriaceae

*** Yops, glycoprotein capsule, multiple enzymes**

Y pestis is a nonmotile, non–spore-forming, Gram-negative bacillus with a tendency toward pleomorphism and bipolar staining. It is a member of the

Enterobacteriaceae family (see Chapter 33) and shares features of the other *Yersinia* pathogenic for humans (*Y pseudotuberculosis, Y enterocolitica*), such as virulence plasmids and multiple *Yersinia* outer membrane proteins (Yops). In addition, *Y pestis* has two virulence plasmids, which code for a glycoprotein gel-like capsule called the F1 antigen and enzymes with phospholipase, protease, fibrinolytic, and plasminogen-activating activity. *Y pestis* also has its own adhesin similar to the invasins of the other *Yersinia.*

PLAGUE

EPIDEMIOLOGY

Black Death into 20th century

The term **plague** is often used generically to describe any explosive pandemic disease with high mortality. Medically, it refers only to infection caused by *Y pestis*, and this appellation was justly earned because *Y pestis* was the cause of the most virulent epidemic plague of recorded human history, the Black Death of the Middle Ages. In the 14th century, the estimated population of Europe was 105 million; between 1346 and 1350, 25 million died of plague. Pandemics continued through the end of the 19th century and the early 20th century despite elaborate quarantine measures developed in response to the obvious communicability of the disease. Yersin isolated the etiologic agent in China in 1894 and named it after his mentor, Pasteur (*Pasteurella pestis*). The name was later changed to honor Yersin (*Yersinia pestis*).

* Sylvatic transmission among rodents ls primary reservoir

Plague is a disease of rodents transmitted by the bite of rat fleas (*Xenopsylla cheopis*) that colonize them. It exists in two interrelated epidemiologic cycles, the **sylvatic** and the **urban** (**Figure 36–2**). Endemic transmission among wild rodents in the sylvatic (Latin *sylvaticus*, belonging to or found in the woods) is the primary reservoir of plague. When infected rats enter a city, circumstances for the urban cycle are created. Humans can enter the cycle from the bite of the flea in either environment. However, chances are greater in the urban setting, particularly with crowding and poor sanitation.

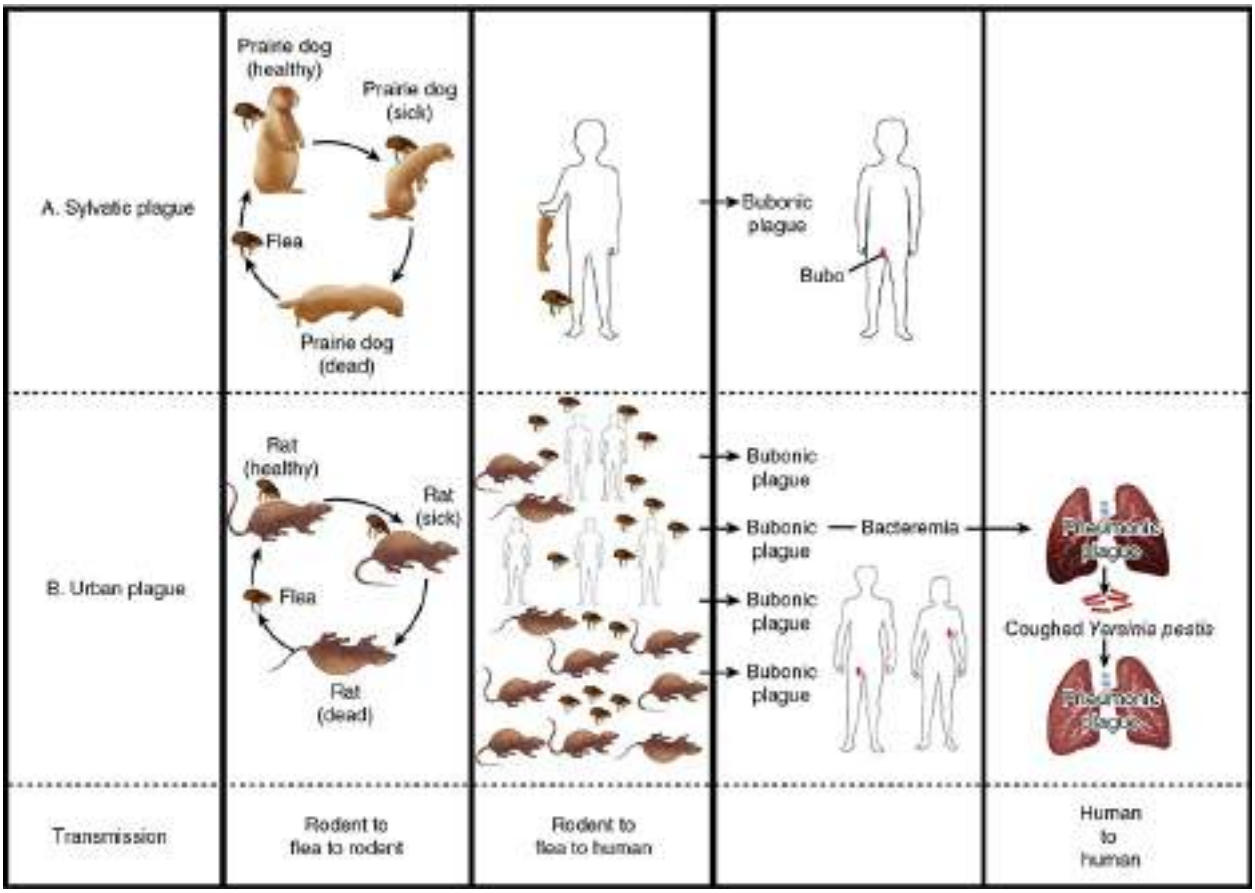

FIGURE 36–2. The epidemiology of plague. A. In the sylvatic cycle, fleas leaving infected rodents, such as mice and prairie dogs, pass the infection to others in the population. Humans rarely contact these rodents but when they do, the flea bite transmits plague. **B.** In the urban cycle, masses of rats are in closer contact with humans, and bites from infected fleas transmit the infection to many. In both cycles, initial transmissions result in bubonic plague. Bacteremia with *Y pestis* may infect the lungs to cause pneumonic plague. Pneumonic plague is transmitted human to human by the respiratory route without the involvement of fleas.

*** Rat migration to cities increases human risk**

*** Fleas regurgitate into bite wounds**

*** Bubo initial lesion**

*** Pneumonia is contagious**

The plagues of the Middle Ages are examples of the urban cycle involving rats and humans. When food is scarce in the countryside, rats migrate to cities. This facilitates rat-to-rat transmission and brings the primary reservoir into closer contact with humans. When the number of nonimmune rats is sufficient, epizootic plague develops among them, with bacteremia and high mortality.

Fleas feeding on the rats become infected, and the bacteria multiply in their intestinal tract eventually blocking the proventriculus, a valve-like organ connecting the esophagus to the midgut. When the rat dies, the fleas seek a new host, which is usually another rat but may be a nearby human. Because of the intestinal blockage, the infected flea regurgitates *Y pestis* into the new bite wound. Therefore, the probability of transmission to humans is greatest when both rat population and rat mortality are high.

The bite of the flea is the first event in the development of a case of **bubonic plague,** which, even if serious enough to kill the patient, is not contagious to other humans. However, some patients with bubonic plague develop a secondary pneumonia by bacteremic spread to the lungs. This **pneumonic plague** is highly contagious person to person by the respiratory droplet route. It is not difficult to understand how rapid spread proceeds in conjunction with crowded unsanitary conditions and continued flea-to-human transmission. A 20th century urban plague epidemic is vividly described through the eyes of a physician in Albert Camus' novel, *The Plague.*

*** Nonepidemic disease due to wild animal contact**

Although urban plague epidemics have been essentially eliminated by rat control and other public health measures, sylvatic transmission cycles persist in many parts of the world, including North America. These cycles involve nonurban mammals such as prairie dogs, deer mice, rabbits, and wood rats. Transmission between them involves fleas. Coyotes or wolves may be infected by the same fleas or by ingestion of infected rodents. By their nature, the reservoir animals rarely come in contact with humans; when they do, however, the infected fleas they carry can transmit *Y pestis.* The most common circumstance is a child who is exploring the outdoors, comes across a dead or dying prairie dog, and pokes, carries, or touches it long enough to be bitten by the fleas leaving the animal. The result is a sporadic case of bubonic plague, which occasionally becomes pneumonic.

*** Most U.S. cases in arid western states**

Sylvatic plague is found in Africa, North and South America, and Asia; however, 95% of human cases currently occur in Africa and Madagascar accounts for nearly half of those. In the United States, the primary enzootic areas are the semiarid plains of the western states. Infected animals and fleas have been detected from the Mexican border to the arid eastern half of Washington

State. The geographic focus of human plague in the United States is in the “four corners” area, where Arizona, New Mexico, Colorado, and Utah meet, but cases have occurred in California, west Texas, Idaho, and Montana. Most years, as many as 15 cases of plague are reported, although this number rose to 30 to 40 in the mid-1980s. These variations are strongly related to changes in the size of the sylvatic reservoir.

PATHOGENESIS

Multiplication in flea foregut aided by low temperature, virulence factors

*** Flea regurgitates bacteria into bite wound**

It should not be surprising that the molecular pathogenesis of plague is quite complex, given its extremely high virulence in both insect and mammalian environments. Of more than 20 known virulence factors, some are deployed primarily in the flea, whereas others are produced only in the rodent or human victim. *Y pestis* has regulatory systems that sense temperature, calcium, and surely other environmental triggers to turn the production of appropriate virulence factors on or off. At ambient temperature (20–28°C) in the flea, factors that facilitate multiplication of the organism (fibrinolysin, phospholipase) and blockage of the proventriculus (coagulase, polysaccharide biofilm) are produced. The flea, sensing starvation, feeds voraciously but due to the intestinal blockage repeatedly regurgitates blood and bacteria into the bite wound. In this wound (rat or human), *Y pestis* is suddenly moved into a new environment.

*** F1 protein capsule antiphagocytic**

*** Pla, Yops produced at 37°C**

*** Yops destroy and disrupt**

In a new warm-blooded (35-37°C) host, *Y pestis* produces a second set of virulence factors including the F1 capsule, a plasminogen activator (Pla), and the Yops (**Figure 36–3**). At this temperature it also synthesizes a form of lipopolysaccharide (LPS) that is not recognized by the TLRs that respond to Gram-negative bacteria. The F1 protein forms a gel-like capsule with antiphagocytic properties that allow the bacteria to persist and multiply. Pla

facilitates metastatic spread through enzymatic activity and adhesion to extracellular matrix proteins. The Yops, though named as a protein family (YopA, YopB, and so on), have diverse biologic activities that fall into two categories. The first is direct destructive enzymatic activity directed at host cells. The other set of actions disrupt intracellular function and are mediated through injection secretion systems (type III). Once inside host cells, including professional phagocytes, these secreted proteins disrupt signaling pathways, destroy cytoskeleton structure, trigger apoptosis, and inhibit cytokine production and acidification of phagosomes.

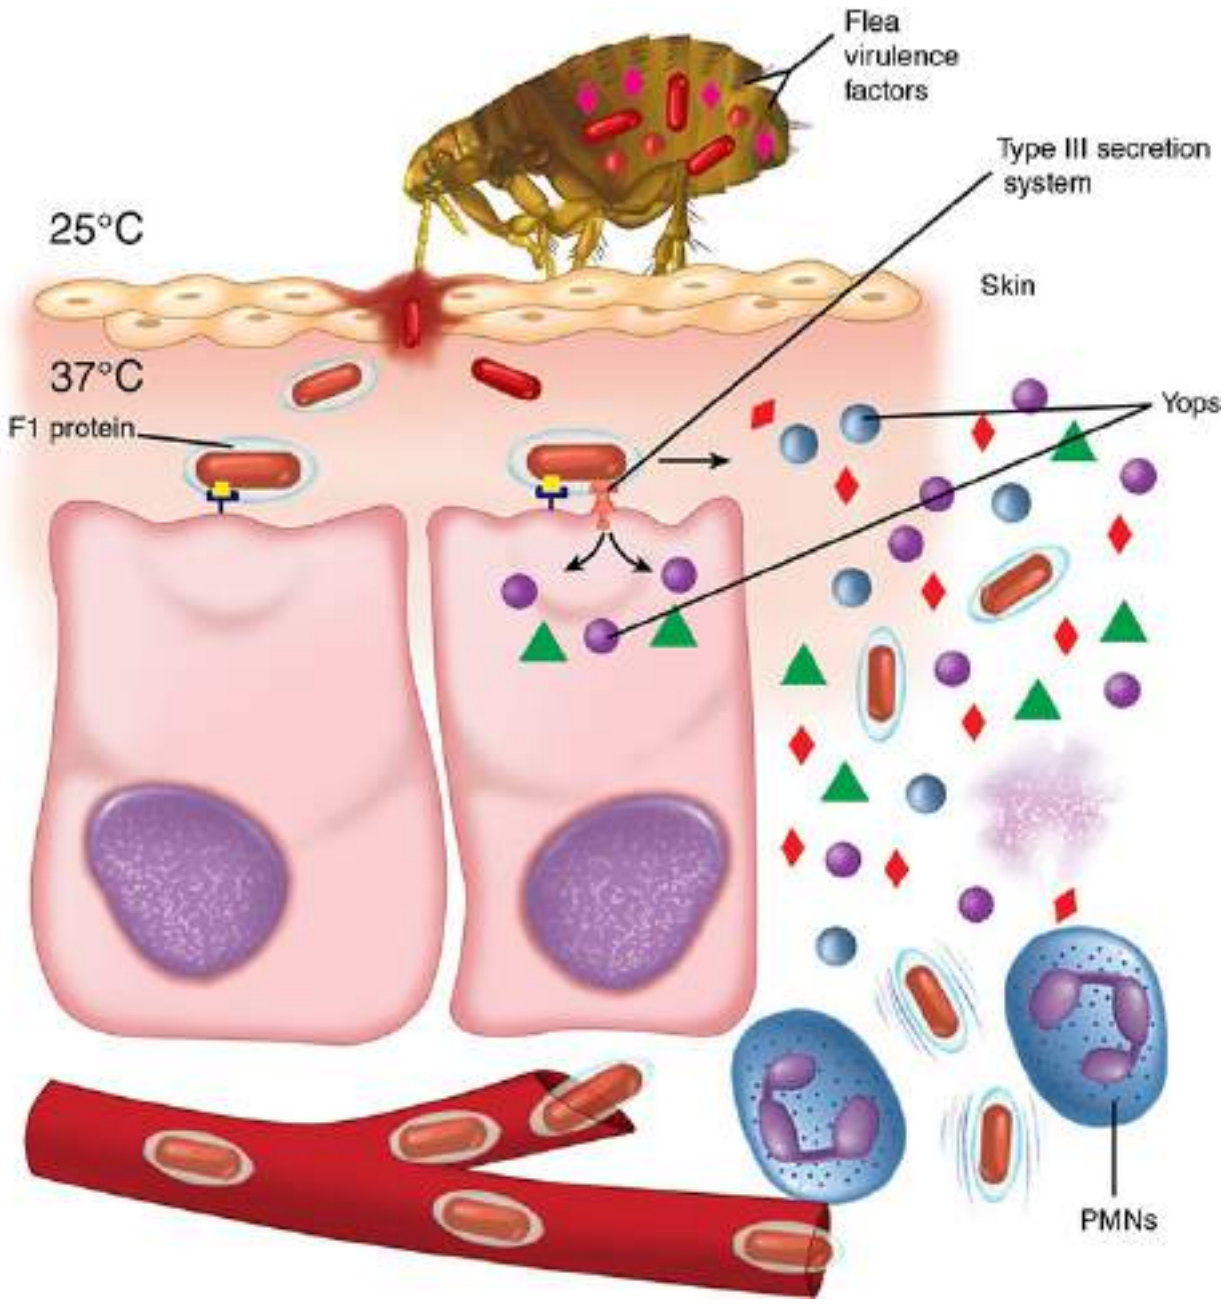

FIGURE 36–3. Plague, cellular view. (*Top*) *Yersinia pestis* is growing in the flea and producing virulence factors unique to that environment. Bacteria are regurgitated as part of the flea's feeding on human skin and reach the subepithelial tissues. Here, triggered by environmental cues such as a new warmer temperature (37°C), they start to produce a new set of virulence factors unique to mammalian victims such as the F1 protein capsule. (*Left*) *Yersinia pestis* attaches to an epithelial cell. (*Middle*) *Yersinia* outer membrane proteins (Yops) begin to be produced. Some are injected by a type III secretion system, others are secreted on the surface. (*Right*) The cell is destroyed and the organisms evade phagocytosis to enter the bloodstream. PMNs, polymorphonuclear neutrophils.

*** Bubo progresses to bacteremia**

*** LPS, other products produce shock**

The organisms eventually reach the regional lymph nodes through the lymphatics, where they multiply rapidly and produce a hemorrhagic suppurative lymphadenitis known clinically as the **bubo.** Spread to the bloodstream quickly follows. The extreme systemic toxicity that develops with bacteremia appears to be due to LPS endotoxin combined with the many actions of Yops, proteases, and other extracellular products. The bacteremia causes seeding of other organs, most notably the lungs, and produces a necrotizing hemorrhagic pneumonia known as pneumonic plague.

IMMUNITY

Anticapsular antibody may be protective

Recovery from bubonic plague appears to confer lasting immunity, but for obvious reasons the mechanisms in humans have not been extensively studied by modern immunologic methods. Animal studies suggest that antibody against the F1 capsular glycoprotein is protective by enhancing phagocytosis, but cell-mediated mechanisms are required for intracellular killing.

PLAGUE: CLINICAL ASPECTS

MANIFESTATIONS

*** Bubonic plague mortality up to 75%**

*** Pneumonic plague fatal if untreated**

Terminal cyanosis = Black Death

The incubation period for bubonic plague is 2 to 7 days after the flea bite. Onset is marked by fever and a painful bubo, usually in the groin (bubo is from the Greek *boubon* for "groin") or, less often, in the axilla (**Figure 36-4**). Without treatment, 50% to 75% of patients progress to bacteremia and die in Gram-negative septic shock within hours or days of development of the bubo. About 5% of victims develop pneumonic plague with mucoid, then bloody sputum. Primary pneumonic plague has a shorter incubation period (2-3 days) and begins only with fever, malaise, and a feeling of tightness in the chest. Cough, production of sputum, dyspnea, and cyanosis develop later in the course. Death on the second or third day of illness is common, and there are no survivors without antibiotic therapy. A terminal cyanosis seen with pneumonic plague is responsible for the term Black Death. Even today, plague pneumonia is almost always fatal if appropriate treatment is delayed more than a day from the onset.

FIGURE 36–4. Bubonic plague. A swollen bubo is seen in the axilla of this man. (Reproduced with permission from Public Health Image Library [PHIL]. Centers for Disease Control and Prevention. Photo contributor Dr. Karl F. Meyer, ID #2061.)

DIAGNOSIS

Immunofluorescent staining, PCR available

Cultures grow on routine media

Gram-stained smears of aspirates from the bubo typically show bipolar-staining Gram-negative bacilli. RT-PCR for the *Y pestis*-specific *pla* gene and detection of F1 antigen by immunofluorescence are available in public health laboratories in endemic areas for immediate identification of smears or cultures. *Y pestis* is readily isolated on the media used for other members of the Enterobacteriaceae (blood agar, MacConkey agar), although growth may require more than 24 hours of incubation. The appropriate specimens are bubo aspirate, blood, and sputum. Laboratories must be notified of the suspicion of plague to avoid delay in the bacteriologic diagnosis and to guard against laboratory infection.

TREATMENT

*** Gentamicin/streptomycin +/– doxycycline**

Gentamicin or streptomycin with or without doxycycline is the treatment of choice for both bubonic and pneumonic plague. Ciprofloxacin or chloramphenicol (if meningitis is present) are alternatives. Timely treatment reduces the mortality of bubonic plague to less than 10%, but the mortality rate of human cases of plague reported in developed countries is still around 20% because of delays in initiation of appropriate therapy.

PREVENTION

*** Avoid sick or dead wild rodents**

*** Chemoprophylaxis for respiratory exposure**

Urban plague has been prevented by rat control and general public health measures such as use of insecticides. Sylvatic plague is virtually impossible to eliminate because of the size and dispersion of the multiple rodent reservoirs. Disease can be prevented by avoidance of sick or dead rodents and rabbits. Eradication of fleas on domestic pets, which have been known to transport infected fleas from wild rodents to humans, is recommended in endemic areas. The continued presence of fully virulent plague in its sylvatic cycle poses a risk

of extension to the urban cycle and epidemic disease in the event of major disaster or social breakdown. Chemoprophylaxis with doxycycline or ciprofloxacin is recommended for those who have had close contact with a case of pneumonic plague. It is also used for the household contacts of a person with bubonic plague because they may have had the same flea contact.

• *FRANCISELLA*

BACTERIOLOGY

*** Growth requirement for –SH compounds**

LPS does not stimulate protective antibodies

F tularensis is a small, facultative, coccobacillary, Gram-negative rod with much the same morphology as *Brucella.* Virulent strains possess a lipid-rich capsule. *F tularensis* is one of the bacterial species of medical importance that does not grow well on routine media used for wound cultures in most clinical laboratories, but it will grow on chocolate agar. *F tularensis* has a special requirement for sulfhydryl compounds, and growth occurs best on a cysteine–glucose blood agar medium after 2 to 10 days of incubation. *Francisella* has the general structure of other Gram-negative bacilli but its outer membrane LPS is unusual in that it fails to stimulate innate immune responses but does induce specific protective antibodies.

TULAREMIA

EPIDEMIOLOGY

*** Infecting dose low**

*** Acquired by tick bites or directly from wild mammals**

Humans most often acquire *F tularensis* by contact with an infected mammal or

a blood-feeding arthropod. Because the infecting dose is very low (less than 100 organisms), many routes of infection are possible. A tick bite or direct contact with an infected animal via a minor skin abrasion is the most common mechanism of infection. About 10% of cases have been linked to contaminated water by contact or ingestion, especially in Europe. Many wild mammals can be infected, including squirrels, muskrats, beavers, and deer. A common history is that of skinning wild rabbits on a hunting trip. Inhalation may also lead to disease. In an outbreak of pulmonary tularemia on Cape Cod, experts believed that lawn mowing and brush cutting facilitated inhalation. Occasionally, the bite or scratch of a domestic dog or cat has been implicated when the animal has ingested or mouthed an infected wild mammal. Infected animals may not show signs of infection, because the organism is well adapted to its natural host. The usual vectors in animals are ticks and deer flies. Ticks may also serve as a reservoir of the organism by transovarial transmission to their offspring.

*** Distribution throughout Northern Hemisphere**

Tularemia is distributed throughout the Northern Hemisphere, although there are wide variations in specific regions. The highly virulent tick/rabbit-associated strains are common only in North America and cases have declined steadily since World War II. In the United States, 100 to 200 cases are reported each year, half of which are in the lower midwestern states (Arkansas, Missouri, Oklahoma). Tularemia is not found in the British Isles, Africa, South America, or Australia.

PATHOGENESIS

*** Entry by trauma, insect, or airborne**

*** LPS not recognized by TLRs**

*** Escapes phagosome into macrophage cytoplasm**

Initial entry of *Francisella* is through a cut, insect bite, or inhalation of airborne bacteria. As with *Brucella* and *Y pestis* the lipid components of its LPS are not recognized by innate TLRs so growth is unimpeded until phagocytes are encountered. Once ingested by macrophages, *Francisella* resides in a phagosome for a time but resists lysosome fusion and escapes to the host cell cytoplasm. These are the general properties of a facultative intracellular

pathogen and indeed the virulence of *F tularensis* has been linked to its ability to multiply within many cell types, including hepatocytes, kidney, and alveolar epithelial cells. A lesion often develops at the site of infection, which becomes ulcerated. The organism then infects the reticuloendothelial organs, often forming granulomas. Early bacteremic spread probably occurs, although it is rarely detected.

IMMUNITY

*** Cell-mediated immunity dominant**

Naturally acquired infection appears to confer long-lasting immunity. Antibody titers remain elevated for many years, but cellular immunity plays the major role in resistance to reinfection. T-cell–dependent reactions involving either CD4+ or CD8+ cell are detectable even before antibody responses.

TULAREMIA: CLINICAL ASPECTS

MANIFESTATIONS

*** Ulceroglandular, oculoglandular, typhoidal, and pneumonic forms**

After an incubation period of 2 to 5 days, tularemia may follow a number of courses, depending on the site of inoculation and extent of spread. All begin with the acute onset of fever, chills, and malaise. In the ulceroglandular form, a local papule at the inoculation site becomes necrotic and ulcerative (**Figure 36–5**). Regional lymph nodes become swollen and painful. The oculoglandular form, which follows conjunctival inoculation, is similar except that the local lesion is a painful purulent conjunctivitis. Ingestion of large numbers of *F tularensis* (more than 10^8) leads to typhoidal tularemia, with abdominal manifestations and a prolonged febrile course that is similar to that of typhoid fever. Oral contamination results in the oropharyngeal form with mucosal ulcers and painful swollen cervical lymph nodes. Inhalation of the organisms can result in pneumonic tularemia or a more generalized infection resembling typhoid. As with plague pneumonia, tularemic pneumonia may also develop through seeding of the lungs by bacteremic spread from any of the other forms. All forms of

tularemia may progress to a systemic infection with lesions in multiple organs.

FIGURE 36–5. Tularemia. Ulcer on the hand of a trapper is infected with *F tularensis*. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Ulceroglandular has lowest mortality

Without treatment, mortality rate ranges from 5% to 30%, depending on the type of infection. Ulceroglandular tularemia, the most common form, generally carries the lowest risk of a fatal outcome estimated at 2%.

DIAGNOSIS

*** Special media for culture**

*** Serodiagnosis common**

*** PCR useful**

Because tularemia is uncommon and *F tularensis* has unique growth requirements, the diagnosis is easily overlooked. Although most strains grow on chocolate agar, laboratories must be alerted to the suspicion of tularemia so that specialized media supplemented with cysteine can be prepared and precautions taken against the considerable risk of laboratory infection. Where available,

PCR-based based assays are useful for samples from humans, animals, and the environment. An immunofluorescent reagent is available in reference laboratories for use directly on smears from clinical material. Because of the difficulty and risk of cultural techniques, many cases of tularemia are diagnosed by serologic tests. Agglutinating antibodies are usually present in titers of 1:40 by the second week of illness, increasing to 1:320 or greater after 3 to 4 weeks. Unless previous exposure is known, single high antibody titers are considered diagnostic.

TREATMENT AND PREVENTION

*** Streptomycin or gentamicin effective**

Gentamicin or streptomycin is the treatment of choice in all forms of tularemia. Doxycycline or ciprofloxacin have also been effective, but relapses are more common than with an aminoglycoside and doxycycline combination. Prevention mainly involves the use of rubber gloves and eye protection when handling potentially infected wild mammals. Prompt removal of ticks is also important. A live attenuated vaccine exists, but it is used only in laboratory workers and those who cannot avoid contact with infected animals.

• *PASTEURELLA MULTOCIDA*

*** Penicillin-susceptible, Gram-negative rods**

*** Most common cause of infected animal bites or scratches**

P multocida, one of many species of *Pasteurella* in the respiratory flora of animals, is a cause of respiratory infection in some. This small, coccobacillary, Gram-negative organism grows readily on blood agar but not on MacConkey agar. It is oxidase-positive and ferments a variety of carbohydrates. Unlike most Gram-negative rods, *P multocida* is susceptible to penicillin. Humans are usually infected by the bite or scratch of a domestic dog or cat. Infection develops at the site of the lesion, often within 24 hours. The typical infection is a diffuse cellulitis with a well-defined erythematous border. The diagnosis is made by culture of an aspirate of pus expressed from the lesion. Frequently, too few organisms are present to be seen on a direct Gram smear. *P multocida* is by far the most common cause of an infected dog or cat bite. *P multocida* is

occasionally isolated from the sputum of patients with bronchiectasis and has been traced to contamination of home inhalation equipment by cats. Infections are treated with penicillin, but amoxicillin-clavulanate is often used empirically because animal bite wounds initially may be polymicrobial.

KEY CONCLUSIONS

- *Brucella*, *Yersinia pestis*, and *F tularensis* all share the ability to evade TLRs and innate immunity and survive in macrophages by inhibiting lysosome fusion.
- *Brucella* thrives in the placental tissue of host animals owing to presence of erythritol; human placentas lack erythritol.
- *Brucella* causes genitourinary tract infections in animals; in humans it causes a chronic systemic illness with recurrent fever, headache, and arthralgia.
- Diagnosis of brucellosis is made by culturing blood or retrospectively by serology.
- *Y pestis* has a plethora of virulence factors (over 20 known) and is often lethal.
- Most plague in humans is bubonic and results from the bites of fleas who feed on infected rodents. Bacteremic spread to the lungs produces pneumonic plague.
- Human to human transmission of pneumonic plague is by direct inhalation of lung secretions.
- Gentamicin therapy with or without doxycycline can be life saving.
- Infections with *F tularensis* are acquired primarily through inhalation, inoculation, or the bite of ticks or deerflies.
- Tularemia has ulceroglandular, oculoglandular, typhoidal, and pneumonic forms.
- Streptomycin or gentamicin is the primary tularemia treatment and doxycycline is an alternative.
- *Pasteurella multocida* causes soft tissue infections most often after a cat bite or scratch; penicillin is effective but amoxicillin-clavulanate is used empirically.

CASE STUDY

Downhill to Death Following Cat Exposure

A 31-year-old man had just returned from visiting a friend in Chaffee County, Colorado. While there, he helped remove an obviously ill domestic cat from the crawl space under a friend's cabin. They also noticed a number of dead chipmunks in a nearby arroyo. Two days after returning to his home in Tucson, the man began to have abdominal cramps. The next day, he had the onset of fever, nausea, vomiting, severe diarrhea, and cough. On the third day, he consulted a physician because of diarrhea and vomiting. On examination, he was febrile (104°F) and dehydrated; no abnormal chest sounds were heard, and he had no lymphadenopathy. The man was treated for gastroenteritis with clindamycin and given oral ciprofloxacin to be taken the following day. The next day, he was hospitalized with cyanosis and septic shock. Chest radiographs revealed a right upper lobar pneumonia. A Gram stain of a sputum sample obtained at hospital admission showed numerous Gram-negative rods. Antibiotic therapy with ceftazidime, erythromycin, and one dose each of penicillin and gentamicin was initiated for treatment of overwhelming sepsis and pneumonia. He died 24 hours after admission.

Investigation by Chaffee County public health officials indicated that the cat, reported to have submandibular abscesses and oral lesions consistent with feline plague, died on August 19 before being evaluated by a veterinarian. The cat was cremated without diagnostic studies. A dead chipmunk found in the area where the cat lived was culture-positive for *Y pestis.*

QUESTIONS

1. This man most probably had which disease?

A. Brucellosis
B. Bubonic plague
C. Pneumonic plague
D. Typhoidal tularemia
E. Pneumonic tularemia

2. By which of the following was his infection likely transmitted?

A. Flea
B. Cat
C. Chipmunk
D. Rat
E. Human

3. Which of the following contributed to his death?

A. Yops
B. Biofilm
C. Erythritol
D. Adenylate cyclase
E. ADP-ribosylation

ANSWERS

1. **(C)**
2. **(A)**
3. **(A)**

Spirochetes

Treponema pallidum • *Leptospira interrogans* • *Borrelia recurrentis* • *Borrelia hermsii* • *Borrelia burgdorferi*

The French disease, for it was that, remained in me more than four months dormant before it showed itself, and then it broke out over my whole body at one instant…with certain blisters, of the size of six-pence, and rose colored.

—Benvenuto Cellini (1500-1571): *The Life of Benvenuto Cellini*

Spirochetes are bacteria with a spiral morphology ranging from loose coils to a rigid corkscrew shape. The three medically important genera include the cause of syphilis, the ancient scourge of sexual indiscretion, and Lyme disease, a more recently discovered consequence of an innocent walk in the woods.

BACTERIOLOGY

MORPHOLOGY AND STRUCTURE

Spiral structure around axial filaments

Motil rotation and flexion

The spiral morphology of spirochetes (**Figure 37–1**) is produced by a flexible, peptidoglycan cell wall around which several axial fibrils are wound. The cell wall and axial fibrils are completely covered by an outer bilayered membrane similar to the outer membrane of other Gram-negative bacteria. In some species, a hyaluronic acid slime layer forms around the exterior of the organism and may contribute to its virulence. Spirochetes are motile, exhibiting rotation and flexion; this motility is believed to result from movement of the axial filaments,

although the mechanism is not clear.

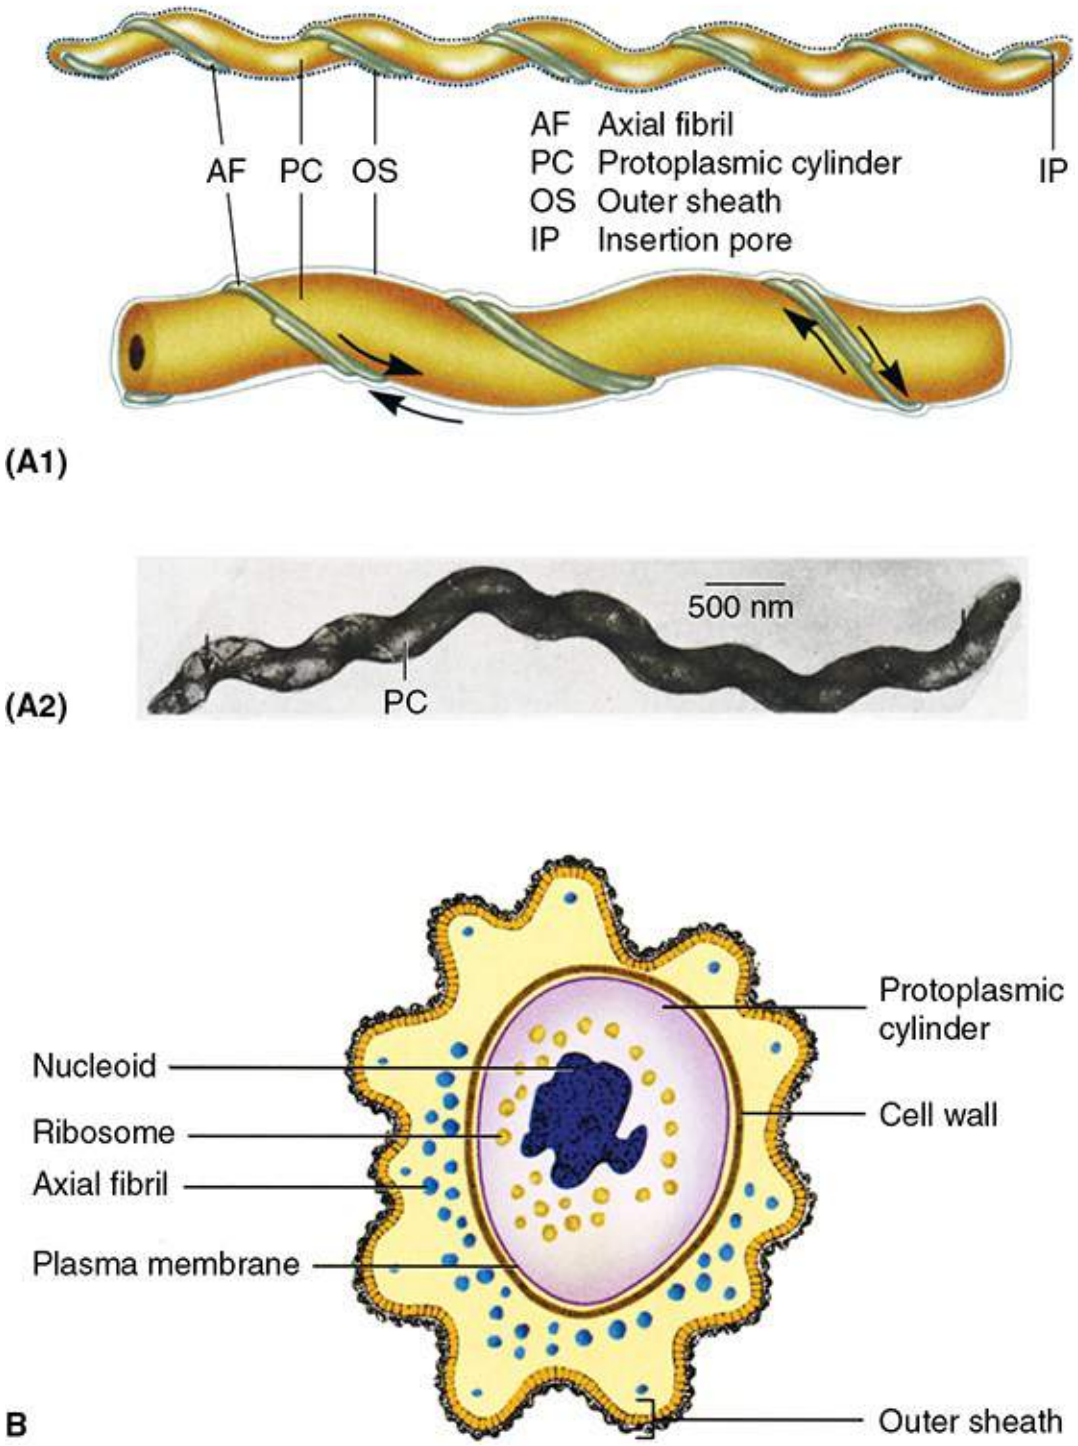

FIGURE 37–1. Spirochete morphology. A1. Longitudinal surface view of typical spirochete. **A2.** Electron micrograph of *Treponema* with axial filaments extending most of cell length. **B.** Cross-section of typical spirochete. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Take stains poorly

Darkfield demonstrates

Many spirochetes are difficult to see by routine microscopy. Although they are Gram negative, many either take stains poorly or are too thin to fall within the resolving power of the light microscope. Only darkfield microscopy (**Figure 37–2**), immunofluorescence, or special staining techniques can demonstrate these spirochetes. Other spirochetes such as *Borrelia* are wider and readily visible in stained preparations, even routine blood smears.

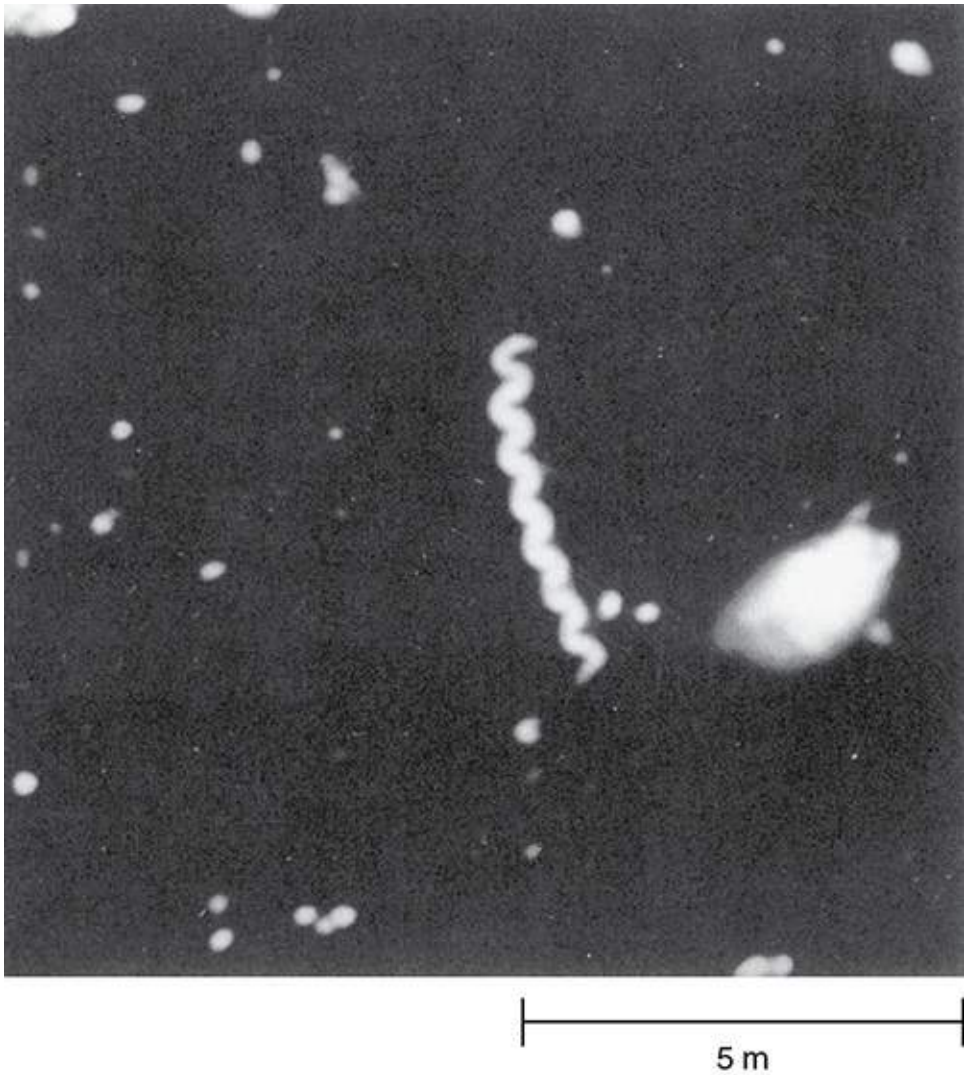

FIGURE 37–2. *Treponema pallidum* seen by darkfield microscopy. The darkfield method creates a bright halo around the corkscrew-shaped spirochetes. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

GROWTH AND CLASSIFICATION

Some not isolated in culture

Aerobic or anaerobic

Parasitic spirochetes grow more slowly *in vitro* than most other disease-causing bacteria. Some species, including the causative agent of syphilis, have not been grown beyond a few generations in cell culture. Some are strict anaerobes, others require low concentrations of oxygen, and still others are aerobic. Compared with other bacterial groups, the taxonomy of the spirochetes is underdeveloped. Because spirochetes are difficult to grow and study; thus, there are relatively few phenotypic properties on which to base a classification. The medically important genera *Treponema*, *Leptospira*, and *Borrelia* have been distinguished primarily by morphologic characters such as the nature of their spiral shape and the arrangement of flagella.

SPIROCHETAL DISEASES

Part of oropharyngeal flora

Some spirochetes are free living; some are members of the microbiota of humans and animals. The oral cavity, particularly the dental crevice, harbors a number of nonpathogenic species of *Treponema* and *Borrelia* as part of its microbiome (**Table 37-1**). Under unusual conditions, these spirochetes, together with anaerobes in the flora, can cause necrotizing, ulcerative infection of the gums, oral cavity, or pharynx (Vincent infection, trench mouth).

TABLE 37–1 Features of Spirochetal Diseases

				DIAGNOSIS			
ORGANISM	MORPHOLOGY	TRANSMISSION	RESERVOIR	MICROSCOPY	CULTURE	SEROLOGY	DISEASE
Treponema pallidum	Corkscrew spirals	Sexual, transplacental, transfusion	Humans	Darkfield of chancre or secondary lesions	None	VDRL, RPR, FTA-ABS, MHA-TP	Syphilis
Leptospira interrogans	Close spirals, hooked ends	Ingestion of contaminated water	Rodents, cattle, dogs	Not recommended[a]	Rarely performed[b]	MAT	Fever, meningitis, hepatitis
Borrelia recurrentis	Loose spirals	Lice	Humans	Giemsa or Wright stain of blood smear	Rarely performed[c]	None	Relapsing fever
Borrelia hermsii	Loose spirals	Ticks[d]	Rodents	Giemsa or Wright stain of blood smear	Rarely performed[c]	None	Relapsing fever
Borrelia burgdorferi	Loose spirals	Ticks[e]	White-footed mice, other rodents (deer)[f]	Not recommended[a]	Rarely performed[c]	EIA + Immunoblot	Lyme disease

EIA, enzyme immunoassay; FTA-ABS, fluorescent treponemal antibody; MAT, microagglutination test; MHA-TP, microhemagglutination test for *T pallidum*; RPR, rapid plasma reagin; VDRL, Venereal Disease Research Laboratory.
[a]Organisms are small in number and rarely seen in clinical lesions.
[b]Culture of blood or urine in semisolid Fletcher medium takes 1 to many weeks and is generally not available.
[c]Culture of blood in liquid Barbour-Stoener-Kelly medium takes 1 to many weeks and is generally not available.
[d]*Ornithodoros hermsii*, p. 9.
[e]*Ixodes scapularis* in the eastern and central United States, *I pacificus* in the western United States.
[f]Transmitting ticks mature on deer that are not actually a reservoir.

Diseases are zoonoses or venereal

The major spirochetal diseases are caused by selected species of three genera that are not found in the microbiota, *Treponema (T pallidum), Leptospira (L interrogans),* and *Borrelia (B**orrelia** recurrentis, B hermsii,* and *B burgdorferi).* Most *Borrelia* and *Leptospira* infections are zoonoses transmitted from wild and domestic animals. *Treponema pallidum* is a strict human pathogen transmitted by sexual contact. Some rare nonvenereal treponemal diseases are summarized in **Appendix 37–1.**

• *TREPONEMA PALLIDUM*

OVERVIEW

Treponema pallidum is a highly motile corkscrew-shaped spirochete containing a minimum of proteins and no lipopolysaccharide (LPS). It has not been isolated in culture. Its disease, syphilis, is typically acquired by the direct contact of mucous membranes during sexual intercourse. The disease begins with a lesion at the point of entry, usually a genital ulcer. After healing of the ulcer, the organisms spread systemically, and the disease may return weeks later as a generalized maculopapular rash called secondary syphilis. The disease may then enter a second eclipse phase called latency. The latent infection may be cleared by the immune system or reappear as tertiary syphilis years to decades later. Tertiary syphilis is characterized by focal lesions whose locale determines the injury. Isolated foci in bone or liver may be unnoticed, but infection of the cardiovascular or nervous systems can be devastating. Progressive dementia or a ruptured aortic aneurysm are two of many fatal outcomes of untreated syphilis.

Extended balance of parasitism and disease

T pallidum is the causative agent of syphilis, a venereal disease first recognized in the 16th century as the “great pox,” which rapidly spread through Europe in association with urbanization and military campaigns. Its extended course and the protean, often dramatic nature of its findings (genital ulcer, ataxia, dementia, ruptured aorta) are due to a state of balanced parasitism that spans decades. The cause of syphilis is actually a subspecies (*T pallidum* subsp. *pallidum*) closely related to other agents that cause rare nonvenereal treponematoses (Appendix 37-1). *T pallidum* is used here to indicate the *pallidum* subspecies.

BACTERIOLOGY

Corkscrew spirals spin

Heat, drying, disinfectants kill

T pallidum is a slim spirochete 5 to 15 µm long with regular spirals whose wavelength and amplitude resemble a corkscrew (Figure 37–2). The organism is readily seen only by immunofluorescence, darkfield microscopy, or silver impregnation histologic techniques. Live cells show characteristic rotating motility with sudden 90-degree angle flexions, which suggest a gentleman quickly bowing at the waist. *T pallidum* is extremely susceptible to any deviation from physiologic conditions. It dies rapidly on drying and is readily killed by a wide range of detergents and disinfectants.

* Growth only in animals

Beyond these observations, the study of the biology and pathogenesis of *T pallidum* is severely impeded by our inability to grow the organism in culture. It multiplies for only a few generations in cell cultures and is difficult to subculture. Sustained growth is achieved only in animals (rabbit testes), which are the sole source of bacteria for diagnostic reagents and scientific study. The *T pallidum* genome is amenable to study, and much of what follows is based on extrapolations comparing genomic sequences found there with those in other pathogenic bacteria. The picture of the syphilis spirochete is that of a minimalist pathogen, growing very slowly and producing few definitive structures or

products.

No LPS, few proteins in outer membrane

The sluggish growth (mean generation time more than 30 hours) of *T pallidum* is felt to be due to lack of enzymes that detoxify reactive oxygen species (catalase, oxidase) and the absence of efficient energy (ATP)-producing pathways such as the tricarboxylic acid cycle and electron transport chain. *T pallidum* shares the Gram-negative structural style of other spirochetes, but its outer membrane lacks LPS and contains few proteins.

SYPHILIS

EPIDEMIOLOGY

*** Transmission via mucosal surfaces, blood**

*** Congenital transplacental infection**

Tertiary syphilis not infectious

T pallidum is an exclusively human pathogen under natural conditions. In most cases, infection is acquired from direct sexual contact with a person who has an active primary or secondary syphilitic lesion (**Figure 37–3**). Partner notification studies suggest transmission occurs in over 50% of sexual contacts in which a lesion is present. Less commonly, the disease may be spread by nongenital contact with a lesion (eg, of the lip), sharing of needles by intravenous drug users, or transplacental transmission to a fetus within the first 3 years of the maternal infection. Late disease is not infectious. Modern screening procedures have essentially eliminated blood transfusion as a source of the disease. The incidence of new cases of primary and secondary syphilis in developed countries declined to an all time low at the end of the 20th century, but since then has risen more than 10%. Worldwide, syphilis remains a major public health problem, with an estimated six million new cases annually. There is evidence that syphilitic lesions are a portal for HIV transmission.

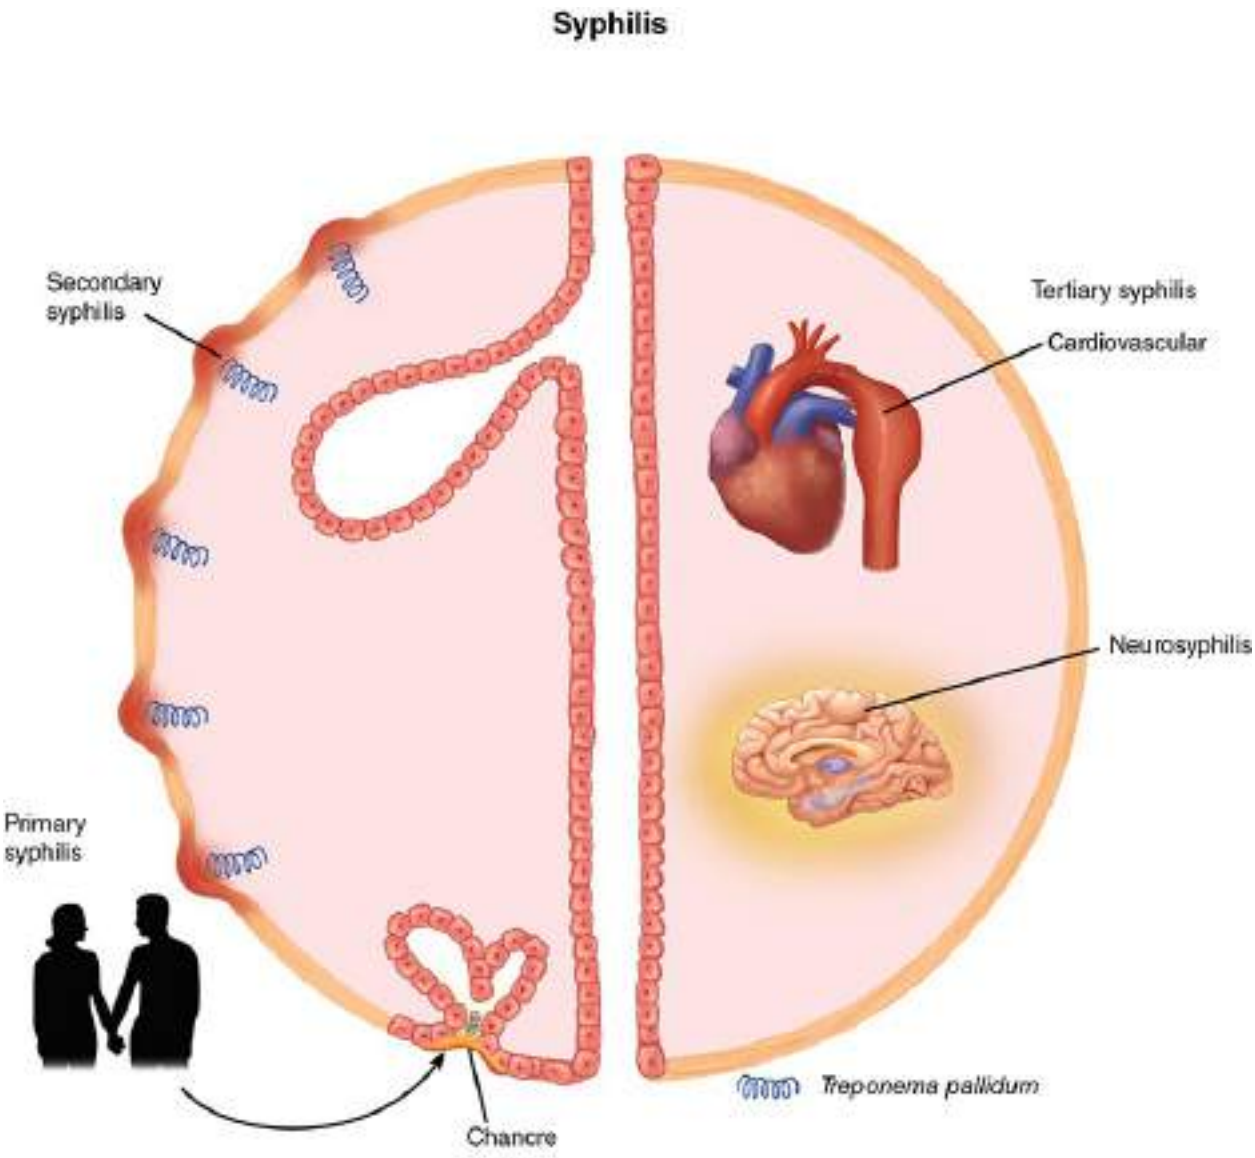

FIGURE 37–3. Syphilis overview. Infection is acquired by sexual contact, and the primary lesion is an ulcer on the genitalia called the chancre. The major feature of secondary syphilis is a maculopapular rash that is teeming with spirochetes. Tertiary syphilis (*right*) involves multiple organ systems. Shown are an aortic aneurysm as part of cardiovascular syphilis and inflammation of the brain in neurosyphilis.

PATHOGENESIS

Mucosal spread to blood

*** Multiplication produces endarteritis, granulomas**

*** Ulcer heals but spirochetes disseminate**

The spirochete reaches the subepithelial tissues through unapparent breaks in the skin or possibly by passage between the epithelial cells of mucous membranes aided by at least one adhesin that binds to fibronectin and elements of the extracellular matrix. Beyond a few candidate adherence or digestive proteins there is little to explain the organism's invasiveness beyond the propulsive motility generated from its corkscrew structure. In the submucosa, it multiplies slowly stimulating little initial tissue reaction. This is probably due to the relative paucity of antigens in the *T pallidum* outer membrane that could be exposed to the immune system. As lesions develop, the basic pathologic finding is an endarteritis. The small arterioles show swelling and proliferation of their endothelial cells. This reduces or obstructs local blood supply, probably accounting for the necrotic ulceration of the primary lesion and subsequent destruction at other sites (**Figure 37–4A–C**). There is no evidence that this injury is due to any toxins or other classic virulence factors produced by *T pallidum.* Although the primary lesion heals spontaneously, the bacteria have already disseminated to other organs by way of local lymph nodes and the bloodstream.

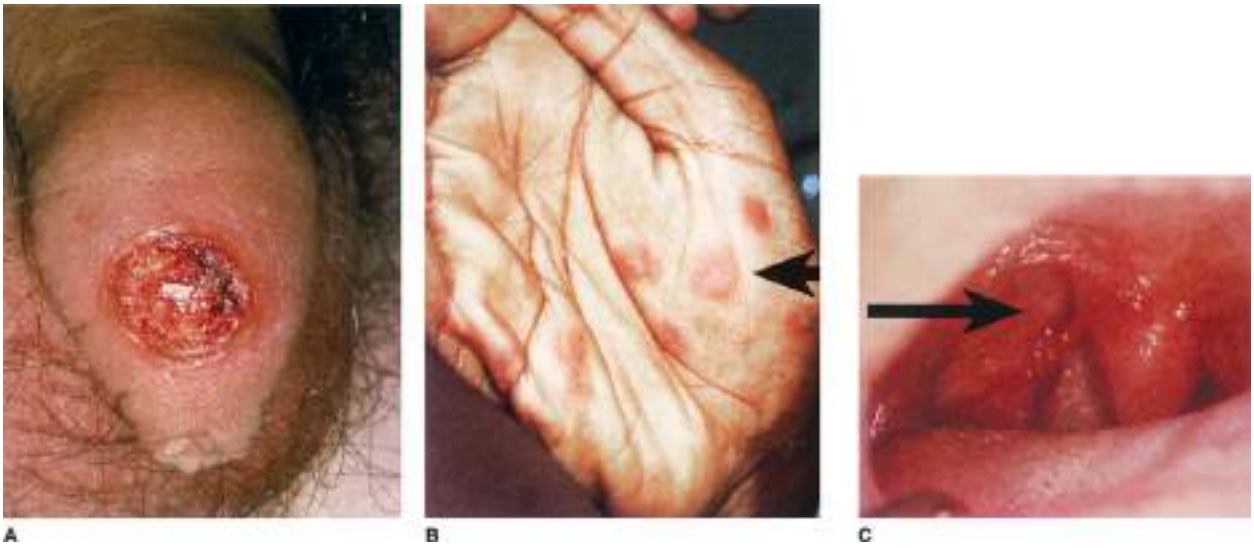

FIGURE 37–4. Syphilitic lesions. A. Primary syphilis. A syphilitic chancre is shown on the foreskin of the penis. Note the sharp edge and raw base of the ulcer. **B.** Secondary syphilis. The maculopapular rash appears on the palm. **C.** Tertiary syphilis. A ruptured gumma appears as a lump and ulcer in the hard palate of the mouth. (A, Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008. B and C, Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Minimal triggers for immune response

The disease is clinically silent until the disseminated secondary stage develops and then is silent again with entry into latency. Although evasion of host defenses is clearly taking place, the mechanisms involved are unknown. *T pallidum* strains found in secondary lesions have not been demonstrated to differ antigenically from those in the primary chancre. It may be that the combination of the low antigen content of its outer membrane combined with the extremely slow multiplication rate allows the organism to stay below whatever critical antigenic mass is required to trigger an effective immune response.

IMMUNITY

Immunity slow, incomplete

Clinical observations suggest an immune response in syphilis that is slow and imperfect. Immunity to reinfection does not appear until early latency, and for at least one-third of those infected the subsequent host response is successful in clearing most but not all of the treponemes.

OMP antibodies with reinfection resistance

T-lymphocyte suppression may link stages

The immune mechanisms involved are far from clear, but appear to involve both humoral and cell-mediated responses. Resistance to reinfection is correlated with appearance of antitreponemal antibody, which is able to immobilize and kill the organism. Exposed treponemal outer membrane proteins (OMPs) are the most probable target of these antibodies. Cell-mediated responses appear to be dominant in syphilitic lesions with T lymphocytes (CD4+ and CD8+) and macrophages, the primary cell types, present. Activated macrophages play a major role in the clearance of *T pallidum* from early syphilitic lesions. The relapsing course of primary and secondary syphilis may reflect shifts in the balance between developing cellular immunity and suppression of T lymphocytes. Syphilis in immunocompromised patients such as those with acquired immunodeficiency syndrome (AIDS) may present with unusually aggressive or atypical manifestations.

SYPHILIS: CLINICAL ASPECTS

MANIFESTATIONS

▪ Primary Syphilis

*** Painless, indurated chancre**

Heals after weeks

The primary syphilitic lesion is a papule that evolves to an ulcer at the site of infection. This is usually the external genitalia or cervix but could be in the anal or oral area depending on the nature of sexual contact. The lesion becomes indurated and ulcerates but remains painless, though slightly sensitive to touch. The fully developed ulcer with a firm base and raised margins is called the **chancre** (Figure 37–4A). Firm, nonsuppurative, painless enlargement of the regional lymph nodes usually develops within 1 week of the primary lesion and may persist for months. The median incubation period from contact until appearance of the primary lesion is about 3 weeks (range 3-90 days). It heals spontaneously after 4 to 6 weeks.

▪ Secondary Syphilis

*** Generalized lymphadenopathy, maculopapular rash**

*** Spirochetes abundant**

Disease continues in one-third

Secondary or disseminated syphilis develops 2 to 8 weeks after the appearance of the chancre in about a third of primary patients. The primary lesion has usually healed but may still be present. This most florid form of syphilis is characterized by a symmetric mucocutaneous maculopapular rash and generalized nontender lymph node enlargement with fever, malaise, and other manifestations of systemic infection. Skin lesions are distributed on the trunk and extremities, often including the palms (Figure 37–4B), soles, and face, and can mimic a variety of infectious and noninfectious skin eruptions. Some patients develop painless mucosal warty erosions called **condylomata lata.**

These erosions usually develop in warm, moist sites such as the genitals and perineum. All the lesions of secondary syphilis are teeming with spirochetes and are highly infectious. They resolve spontaneously after a few days to many weeks, but the infection itself has resolved in only one-third of patients. In the remaining two-thirds, the illness enters the latent state.

▪ Latent Syphilis

Relapses interrupt latency

Bloodborne transmission risk

Latent syphilis is by definition a stage in which no clinical manifestations are present, but continuing infection is evidenced by serologic tests. In the first few years, latency may be interrupted by progressively less severe relapses of secondary syphilis. In late latent syphilis (>4 years), relapses cease, and patients become resistant to reinfection. Transmission to others is possible from relapsing secondary lesions and by transfusion or other contact with blood products. Mothers may transmit *T pallidum* to their fetus throughout latency. About one-third of untreated cases do not have any manifestation of disease beyond this stage.

▪ Tertiary Syphilis

Another one-third of patients with untreated secondary syphilis develop tertiary syphilis. The manifestations may appear as early as 5 years after infection but characteristically occur after 15 to 20 years. The manifestations depend on the body sites involved, the most important of which are the nervous and cardiovascular systems.

*** Meningitis, degenerative changes, psychosis**

*** Demyelination causes neuropathies**

Paresis has many signs

Neurosyphilis is due to the damage produced by a mixture of meningovasculitis and degenerative parenchymal changes in virtually any part of the nervous system. The most common entity is a chronic meningitis with fever, headache, focal neurologic findings, and increased cells and protein in the cerebrospinal fluid (CSF). Cortical degeneration of the brain causes mental

changes ranging from decreased memory to hallucinations or frank psychosis. In the spinal cord, demyelination of the posterior columns, dorsal roots, and dorsal root ganglia produces a syndrome called **tabes dorsalis** (**Figure 37–5**), which includes ataxia, wide-based gait, foot slap, and loss of sensation. The most advanced central nervous system (CNS) findings include a combination of neurologic deficits and behavioral disturbances called **paresis,** which is also a mnemonic (**p**ersonality, **a**ffect, **r**eflexes, **e**yes, **s**ensorium, **i**ntellect, **s**peech) for the myriad of changes seen.

FIGURE 37–5. Tabes dorsalis. Loss of axons and myelin is evident in the posterior columns of the spinal cord (Woelke stain). (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

*** Aortitis leads to aneurysm**

*** Gummas localized granulomas**

Cardiovascular syphilis is due to arteritis involving the vasa vasorum of the aorta and causing a medial necrosis and loss of elastic fibers. The usual result is dilatation of the aorta and aortic valve ring. This in turn leads to aneurysms of the ascending and transverse segments of the aorta and/or aortic valve incompetence. The expanding aneurysm can produce pressure necrosis of adjacent structures or even rupture. In **gummatous syphilis** a localized, granulomatous reaction to *T pallidum* infection called a **gumma** (Figure 37–4C) may be found in skin, bones, joints, or other organs. Any clinical manifestations are related to the nature of the mass and local destruction as with other mass-producing lesions like tumors.

▪ Congenital Syphilis

*** Rhinitis, rash, bone changes**

Congenital syphilis increasing

Fetuses are susceptible to syphilis only after the fourth month of gestation and adequate treatment of infected mothers before that time prevents fetal damage. Because active syphilitic infection is devastating to infants, routine serologic testing is performed in early pregnancy and should be repeated in the last trimester in women at high risk for acquiring syphilis. Untreated maternal infection may result in fetal loss or congenital syphilis, which is analogous to secondary syphilis in the adult. Although there may be no physical findings, the most common are rhinitis and a maculopapular rash. Bone involvement produces characteristic changes in the architecture of the entire skeletal system (saddle nose, saber shins). Anemia, thrombocytopenia, and liver failure are terminal events. The incidence of congenital syphilis in the United States more than doubled between 2013 and 2017 reaching 918 cases, the most in 20 years.

DIAGNOSIS

▪ Microscopy

Darkfield requires fluid deep in lesion

*** Negative if small numbers**

T pallidum can be seen by darkfield microscopy in primary and secondary lesions, but the execution of this procedure requires experience and attention to detail. The microscopist must observe the corkscrew morphology and characteristic motility to make a diagnosis (Figure 37–2). A negative result from examination does not exclude syphilis; to be readily seen, the fluid must contain thousands of treponemes per milliliter. Darkfield microscopy of oral and anal lesions is not recommended because of the risk of misinterpretation of other spirochetes present in the resident flora.

Would a darkfield exam work during secondary syphilis?

Direct fluorescent antibody methods have been developed but are available only in certain centers.

▪ Serologic Tests

Most cases of syphilis are diagnosed using serologic tests that detect antibodies directed at either lipid or specific treponemal antigens. The former, called nontreponemal tests are positive only in active syphilis at the expense of a small proportion of false positives. The latter, called treponemal tests, detect antibody directed at *T pallidum* antigens. Treponemal tests are thus more specific than the nontreponemal, but do not distinguish between active and long past, even successfully treated syphilis. Their complementary deployment in the screening, diagnosis, and therapeutic evaluation of syphilis is described below.

▪ Nontreponemal Tests

*** Reagin is antibody to a lipid complex**

Levels peak in secondary syphilis

*** Nonspecific reactions in autoimmune diseases**

Nontreponemal tests measure antibody directed against **cardiolipin,** a lipid complex so called because one component was originally extracted from beef heart. Anticardiolipin antibody is called **reagin,** and the tests that detect it depend on immune flocculation of cardiolipin in the presence of other lipids. The most common nontreponemal tests are the rapid plasma reagin (RPR) and the Venereal Disease Research Laboratory (VDRL). The results become positive in the early stages of the primary lesion and, with the possible exception of some patients with advanced HIV infection, are uniformly positive during the secondary stage. They slowly wane in the later stages of the disease. In neurosyphilis, VDRL test results on CSF may be positive when the serum VDRL has reverted to negative. Nontreponemal tests are nonspecific; they may be falsely positive in a variety of autoimmune diseases or in diseases involving substantial tissue or liver destruction, such as lupus erythematosus, viral hepatitis, infectious mononucleosis, and malaria. False-positive results can also occur occasionally in pregnancy and in patients with HIV infection.

*** Titer used to follow therapy**

Sensitivity and low cost make nontreponemal tests preferred for screening, but positive results must be confirmed by one of the more specific treponemal tests described in the following text. The tests are also valuable for monitoring

treatment because the height of the antibody titer is directly related to activity of disease. With successful antibiotic therapy, positive nontreponemal serologies slowly revert to negative.

▪ Treponemal Tests

* *T pallidum* is the antigen

Treponemal tests detect antibody specific to *T pallidum*. The microhemagglutination test for *T pallidum* (MHA-TP), uses antigens attached to the surface of erythrocytes, which then agglutinate in the presence of specific antibody. A variety of enzyme immunoassay (EIA) procedures also detect specific antibody.

Think ▸▸ Apply 37-1: Although it is not so easy to get specimens from skin papules a darkfield should be positive because the rash lesions are teeming with *T pallidum* spirochetes. The serologic tests are all positive too.

* Treponemal positive confirms RPR, VDRL

Reverse algorithm increasing

Treponemal tests are considerably more specific than the cardiolipin-based nontreponemal tests. Their primary role in diagnosis is to confirm positive RPR and VDRL results obtained in the evaluation of a patient suspected of having syphilis or in screening programs. These tests are less useful for screening or after therapy because, once positive, they usually remain so for life except for the immunocompromised. The traditional approach is a two-step process. Initial screening is done with a nontreponemal test, and if positive, the result is confirmed with a treponemal test. In recent years, a “reverse algorithm” has become increasing popular with the availability of automated treponemal methods. Here the treponemal test is done first followed by the nontreponemal if positive. For persons with symptoms the added cost of this approach may be offset by improved efficiency of emergency room and hospital isolation decision-making. The time course of serologic tests in the various stages of syphilis is illustrated in **Figure 37–6**.

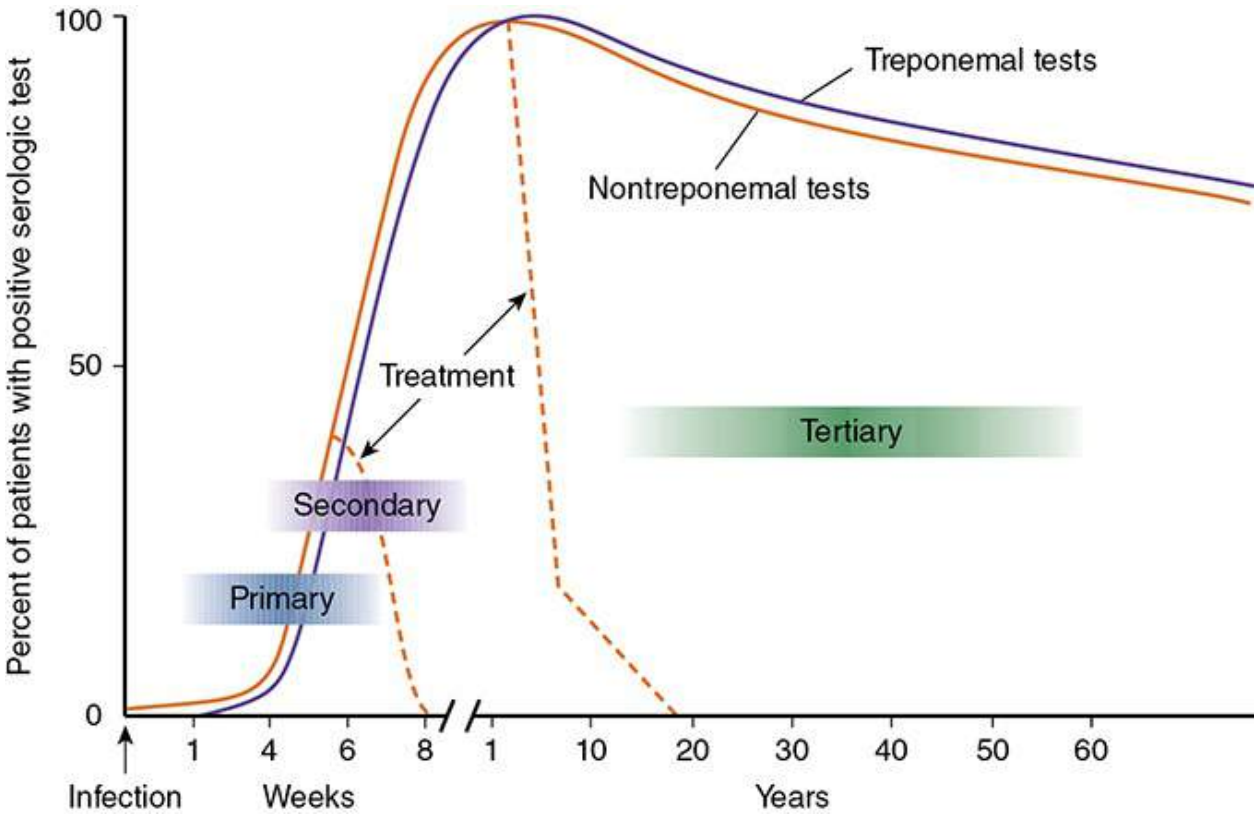

FIGURE 37–6. Syphilis serology. The time course of treponemal and nontreponemal tests in treated and untreated syphilis is shown. The nontreponemal test results (VDRL, RPR) rise during primary syphilis and reach their peak in secondary syphilis. They slowly decline with advancing age. With treatment, they revert to normal over a few weeks. The treponemal tests (FTA-ABS, MHA-TP) follow the same course but remain elevated even after successful treatment. FTA-ABS, fluorescent treponemal antibody; MHA-TP, microhemagglutination test for *T pallidum*; RPR, rapid plasma reagin; VDRL, Venereal Disease Research Laboratory.

IgM for congenital syphilis

The use of serologic tests in the diagnosis of congenital syphilis is complicated by the presence of IgG antibodies in infants, who acquire it transplacentally from their mothers. If available, treponemal IgM tests are useful in establishing the presence of an acute infection in infants.

TREATMENT AND PREVENTION

* Penicillin is preferred

T pallidum remains exquisitely sensitive to penicillin, which is the preferred treatment in all stages. In primary, secondary, or latent syphilis, persons hypersensitive to penicillin may be treated with doxycycline or tetracycline. The

efficacy of agents other than penicillin has not been established in tertiary or congenital syphilis. It is recommended that penicillin-hypersensitive patients with neurosyphilis or congenital syphilis be desensitized rather than use an alternate antimicrobial. The Jarisch-Herxheimer reaction is a bacterial sepsis like reaction beginning in the first 8 hours after penicillin administration. It is prevented or treated with antiinflammatory agents like asprin.

KEY CONCLUSIONS

- The corkscrew morphology of *Treponema pallidum* can be seen by darkfield microscopy but the organism has not been grown in culture.
- *T pallidum* has minimal structural proteins, no LPS and a very small genome. It persists by failing to trigger an effective immune response while slowly causing an endarteritis at multiple times and locations.
- Syphilis occurs in three stages. Primary syphilis includes the chancre (ulcer) and systemic dissemination. Secondary syphilis is manifest by a diffuse maculopapular rash. Tertiary syphilis includes destructive cardiovascular, nervous system, and tissue lesions.
- A latent phase between secondary and tertiary syphilis may last for decades.
- Diagnosis of syphilis is by darkfield microscopy together with treponemal and nontreponemal serologic tests.
- Penicillin treatment stops the disease process at any stage.

• *LEPTOSPIRA INTERROGANS*

OVERVIEW

Leptospira interrogans may be seen by darkfield microscopy or grown in culture but is primarily detected by serologic testing. Leptospirosis is a systemic flu-like illness associated with water contaminated by animal urine. It begins with fever, nausea, vomiting, headache, abdominal pain, and severe myalgia. In severe cases, a second phase is characterized by impaired hepatic and renal function with jaundice, prostration, and circulatory collapse. The CNS is often involved, with stiff neck and inflammatory changes in the CSF.

BACTERIOLOGY

Loose spirals seen in darkfield

L interrogans is a member of the genus *Leptospira* that is pathogenic to humans and animals. There are other free-living species of *Leptospira*. This species is a slim spirochete 5 to 15 µm long, with a single axial filament; fine, closely wound spirals; and hooked ends (**Figure 37–7**). It is not visualized with the usual staining procedures, and detection is best accomplished using darkfield microscopy. The outer membrane contains LPS and OMPs with adhesive or factor H-binding properties.

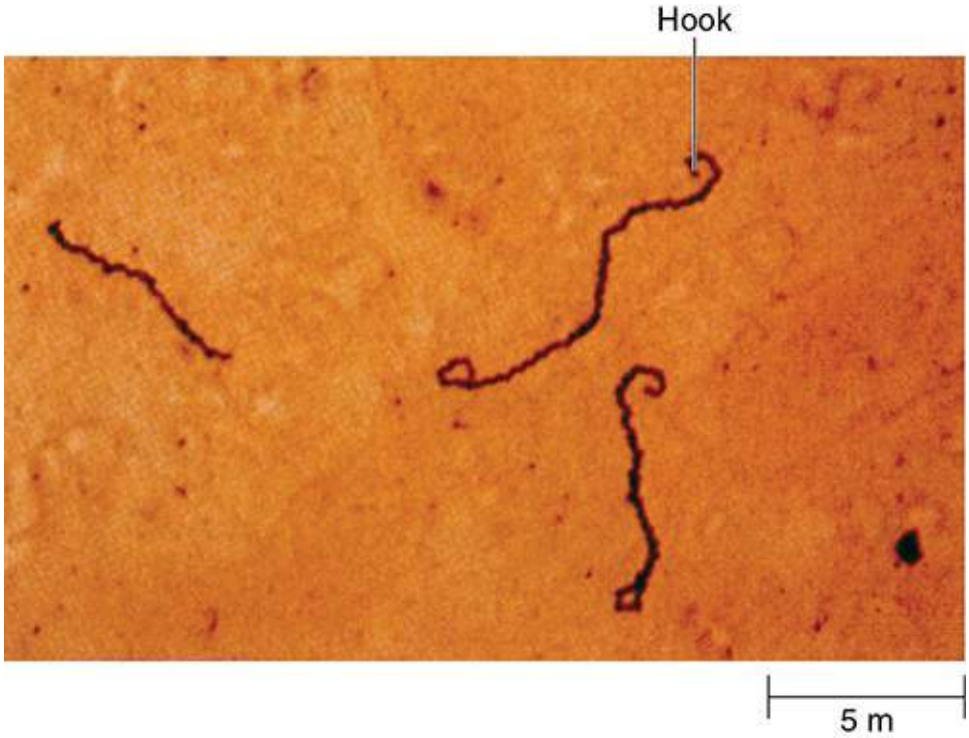

FIGURE 37–7. ***Leptospira interrogans*.** Note the tight primary coiling, loose loops, and hooked ends of the spirochete. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

* Survives in water

L interrogans has over 200 serotypes which are of epidemiologic and epizoologic importance but have no clinical significance. *L interrogans* can survive days or weeks in some waters in the environment at a pH above 7.0. Acidic conditions, such as those that may be found in urine, rapidly kill the organism. It is highly sensitive to drying and to a wide range of disinfectants.

LEPTOSPIROSIS

EPIDEMIOLOGY

*** Animals transmit via water**

Leptospirosis is a worldwide disease of a variety of wild and domestic animals, particularly rodents, cattle, and dogs. It is usually transmitted to humans directly or indirectly through water contaminated with animal urine. Secondary human-to-human transmission occurs rarely. Individuals who are exposed to animals (eg, farmers, veterinarians, slaughterhouse employees) are at increased risk, although most clinical cases are now associated with recreational exposure to contaminated water (eg, irrigation ditches or other bodies of water receiving farmland drainage).

PATHOGENESIS AND IMMUNITY

*** Enters through mucosal breaks**

*** Blood and CNS spread**

The organism gains entrance to the tissues through small skin breaks, the conjunctiva, or, most commonly, ingestion through the upper alimentary tract mucosa. The active motility of the hooked ends driven by periplasmic flagella may allow the organism to burrow into tissues. A few OMPs mediate adherence and one with serum factor H-binding properties interferes with complement-mediated killing. The organisms spread widely through the bloodstream to all parts of the body including the CSF. The kidney is a target organ in human disease, causing tubular infection and interstitial nephritis.

Antibody may be part of disease

Clearing of the bacteremia is associated with the appearance of circulating antibody but little else is known of immune mechanisms. Antibody is also rising during the second phase of the disease, which suggests an immunologic component to its pathogenesis. This is supported by the absence of response to antimicrobials when given at this stage and the typical failure to recover the

organism from the CSF in cases of leptospiral meningitis.

LEPTOSPIROSIS: CLINICAL ASPECTS

MANIFESTATIONS

Initial disease flu-like

*** Meningitis, muscle aches**

Most infections are subclinical and detectable only serologically. After an incubation period of 7 to 13 days, an influenza-like febrile illness with fever, chills, headache, conjunctival suffusion, and muscle pain develops in persons who become ill. This disease phase is associated with bacteremia. Leptospires are also found in the CSF at this stage, but without clinical or cytologic evidence of meningitis. The fever often subsides after about a week coincident with the disappearance of the organisms from the blood, but it may recur with a variety of clinical manifestations depending partly on the serogroup involved. This second phase of the disease usually lasts 3 or more weeks and may manifest as an aseptic meningitis resembling viral meningitis or as a more generalized illness with muscle aches, headache, rash, pretibial erythematous lesions, biochemical evidence of hepatic and renal involvement, or all of these. In its most severe form (Weil disease), there is extensive vasculitis, jaundice, renal damage, and sometimes a hemorrhagic rash. The mortality rate in such cases may be as high as 10%.

DIAGNOSIS

Primary diagnosis serologic

The diagnosis of leptospirosis is primarily serologic. Although the spirochetes can theoretically be detected, darkfield examination of body fluids is not recommended. The yield is very low and the chance for confusion with fibrin and debris is significant. Likewise, leptospires can be isolated from the blood, CSF, or urine, but culture is rarely attempted because the organisms take weeks

to grow in a special medium that few laboratories bother to stock. The standard serologic test the microscopic agglutination test (MAT) is limited to reference laboratories. There are two FDA-approved serologic test kits that may be available in locales where the disease is common.

TREATMENT AND PREVENTION

* Penicillin primary treatment

Penicillin is the primary treatment for all forms of leptospirosis. Doxycycline and ceftriaxone are alternatives. Doxycycline is recommended as chemoprophylaxis for individuals engaging in high-risk activities, such as swimming in jungle rivers or kayaking in developing countries. Other measures include rodent control, drainage of waters known to be contaminated, and care on the part of those subject to occupational exposure to avoid ingestion or contamination with *L interrogans.* Vaccines are used in cattle and household pets to prevent the disease, and this has reduced its occurrence in humans.

KEY CONCLUSIONS

- Leptospirosis is spread by animal urine contaminating lakes and streams.
- Headache, rash, and meningitis are the primary clinical features.
- The diagnosis is serologic.
- Penicillin, ceftriaxone, and doxycycline are effective therapy.

• *BORRELIA*

Relapsing fever, Lyme disease caused by different species

More than 15 species of *Borrelia* have been associated with human disease, and other species are responsible for similar diseases in animals. *Borrelia burgdorferi* is the cause of Lyme disease. Other members of the genus cause relapsing fever, an illness with intermittent fevers and little else. The relapsing fevers differ in their specific vector and geographic distribution. The human body louse is the vector for *B recurrentis*, but the remainder of the relapsing fevers are linked to several ticks and species of *Borrelia*; these are discussed

together here as *B hermsii*, the most common cause of relapsing fever in North America.

Loose spirals take common stains

Many genes in plasmids

Borrelia are long (10-30 µm), slender, spirochetes containing multiple (7-20) axial flagella. In contrast to *Treponema* and *Leptospira*, its spirals form loose, irregular waves. The basic organizational structure of the cell and its motility conform to that of the other Gram-negative spirochetes, but unlike the others, *Borrelia* are readily demonstrated by common staining methods such as the Giemsa or Wright stains. *Borrelia* are microaerophilic and have been successfully grown in specially supplemented (*N*-acetylglucosamine, fatty acids) liquid or semisolid media. A distinct feature of *Borrelia* is the partitioning of the genome between the chromosome and multiple circular and linear plasmids. In some species, a large proportion (>40%) of the genome is in the plasmids, including genes important in animal and human disease.

BORRELIA HERMSII AND BORRELIA RECURRENTIS

OVERVIEW

Multiple species of *Borrelia* spirochetes cause relapsing fever. *Borrelia hermsii* is the most common of the tick borne species and *B recurrentis* the only louse-borne species. Relapsing fever is an illness with fever, headache, muscle pain, and weakness but no signs pointing to any organ system. It lasts about 1 week and returns a few days later. The relapses may continue for as many as four cycles. During each relapse, spirochetes are present in the bloodstream.

BACTERIOLOGY

*** Proteins undergo antigenic variation**

Recombination between linear plasmids

The outer membrane of all *Borrelia* species contains abundant OMPs and lipoproteins. In some species, these surface proteins have been observed to vary antigenically too abundantly to be explained by simple mutation. Experiments

with *B hermsii* have demonstrated up to 40 antigenically distinct variants of the same protein arising from a single cell. The genetic mechanism for this antigenic variation involves recombination between genes located in the distinctive linear plasmids. Multiple copies of the genes for these proteins are present. Some genes express the protein, whereas others are "silent" because they lack crucial promoter sequences. When structural sequences from a silent gene are transferred by recombination to an expressing gene on another plasmid, the protein expressed is altered, which may make it antigenically different. This recombination mechanism resembles that described for antigenic variation of gonococcal pili (see Chapter 30, Figures 22–5, 30–7), but the number of possible *B hermsii* variants is more limited than with *N gonorrhoeae*.

RELAPSING FEVER

EPIDEMIOLOGY

*** Body lice or ticks transmit spirochete**

Relapsing fever occurs in two forms linked to the mode of transmission and the *Borrelia* species involved. The louse-borne form usually appears in epidemics, because of circumstances connected with body lice, whereas the tick-borne form does not. For this reason, the two forms are sometimes called epidemic (louse-borne) and endemic (tick-borne) relapsing fever. Here they are identified simply by the insect involved.

*** Ticks feed on rodents, small animals**

*** Painless tick bite transmits bacteria**

The occurrence and distribution of tick-borne relapsing fever are determined by the biology of multiple species of a single tick genus (*Ornithodoros*) and their relation to the primary *Borrelia* reservoir in rodents and other small animals (rabbits, birds, lizards). *Borrelia hermsii* is one of at least 15 *Borrelia* species associated with this cycle. Humans are infected when they accidentally enter this cycle and are bitten by an infected tick. The bite is painless and the feeding period is brief (less than 20 minutes). Because the ticks usually feed at night,

cases of relapsing fever are most often associated with overnight recreational forays into wild, wooded areas. A large outbreak in the United States involved National Park employees and tourists who slept in tick- and rodent-infested cabins on the Northern Rim of the Grand Canyon.

*** Body lice infected from human blood**

*** Lice transferred human to human**

The epidemiologic conditions associated with louse-borne relapsing fever are much more exacting. The human body louse has no other host, infected lice live no more than 2 months, and there is no transovarial passage to progeny. *B recurrentis* is the only species involved. Lice are infected from human blood, but the spirochetes multiply in their hemolymph, not any of the feeding parts or excrement. This means they can infect another human only if the louse is crushed by scratching and the *Borrelia* reach a superficial wound or mucosal surface. Infected lice must be passed human to human for the disease to persist. These conditions are met by circumstances that combine overcrowding with extremely low levels of general hygiene. War, other kinds of social breakdown, and dire poverty are the prime associates. Currently, this variety of relapsing fever appears to be limited to East and Central Africa and the Peruvian Andes.

PATHOGENESIS

*** Spirochetes in blood**

*** OMPs altered by recombination**

The disease manifestations develop at times when thousands of spirochetes are circulating per milliliter of blood. The febrile illness has endotoxin-like features, but the exact mechanisms of disease are unknown. Between episodes, the organisms disappear from the blood and are sequestered in internal organs only to reappear during relapses. The OMPs are antigenically different with each relapse. The relapsing cycles correlate with antibody production to the new protein generated by recombination between plasmids.

IMMUNITY

Antibody controls disease

Immunity to relapsing fever is largely humoral and appears to involve lysis of the organism in the presence of complement. The disease is controlled when number of variants from the antigenic repertoire are no longer able to escape the immune response.

RELAPSING FEVER: CLINICAL ASPECTS

MANIFESTATIONS

*** Fever, headache, muscle pain**

After a mean incubation period of 7 days, massive spirochetemia develops, with high fever, rigors, severe headache, muscle pains, and weakness. The febrile period lasts about 1 week and terminates abruptly with the development of an adequate immune response. The disease relapses 2 to 4 days later, usually with less severity, but following the same general course. Tick-borne relapsing fever is usually limited to one or two relapses, but up to 30 may occur.

Louse-borne more severe

Louse-borne relapsing fever is more severe than tick-borne disease, possibly because of predisposing social conditions. Fatalities are rare in tick-borne disease but may be as high as 40% in untreated louse-borne fever. There is usually not more than one or two relapses. Fatal outcomes are due to myocarditis, cerebral hemorrhage, and hepatic failure.

DIAGNOSIS

*** Blood smears demonstrate *Borrelia***

Diagnosis of relapsing fever is readily made during the febrile period by Giemsa or Wright staining of blood smears. The appearance of the spirochete among the red cells is characteristic. Culture and serologic tests are available only in reference laboratories.

TREATMENT

*** Doxycycline primary treatment**

Patients with relapsing fever respond well to doxycycline, tetracycline, or penicillin therapy. If the level of spirochetes is high at the time treatment is initiated, a systemic febrile reaction (Jarisch-Herxheimer) resembling Gram-negative sepsis may ensue. This is felt to be due to rapid lysis of the organisms with release of outer membrane LPS. It is more common in louse-borne than tick-borne relapsing fever.

PREVENTION

Attention to general hygiene important

Prevention of tick-borne relapsing fever involves attention to deticking, insecticide treatment, and rodent control around habitations such as mountain cabins, which are known to be associated with infection. Control of louse-borne relapsing fever involves delousing, particularly dusting of clothing with appropriate insecticides. Ultimately, improved hygiene stops outbreaks and prevents further occurrences.

KEY CONCLUSIONS

- *Borrelia hermsii* and other species of *Borrelia* cause tick-borne relapsing fever.
- *Borrelia recurrentis* causes louse-borne relapsing fever in lice, which must be passed human to human.
- Relapses are related to antigenic variation of OMPs.
- Spirochetes are seen in routine blood smears.

BORRELIA BURGDORFERI

OVERVIEW

B burgdorferi is transmitted to humans by *Ixodes* ticks following a complex life cycle involving ticks, mice, and deer. The spirochete has multiple classes of OMPs, which undergo antigenic variation in the

multiple stages of the life cycle and in human infection. Acute Lyme disease is characterized by fever, a migratory “bull’s eye” skin rash, muscle and joint pains, often with evidence of meningeal irritation. In a chronic form evolving over several years, meningoencephalitis, myocarditis, and a disabling recurrent arthritis may develop.

BACTERIOLOGY

Osps differ at stages of infection

B burgdorferi consists of at least 20 subspecies which differ in geographic distribution and some clinical manifestations. Three of these are the primary causes of Lyme disease. All these are referred to here as *B burgdorferi*. As with other species of *Borrelia*, there are multiple classes of OMPs, many of which undergo antigenic variation. Recent studies have focused on a class called outer surface proteins (Osps), which have been linked to aspects of pathogenesis and immunity. In response to environmental signals (temperature, pH) two of these proteins, OspA and OspC, are differentially expressed, depending on the stage of tick or mammalian infection.

LYME DISEASE

EPIDEMIOLOGY

*** Transmitted in tick–mouse–deer cycle**

*** Infect humans in the woods**

B burgdorferi exists in a complex cycle involving ticks, mice, and deer (**Figure 37–8**). Lyme disease occurs when the ticks feed on humans who enter their wooded habitat. The disease is endemic in several regions of the United States, Canada, and temperate Europe and Asia. Approximately 90% of the more than 30,000 cases reported each year in the United States occur in areas along the northeastern and mid-Atlantic seaboard, including Old Lyme, Connecticut, where the disease was first recognized.

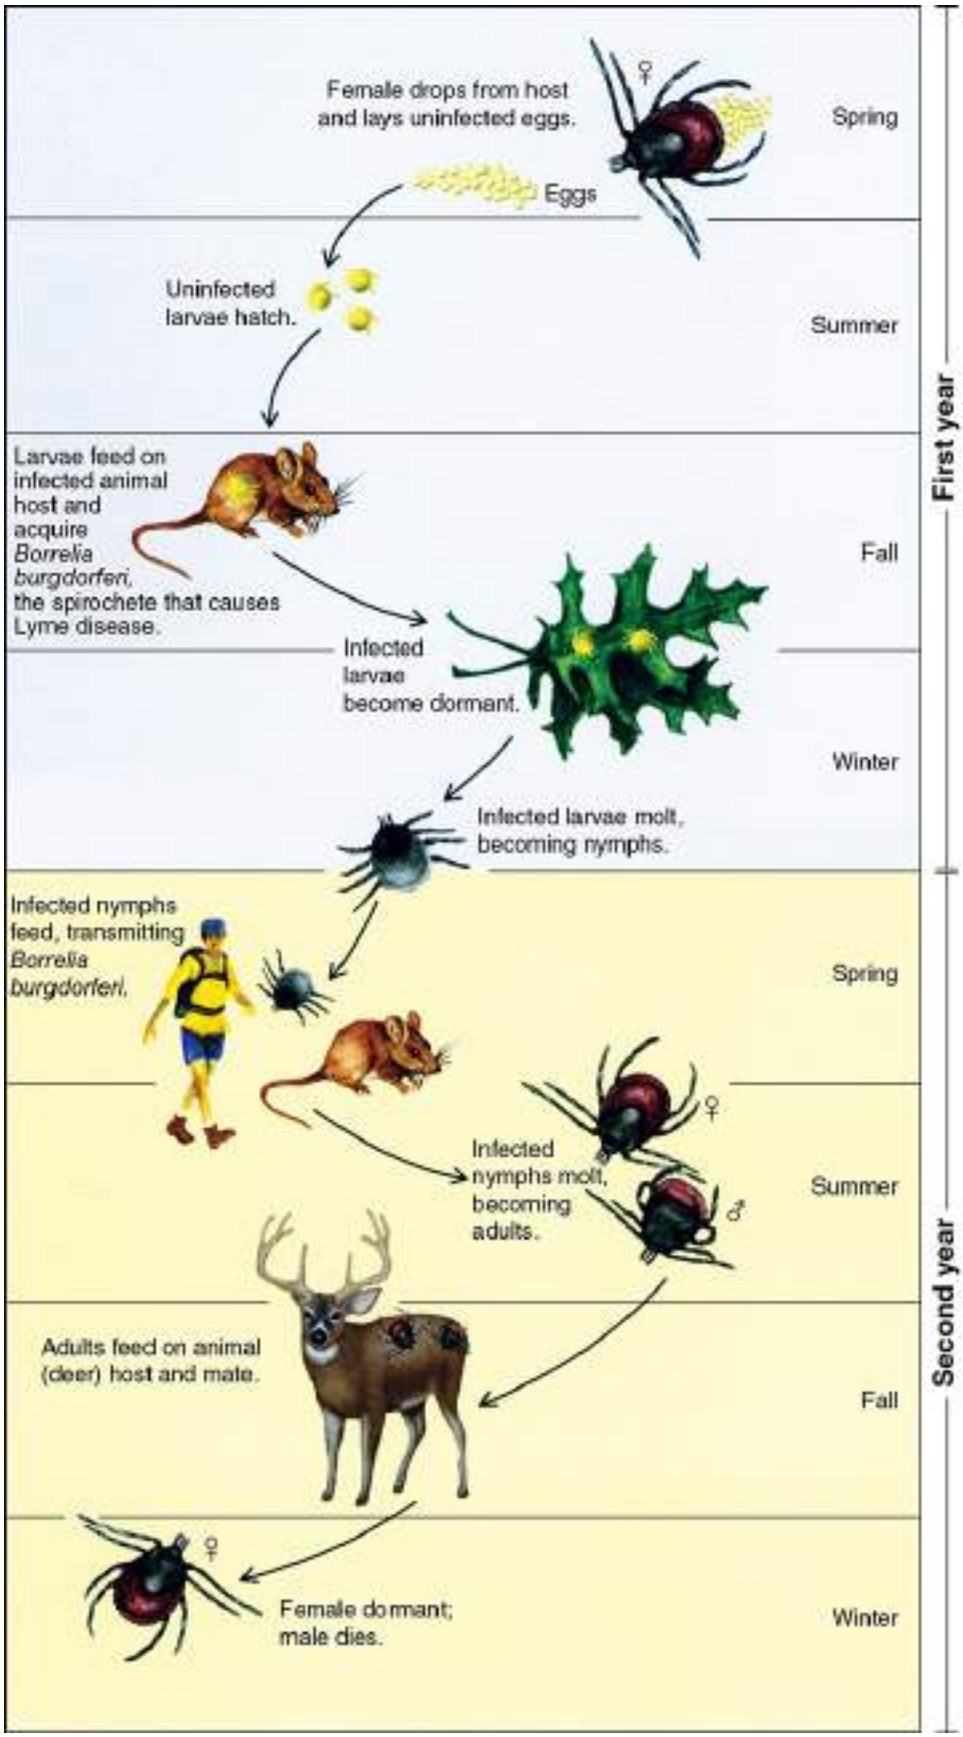

FIGURE 37–8. Lyme disease life cycle. The life cycle covers 2 years during which the tick obtains three blood meals. The males die soon after mating; the females die after depositing their eggs in the following spring. Variations depend on climate and food availability for the natural hosts. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

*** Adult and nymph stages infect humans**

*** No deer, no disease**

The primary reservoir of *B burgdorferi* is rodents, particularly white-footed mice. Infection is transmitted by *Ixodes* ticks (**Figure 37–9**), whose complete life cycle involves rodents for the early stages and deer for adult maturation. In the spring, fertile female ticks, engorged from their blood meals, fall from their deer hosts to the ground and deposit their eggs. During the summer, the tick larvae seek out and obtain a blood meal from mice and the *B burgdorferi* ingested by the larvae are maintained through the subsequent development stages of the tick. The following spring or summer, the small (1-2 mm) nymphs feed again on vertebrate hosts to obtain the blood required for maturation to adulthood. The engorged, satiated nymphs fall off their hosts and mature into adults by parasitizing available deer, thus completing a life cycle that has occupied a full 2 years. Vertebrates other than deer can be infected by both the adult and nymph stages of the tick, but human Lyme disease is acquired primarily from nymphs, because they are active at the time of year when humans are most likely to invade their ecosystem. The infecting dose is very low (<20 organisms), making even a single tick bite a risk for disease. Deer are essential to the mating and survival of the tick, and thus the disease does not occur in areas in which deer are not abundant.

FIGURE 37–9. The deer tick (*Ixodes scapularis*) adult and nymph. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

PATHOGENESIS

OspA in ticks

* OspC in mammals

Because Lyme disease is a recently discovered disease with a complex biology, it is not surprising that the pathogenic mechanisms in humans remain to be established clearly. Studies in ticks have shown changes in the antigenic makeup of *B burgdorferi* as it migrates from the midgut and salivary glands and again after it reaches mammalian tissue. OspA is the major outer surface protein expressed when *B burgdorferi* resides in ticks, where it mediates binding to midgut cells. OspA expression diminishes during tick feeding and engorgement, whereas OspC increases, so that by the time of transmission to animal hosts, OspC predominates. OspC binds mammalian plasminogen and has been shown to protect the spirochetes from macrophage ingestion. Antibody against OspC is protective in animals.

Proteins bind to fibronectin, factor H

* Peptidoglycan stimulates inflammation

After infection, the *B burgdorferi* surface proteins that mediate adhesion to fibronectin or elements of the extracellular matrix could be important in the early stages of disease. By analogy with other bacterial proteins that bind serum factor H, similar Osps of *B burgdorferi* are likely to facilitate persistence by interference with effective complement deposition. The spirochete is not known to produce digestive enzymes, but tissue spread and dissemination may be facilitated by the utilization of host proteases. As the organism spreads, inflammation is stimulated by the cell wall peptidoglycan and possibly by elements of the outer membrane, although *B burgdorferi* lacks classic LPS. When deposited in joint tissues, these elements may contribute to the arthritis of Lyme disease.

Downregulation of immune function

* Arthritis may be autoimmune

Clinical investigations in patients with Lyme disease have noted modulation of immune responses, including inhibition of mononuclear and natural killer cell function, lymphocyte proliferation, and cytokine production. The ability of *B burgdorferi* to downregulate deleterious immune responses could serve as a survival strategy or play a role in chronic disease. Chronic disease, particularly Lyme arthritis, has aspects of autoimmunity. A subcategory of arthritis patients refractory to antimicrobial therapy have been shown to have heightened and persistent humoral immune responses to OspA.

IMMUNITY

Target of antibody unclear

The immune response to *B burgdorferi* infection develops slowly, with IgM followed by IgG antibody over weeks to months. Although immune-mediated killing by the classical complement pathway has been demonstrated, the molecular target is unknown. Host neutrophils and macrophages can phagocytose opsonized spirochetes and induce a metabolic burst leading to spirochetal death.

LYME DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

* Spreading from bite site

Lyme borreliosis is a highly variable disease involving many body systems. It occurs in overlapping patterns that come and go at different times. The skin lesion spreading from the site of the tick bite is its most distinctive feature. Relapsing arthritis is the most persistent finding and the one most likely to become chronic. Lyme disease is rarely fatal, but if untreated, it is often a source of chronic ill health.

* Expanding rings called erythema migrans

* Febrile aches mark acute disease

The primary lesion begins sometime in the first month after a tick bite, which is often unnoticed. A macule or papule appears at the site of the bite and expands to become an annular lesion with a raised, red border and central clearing forming a bull's-eye pattern. As the bull's-eye ring expands and evolves, it forms the complex known as **erythema migrans** (**Figure 37–10**). Along with the skin lesions, fever, fatigue, myalgia, headache, joint pains, and mild neck stiffness are often present. Approximately 50% of untreated patients develop secondary skin lesions that closely resemble the primary one, but are not at the site of the tick bite. In untreated patients, the skin lesions usually disappear over a period of weeks, but constitutional symptoms may persist for months.

FIGURE 37–10. Erythema migrans. The typical rash of Lyme disease is shown evolving in concentric rings around the site of the tick bite. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Nerve palsies, cardiac findings

Days to months after the onset of the primary lesion, a second stage may develop in which involvement of the nervous or cardiovascular system is superimposed. Neurologic abnormalities include a fluctuating meningitis, cranial nerve palsies, and peripheral neuropathy. Cardiac disease is usually limited to conduction abnormalities (atrioventricular block), but in some cases acute myocarditis can lead to cardiac enlargement. Both neurologic and cardiac abnormalities fluctuate in intensity, but generally resolve completely in a matter of weeks.

* Fluctuating arthritis becomes chronic

Weeks to years after the onset of infection, arthritis marks the continuing

state of the disease. It develops in almost two-thirds of untreated patients. Without therapy, the spirochetes may persist in localized niches for years. Typically, this too follows a fluctuating or intermittent course, generally involving the large joints, particularly the knees. The arthritis may become chronic with erosion of the bone and cartilage, although the spirochetes are rarely demonstrable in the lesions. Less common chronic neurologic dysfunctions include subtle encephalitis affecting memory, mood, or sleep, and peripheral neuropathies.

DIAGNOSIS

Culture not practical

Presently, the diagnosis of early Lyme disease is based on exposure and typical clinical findings. Although *B burgdorferi* can be cultured from erythema migrans skin lesions, blood, joint fluid, and CSF, few laboratories have the skill to accomplish this or even stock the special medium required. The spirochetes are seldom detected on any kind of direct microscopic examination. Nucleic acid amplification procedures able to detect *B burgdorferi*-specific DNA sequences in body fluids (joint, CSF) have been developed.

*** EIA followed by immunoblot**

With culture generally unavailable, the diagnosis in later stages of disease usually rests on the demonstration of circulating antibodies to *B burgdorferi*. The current recommendation is to first perform a sensitive screening test (EIA) followed by a confirmatory immunoblot (Western blot), which detects specific antigens of the organism. For persons who lack a typical clinical or epidemiologic history, great caution should be exercised before making a diagnosis of Lyme disease based only on positive serologic tests.

TREATMENT

Doxycycline, amoxacillin primary treatment

Doxycycline is the primary treatment for persons 8 years and above. Amoxicillin is used in children and pregnant women. Cefuroxime is a third choice in the face of allergy. The response to treatment is typically slow, requiring the continuation

of antimicrobials for 30 to 60 days. Chronic Lyme disease is most probably an autoimmune state, and thus antimicrobial agents would not be effective.

PREVENTION

Preventing bites, removing ticks

The most useful preventive measures in endemic areas are the use of clothes that reduce the likelihood of the infected nymph reaching the legs or arms, careful search for nymphs after potential exposure, and removal of the tick by its head with tweezers. Duration of tick attachment to humans is also a factor in transmission; the risk is greatest when the tick has been feeding for at least 48 to 72 hours. Some insect repellents may provide added protection. Prophylactic doxycycline may be used following a tick bite, but only in a highly endemic region.

Why no vaccine? What would you use as an immunogen?

KEY CONCLUSIONS

- *Borrelia burgdorferi* has a complex life cycle involving ticks, mice, and deer in the woods.
- Erythema migrans, the primary Lyme disease manifestation, is a dramatic moving annular rash.
- Chronic Lyme disease involves inflammation of joints, cardiovascular and nervous systems which may be immunopathologic.
- A two-step serologic diagnosis must be interpreted together with clinical and epidemiologic observations.

CASE STUDY

A Rash and Facial Paralysis

This 39-year-old man was in his usual state of good health and had just

returned from a summer trip to Rhode Island. One week after returning home, he developed a fever and muscle aches, which resolved and were followed 2 weeks later with a rash on his right forearm, right hip, and left knee. At each site, the rash was initially localized but then over a few days moved outward forming large erythematous rings. Two weeks after the rash started, he felt a numbness on the left side of his face followed by a sagging and inability to move the facial muscles below his eye.

On physical examination, the patient was afebrile and had normal vital signs. A skin examination demonstrated the three skin lesions noted above, which had, according to the patient, faded significantly. A neurologic examination demonstrated left facial nerve weakness. The remainder of the examination was normal.

Laboratory studies included a normal complete blood count. A lumbar puncture was performed. CSF contained 78 nucleated cells/mm^3 with 88% lymphocytes and 12% monocytes. CSF glucose level was 60 mg/dL, and protein level was 55 mg/dL.

Think ▸▸ Apply 37-2: A vaccine using OspC as the antigen was developed and marketed. Its approach was novel as it would have to be effective during the tick bite. It has now been withdrawn. Antigenic variation could be a problem.

QUESTIONS

1. To consider a diagnosis of Lyme disease, what additional history would be most helpful from this patient?

A. Food consumption
B. Swimming in lakes or streams
C. Sexual contact
D. Hiking locales
E. Illness of friends

2. What laboratory test would be most likely to confirm this diagnosis?

A. *Borrelia burgdorferi* immunoassay
B. *Borrelia burgdorferi* immunoblot
C. *Borrelia burgdorferi* immunoassay plus immunoblot
D. Darkfield examination of rash
E. PCR of CSF

3. What molecular structure of *B burgdorferi* facilitates its life cycle in ticks?

A. OspA
B. OspB
C. OspC
D. LPS
E. Peptidoglycan

ANSWERS

1. (D)

2. (C)

3. (A)

APPENDIX 37–1 **Nonvenereal Treponemes**

DISEASE	CAUSE	MAJOR GEOGRAPHIC LOCATION	PRIMARY LESION	SECONDARY LESIONS	TERTIARY LESIONS
Bejel	*T pallidum*, subspecies *endemicum*[a]	Middle East; arid, hot areas	Oral cavity[b]	Oral mucosa	Rare; gummatous lesions of skin, periosteum, bone, and joint
Yaws	*T pallidum*, subspecies *pertenue*	Humid, tropical belt	Skin; papillomatous	Systemic; resemble syphilis	Rare; gummatous lesions of skin, periosteum, bone, and joint[c]
Pinta	*T carateum*	Central and South America	Skin; erythematous papule	Skin; merge into primary lesion; altered pigmentation	Areas of altered skin pigmentation and hyperkeratoses

[a]Probably a variant of that causing venereal syphilis.
[b]Often inapparent.
[c]Neurologic manifestations usually absent.

chapter 38

Mycoplasma

Mycoplasma pneumoniae • *Mycoplasma genitalium* • *Mycoplasma hominis*

OVERVIEW

Mycoplasma are tiny bacteria that lack a cell wall. Their outer cell membrane contains sterols that they obtain from the tissues in which they grow. *Mycoplasma pneumoniae* is second only to the pneumococcus as a cause of community-acquired pneumonia. However, *M pneumoniae* has a predilection for younger persons and spreads person-to-person in families or closed groups, whereas the elderly are at greatest risk for pneumococcal pneumonia. Mycoplasmal infection presents as tracheobronchitis or pneumonia with headache and a persistent nonproductive cough, often worse at night. Chest radiographs usually show unilateral patchy infiltrates without lobar consolidation, hence the term atypical pneumonia. The course is almost always benign, but improvement is accelerated by treatment with doxycycline or azithromycin. In the past, diagnosis was confirmed if at all by serology or rarely by culture. Multiplex PCR platforms for respiratory pathogens and pneumonia have changed the approach to diagnosis.

There has been a resurgence interest and research in *Mycoplasma genitalium (*MG*),* which is second only to *Chlamydia trachomatis* as a cause of cervicitis, urethritis, and pelvic inflammatory disease (PID). The recognition of MG as a major cause of sexually transmitted infection (STI) has been transformed by NAA testing, since it does not grow in culture. Gene variations that result in resistance to macrolides and fluoroquinolones are an emerging problem globally.

Mycoplasma hominis is a resident of the genitourinary tract; however, its clinical manifestations are uncommon and extragenital. It can cause transient bacteremia with parturition, localized infection in joints, including prosthetic ones, and sternal wound infections after cardiac surgery. *M hominis* can be grown on chocolate agar from tissue or aspirated fluid obtained sterilely from these sites. Confirmed infections are treated with doxycycline or a fluoroquinolone; they are resistant to macrolides and β-lactams.

The role of *Ureaplasma* in human disease syndromes remains ill-defined.

This chapter includes two genera of unique microbes that lack a cell wall but otherwise resemble bacteria. They differ from viruses by having both DNA and RNA and by the ability to grow in cell-free media. They are ubiquitous in nature as the smallest of free-living microorganisms. Numerous *Mycoplasma* species have been isolated from animals and humans, but *M pneumoniae* stands out as the clearest and most important human pathogen. The other species associated with human disease are summarized in **Table 38-1**.

TABLE 38–1 Features of Pathogenic *Mycoplasma* and *Ureaplasma*

	PRIMARY SITE	MOTILITY	ATTACHMENT (PROTEINS)	DISEASE
M pneumoniae	Respiratory	Gliding	Terminal organelle (P1, P30)	Pneumonia
M hominis	Genitourinary			Extra-intestinal infections
M genitalium	Genitourinary	Gliding	Terminal organelle (MgPa)	Urethritis, cervicitis, PID
Ureaplasma sp.	Genitourinary			Role ill-defined as yet

PID, Pelvic inflammatory disease.

GENERAL FEATURES

*** No cell wall**

*** Cell membrane contains sterols**

Not stained by common methods

*** NAA useful**

Mycoplasma and *Ureaplasma* are taxonomically placed in the Mollicutes, a class of prokaryotes that lack a cell wall. Although their DNA does not resemble any other prokaryote, evolutionary studies suggest they are derived from Gram-positive bacteria by reductive evolution. They are very small (diameter 0.2-0.3 μm), highly pleomorphic, and appear as coccoid bodies, filaments, and bottle-shaped forms. The cells are bounded only by a single trilaminar membrane which, unlike bacteria, contains sterols. The sterols are not synthesized by the organism but are acquired as essential components from the tissue in which the organism is growing. Flagella and pili are lacking, but surface organelles mediating attachment have been identified for some species. Lacking a cell wall, *Mycoplasma* and *Ureaplasma* stain poorly or not at all with the usual stains. Their double-stranded DNA genome is small, in part due to the lack of genes encoding a complex cell wall. *M pneumoniae* is an aerobe, but most other species are facultatively anaerobic. Although possible to isolate with special media, the laborious techniques required have been supplanted by NAATs. The exception is *M hominis*, which grows on chocolate agar. As the center of a

colony grows into the agar and looks denser, it takes on the appearance of an inverted “fried egg.”

• MYCOPLASMA PNEUMONIAE

MYCOPLASMA PNEUMONIAE

*** Organelle mediates attachment and gliding motility**

In addition to the general features of *Mycoplasma*, *M pneumoniae* has a terminal organelle that is a membrane-bound protrusion of the cytoplasm capped by a button. This structure contains a number of proteins (P1, P30) that are involved in attachment to cell surfaces. It also mediates a form of movement called gliding motility in which the organism advances over smooth surfaces in the direction of the protrusion. *M pneumoniae* also produces an ADP-ribosylating toxin.

MYCOPLASMAL PNEUMONIA

EPIDEMIOLOGY

*** Infecting dose very low**

*** Worldwide, often in teenagers**

Outbreaks in families, closed communities

M pneumoniae accounts for approximately 10% of all cases of pneumonia. Infection is acquired by droplet spread. Experimental challenges indicate that the human infectious dose is very low, possibly less than 100 organisms. Infections with *M pneumoniae* occur worldwide, but they are especially prominent in temperate climates. Epidemics at 4- to 6-year intervals have been noted in both

civilian and military populations. The most common age range for symptomatic *M pneumoniae* infection is between 5 and 15 years, and the disease accounts for more than one-third of all cases of pneumonia in teenagers (but is also seen in older persons). Infections in children younger than 6 months are uncommon. The disease often appears as a sporadic, endemic illness in families or closed communities because its incubation period is relatively long (2-3 weeks) and because prolonged shedding in nasopharyngeal secretions may cause infections to be spread over time. In families, attack rates in susceptible persons approach 60%. Asymptomatic infections occur, but most studies have suggested that more than two-thirds of infected cases develop some evidence of respiratory tract illness.

PATHOGENESIS

Adherence mediated by protrusion-associated proteins

*** ADPR toxin interferes with ciliary action, leads to desquamation**

M pneumoniae infection involves the trachea, bronchi, bronchioles, and peribronchial tissues and may extend to the alveoli and alveolar walls. The organism appears to thrive on the phospholipids present in lung epithelia. Initially, *M pneumoniae* attaches to the cilia and microvilli of the cells lining the bronchial epithelium. This attachment is mediated by protrusion-associated proteins (P1, P30) which bind to complex oligosaccharides containing sialic acid found in the apical regions of bronchial epithelial cells (**Figure 38–1**). The oligosaccharide receptors are chemically similar to antigens on the surface of erythrocytes and are not found on the nonciliated goblet cells or mucus, to which *M pneumoniae* does not bind. Other proteins bind to elements of the extracellular matrix-like fibronectin. The ADP-ribosylating toxin interferes with ciliary action and causes nuclear vacuolization and fragmentation of tracheal epithelial cells. This leads to inflammation and desquamation of the involved mucosa (**Figure 38–2**). The inflammatory response is most pronounced in the bronchial and peribronchial tissue and is composed of lymphocytes, plasma cells, and macrophages, which may infiltrate and thicken the walls of the bronchioles and alveoli. Organisms are shed in upper respiratory secretions for 2 to 8 days before the onset of symptoms, and shedding continues for as long as 14 weeks after infection.

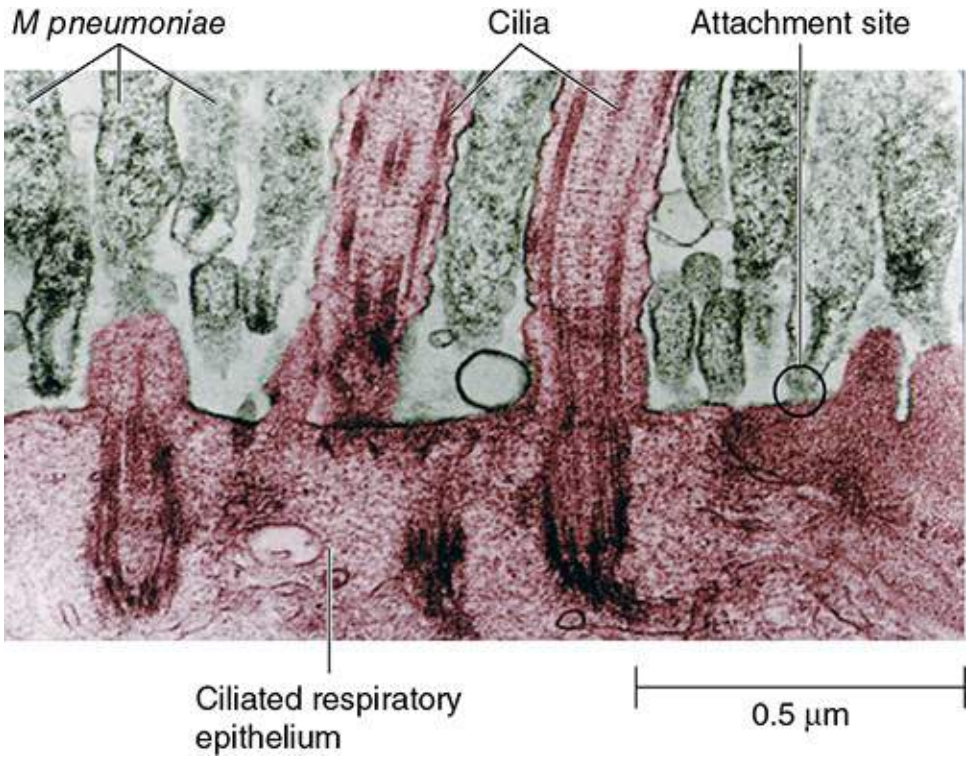

FIGURE 38–1. ***Mycoplasma pneumoniae*** **infecting respiratory epithelium.** Transmission electron micrograph. Note the distinctive appearance of the tips of the mycoplasmas adjacent to the host epithelium. The tips probably represent a site on the microorganism that is specialized for attachment. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

IMMUNITY

Antibody peaks at 2 to 4 weeks

* Cold agglutinins are IgM

Both T- and B-cell–mediated immune responses occur, and generally appear to be effective in preventing reinfection. Complement-fixing serum antibody titers reach a peak 2 to 4 weeks after infection and gradually disappear over 6 to 12 months. Also, nonspecific immune responses to the glycolipids of the outer membrane of the organism often develop, which can be detrimental to the host. For example, cold hemagglutinins are IgM antibodies that react with an altered antigen on human RBCs and are seen in about two-thirds of symptomatic patients infected with *M pneumoniae*.

Immunity is incomplete

Immunity is not complete, and reinfection with *M pneumoniae* may occur. Clinical disease appears to be more severe in older than in younger children, which has led to the suggestion that many of the clinical manifestations of disease are the result of immune responses rather than invasion by the organism. High titers of cold agglutinins may be associated with hemolysis and Raynaud phenomenon.

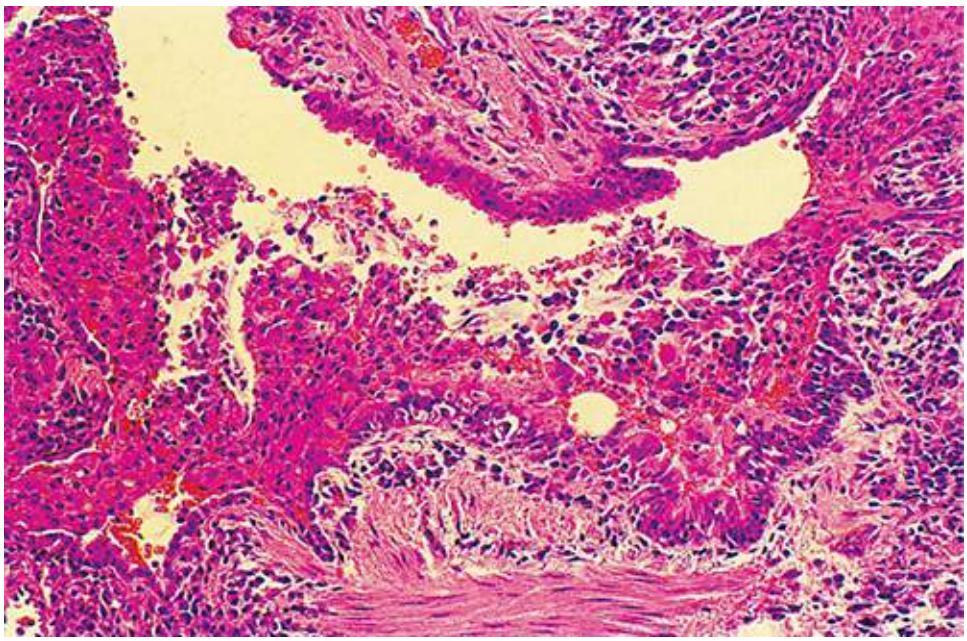

FIGURE 38–2. *Mycoplasma pneumoniae* bronchiolitis. This lung section shows destruction of the bronchiolar wall and mucosal ulceration. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

MYCOPLASMAL PNEUMONIA: CLINICAL ASPECTS

MANIFESTATIONS

*** Walking pneumonia has insidious onset**

*** Nonproductive cough**

A mild tracheobronchitis with fever, cough, headache, and malaise is the most common syndrome associated with acute *M pneumoniae* infection. The pneumonia is typically less severe than other bacterial pneumonias. It has been described as walking pneumonia because most cases do not require

hospitalization. The disease is of insidious onset, with fever, headache, and malaise for 2 to 4 days before the onset of respiratory symptoms. Pulmonary symptoms are generally limited to a non- or minimally productive cough. Radiographs show a unilateral or patchy pneumonia, usually in a lower lobe, although multiple lobes are sometimes involved. Small pleural effusions are seen in up to 25% of cases. The average duration of untreated illness is 3 weeks. The severity of pulmonary involvement is greater in patients with immune deficiencies.

Pharyngitis, otitis common

Pharyngitis with fever and sore throat may also occur. Nonpurulent otitis media or myringitis may occur concomitantly in up to 15% of patients with *M pneumoniae* pneumonitis, but bullous myringitis is rare. A variety of other extrapulmonary complications have been described, involving skin (erythema multiforme), peripheral vasospasm (Raynaud phenomenon), central nervous system (encephalitis, myelitis), joints (arthralgias), and other sites.

DIAGNOSIS

*** Serologic diagnosis now replaced by PCR**

Clinical diagnosis of *M pneumoniae* infection may be difficult because the manifestations overlap with those of other respiratory infections. Gram-stained sputum usually shows some mononuclear cells, but because it lacks a cell wall, *M pneumoniae* is not seen. The absence of bacteria suggests a viral or *Mycoplasma* etiology. The organism can be isolated from throat swabs or sputum of infected patients using special culture media and methods, but growth is slow, and isolation usually requires incubation for a week or longer. Thus, serologic tests rather than culture were used historically for specific diagnosis. A fourfold rise of serum antibody titer or seroconversion in acute and convalescent sera indicated *M pneumoniae* infection. The most widely used serologic method was complement fixation. With the relatively long incubation period and insidious onset of the disease, many patients already had high antibody titers at the time they were first seen. Consequently, a single high titer, such as a complement fixation titer greater than 1:128 or IgM-specific antibody (measured by enzyme immunoassay or immunofluorescence), supported recent infection. These methods have been replaced by multiplex PCR panels in most clinical microbiology laboratories.

TREATMENT

Doxycycline, azithromycin, fluoroquinolones

Doxycycline and azithromycin for children are the preferred agents used for treatment of *M pneumoniae* pneumonia. Fluoroquinolones are effective alternatives. β-Lactams are ineffective because *M pneumoniae* lacks a cell wall. Almost all patients with *M pneumoniae* pneumonia recover, but treatment markedly shortens the course of illness.

• OTHER *MYCOPLASMA* AND *UREAPLASMA*

Mycoplasma genitalium has emerged as a sexually transmitted infection (STI) second only to *Chlamydia trachomatis* as an established cause of nongonococcal urethritis in men and pelvic inflammatory disease in women (Table 38-1). The increased recognition and diagnosis of *M genitalium* as an important STI is the result of wider use of NAA testing, since it does not grow in culture. The optimal sample for NAA testing is a first-voided urine specimen that is leucocyte esterase-positive. Gene variations that result in resistance to macrolides and fluoroquinolones are a growing problem for treatment globally, since doxycycline-moxifloxacin or doxycycline-azithromycin are recommended for therapy.

M hominis is a resident the genitourinary tract; however, its clinical manifestations are uncommon and extragenital. It can cause amnionitis, transient bacteremia with parturition, localized infection in joints (including prosthetic ones), sternal wound infections after cardiac surgery, and pericardial infections. *M hominis* can be grown on chocolate agar from tissue or aspirated fluid obtained sterilely from these sites. Confirmed infections are treated with doxycycline or a fluoroquinolone; they are resistant to macrolides and β-lactams.

The role of *Ureaplasma* in human disease syndromes remains ill-defined.

KEY CONCLUSIONS

- *Mycoplasma* lack a cell wall and cell membrane contains sterols.
- *Mycoplasma pneumoniae* causes tracheobronchitis and atypical pneumonia in youth.
- Persistent dry cough, fever, and headache with patchy infiltrates on chest radiographs are common features.

- Doxycycline and azithromycin (for children) shorten the course of illness.
- *Mycoplasma genitalium* causes urethritis and pelvic inflammatory disease.
- *Mycoplasma hominis* causes extragenital infections (joints, sternal wounds).

CASE STUDY

A Teenager with Respiratory Complaints

In July, a 14-year-old girl presents with cough and fever to 102°F. She does not appear seriously ill. Chest examination is abnormal and chest radiograph shows bilateral, patchy infiltrates. Her brother, aged 12, had a similar illness 3 weeks earlier.

QUESTIONS

1. Which is the most likely cause of this girl's illness?

A. *Legionella pneumophila*
B. *Chlamydiophila pneumoniae*
C. *Mycoplasma pneumoniae*
D. Influenza A virus
E. *Metapneumovirus*

2. Which is the most appropriate diagnostic test?

A. Culture
B. Immunofluorescent assay on sputum
C. Serology

3. Which is the treatment of choice for this patient?

A. Penicillin
B. Ribavirin
C. Oseltamivir
D. Azithromycin
E. Ceftriaxone

ANSWERS

1. (C)

2. (C)

3. (D)

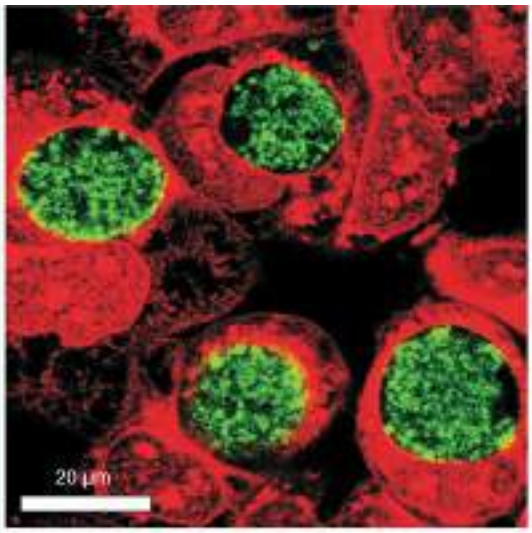
chapter 39

Chlamydia

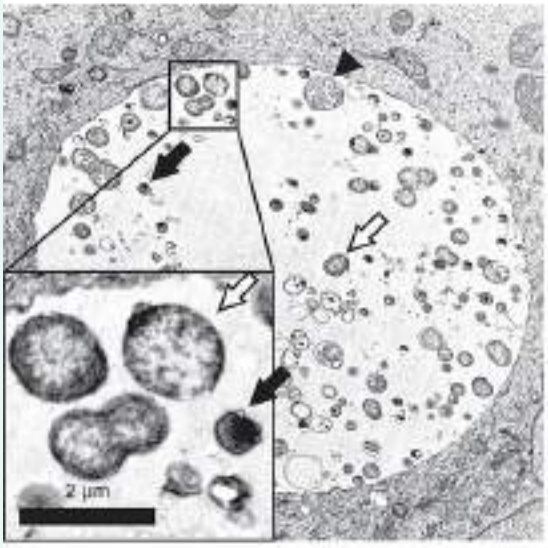
Chlamydia trachomatis • *Chlamydophila psittici* • *Chlamydophila pneumoniae*

OVERVIEW

Chlamydiae are obligate intracellular bacteria whose cells lack peptidoglycan and who share a common replicative cycle that involves two forms: elementary and reticulate bodies (**Figure 39–1**). Elementary bodies (EBs) are smaller, have rigid cell walls, can survive outside cells, and are infectious. Once EBs attach to the cell membranes of susceptible cells, they enter the cell by endocytosis and transform into larger, but fragile reticulate bodies (RBs) that multiply by binary fission and form more EBs that are released by exocytosis or cell rupture to infect adjacent cells and begin the cycle anew. Despite their biologic similarities, the *Chlamydia* are diverse in their tropisms and clinical features even within a single species. *Chlamydia trachomatis* primarily produces infections of the conjunctiva or genital tract depending on which biovar is involved. Trachoma is a progressive conjunctivitis with inflammation and scarring resulting in blindness and is caused by *C trachomatis* biovars A, B, and C. Sexually transmitted biovars D-K cause urethritis, cervicitis, salpingitis, and neonatal infections of the eye and respiratory tract after vaginal delivery by infected mothers. L biovars of *C trachomatis* cause lymphogranuloma venereum (LGV), a sexually transmitted disease that manifests as painless genital ulcers followed by painful suppuration of regional inguinal lymph nodes. LGV biovars can also cause ulcerative proctitis, rectal fistulae, and strictures.

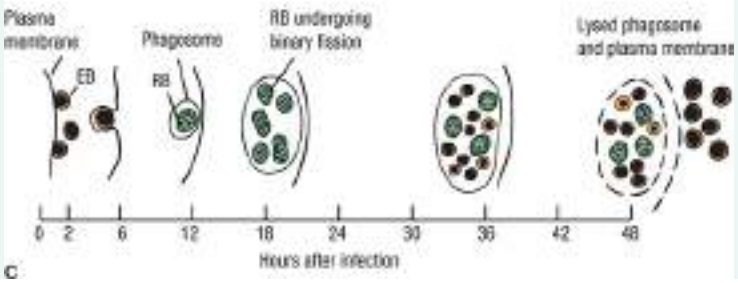


A



B

Elementary body	Reticulate body (initial body)
Size about 0.3 µm	Size 0.5–1.0 µm
Rigid cell wall	Fragile cell wall
Relatively resistant to sonication	Sensitive to sonication
Resistant to trypsin	Lysed by trypsin
RNA:DNA content = 1:1	RNA:DNA content = 3:1
Toxic for mice	Nontoxic for mice
Isolated organisms infectious	Isolated organisms not infectious
Adapted for extracellular survival	Adapted for intracellular growth



C

FIGURE 39–1. Chlamydia life cycle. A. Fluorescence light micrograph of human cells (red) infected with *Chlamydia trachomatis* (green). **B.** A transmission electron micrograph of human cells that contain reticulate bodies (white arrows), elementary bodies (black arrows), and an intermediate form called "aberrent bodies" (black arrowhead). **C.** A schematic representation of the infectious cycle of Chlamy.

Chlamydophila species cause atypical pneumonia. *Chlamydophila psittici* causes psittacosis, a zoonotic pneumonia contracted by inhalation of respiratory secretions or aerosols of cloacal droppings of infected birds of diverse species. *Chlamydophila pneumoniae* causes community-acquired pneumonia that mimics *Mycoplama pneumoniae* in its person-to-person transmission, clinical features, and treatment.

Members of the genus *Chlamydia* are obligate intracellular bacteria that lack peptidoglycan in their cell wall. *Chlamydia trachomatis* is the most important human pathogen and is a major cause of conjunctivitis and genital tract infections. A chronic form of *C trachomatis* conjunctivitis, called trachoma, is the leading preventable cause of blindness in the world. *Chlamydophila pneumoniae* and *Chlamydophila psittaci* are respiratory pathogens. Our knowledge of biology and pathogenesis of these bacteria is based primarily on the study of *C trachomatis*.

• *CHLAMYDIA TRACHOMATIS*

BACTERIOLOGY

*** No peptidoglycan layer**

*** Requires host cell metabolism**

C trachomatis are round cells between 0.3 and 1 μm in diameter depending on the stage in the replicative cycle (see below). Their envelope is of the Gram-negative type, including an outer membrane that contains lipopolysaccharide and proteins. A major difference is that chlamydiae lack the thin peptidoglycan layer between the outer membrane and the plasma membrane. Although there is no detectable peptidoglycan in chlamydial cells, genomic studies have demonstrated an almost complete set of genes for peptidoglycan synthesis. The outer membrane includes a major outer membrane protein (MOMP) that is immunogenic. *Chlamydia* are obligate intracellular parasites because they rely on the host cell for key amino acids and energy-generating metabolites like ATP.

Among bacteria only the mycoplasmas have a smaller genome.

DNA homology between *C trachomatis*, *C psittaci*, and *C pneumoniae* is less than 30%, although 16S rRNA sequence analysis suggests they share a common origin. The three species share a common group antigen. Their major differential features are shown in **Table 39-1**. *C trachomatis* has multiple biovars, each with a different tissue tropism. Biovars A-C infect ocular epithelial cells and cause trachoma; biovars D-K target urogenital epithelial cells and cause nongonococcal urethritis (NGU), mucopurulent cervicitis, and inclusion conjunctivitis; and biovars L_1-L_3 infect genital colorectal tissues and cause lymphogranuloma venereum (LGV).

TABLE 39–1 Features of Human *Chlamydia* and *Chlamydophila* Infection

SPECIES	BIOVARS	CELL TROPISM	RESERVOIR	TRANSMISSION	DISEASE	COMPLICATIONS
Chlamydia trachomatis	A-C	Conjunctiva	Humans	Hand-eye, fomites, flies	Conjunctivitis	Blindness
C trachomatis	D-K	Urogenital	Humans	Sexual, perinatal	NGU, cervicitis, proctitis	PID, infertility
C trachomatis	L_1, L_2, L_3	Urogenital, colorectal	Humans	Sexual	LGV, ulcers, lymphadenopathy	
Chlamydophila psittaci	Many	Respiratory, systemic	Birds	Aerosol inhalation	Pneumonia	
Chlamydophila pneumoniae	One	Respiratory	Humans	Respiratory droplets	Pneumonia	

LGV, lymphogranuloma venerum; NGU, nongonococcal urethritis; PID, pelvic inflammatory disease.

REPLICATIVE CYCLE

*** EB induces endocytosis, cytoskeletal rearrangement**

*** RBs replicate forming inclusion then EBs**

Cell apoptosis regulated

The replicative cycle of chlamydiae is illustrated in Figure 39–1. It involves two major forms of the organism: a small, hardy infectious form termed the elementary body (EB), and a larger fragile intracellular replicative form called the reticulate body (RB). The EB is a metabolically inert form that neither expends energy nor synthesizes protein. The cycle begins when the EB attaches to the plasma membrane of susceptible target cells and induces its own endocytosis. This is accomplished in part by the secretion of a preformed translocated actin recruiting protein (Tarp) which induces actin cytoskeletal rearrangements in the target cell. Utilizing stores of ATP the EB then begins the

process of converting to the replicative RB. With inhibition of lysosomal fusion in the host cell, the organism forms its own membrane-bound vesicle called the inclusion. After RBs increase in number, the process reverses and the RBs reorganize and condense to yield multiple EBs. They are then released by exocytosis, extrusion of intact inclusions, or cell lysis to infect adjacent cells. The efficiency of this cycle is optimized by a chlamydial protease-like activity factor (CPAF) which regulates cellular apoptosis signals. In the growth phase apoptosis is inhibited, but at the release stage cell death proceeds. Both Tarp and CPAF are injected by secretion systems (type III). Tarp is injected across the plasma membrane, CPAF across the inclusion membrane. A variant in the overall replicative cycle is called the persistent state in which the EBs and RBs become dormant but are still able to resume multiplication. This state can be induced by some cytokines (IFN-γ), nutrient restriction, and interestingly, penicillin. As indicated earlier, *Chlamydia* lacks the peptidoglycan target of penicillin but still has a set of genes for its synthesis.

CHLAMYDIA TRACHOMATIS DISEASE

EPIDEMIOLOGY

*** Finger and fomite eye transmission**

*** Neonatal contracted during delivery**

C trachomatis causes disease in several sites, primarily the conjunctiva and genital tract. In its various forms, this infection is one of the most frequent in the world. Humans are the sole reservoir. Person-to-person spread is through direct contact or via fomites. Inclusion conjunctivitis is of two types: biovars A-C cause trachoma (see below) in children and adults whereas neonatal conjunctivitis is seen among population groups in whom the strains (biovars D-K) causing genital infections are common. Newborns acquire *C trachomatis* through direct contact with infective cervical secretions of the mother at delivery. Adults can also develop conjunctivitis by contact with genital secretions.

Trachoma, a chronic follicular conjunctivitis, afflicts an estimated 500 million persons worldwide and blinds 7 to 9 million, particularly in Africa. The

disease is usually contracted in infancy or early childhood from the mother or other close contacts. Spread is by contact with infective human secretions, directly via hands to the eye or via fomites..

High rate of sexual transmission

The prevalence of chlamydial urethral infection in U.S. men and women ranges from 5% in the general population to 20% in those attending sexually transmitted disease clinics. Approximately one-third of male sexual contacts of women with *C trachomatis* cervicitis develop urethritis after an incubation period of 2 to 6 weeks. The proportion of men with mild to absent symptoms is higher than in gonorrhea.

PATHOGENESIS

Early release of cytokines

Fibrosis and scarring later

*** Recurrent infections cause trachoma**

Chlamydiae have a tropism for columnar epithelial cells of the endocervix and upper genital tract of women, and the urethra, rectum, and conjunctiva of both sexes. Depending on the biovar a wide range of other cells may be infected including endothelium, smooth muscle, lymphocytes, and macrophages. Initial attachment is probably mediated by MOMP and possibly other outer membrane proteins followed by cellular invasion by the mechanisms described above. The LGV biovars can also enter through breaks in the skin or mucosa. Once the replication cycle is established, the primary injury is due to inflammation secondary to the release of proinflammatory cytokines such as interleukin-8 by infected epithelial cells. Chlamydial lipopolysaccharides probably also play an important role in initiation of the inflammatory process. This results in early tissue infiltration by polymorphonuclear leukocytes, later followed by lymphocytes, macrophages, plasma cells, and eosinophils. If the infection progresses further (because of lack of treatment and/or failure of immune control), aggregates of lymphocytes and macrophages may form in the submucosa; these can progress to necrosis, followed by fibrosis and scarring. The chronic progressive inflammation with scarring seen in trachoma is due to persistent or recurrent infections over many years beginning in childhood. In the

later stages the process may be primarily immunopathologic. Live *Chlamydia* may not be present and inflammation can be triggered by *C trachomatis* antigens to which the patient has been sensitized.

IMMUNITY

Immunity incomplete

*** T_H1 responses most protective**

Immunity to *C trachomatis* infections seems to take a long time to develop and even then is incomplete. Up to 50% of women with genital infections may still be shedding the organism a year later. The intracellular location and the prospect that low levels of cytokines may induce the persistent state are complicating features. T_H1 responses seem to be the most protective. T_H2 responses directed at MOMP may participate as well but antibody is also associated with immunopathologic injury in the chronic forms like trachoma.

CHLAMYDIA TRACHOMATIS: CLINICAL ASPECTS

MANIFESTATIONS

▪ Eye Infections

*** Trachoma and neonatal conjunctivitis due to different serotypes**

Trachoma and inclusion conjunctivitis are distinct diseases of the eye that have some overlap in their clinical manifestations. Trachoma, a chronic conjunctivitis caused by *C trachomatis* biovars A-C, is usually seen in poor countries and often leads to blindness. Neonatal inclusion conjunctivitis, an acute infection commonly caused by biovars D-K, is usually not associated with chronicity or permanent eye damage.

Trachoma

Conjunctival vascularization then scarring

Chronic inflammation of the eyelids and increased vascularization of the corneal conjunctiva are followed by severe corneal scarring and conjunctival deformities (**Figure 39–2**). Visual loss often occurs 15 to 20 years after the initial infection as a result of repeated scarring of the cornea.

FIGURE 39–2. Trachoma. An active infection showing follicular hypertrophy. The inflammatory nodules cover the thickened conjunctiva. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Inclusion Conjunctivitis

Pneumonia in infants has delayed, gradual onset

Neonatal inclusion conjunctivitis usually presents as an acute, watery then mucopurulent eye discharge 5 to 12 days after birth. Infection occurs in roughly one-third of infants born vaginally to infected mothers. The infection is not prevented by prophylaxis with topical erythromycin or tetracycline. Untreated, it may persist for 3 to 12 months. Inclusion conjunctivitis is clinically similar in adults and is usually associated with concomitant genital tract disease. Diagnosis can be made quickly by demonstrating characteristic cytoplasmic inclusions in smears of conjunctival scrapings (**Figure 39–3**). In both neonates and adults, systemic therapy is preferred because the nasopharynx, rectum, and vagina may also be colonized and other forms of disease may develop, such as aspiration pneumonia in neonates. More than 50% of all infants born to mothers excreting

C trachomatis during labor show evidence of infection during the first year of life. Most develop inclusion conjunctivitis, but 5% to 10% develop neonatal pneumonia. *C trachomatis* accounts for about one-third to one-half of all cases of interstitial pneumonia in infants. The illness usually develops in a child between 6 weeks and 6 months of age and has a gradual onset. The infant is usually afebrile, but develops difficulty in feeding, a characteristic staccato (pertussis-like) cough, and shortness of breath. The disease is rarely fatal, but may be associated with decreased pulmonary function later in life.

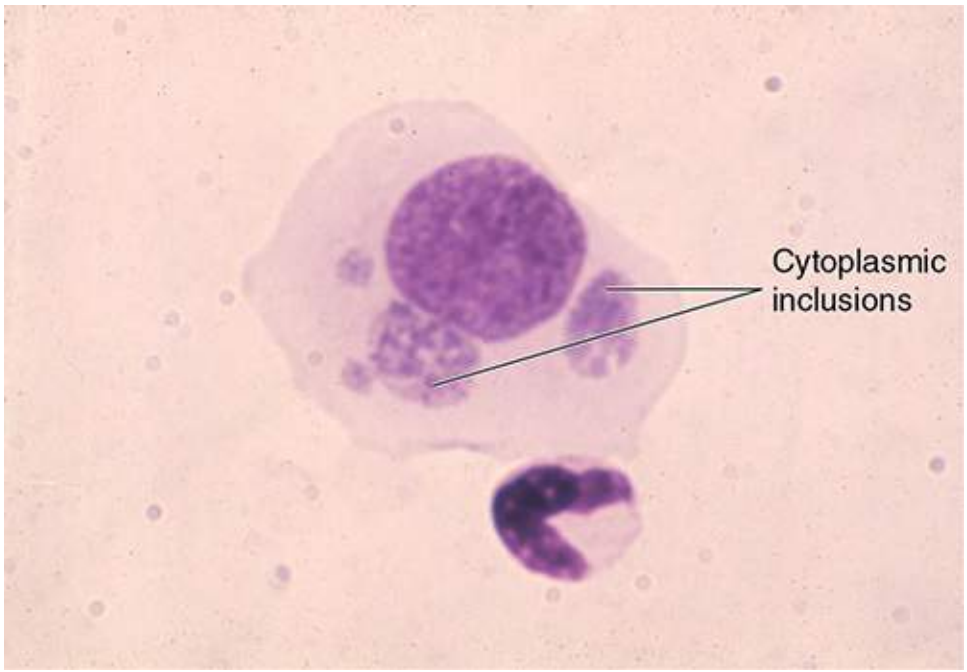


FIGURE 39–3. *Chlamydia trachomatis* cytoplasmic inclusion bodies in a conjunctival epithelial cell. (Reproduced with permission from Willey J, Sherwood L, Woolverton C: *Prescott's Principles of Microbiology*. New York, NY: McGraw Hill; 2008.)

Why does inclusion conjunctivitis not lead to trachoma?

Think ▸▸ Apply 39-1: The differences in disease spectrum between the *C trachomatis* biovars is based on epidemiologic evidence. A biologic difference is presumed but not proven. Trachoma follows chronic, repeated eye infection, and immunopathologic events. It is possible that due to the perinatal mode of

transmission followed by treatment, subsequent infections fail to occur with inclusion conjunctivitis.

▪ Genital Infections

* Clinical spectrum similar to *N gonorrhoeae*

The clinical spectrum of sexually transmitted infections with *C trachomatis* is similar to that of *Neisseria gonorrhoeae*. *C trachomatis* can cause urethritis and epididymitis in men and cervicitis and salpingitis in women. In addition, three biovars of *C trachomatis* cause LGV, a distinctly different sexually transmitted disease (Table 39-1).

* Salpingitis and PID cause sequelae

C trachomatis urethritis is manifested by dysuria and a thin urethral discharge akin to that of *Mycoplasma genitalium*. Infections of the uterine cervix may produce vaginal discharge but are usually asymptomatic. Ascending infection in the form of salpingitis and pelvic inflammatory disease (PID) occurs in an estimated 5% to 30% of infected women. The scarring produced by chronic or repeated infection is an important cause of sterility and ectopic pregnancy.

* Papule and inguinal adenopathy

* Chronic abscesses, strictures, fistulas

LGV is a sexually transmitted infection caused by *C trachomatis* strains L_1, L_2, or L_3. It occurs principally in South America, Africa, Southeast Asia, India, and Caribbean countries. The clinical course is characterized by a transient genital lesion followed by multilocular suppurative involvement of the inguinal lymph nodes (**Figure 39–4**). The primary genital lesion is usually a small painless ulcer or papule, which heals in a few days and may go unnoticed. The most common presenting complaint is inguinal adenopathy. Nodes are initially discrete, but as the disease progresses, they become matted and suppurative. The skin over the node may be thinned, and multiple draining fistulas develop. Systemic symptoms such as fever, chills, headaches, arthralgia, and myalgia are common. Late complications include urethral or rectal strictures and perirectal abscesses and fistulas. In homosexual men, LGV strains can cause a

hemorrhagic ulcerative proctitis. Lymph nodes may need to be aspirated to prevent rupture.

FIGURE 39–4. Lymphogranuloma venerum. Ulcerated inguinal lymph node. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

DIAGNOSIS

Epithelial cells required

* NAA sensitive and specific

Appropriate specimen collection is the first step in making an etiologic diagnosis of chlamydial infections, which are now done by molecular methods. Because *C trachomatis* is an obligate intracellular microorganism, swab specimens from conjunctiva, urethra, and endocervix should include epithelial cells for detection

by nucleic acid hybridation with DNA probes for chlamydial 16S rRNA. Nucleic acid amplification (NAA) tests are rapid, sensitive, and specific for genital *Chlamydia* infections. An ideal specimen is the first 20 mL of voided urine; some platforms also are validated for use with vaginal, cervical, urethral, and rectal swabs. NAATs that detect both *C trachomatis* and *N gonorrhoeae* are commonly used.

*** Serodiagnosis limited to LGV**

Chlamydial serology may be useful in the diagnosis of LGV, where a single high complement fixation (CF) antibody titer (1:64 or greater) or a fourfold rise supports a presumptive diagnosis. In 80% to 90% of patients, the LGV CF test is positive shortly after the appearance of inguinal lesions. The most satisfactory method for diagnosis of LGV is isolation of an LGV strain of *C trachomatis* from tissue or lymph node aspirates, but cultures are rarely done now.

TREATMENT

*** Azithromycin, doxycycline effective**

Strains of *C trachomatis* are susceptible to macrolides and doxycycline. Azithromycin is the preferred therapy, because it is given as a single oral dose for non-LGV *C trachomatis* infection. Doxycycline is an alternative for *C trachomatis* and is the drug of choice for treating LGV. For trachoma, a single dose of azithromycin is the treatment of choice.

PREVENTION

Treat high-risk individuals

Reinfection prevention essential

Prophylaxis for infants using topical erythromycin or silver nitrate on the conjunctiva has limited effectiveness for *Chlamydia*, because 15% to 25% of exposed infants still develop inclusion conjunctivitis. The primary approach to prevention of all forms of genital and infant *C trachomatis* infection entails detection of this infection in sexually active individuals and appropriate treatment with azithromycin, including infected women late in pregnancy. For

trachoma, corrective surgery may prevent blindness and is required for severe corneal and conjunctival scarring. Control of trachoma is directed toward prevention of continued reinfection during early childhood. Improvement in general hygienic practices is the most important factor in decreasing transmission of infection within families, but one of the most difficult to implement on a broad scale.

• *CHLAMYDOPHILA PSITTACI*

▪ Epidemiology

*** Pneumonia contracted from birds**

Human psittacosis (ornithosis) is a zoonotic pneumonia contracted through inhalation of respiratory secretions or dust from droppings of infected birds. It was initially described in psittacines, such as parrots and parakeets, but was subsequently shown to occur in over 100 avian species, including turkeys. The disease is usually latent in its natural host, but may become active, particularly with the stress of recent captivity or transport; *C psittaci* is then excreted in large amounts. Until recently classified with the genus *Chlamydia*, the closely related *C psittaci* (and *C pneumoniae*) were splint off based on differences in ribosomal RNA sequence analysis.

Associated with poultry processing and many birds

Psittacosis in humans is seen mainly as an occupational hazard of poultry workers and bird fanciers, particularly owners of psittacine birds. Reported cases of human psittacosis in the United States decreased during the 1950s, in association with the use of antimicrobials in poultry feeds and quarantine regulations for imported psittacine birds. Currently, 100 to 200 cases of psittacosis are reported each year. *C psittaci* is highly infectious and its airborne infectious potential is enough for *C psittaci* to be placed on lists of potential bioterrorism weapons. Nonetheless, human-to-human transmission is rare.

CLINICAL DISEASE AND TREATMENT

Bilateral interstitial pneumonia

*** Diagnosis serologic**

Treatment with doxycycline

The incubation period for psittacosis is 5 to 15 days. Psittacosis in humans is an acute infection of the lower respiratory tract, usually presenting with acute onset of fever, headache, malaise, muscle aches, dry hacking cough, and bilateral interstitial pneumonia. Occasionally, systemic complications such as myocarditis, encephalitis, endocarditis, and hepatitis may develop. The liver and spleen are often enlarged. The diagnosis of psittacosis should be suspected in any patient with acute onset of febrile lower respiratory illness who gives a history of close exposure to birds. Indeed, a history of bird exposure should be especially sought in patients who appear to have a bilateral pneumonia not proven to be caused by other agents. Spread can occur from both symptomatic and asymptomatic infections of birds. The specific diagnosis is usually made by demonstrating a fourfold rise in the titer of microimmunofluorescence or CF antibodies or a single IgM titer of higher than 1:32 or greater A drawback of CF titers are cross-reactions with *C trachomatis* and *C pneumoniae*. Treatment with doxycycline (preferred) or azithromycin is effective if given early in the course of illness.

• *CHLAMYDOPHILA PNEUMONIAE*

Manifestations similar to *M pneumoniae*

Azithromycin, levofloxacin, or doxycycline preferred treatment

C pneumoniae has been shown to be as common a cause of community-acquired pneumonia that mimics the features of *M pneumoniae* infection. Since this agent has been recognized as a cause of pneumonia for little more than a decade, its clinical features and disease mechanisms are still in development. It is estimated that 10% of pneumonia and 5% of bronchitis cases are due to this agent. Epidemiologic evidence indicates that infection occurs throughout the year and is spread between humans by person-to-person contact. Outbreaks of community-acquired pneumonia caused by *C pneumoniae* have been reported as has apparent nosocomial spread. Reinfections occur, and clinically evident *C pneumoniae* infection may occur more often in the elderly than in younger individuals. Most infections manifest as pharyngitis, lower respiratory tract

disease, or both, and the clinical spectrum is similar to that of *M pneumoniae* infection. Pharyngitis or laryngitis may occur 1 to 3 weeks before bronchitis or pneumonia, and cough may persist for weeks. The diagnosis is established by NAATs; both *C pneumoniae* and *M pneumoniae* are included in widely available respiratory and pneumonia multiplex PCR panels, whereas *C. psittaci* is not. Treatment with azithromycin, doxycycline, or levofloxacin is effective in ameliorating the signs and symptoms of *C pneumoniae* infection.

KEY CONCLUSIONS

- The chlamydiae share a common mode of replication but differ in tropisms.
- *Chlamydia trachomatis* biovars A-C cause trachoma, a leading cause of blindness in impoverished populations.
- *C trachomatis* biovars D-K are sexually transmitted, cause urogenital disease, and neonatal infection after vaginal delivery to infected mothers.
- *C trachomatis* biovars L_1-L_3 cause genital and rectal disease by sexual transmission.
- Both *Chlamydophila* species cause pneumonia.
- *Chlamydophila psittaci* is a zoonotic pathogen that causes psittacosis and is acquired from birds.
- *Chlamydophila pneumoniae* resembles *Mycoplama pneumoniae* in its clinical features with nonproductive cough and patchy lung infiltrates.
- Apart from *C psittaci,* all the chlamydiae are exclusively human pathogens.
- Azithromycin or doxycycline are used for therapy of infections with the chlamydiae.

CASE STUDY

An Unanticipated Result

A 29-year-old man presents with a 2-day history of burning on urination and a thin, watery urethral discharge. He had unprotected sex with a new female partner 4 weeks ago. A Gram stain reveals 50% polymorphonuclear (PMN) and 50% mononuclear leukocytes. No microorganisms are visible.

QUESTIONS

1. Which is the most likely cause of this man's urethritis?

A. *Neisseria gonorrhoeae*
B. *Ureaplasma urealyticum*
C. *Chlamydia trachomatis*
D. *Trichomonas vaginalis*
E. *Mycoplasma hominis*

2. Which is the most sensitive test to detect the pathogen?

A. Culture
B. Serology
C. Immunofluorescent assay
D. Nucleic acid amplification assay

3. To which is the causative microbe susceptible?

A. Not susceptible to antibiotics
B. Most susceptible to β-lactam antibiotics
C. Resistant to quinolones
D. Susceptible to macrolides

ANSWERS

His mouth was dry and sticky; a heavy fog weighed down his brain.

—Anton Chekhov (a physician): *Typhus*

OVERVIEW

The agents covered in this chapter are all small, Gram-negative, if they stain at all, intracellular coccobacilli that are arthropod-borne to humans. Their epidemiology, however, is determined largely by the distribution and habits of their arthropod vectors (ticks, fleas, mites, and sandflies). Clinical features also differ by pathogen, but all respond to doxycycline therapy. The rickettsioses fall into two categories: spotted fever group (SFG) and typhus group (TG). With molecular tools, including sequencing, many new rickettsia are being described in both groups, but only the most important currently or historically are presented here.

In the SFG are tick-transmitted *Rickettsia rickettsii* that causes Rocky Mountain spotted fever (RMSF) and mite-borne *Rickettsia akari* that causes rickettsialpox. In the TG is louse-borne *Rickettsia prowazekii* that causes epidemic typhus, flea-transmitted *Rickettsii typhi* that causes murine typhus, and mite-borne *Orientia tsutsugamushi* that causes scrub typhus. By far the most important rickettsiosis in the United States in both incidence and severity is RMSF, whereas epidemic typhus ranks foremost historically in Europe. Both RMSF and typhus are characterized by fever, headache, myalgia, and rash. In RMSF, the rash appears first on the palms and soles, wrists, and ankles and migrates centripetally; whereas in epidemic typhus, the rash moves in the opposite direction beginning on the trunk and spreading to the extremities. Both diseases may be fatal as the result of severe vascular collapse.

Ehrlichia and *Anaplasma* are both transmitted by ticks. *Ehrlichia chaffeensis* primarily infects monocytes and causes human monocytic ehrlichiosis (HME) and *Anaplasma phagocytophilum* infects polymorphonuclear granulocytes and causes human granulocytic anaplasmosis (HGA). Both HME and HGA manifest with fever, headache, malaise, leukopenia, and thrombocytopenia. A rash may be seen, but is neither common nor prominent.

Bartonella species are louse-borne *Bartonella quintana* that causes trench fever, sandfly-borne *Bartonella bacilliformis* that invades red blood cells and causes Oroya fever and verruga peruana, and *Bartonella henselae* (bacillary angiomatosis and cat-scratch disease) that is transmitted by scratches or

bites of cats or their fleas.

Obligate intracellular parasites

This chapter takes up four groups of Gram-negative bacilli whose obligate or preferred growth is inside eukaryotic cells where they rely on the host cell for some essential nutrients. They are animal pathogens transmitted by arthropods to humans who are in the wrong place at the wrong time. The diseases vary depending on whether the target is endothelial cells, phagocytes, or erythrocytes. Most have prolonged fevers, often with vasculitis. These include classic ones like Rocky Mountain spotted fever (RMSF), typhus, and cat-scratch disease (CSD), as well as recently recognized infections like human ehrlichiosis and anaplasmosis.

• *RICKETTSIA*

BACTERIOLOGY

STRUCTURE

Gram-negative coccobacilli stained best by immunofluorescence

Abundant outer membrane proteins

Rickettsiae are small coccobacilli, which measure no more than 0.3 to 0.5 µm. Although the Gram reaction is negative, rickettsiae take the usual bacterial stains poorly and are better demonstrated by specific immunofluorescence. The ultrastructural morphology, which is similar to that of other Gram-negative bacteria, includes a Gram-negative type of cell envelope, ribosomes, and a nuclear body. Chemically, the cell wall contains lipopolysaccharide and at least two large proteins in the outer membrane, as well as peptidoglycan. The outer membrane proteins extend to the cell surface, where they are the most abundant protein present. They are discussed here as members of either the SFG or TG. Due to differences in protein composition and its lack of lipopolysaccharide, *Orientia tsutsugamushi* (formerly *R tsutsugamushi*) has been placed in a separate genus.

METABOLISM

Rickettsia grows freely in the cytoplasm of eukaryotic cells to which they are highly adapted, in contrast to *Ehrlichia* and *Bartonella* that replicate in cytoplasmic vacuoles. Rickettsiae can be grown only in the living eukaryotic cells found in cell cultures, organ cultures, and embryonated eggs. *Rickettsia* is able to adhere to a wide variety of cell types through the binding of outer membrane proteins. They enter cells by induced phagocytosis and escape to the cytoplasms by elaboration of a phospholipase. In the cytoplasm the SFG *rickettsiae* move about utilizing an actin-based motility similar to that already described for *Listeria* and *Shigella* (see Chapters 26 and 33). Intracytoplasmic growth eventually produces lysis of the cell.

*** Grow in cytoplasm following induced endocytosis**

*** Exogenous cofactors and ATP required**

*** Lose infectivity outside host cell**

The obligate intracellular parasitism of *Rickettsiae* has several interesting features. Failure to survive outside the cell is related to requirements for nucleotide cofactors (coenzyme A, NAD), amino acids, phosphorylated sugars, and ATP. Outside the host cell, *Rickettsiae* not only cease metabolic activity, but leak protein, nucleic acids, and essential small molecules. This instability leads to rapid loss of infectivity because the penetration of another cell requires energy. Over time, *Rickettsiae* have lost some of their core metabolic capabilities by reductive evolution and instead use transport systems which extract these essential elements from their host cells.

RICKETTSIAL DISEASE

EPIDEMIOLOGY

Most rickettsiae have animal reservoirs and are spread by ticks, lice, fleas, or mites, which are prominent components of their life cycles (**Table 40-1**). The global distribution of specific rickettsial infections is determined by climate, reservoir, vector, and human interactions as detailed under the clinical aspects of each entity. These epidemiologic differences of rickettsial infections are

important despite their shared features in pathogenesis. Rickettsial infections of humans usually result in clinical illness.

TABLE 40–1 **Features of *Rickettsia, Ehrlichia, Anaplasma,* and *Bartonella***

ORGANISM	TARGET	DISEASE	DISTRIBUTION	VECTOR	RESERVOIR
Rickettsia rickettsii	Vascular endothelium	Rocky Mountain spotted fever	North, Central, and South America	Tick	Rodents, dogs
R conorii, R africae, R australis	Vascular endothelium	Other spotted fevers	Worldwide	Tick	Rodents, dogs

*Only at elevations between 1 and 3 km in the Andes mountains.

PATHOGENESIS

*** Infect vascular endothelium with vasculitis, thrombosis**

*** Increased vascular permeability leads to hypotension**

Following transmission from the salivary gland of infected ticks the bacteria spread locally creating a necrotic eschar. The major rickettsial species have a tropism for vascular endothelium. The primary pathologic lesion is a vasculitis in which they multiply in the endothelial cells lining the small blood vessels (**Figure 40–1**). Pathophysiologically, this leads to increased vascular permeability, hypovolemia, and hypotension. Focal areas of endothelial proliferation and perivascular infiltration leading to thrombosis and leakage of red blood cells into the surrounding tissues account for the rash and petechial lesions. Vascular lesions occur throughout the body and produce the systemic manifestations of the disease. These lesions are most apparent in the skin but are most lethal in the adrenal glands. *Orientia tsutsugamushi* infects mononuclear

cells but still produces fever and rash.

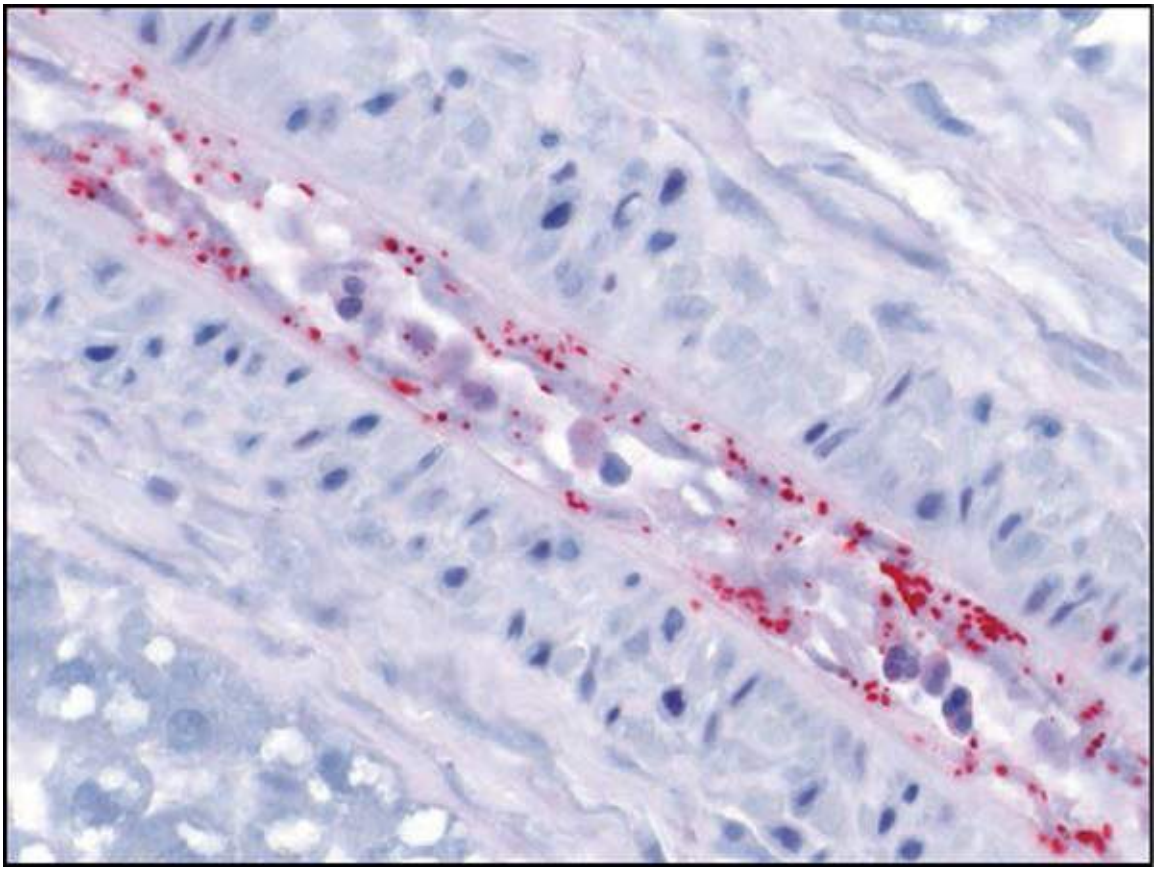

FIGURE 40–1. Rickettsial vasculitis. Immunohistochemical stain shows *Rickettsia rickettsia* (red) in endothelial cells that line the blood vessel. (Reproduced with permission from Biggs HM, Behravesh CB, Bradley KK, et al: Diagnosis and Management of Tickborne Rickettsial Diseases: Rocky Mountain Spotted Fever and Other Spotted Fever Group Rickettsioses, Ehrlichioses, and Anaplasmosis - United States, *MMWR Recomm Rep* 2016 May 13;65(2):1-44.)

RICKETTSIAL DISEASE: CLINICAL ASPECTS

SPOTTED FEVER GROUP

Tick-borne rickettsioses worldwide

The most important rickettsial disease in North America is RMSF, which is caused by *Rickettsia rickettsii.* A number of other spotted fever rickettsioses are found in other parts of the world (Table 40-1); the name often reveals the locale (eg, Mediterranean spotted fever, Marseilles fever). They are caused by

Rickettsia species, serologically related to, but distinct from, *R rickettsii* (eg, *R conorii* and *R africae*). Another less severe spotted fever, rickettsialpox, also occurs in North America.

▪ Rocky Mountain Spotted Fever

RMSF is an acute febrile illness that occurs in association with residential and recreational exposure to wooded areas where infected ticks exist. The frequency of reported cases of spotted fever group (SFG) rickettsia in the United States has increased 10-fold in the past 2 decades (**Figure 40–2**).

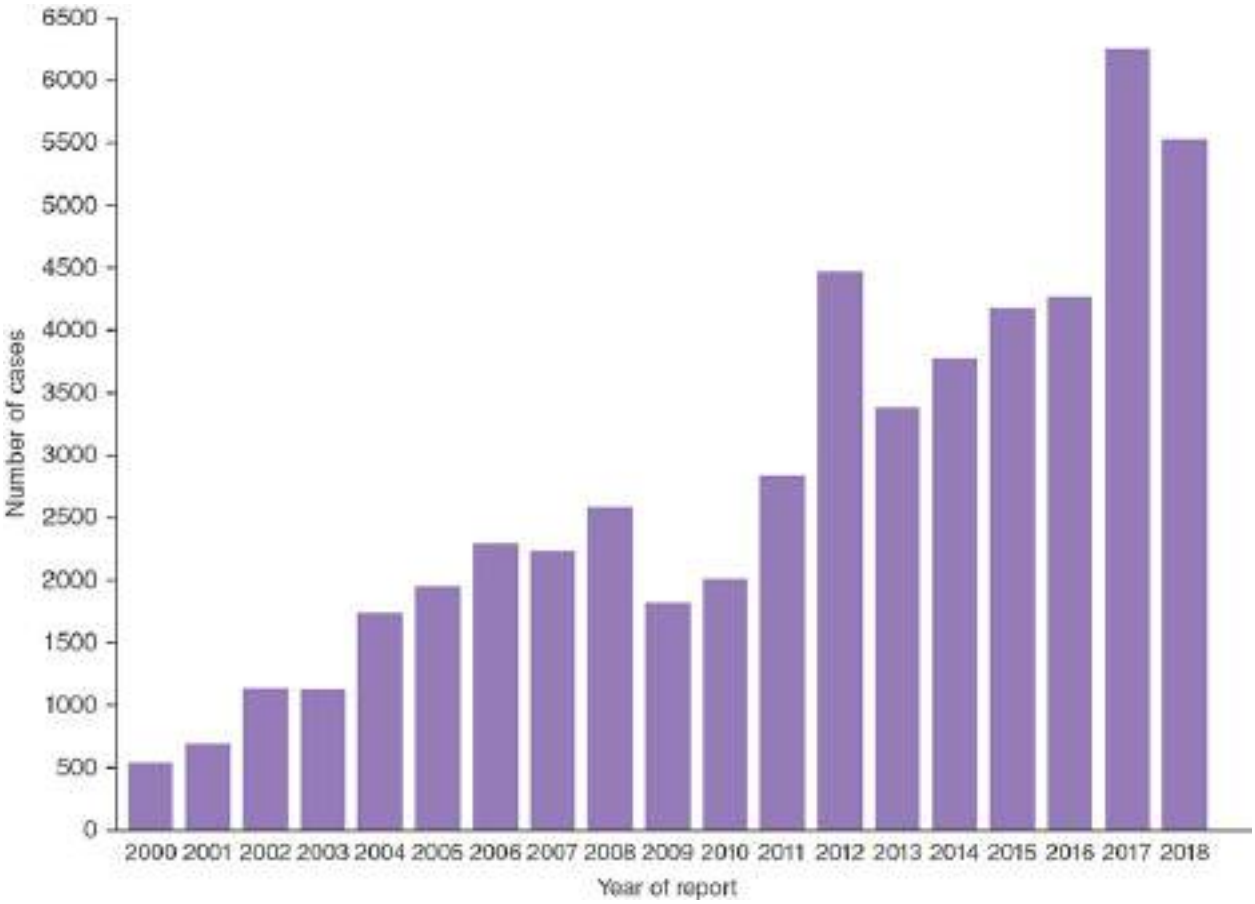

FIGURE 40–2. Yearly reported cases of spotted fever rickettsioses (SFR) in the United States, 2000-2018 (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. Rocky Mountain Spotted Fever (RMSF). April, 2020.)

Epidemiology

* Transovarial spread perpetuates tick infection

Rickettsia rickettsii is primarily a parasite of ticks. In the western United States,

the wood tick (*Dermacentor andersoni*) is the primary vector. *Dermacentor variabilis* is the most common tick vector in the eastern, central, and Pacific coastal U.S. The brown dog tick *Rhipicephalus sanguineus* is found throughout the United States and northern Mexico and is an emerging vector in the Southwest. Various *Amblyomma* ticks are vectors of SFG rickettsiae from Mexico to Argentina. *Rickettsia rickettsii* does not kill its arthropod host, so the parasite is passed through unending generations of ticks by transovarial spread. Adult females require a blood meal to lay eggs and thus may transmit the disease. Infected adult ticks have been shown to survive as long as 4 years without feeding.

Children at greatest risk

Rickettsia rickettsii is found in North, Central, and South America. Cases of RMSF have been reported from every state in the continental U.S., have increased markedly in recent years (**Figure 40–2**), and have extended their geographical range (**Figure 40–3**) in concert with changes in climate and tick habitat. The highest incidence now occurs in persons over the age of 40 years, whereas the highest case-fatality rate is among children less than 10 years old. Men outnumber women in SFG cases. The illness is generally seen between April and September because of increased exposure to ticks, but RMSF has occurred in all months. A history of tick bite can be elicited in approximately 70% of cases.

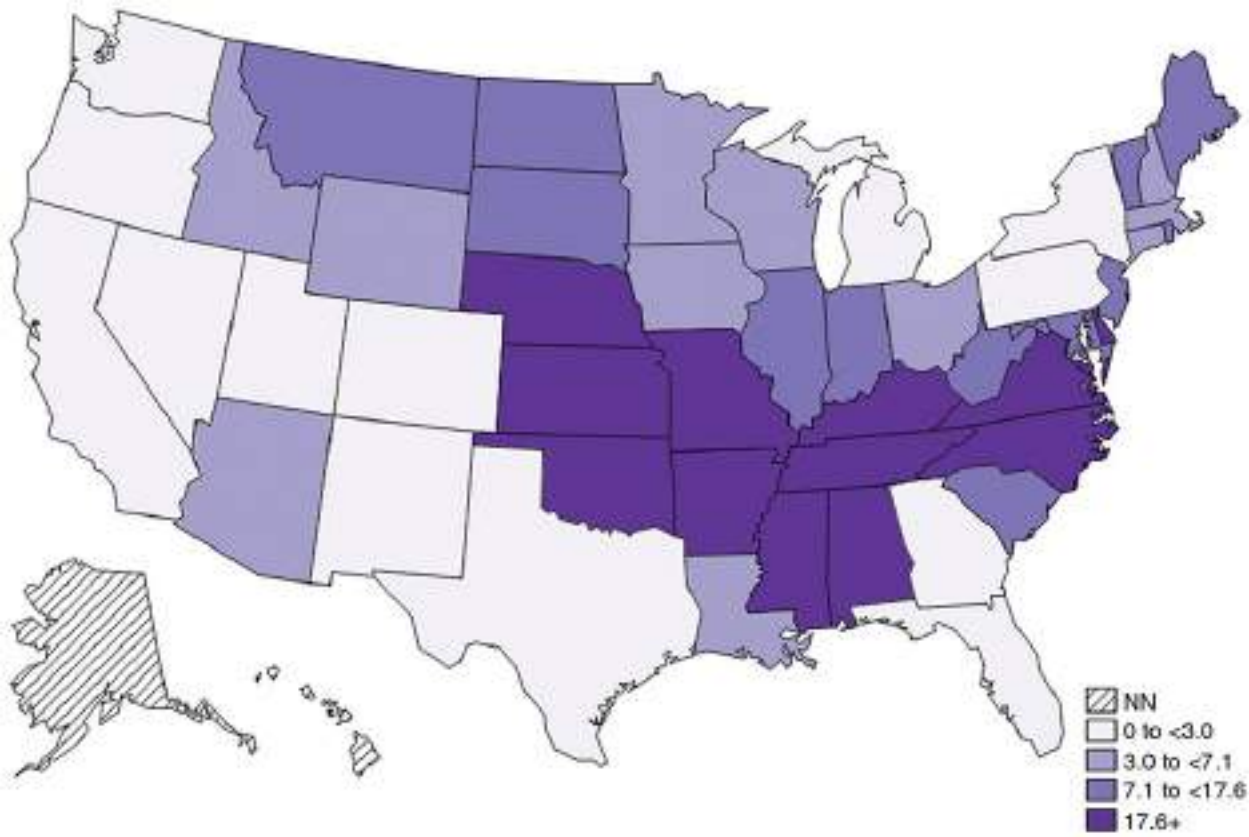

FIGURE 40–3. Geographical distribution and annual incidence of spotted fever rickettsioses (SFR) in the United States, 2018. The geographical range and annual incidence (per million persons) for cases of SFR in the United States for 2018 are shown. Both the range and frequency of RMSF are increasing. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. Rocky Mountain Spotted Fever (RMSF). April, 2020.)

Manifestations

Incubation 2 to 14 days

* Rash spreads from extremities to trunk, often involves palms and soles

The incubation period between the tick bite and the onset of illness is usually 6 to 7 days, but it may be from 2 days to 2 weeks. Fever, headache, rash, toxicity, mental confusion, and myalgia are the major clinical features. The rash is the most characteristic feature of the illness, but may not occur in up to one-third of cases. Rash usually develops on the second or third day of illness as small erythematous macules that rapidly become petechial (**Figure 40–4**). The lesions appear initially on the wrists and ankles and then spread up the extremities to the trunk in a few hours. A diagnostic feature of RMSF is the frequent appearance of

the rash on the palms and soles, a finding not usually seen in maculopapular eruptions associated with other rickettsial infections, including typhus. Muscle tenderness, especially in the gastrocnemius, is characteristic and may be extreme. If untreated, or occasionally in patients despite therapy, complications such as disseminated intravascular coagulation, thrombocytopenia, encephalitis, vascular collapse, and renal and heart failure may ensue.

FIGURE 40–4. Rocky Mountain spotted fever. The rash begins on the arms and legs and spreads centrally. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective,* 6th ed. New York, NY: McGraw Hill; 2008.)

Diagnosis

Unlike many infections, the most important consideration in the diagnosis of RMSF is the early initiation of doxycycline therapy solely on the basis of clinical signs, symptoms, and epidemiologic features. Doing so can be life saving. All the diagnostic methods have limitations in speed, sensitivity, specificity, or availability.

*** IFA serologic diagnosis**

Fourfold antibody increase confirms diagnosis

Culture of rickettsiae is both difficult and hazardous. Therefore, serologic tests are the primary means of a specific diagnosis of *R rickettsii*. The indirect fluorescent antibody (IFA) test on acute and convalescent serum specimens is the most sensitive and specific and is the reference method. IFA is usually available only in state health or reference laboratories. RT-PCR is relatively insensitive for the diagnosis of RMSF. It is often difficult to establish the diagnosis of RMSF early in the course of illness. However, antibodies may appear by the sixth or seventh day of illness, and a fourfold rise in antibody titer between acute serum and convalescent serum establishes the diagnosis.

Treatment

*** Early treatment life saving**

*** Doxycycline primary treatment**

Appropriate antibiotic therapy is highly effective if given during the first week of illness. If delayed into the second week or when pathologic processes such as disseminated intravascular coagulation are present, therapy may be futile. The antibiotic of choice is doxycycline for both children and adults. Sulfonamides may worsen the disease process and are thus contraindicated. Before specific therapy became available, the mortality rate associated with RMSF was approximately 25%. Treatment has reduced this figure to between 5% and 7%. Death results primarily in patients in whom clinical recognition and therapy are delayed into the second week of illness.

Prevention

*** Protective clothing, tick removal**

The major means of preventing RMSF is avoidance or reduction of tick contact. Frequent tick removal in tick-infested areas is important, because ticks generally must feed for 6 hours or longer before they can transmit the disease. Tick surveys in the Carolinas have shown infection in about 5% of samples.

▪ Rickettsialpox

*** Benign disease transmitted by rodent mites**

Rickettsialpox was first recognized in 1946 in New York City, where an average

of five cases per year continue to occur. It has been reported in other U.S. cities and in Eastern Europe, Korea, and South Africa. It is a benign rickettsial illness caused by *Rickettsia akari* and transmitted by a rodent mite. Distinguishing features of the disease include an eschar at the site of the bite and a vesicular rash. The house mouse and other semi-domestic rodents are the primary reservoirs. Humans acquire infection when the mite seeks an alternative host.

*** Local eschar followed by fever, vesicular rash**

*** Doxycycline therapy**

Rickettsialpox is a biphasic illness. The first phase is the local lesion at the bite, which starts as a papulovesicle and develops into a black eschar in 3 to 5 days. Fever and constitutional symptoms appear as the organism disseminates. The second phase of the disease is a diffuse rash distributed randomly in the body, which, like the local lesion, becomes vesicular and develops into eschars. However, the rash does not occur on the palms or soles. Rickettsialpox is self-limiting after 1 week, and no deaths have been reported. Doxycycline therapy shortens the course to 1 to 2 days.

TYPHUS GROUP

▪ Epidemic Louse-Borne Typhus Fever

*** Epidemic louse-borne due to *R prowazekii***

Primary louse-borne typhus fever is caused by *R prowazekii*, which is transmitted to humans by the body louse. Historically, it has appeared during times of misery (war, famine) that create conditions favorable to human body lice (crowding, infrequent bathing). This is the only rickettsial disease that can occur as an epidemic. Foci of typhus persist in parts of Africa, Latin America, and Asia. After the Civil War in Burundi in 1993, upwards of 100,000 cases of epidemic typhus occurred in refugees with case-fatality rates exceeding 5%. In disrupted countries, the homeless population is a focus. Epidemic typhus has not been seen in the United States for more than half a century. *R prowazekii* has been recovered from flying squirrels and their ectoparasites in the southeastern United States, and a few human cases of sylvatic typhus have occurred in these areas.

*** Human blood feeding plus louse defecation**

No transovarial transmission

The chain of epidemic typhus infection starts with *R prowazekii* circulating in a patient's blood during an acute febrile infection. The human body louse becomes infected during one of its frequent blood meals, and after 5 to 10 days of incubation, large numbers of rickettsiae appear in its feces. Since the louse defecates while it feeds, the organisms can be rubbed into the louse bite wounds when the host scratches the site. Dried louse feces are also infectious through the mucous membranes of the eye or respiratory tract. The louse dies of its infection in 1 to 3 weeks, and the rickettsiae are not transmitted transovarially.

*** Fever, headache, rash, high mortality**

*** Rash begins on trunk not extremities**

Fever, headache, and rash begin 1 to 2 weeks after the bite. A maculopapular rash occurs in 20% to 80% of patients and appears first on the trunk and then spreads centrifugally to the extremities, a pattern opposite to that of RMSF. Headache, malaise, and myalgia are prominent components of the illness. Complications include myocarditis and central nervous system dysfunction. In untreated disease, the fatality rate increases with age from 10% to as high as 60%. The diagnostic test of choice is serology, but therapy must be initiated immediately on clinical suspicion. Treatment with doxycycline is effective. Louse control is the best means of prevention and is particularly important in controlling epidemics. No effective vaccine is available.

Endemic (Murine) Typhus

*** Transmitted by rat fleas**

Endemic or murine typhus is caused by *Rickettsia typhi* and transmitted to humans by the rat flea (*Xenopsylla cheopis*). Human illness is incidental to the natural transmission of the disease among urban rats, which serve as the reservoir. The disease occurs worldwide but only 50 to 100 cases of murine typhus are reported in the United States each year. These typically occur along the Gulf Coast of Texas and in Southern California.

*** Resembles typhus but less severe**

Shares antigens with *R prowazekii*

The pathogenesis is similar to that of louse-borne typhus, but the history includes exposure to rats, rat fleas, or both. The flea defecates when it takes a blood meal, and the infected feces gain access through the bite wound. After an incubation period of 1 to 2 weeks, illness begins with headache, myalgia, and fever. The rash is maculopapular, not petechial; it starts on the trunk and then spreads to the extremities in a manner similar to typhus. Because of antigens shared by *R typhi* and *R prowazekii*, serologic tests may not separate the two diseases. In the untreated patient, fever may last 12 to 14 days. With doxycycline therapy, the course is reduced to 2 to 3 days. Mortality and complications are rare, even if the disease is untreated.

Scrub Typhus

*** Transmitted by rodent mite larvae**

*** Local eschar, fever, headache, rash, lymphadenopathy**

Scrub typhus is found predominantly in South Asia, China, and Indonesia (the scrub typhus triangle). The causative organism is *Orientia tsutsugamushi*, a rickettsial organism. The geographic range of scrub typhus is expanding with many cases now documented in India, Micronesia, and the Maldives. In 2016, it was elegantly documented by IFA, ELISA, and polymerase chain reaction (PCR) in southern Chile. Mites that infest rodents are the reservoir as well as vectors and transmit the rickettsiae to their own progeny via infected ova. Humans pick up the mites as they pass by low trees or brush. The mite larvae (chiggers) deposit rickettsiae as they feed. The typical initial lesion, a necrotic eschar at the site of the bite on the extremities, develops in only 50% to 80% of cases. Fever increases slowly over the first week, sometimes reaching 40.5°C. Headache, rash, and generalized lymphadenopathy follow later.

Serologic diagnosis by IFA

The maculopapular rash, which appears after about 5 days, is more evanescent than that seen with louse-borne or murine typhus. Hepatosplenomegaly and conjunctivitis may also appear. Specific diagnosis requires demonstration of a serologic response with the IFA test or PCR on blood or biopsy. The prognosis is good with doxycycline therapy, but the mortality rate of untreated patients is as high as 30%.

Ehrlichia and Anaplasma

*** No LPS or peptidoglycan**

*** Intracellular parasites of monocytes or PMNs**

Endocytotic vacuole resists lysosomal fusion

Ehrlichia and *Anaplasma* include several species of tick-borne Gram-negative bacteria that cause animal and human disease. The principal diseases are HME, which is due to *E chaffeensis*, and HGA, which is due to *Anaplasma phagocytophilum.* The structure of these species does not include lipopolysaccharide or peptidoglycan, but they can independently carry out basic metabolic tasks such as the Krebs cycle and generation of ATP. All are obligate intracellular pathogens that infect WBCs. The preferred bone marrow derived lineage of WBC varies with the animal species infected. In humans, *E chaffeensis* primarily infects mononuclear cells and *A phagocytophilum* polymorphonuclear cells (PMNs). They enter their preferred cell type by receptor-induced endocytosis and multiply in the endocytotic vacuole. The replicative cycle includes replicative forms and denser infectious forms in inclusions (morulae) similar to those seen in *Chlamydia*. Replication and survival are enhanced by blocking lysosomal fusion with their vacuole and resistance to killing by reactive oxygen species. No toxins or other virulence factors have been described. Injury in human disease is primarily related to inflammatory host responses and can be especially severe in HIV-positive patients.

*** Tick-borne and WBC associated**

E chaffeensis infections tend to occur in the southeastern and lower Midwestern United States and are transmitted by *Amblyomma* ticks, whereas HGA tends to cluster in the northern states with a distribution similar to Lyme disease and is also transmitted by *Ixodes* ticks (**Figures 40–5 and 40–6**). It has also been reported from other areas of the world, including Asia and Europe. HGA exceeds the frequency of ehrlichiosis and is second only to Lyme disease (see Chapter 37) as a tick-borne infection in the United States but both are increasing. HME is transmitted by the lone star tick (*Amblyomma americanum*), and the white-tailed deer is the animal reservoir. HGA is transmitted by *Ixodes* ticks, as is Lyme disease, and the animal reservoir is small mammals (eg, mice,

rats, voles). The findings are clinically similar to RMSF, but rashes are less commonly seen. Although rash is rare in anaplasmosis, it can be seen in 33% of cases of ehrlichiosis, especially later in the disease course. Mortality can exceed 3% in untreated ehrlichiosis, which is more severe in the elderly and may have neurologic (meningoencephalitis) findings.

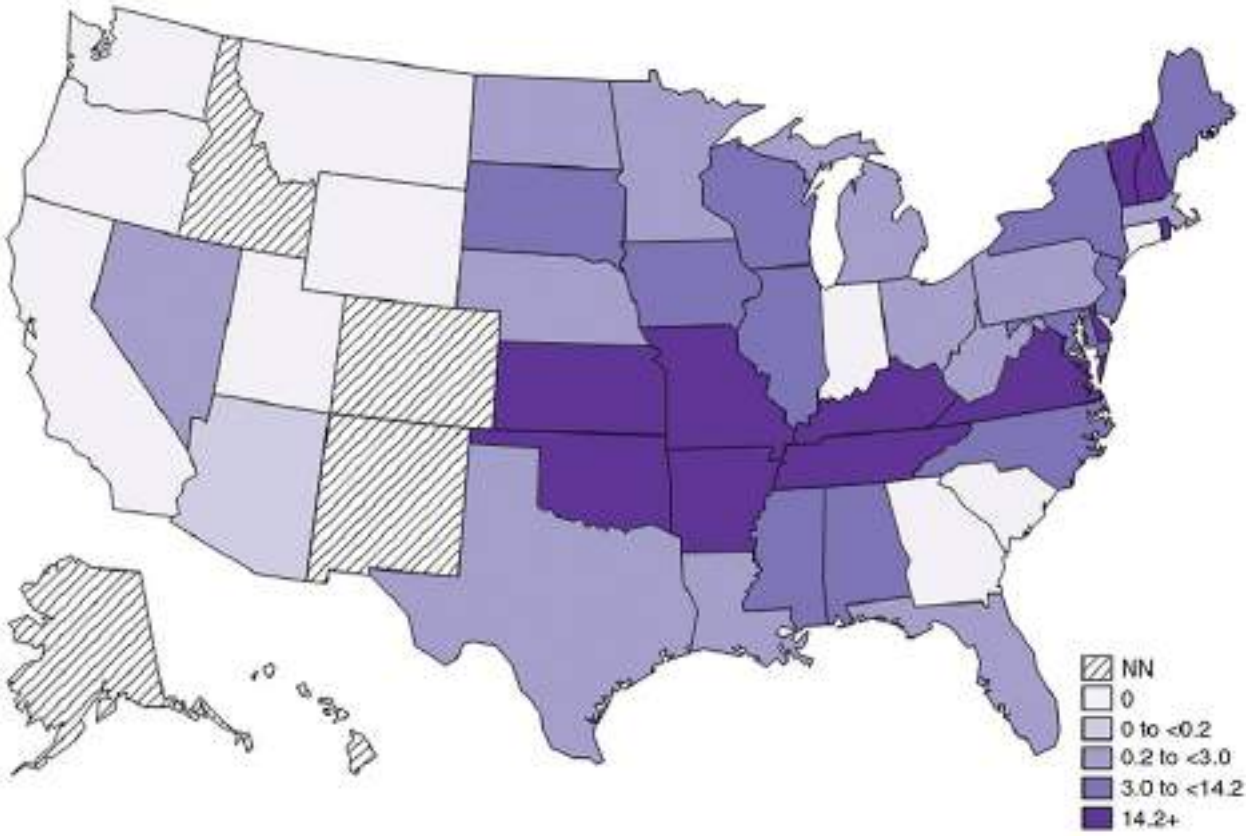

FIGURE 40–5. Geographical distribution and annual incidence of ehrlichiosis in the United States, 2018. The geographical range and annual incidence (per million persons) for cases of ehrlichiosis in the United States for 2018 are shown. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. *Ehrlichiosis*. March, 2020.)

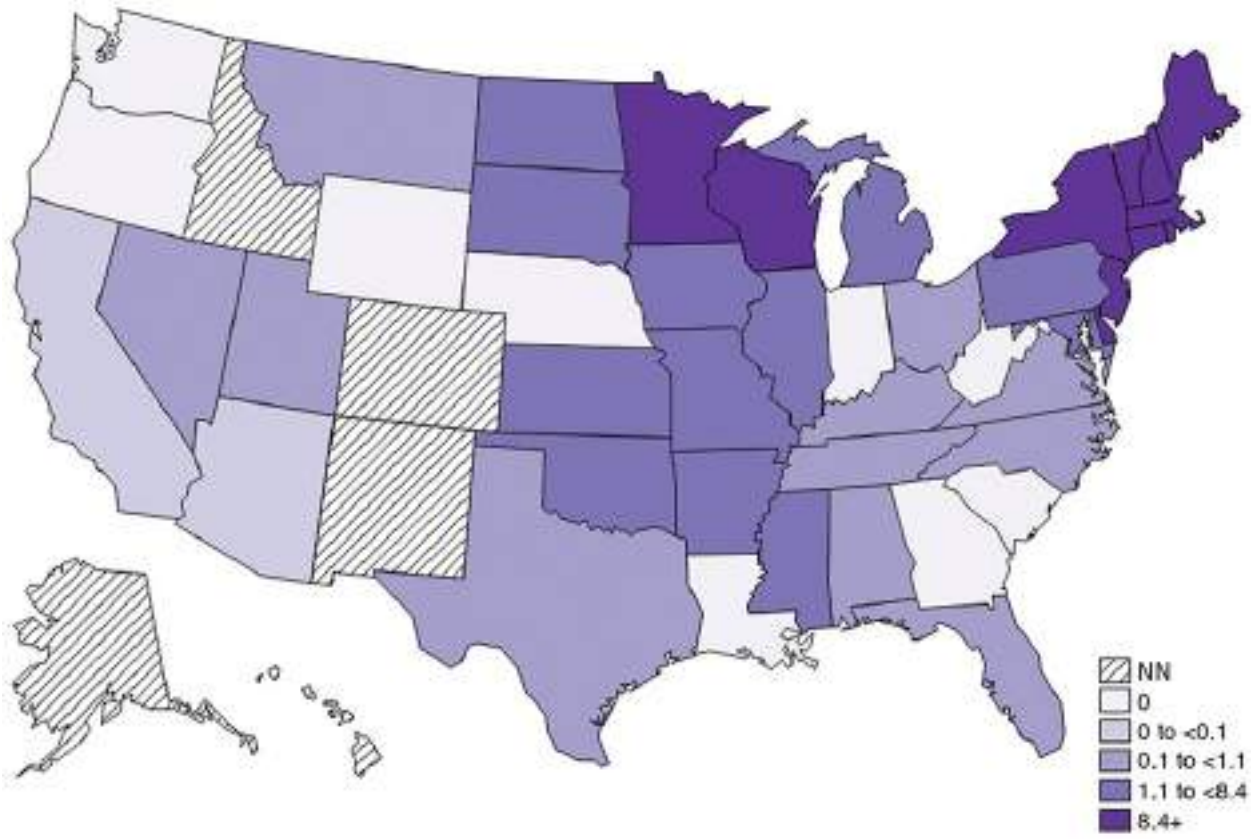

FIGURE 40–6. Geographical distribution and annual incidence of anaplasmosis in the United States, 2018. The geographical range and annual incidence (per million persons) for cases of Anaplasmosis in the United States for 2018 are shown. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. *Anaplasmosis*. March, 2020.)

Inclusions in monocytes (*Ehrlichia*) or granulocytes (*Anaplasma*)

Treatment is doxycycline

A preliminary diagnosis of ehrlichiosis or anaplasmosis may be suggested by observation of characteristic intracytoplasmic inclusions (morulae) in mononuclear cells (HME) or granulocytes (HGA), respectively (**Figure 40–7**). The diagnosis of either is usually made serologically by a fourfold or greater rise in IFA antibody or a titer greater than or equal to 1:64 to the specific antigen. PCR for both ehrlichiosis or anaplasmosis is more sensitive than it is for RMSF. Both IFA and PCR methods are the province of public health or reference laboratories. Clinical laboratory clues to human ehrlichiosis or anaplasmosis include a falling leukocyte count, thrombocytopenia, anemia, and impaired liver and renal function. Doxycycline is the drug of choice for both. The risk of infection can be reduced by avoiding wooded areas and tick bites.

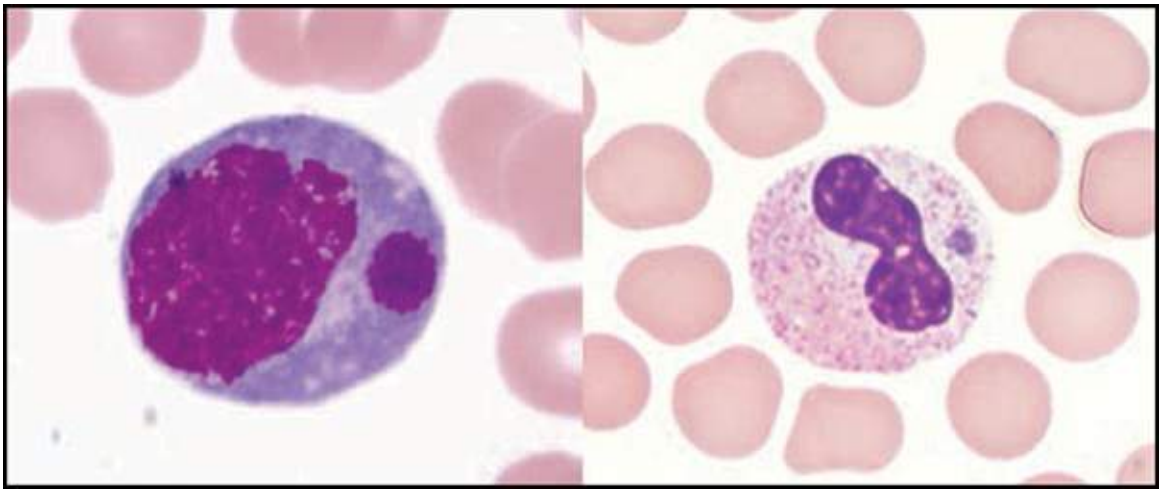

FIGURE 40–7. Peripheral blood smears of ehrlichiosis and anaplasmosis. Wright stain of peripheral blood smears showing intramonocytic morula associated with *Ehrlichia chafeensis* infection (left) and an intragranulocytic morula (right) associated with *Anaplasma phagocytophilum* infection. (Reproduced with permission from Biggs HM, Behravesh CB, Bradley KK, et al: Diagnosis and Management of Tickborne Rickettsial Diseases: Rocky Mountain Spotted Fever and Other Spotted Fever Group Rickettsioses, Ehrlichioses, and Anaplasmosis - United States, *MMWR Recomm Rep* 2016 May 13;65(2):1-44.)

Why is PCR useful for the diagnosis of ehrlichiosis and anaplasmosis but not RMSF?

Think ▸▸ Apply 40-1: The location of *Rickettsia rickettsia* is in endothelial cells (see Figure 40–1), but Ehrlichia and Anaplasma are found circulating in the bloodstream (see Figure 40–7). Similarly, blood-smear microscopy may disclose diagnostic circulating monocytes (ehrlichiosis) or granulocytes (anaplasmosis) with inclusions (morulae), whereas these are not found with RMSF.

Bartonella

*** Persist in vascular endothelium, RBCs**

*** Tumor-like vascular lesions filled with bacteria**

Bartonella species cause a variety of diseases, the best known of which are

trench fever (*Bartonella quintana*) and CSD (*B henselae*). They are coccobacillary Gram-negative bacilli genomically most closely related to the genus *Brucella* (see Chapter 36). Contrary to other bacteria discussed in this chapter, *Bartonella* species can be cultured on artificial media. Pathogenically they employ a unique strategy that involves persistence in an intraerythrocytic niche in both the bloodsucking arthropods that transmit them and the animals they infect. The mammalian reservoirs vary with each species. Upon infection *Bartonella* species are unable to enter erythrocytes directly but must first mature in a primary site thought to be vascular endothelial cells. Following release from the primary site, they attach to RBCs, form pits, invade, and multiply inside. Pathologically, tumor-like angiogenic lesions filled with immature capillaries, swollen endothelium, and bacteria may be produced. This cycle of multiplication within two vascular cell types also shields *Bartonella* from both innate and adaptive immune responses.

* *B quintana* causes trench fever

B quintana causes **trench fever,** which has a worldwide distribution. The name derives from its prominence in the trenches of World War I. This disease has a reservoir in humans, and its vector is the body louse. Most cases are mild or subclinical. When symptomatic, the patient has sudden onset of chills, headache, relapsing fever, and a maculopapular rash on the trunk and abdomen. Illness can last for 4 to 5 days, can recur in repeated 4- to 5-day bouts, or can persist uninterruptedly for up to 6 weeks. The disease is suggested by a history of louse contact. More recently, *B quintana* bacteremia and endocarditis have been described in homeless alcoholic men in both France and the United States. The diagnosis can be made by culturing the organism on special agar medium or by demonstrating seroconversion.

Bartonella bacilliformis, the first discovered *Bartonella*, is the cause of Oroya fever, an acute hemolytic anemia and, in its chronic phase, verruga peruana which features nodular, highly vascular skin lesions. The link between the two was not known until a Peruvian medical student inoculated himself with blood from a verruga peruana lesion and tragically died from Oroya fever. Infections with this agent are seen only in South America at intermediate altitudes, in keeping with the distribution of its sandfly vector.

Another species, *B henselae*, has been associated with a number of diseases, the most common of which is CSD. CSD is a febrile lymphadenitis with systemic symptomatology that sometimes persists for weeks to months. Approximately 25,000 cases occur in the United States each year. The disease is

transmitted by cat scratches or bites and perhaps by the bites of cat fleas. Manifestations may include skin rashes, conjunctivitis, encephalitis, and prolonged fever. Occasionally endocarditis and granulomatous or suppurative hepatosplenic and osseous lesions occur. In up to 10% of patients with CSD, ocular complications ensue of which the most dramatic is neuroretinitis with acute loss of vision. Its hallmark is the macular star (**Figure 40–8**). Fortunately, the blindness from the optic disk edema and retinal inflammation usually resolves over weeks to months with azithromycin therapy.

FIGURE 40–8. Macular star in retina of eye. Macular star associated with *Bartonella henselae* neuroretinis shows stellar macular exudation.(Used with permission from Steven R. Conlon, Sr. Photographer, Department of Pathology, Duke University, School of Medicine.)

*** CSD common in children**

*** Persistent lymphadenitis**

Neuroretinitis with transient blindness

Bartonella henselae has been isolated directly from the blood of cats, although the latter do not appear ill. It can also be isolated from human blood, lymph nodes, and other materials using special media. Organisms can sometimes be directly demonstrated in infected tissues by using the Warthin-Starry silver impregnation stain. A serologic response to *B henselae* antigens is the primary method of diagnosis. Azithromycin may reduce the duration of lymph node enlargement and symptoms.

Untreated AIDS with severe, protracted infections

Bacillary angiomatosis, a proliferative disease of small blood vessels of the skin and viscera, seen in patients with AIDS and other immunocompromised hosts, has been linked with *Bartonella* by molecular methods used to amplify ribosomal RNA gene fragments directly from tissue samples. Subsequently, both *B henselae* and *B quintana* have been cultured from patients with bacillary angiomatosis. Other conditions seen primarily in patients with AIDS, such as hepatitis and bacteremia with fever, have also been associated with *B henselae*. *Bartonella* infections in AIDS and other immunosuppressed patients, as well as the bacteremia observed in alcoholic and homeless men, generally respond to prolonged courses of azithromycin or doxycycline. *Bartonella* endocarditis usually requires valve replacement as well.

KEY CONCLUSIONS

- *Rickettsia*, *Ehrlichia*, *Anaplasma*, and *Bartonella* are all small, Gram-negative bacilli that are arthropod-borne and dwell inside target cells on which they depend for survival.
- *Rickettsia* consists of two groups: SFG and TGR.
- SFG includes tick-borne *R rickettsii* (RMSF) and mite-borne *R akari* (rickettsialpox).
- TG includes louse-borne *R prowazekii* (epidemic typhus) and flea-borne *R typhi* (endemic or murine typhus).
- Geographical range of mite-borne *Orientia tsutsugamushi* (scrub typhus) is increasing.
- Both RMSF and typhus are characterized by fever, headache, myalgia, and rash.
- Rash of RMSF begins on extremities and spreads to the trunk, whereas in typhus the rash begins centrally and moves to the periphery.

- *Ehrlichia* targets monocytes (HME) and *Anaplasma* targets granulocytes (HGA); both are tick-borne.
- HME and HGA both present with fever, headache, and malaise and cause diminished WBCs and platelets: rash is infrequent.
- *Bartonella* species are louse-borne *B quintana* (trench fever), sandfly-transmitted *B bacilliformis* (Oroya fever), and *B henselae* (bacillary angiomatosis and cat-scratch disease). They are transmitted by scratches or bites of cats or their fleas.
- Doxycycline or azithromycin is effective for all the infections above and may be life saving.

CASE STUDY

Fever and Rash Following Tick Bite

A 6-year-old girl from North Carolina was in her usual state of good health until 10 days before admission, when she had a tick removed from her scalp. She developed a sore throat, malaise, and a low-grade fever 8 days after tick removal. She was seen by her pediatrician when she began developing a pink, macular rash, which started on her palms and lower extremities and spread to cover her entire body. The pediatrician's diagnosis was viral exanthem. One day before admission, she developed purpura, emesis, diarrhea, myalgias, and increased fever. On the day of admission, she was taken to her local hospital emergency room because of mental status changes. Her physical examination was significant for diffuse purpura; periorbital, hand, and foot edema; cool extremities with weak pulses; and hepatosplenomegaly. Her laboratory studies revealed: Na^+ level of 125 mmol/L, platelet count 26,000/mm^3, WBC count 14,900/mm^3, hemoglobin level of 8.8 g/L, and greatly increased coagulation times. Ampicillin therapy was begun, and she was intubated but died soon after transfer to another institution.

QUESTIONS

1. What feature in this patient's history is most helpful?

A. Sore throat
B. Rash
C. Tick bite
D. Diarrhea
E. Leukocytosis

2. To confirm a diagnosis of Rocky Mountain spotted fever, what would be the most useful laboratory test?

A. Culture
B. Gram stain
C. Serology
D. Darkfield examination

3. The primary cause of the fatal outcome in this patient is the tropism of *Rickettsia* for:

A. Skin
B. WBCs
C. Enterocytes
D. Muscle
E. Blood vessels

ANSWERS

1. (C)

2. (C)

3. (E)

chapter 41

Dental and Periodontal Infections

Dental caries, periodontitis, and the tooth loss and other sequelae that follow are secondary to the microbial build-up on teeth called plaque. The prevention and/or halting of the progression of these diseases relies on the elimination of dental plaque from the tooth surfaces. In addition to causing caries and chronic periodontitis, the bacteria of dental plaque play a role in more aggressive forms of periodontitis and necrotizing periodontal diseases.

DENTAL PLAQUE

Dental plaque is a bacterial biofilm

Plaque forms in stages

Dental plaque is an adherent dental deposit that forms on the tooth surface composed almost entirely of bacteria derived from the resident microbiota of the mouth. From a microbial pathogenesis standpoint, dental plaque is the most prevalent and densest of human biofilms (**Figure 41–1**). The biofilm first forms in relation to the dental pellicle, which is a physiologic thin organic film covering the mineralized tooth surface composed of proteins and glycoproteins derived from saliva and other oral secretions. As the plaque biofilm evolves, it does so in relation to the pellicle, not the mineralized tooth itself. The formation of plaque takes place in stages and layers at two levels. The first is the anatomic location of the plaque in relation to the gingival line. The earliest plaque is supragingival, which may then extend to subgingival plaque. The second level is the layering within the plaque, the bacterial species involved, and the bacteria/pellicle and bacteria/bacteria binding mechanisms required.

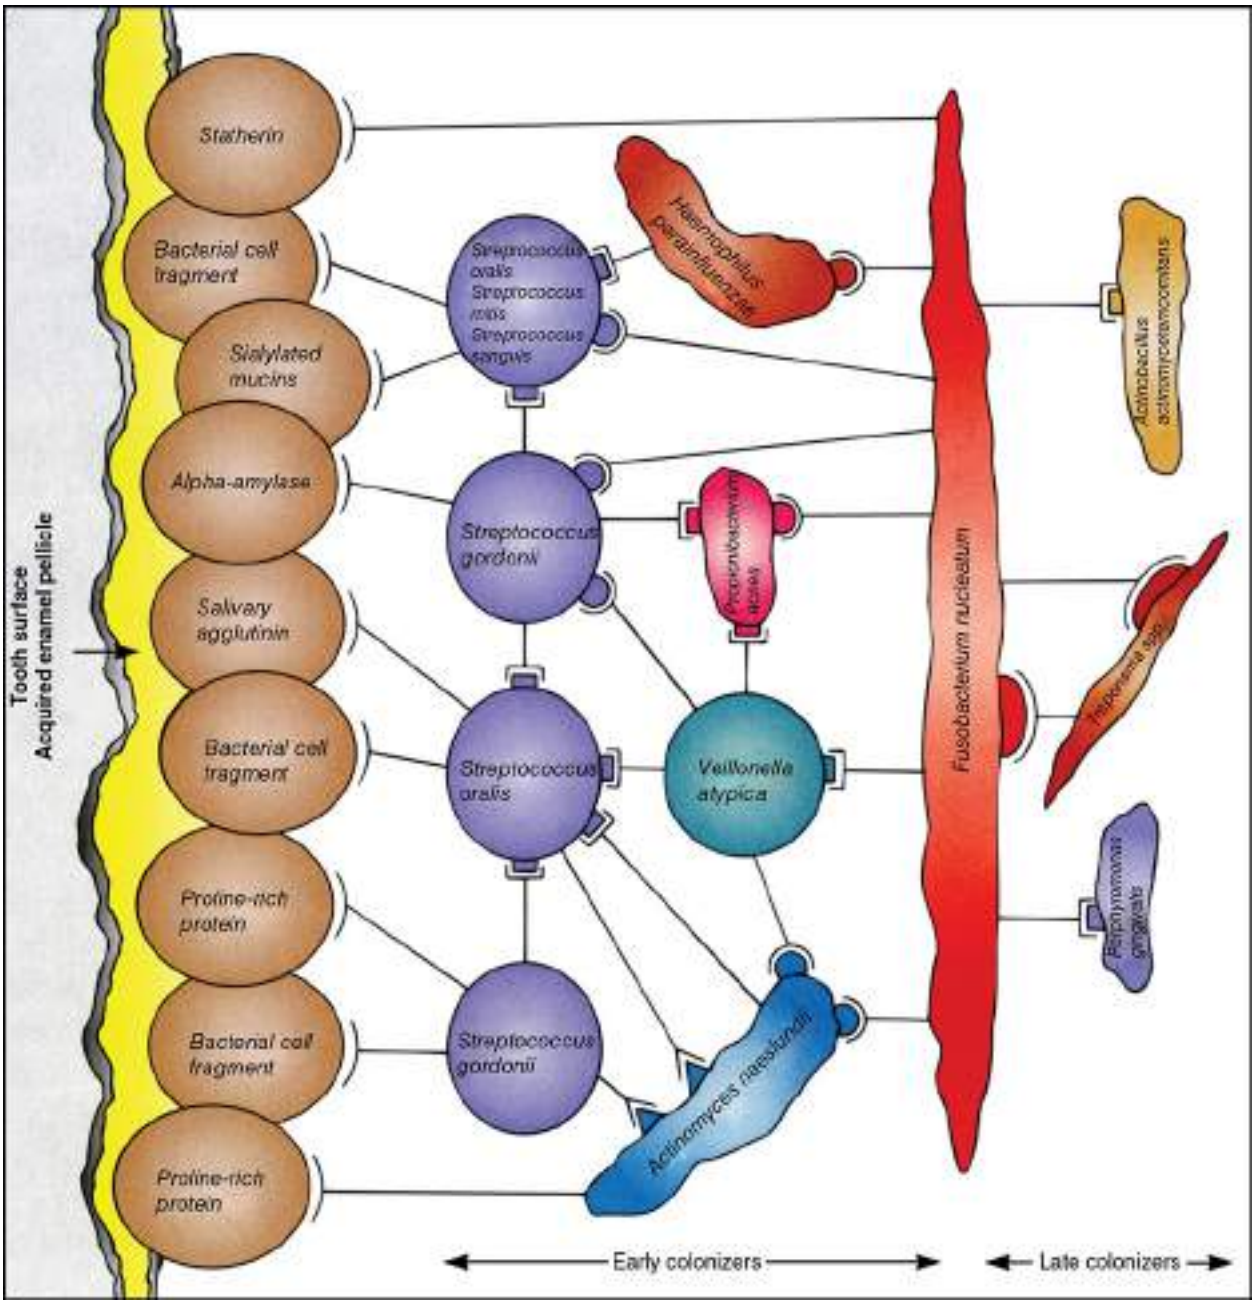

FIGURE 41–1. Dental plaque biofilm. The stages of formation of the bacterial biofilm called dental plaque are shown. Early colonizers bind to the enamel pellicle and late colonizers bind to the other bacteria. (Reproduced with permission from Willey J, Sherwood L, Woolverton C: *Prescott's Principles of Microbiology*. New York, NY: McGraw Hill; 2008.)

Attachment of bacteria to dental pellicle begins colonization

Early and late colonizers differ

Adhesion mechanisms create biofilm

The initial supragingival plaque primarily involves Gram-positive bacteria using specific ionic and hydrophobic interactions as well as lectin-like (carbohydrate binding) surface structures to adhere to the pellicle and to each other. The prototype early colonizer is *Streptococcus sanguis*, but other streptococci (*S mutans, S mitis, S salivarius, S oralis, S gordonii*), lactobacilli, and *Actinomyces* species are usually present. If the early colonizers are undisturbed, the late colonizers appear in the biofilm in as little as 2 to 4 days. These are primarily Gram-negative anaerobes including anaerobic spirochetes. These include *Fusobacterium, Porphyromonas, Prevotella, Veillonella, Treponema denticola,* and more *Actinomyces* species. These bacteria use similar mechanisms to bind to the early colonizers and to each other. This sets up a highly complex biofilm in which coaggregation involves structures that the bacteria brought with them (lectins), quorum sensing, and new metabolic activity. An example of the latter is the formation of extracellular glucan polymers, which act like a cement binding the plaque biofilm together. The biofilm also fastens nutrient and growth regulatory relationships between its members and provides a shield from the outside. In all, there are thought to be 300 to 400 bacterial species present in mature dental plaque. The structure of the involved bacteria is shown in Figure 41–1 and its gross and microscopic appearance in **Figure 41–2.**

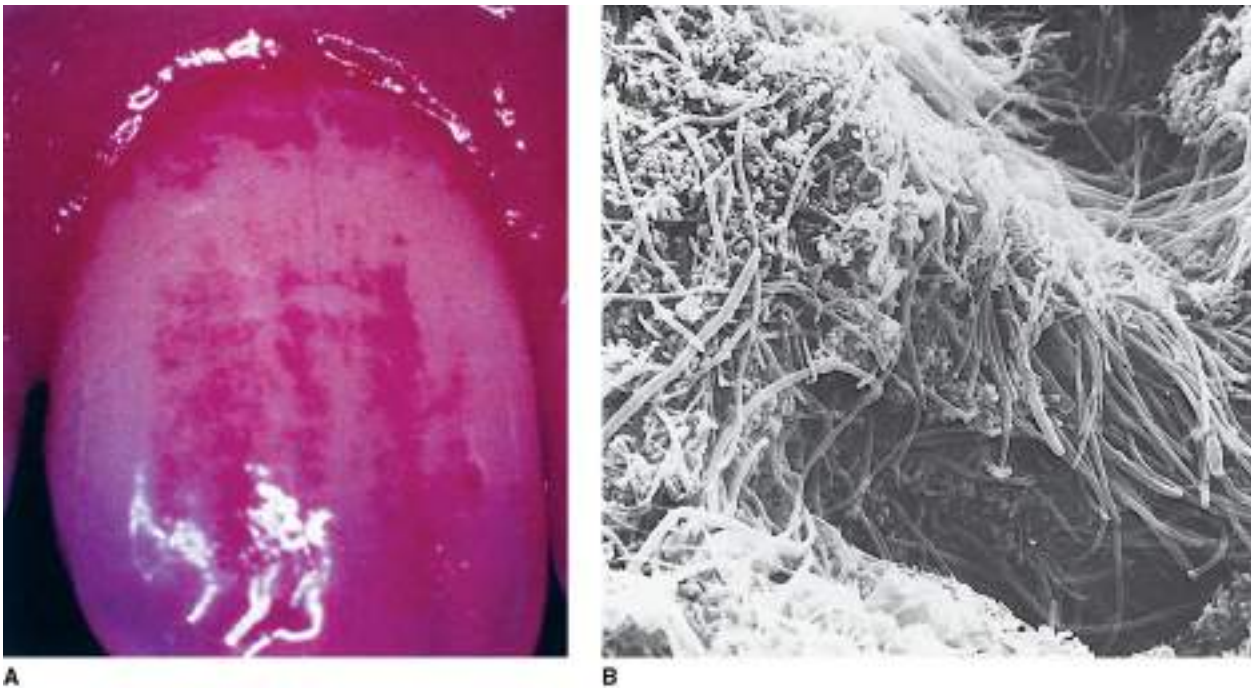

FIGURE 41–2. Dental plaque. A. Disclosing tablets containing vegetable dye stain heavy plaque accumulation at the junction of the tooth and gingiva. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Plaque accumulates in non–self-cleansing areas

Subgingival plaque differs in bacterial composition

Dental plaque would coat the tooth surfaces uniformly but for its physical removal during chewing and other oral activities. Characteristically, plaque remains in the non–self-cleansing areas of the teeth such as pits and fissures, along the margins of the gingiva, and between the teeth. For this reason, plaque-related diseases—caries, gingivitis, and periodontitis—occur most frequently and most severely at these locations. Subgingival plaque extends below the gum line to the sulcus around the tooth and periodontal pockets, which are pathologic extensions of the sulcus. This plaque has a thin adherent layer attached to the tooth surface and a nonadherent bacterial zone between that and the epithelial cells lining the sulcus. Supragingival plaque lacks such a distinct nonadherent zone. The bacterial composition of subgingival plaque is shifted toward the Gram-negative anaerobic bacteria and spirochetes. In addition to the late colonizers cited above, it may also include members of the *Campylobacter*, *Capnocytophagia,* and *Eikenella* genera.

Removal of plaque prime element of oral hygiene

Chemicals may be used along with brushing and flossing

Because the causative organisms of both dental caries and chronic periodontitis are believed to be in the dental plaque, a prime method for maintaining oral health is regular home care practices for plaque removal. Dental plaque cannot be effectively removed from the teeth solely by chemical or enzymatic means, and the use of antibiotics for prophylactic inhibition of plaque formation cannot be clinically justified, although patients undergoing long-term antibiotic treatment for other medical reasons demonstrate a lower incidence of caries and periodontal disease. Antiseptic substances that bind to tooth surfaces and inhibit plaque formation, such as the bis-biguanides, chlorhexidine, and alexidine, have been shown to be effective in reducing plaque, caries, and gingival inflammation. A commercial preparation containing 0.12% chlorhexidine can be used in controlling dental plaque and associated disease. Toothpaste and mouth rinse additives such as phenolic compounds, essential oils, triclosan, fluorides, herbal extracts, and quaternary ammonium compounds have been shown to have some plaque-reducing ability as well. The use of these substances must be accompanied by proper tooth brushing, flossing, and periodic

professional cleaning to ensure effective disease prevention.

DENTAL CARIES

Caries produced by plaque bacteria

Dental caries are the result of progressive destruction of the mineralized tissues of the tooth. This is primarily caused by the acid products of glycolytic metabolic activity when the plaque bacteria are fed the right substrate. The basic characteristic of the carious lesion is that it progresses inward from the tooth surface, either the enamel-coated crown or the cementum of the exposed root surface, involving the dentin and finally the pulp of the tooth (**Figures 41–3** and **41–4**). From there, infection can extend into the periodontal tissues at the root apex or apices.

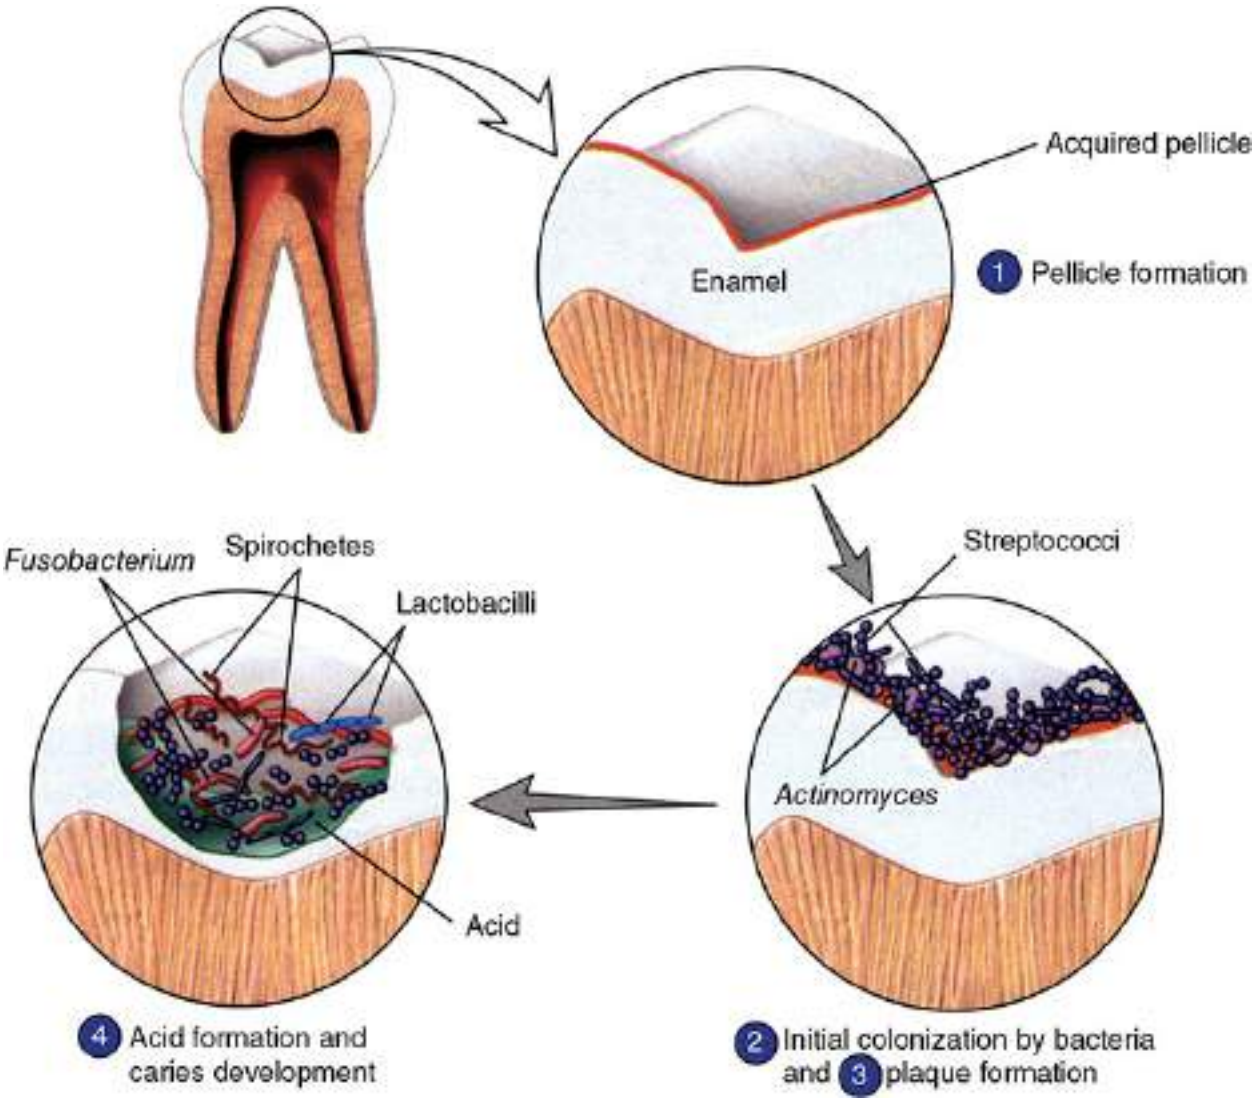

FIGURE 41–3. Cariogenesis. A microscopic view of pellicle and plaque formation, acidification, and destruction of tooth enamel. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

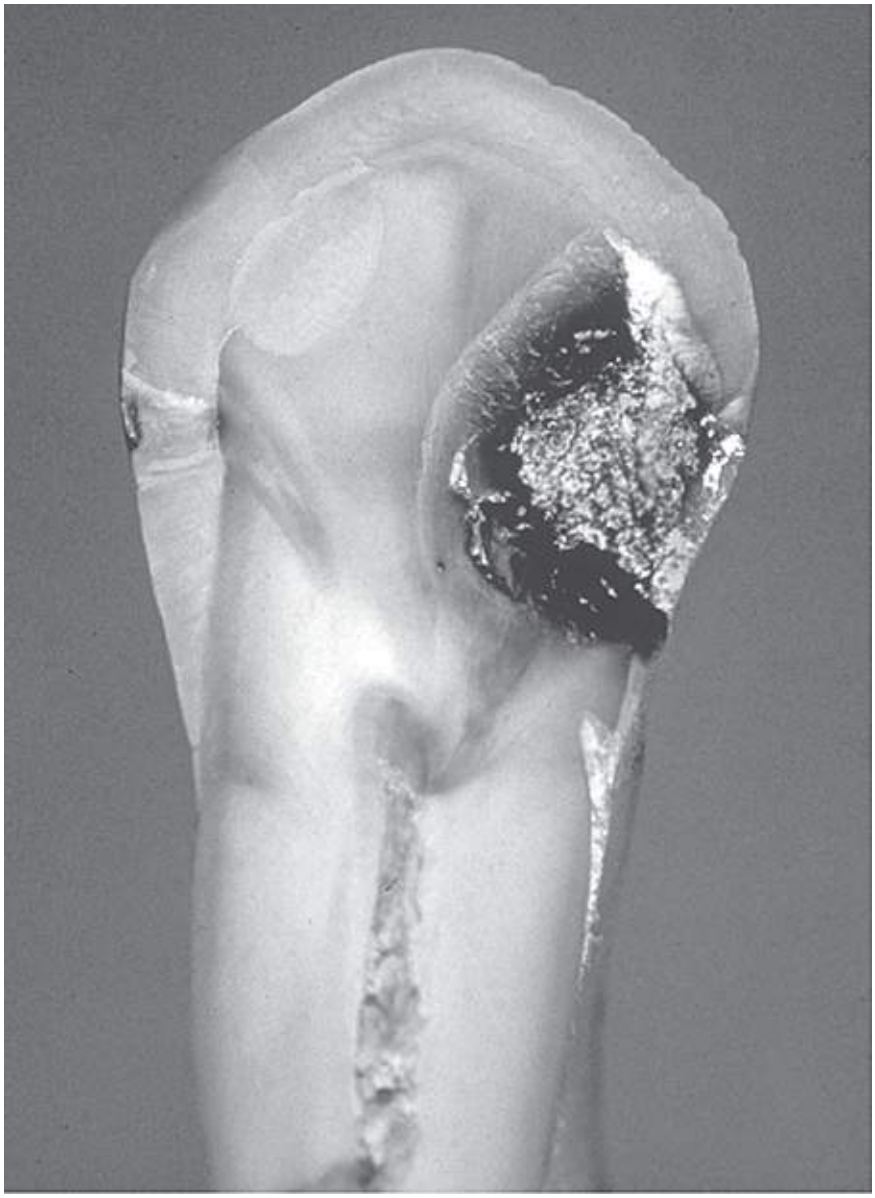

FIGURE 41–4. Hemisected human tooth showing an advanced carious lesion on the right side of the crown and a much smaller lesion on the left side. Note the progression of the lesion through the enamel and dentin, pointing toward the pulp chamber in the center of the tooth.

Members of biofilm produce acid

S mutans is most cariogenic

The microbial basis of dental caries has been long established based on work first with *Lactobacillus acidophilus* and then *S mutans.* Although *S mutans* is now regarded as the dominant organism for the initiation of caries, multiple members of the plaque biofilm participate in the evolution of the lesions. These

include other streptococci (*S salivarius, S sanguis, S sobrinus*), lactobacilli (*L acidophilus, L casei*), and actinomycetes (*A viscosus* and *A naeslundii*). The acid products produced by the interaction of *S mutans* with multiple species in the biofilm are the underlying cause of dental caries.

Demineralization is by acid production from dietary carbohydrate

Acid production facilitated by sticky carbohydrates

Demineralization–remineralization related to snacking

Dietary monosaccharides and disaccharides such as glucose, fructose, sucrose, lactose, and maltose provide an appropriate substrate for bacterial glycolysis and acid production to cause tooth demineralization. A possible edge for *S mutans* is its ability to metabolize sucrose more efficiently than other oral bacteria. It also has regulatory systems which stimulate the conversion of dietary carbohydrates to acid and intracellular storage polymers. Ingested carbohydrates permeating the dental plaque are absorbed by the bacteria, and are metabolized so rapidly that organic acid products accumulate and cause the pH of the plaque to drop to levels sufficient to react with the hydroxyapatite of the enamel, demineralizing it to soluble calcium and phosphate ions. Production of acid and the decreased pH are maintained until the substrate supply is exhausted. Upon exhaustion of the immediate source *S mutans* is able to survive long periods of sugar starvation. Obviously, foods with high sugar content, particularly sucrose, which adhere to the teeth and have long oral clearance times are more cariogenic than less retentive foodstuffs such as sugar-containing liquids. Once the substrate is exhausted, the plaque pH returns slowly to its more neutral pH resting level and some recovery can take place. This sets up a demineralization–remineralization cycle, which depends on carbohydrate refueling from the diet. With repeated snacking between meals, the plaque pH may never return to normal and demineralization dominates.

Polyglycans from sucrose important in adherence, carbohydrate storage

Acidogenesis prolonged by intracellular glycogen stores

An additional factor with sucrose is that it is also used in the synthesis of extracellular polyglycans such as dextrans and levans by transferase enzymes on the bacterial cell surfaces. This polyglycan production by *S mutans* contributes

to aggregation and accumulation of the organism on the tooth surface. Extracellular polyglycan may also increase cariogenicity by serving as an extracellular storage form of substrate. Certain microorganisms synthesize extracellular polyglycan when sucrose is available but then break it down into monosaccharide units to be used for glycolysis when dietary carbohydrate is exhausted. Some oral bacteria also use dietary monosaccharides and disaccharides internally to form glycogen, which is stored intracellularly and used for glycolysis after the dietary substrate has been exhausted; thus, the period of acidogenesis is again prolonged and the cariogenicity of the microorganism increased. These microorganisms can prolong acidogenesis beyond the oral clearance time of the substrate.

Extension to pulp and periapical locations complicate infections

Severe complications spread to bone or local fascia

The most common complications of dental caries are extension of the infection into the pulp chamber of the tooth (pulpitis), necrosis of the pulp, and extension of the infection through the root canals into the periapical area of the periodontal ligament. Periapical involvement may take the form of an acute inflammation (periapical abscess), a chronic nonsuppurating inflammation (periapical granuloma), or a chronic suppurating lesion that may drain into the mouth or onto the face via a sinus tract. A cyst may form within the chronic nonsuppurating lesion as a result of inflammatory stimulation of the epithelial rests normally found in the periodontal ligament. If the infectious agent is sufficiently virulent or host resistance is low, the infection may spread into the alveolar bone (osteomyelitis) or the fascial planes of the head and neck (cellulitis). Alternatively, it may ascend along the venous channels to cause septic thrombophlebitis. Because most carious lesions represent a mixed infection by the time cavities have developed, it is not surprising that most oral infections resulting from the extension of carious lesions are mixed and frequently include anaerobic organisms.

Greatest cause of tooth loss in children and young adults

Require microflora and suitable substrates for organic acid production

Dental caries is the single greatest cause of tooth loss in the child and young

adult. Its onset can occur very soon after the eruption of the teeth. The first carious lesions usually develop in pits or fissures on the chewing surfaces of the deciduous molars and result from the metabolic activity of the dental plaque that forms in these sites. Later in childhood, the incidence of carious lesions on smooth surfaces increases; these lesions are usually found between the teeth. The factors involved in the formation of a carious lesion are (1) a susceptible host or tooth, (2) the proper microflora on the tooth, and (3) a substrate from which the plaque bacteria can produce the organic acids that result in tooth demineralization.

Saliva protects by mechanical flushing and multiple chemical actions

The newly erupted tooth is most susceptible to the carious process. It gains protection against this disease during the first year or so by a process of posteruptive maturation believed to be attributable to improvement in the quality of surface mineral on the tooth. Saliva provides protection against caries, and patients with dry mouth (xerostomia) suffer from high caries attack rates unless suitable measures are taken. In addition to the mechanical flushing and diluting action of saliva and its buffering capacity, the salivary glands also secrete several antibacterial products. Thus, saliva is known to contain lysozyme, a thiocyanate-dependent sialoperoxidase, and immunoglobulins, principally those of the secretory IgA class. The individual importance of these antibacterial factors is unknown, but they clearly play some role in determining the ecology of the oral microbiota.

Fluoride produces more acid-resistant mineral phase of tooth

Proper levels of fluoride, either systemically or topically administered, result in dramatic decreases in the incidence of caries (50-60% reduction by water fluoridation, 35-40% reduction by topical application). In the case of systemic fluoridation, the protective effect is thought to result from the incorporation of fluoride ions in place of hydroxyl ions of the hydroxyapatite during tooth formation, producing a more perfect and acid-resistant mineral phase of tooth structure. Topical application of fluoride is believed to achieve the same result on the surface of the tooth by initial dissolution of some of the hydroxyapatite, followed by recrystallization of apatite, which incorporates fluoride ions into its lattice structure. Another important mode of action, namely, the inhibition of demineralization, and the promotion of remineralization of incipient carious lesions by fluoride ions in the oral fluid, has more recently been proposed as an

important anticaries mechanism of fluoride, perhaps more important than the other proposed mechanisms. In any event, fluoridation represents the most effective means known for rendering the tooth more resistant to the carious process.

CHRONIC PERIODONTITIS

Causes destruction of supporting tissues

Plaque-induced periodontal disease encompasses two separate disease entities: gingivitis and chronic periodontitis. These diseases are believed to be related, in that gingivitis, although a reversible condition, is thought to be an early stage leading ultimately to chronic periodontitis in the susceptible subject. The term **gingivitis** is used when the inflammatory condition is limited to the marginal gingiva and bone resorption around the necks of teeth has not yet begun. Gingivitis develops within 2 weeks in individuals who fail to practice effective tooth cleansing. **Chronic periodontitis** is used to describe the stage of chronic periodontal disease in which there is progressive loss of tooth support owing to resorption of the alveolar bone and periodontal ligament. Periodontitis can also lead to periodontal abscess when the chronic inflammatory state around the necks of the teeth becomes acute at a specific location.

Subgingival plaque causes collagen loss

Both gingivitis and chronic periodontitis are caused by bacteria in the dental plaque that lie in close proximity to the necks of the teeth and marginal gingival tissues. Thus, subgingival plaque found within the gingival crevice or the sulcus around the necks of the teeth is thought to house the etiologic agent(s). The characteristic histopathologic picture of gingivitis is of a marked inflammatory infiltrate of polymorphonuclear leukocytes, lymphocytes, and plasma cells in the connective tissue that lies immediately adjacent to the epithelium lining the gingival crevice and attached to the tooth. Collagen is lost from the inflamed connective tissue. There does not seem to be any direct invasion of the gingival tissues by large numbers of intact bacteria, at least in the early stages of the disease.

Polymicrobial anaerobic infection from subgingival plaque

Synergistic interactions facilitate growth

Virulence factors cause disease

All forms of periodontitis are polymicrobial infections primarily involving anaerobic bacteria in much the same way described for other anaerobes in Chapter 29. The agents involved are derived from the predominantly Gram-negative anaerobic flora of the subgingival plaque (see previous text) led by *Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis,* and *Treponema denticola.* Just as bacteria–bacteria interactions determine the plaque, cross-feeding and growth stimulation have been observed between these two organisms when grown together. This kind of synergism between *P gingivalis, T denticola,* and other plaque members is felt to foster progression of gingivitis to chronic periodontitis. Some of these organisms have also been shown to produce virulence factors similar to those associated with other invasive bacterial pathogens. *T denticola* is able to bind serum factors that interfere with complement deposition, and *P gingivalis* is a potent producer of extracellular proteases. The former facilitates survival in tissues and the latter injury to those tissues. Recent studies indicate bacterial interactions with Toll-like receptors (TLRs) may trigger these inflammatory responses.

Chronic periodontitis causes tooth loss

Acute juvenile periodontitis associated with *Actinobacillus*

Chronic periodontitis is responsible for most tooth loss in people older than 35 to 40 years. The disease progresses slowly and results in the progressive destruction of the supporting tissues of the tooth (periodontal ligament and alveolar bone) from the margins of the gingiva toward the apices of the roots of the teeth. Progression may occur as a series of acute episodes separated by quiescent periods of indeterminate duration. More aggressive forms of periodontitis result in more rapid loss of tooth support. Aggressive types of disease called localized aggressive periodontitis occur in adolescents, and generalized aggressive periodontitis occurs in young adults. There is some evidence that the causative agents may differ in this form of periodontitis. A small capnophilic (carbon dioxide-requiring) Gram-negative rod (*Actinobacillus actinomycetemcomitans*) has been indicted based on studies of the flora of disease sites. A virulence factor found in those strains of *A actinomycetemcomitans* that are associated with this disease is the production of a leukotoxin by the bacteria.

With continued progress, periodontitis and bone resorption develop

Periodontal abscess may result

As the disease progresses, a point may be reached at which the alveolar bone around the necks of the teeth is resorbed; the condition is then no longer termed gingivitis but periodontitis. With resorption of the bone, the attachment of the periodontal ligament is lost and the gingival sulcus deepens into a periodontal pocket. Periodontitis is not considered to be a reversible disease in that the lost alveolar bone and periodontal ligament do not regenerate with cessation of the inflammation, even though further progression may be halted. If unchecked, bone resorption progresses to loosening of the tooth, which may ultimately be exfoliated. **Figure 41–5** shows a case of advanced chronic periodontitis. Occasionally, the neck of a periodontal pocket becomes constricted, the bacteria proliferate causing an acute inflammatory response in the occluded pocket, and a periodontal abscess results. This acute exacerbation requires drainage in the same way as abscesses elsewhere for the patient to obtain symptomatic relief.

FIGURE 41–5. Periodontitis. A. Normal gingival. **B.** Periodontal disease, with plaque, inflammatory changes, bleeding, and shortening of the gingival between the teeth. NECROTIZING PERIODONTAL DISEASES

Acute onset with painful ulcerative lesions

Fusospirochetal etiology together with other anaerobes

Necrotizing ulcerative gingivitis (also called acute necrotizing ulcerative gingivitis, Vincent infection, or trench mouth) and necrotizing ulcerative periodontitis represent a spectrum of acute inflammatory disease starting with destruction limited to the soft tissues (gingivitis) and extending to destruction of the alveolar bone and periodontal ligament (periodontitis). This disease spectrum is distinctly different from gingivitis–chronic periodontitis. It has an acute onset, frequently associated with periods of stress and poor oral hygiene. Rapid ulceration of the interdental areas of the gingiva results in destruction of the interdental papillae. The inflammatory condition initially confined to the gingival tissues can quickly extend into pathologic bone resorption. Unlike gingivitis and chronic periodontitis, acute necrotizing periodontal disease is painful. As the oral epithelium is destroyed, the causative bacteria come into direct contact with the underlying tissues and may invade them. Spirochetes and fusiform bacteria have been implicated; thus, the term **fusospirochetal disease** has been used to describe this infection, which can also be manifested as ulceration in other areas of the pharynx or oral cavity. *Prevotella intermedia* has also been found in high numbers in the lesions. Morphologic studies have shown that the spirochetes actually appear to invade the tissues. The disease may be treated with systemic antibiotics and topical antimicrobials for immediate relief of symptoms, but resolution depends on thorough professional cleaning of the teeth and institution of good home care.

PART IV

Pathogenic Fungi

J. Andrew Alspaugh • Julie M. Steinbrink

chapter 42

Fungi—Basic Concepts

OVERVIEW

The fungal kingdom encompasses a diverse and rich group of organisms ranging from microscopic yeasts to mushrooms. Most fungi are free-living in nature where they function as decomposers in the energy cycle. Of the more than 90,000 known fungal species, fewer than 200 have been reported to produce disease in humans. Once considered clinical rarities, human fungal infections are becoming increasingly common, especially among immunocompromised patients. Therefore, it is important to understand the unique clinical and microbiological features of these diseases.

CLINICAL CONTEXT

A "yeast" is identified growing from a patient's blood culture.

1. What are fungi, and do they commonly cause important human diseases?
2. How does the lab technologist identify the species of this fungus?
3. How does the clinician know if this microorganism is relevant to the care of the patient?

• MYCOLOGY

* Fungal cell organization is eukaryotic

Fungi are eukaryotes with a higher level of biologic complexity than bacteria. Fungi may be unicellular or may differentiate and become multicellular by the development of long, branching filaments. They lack the chlorophyll of plants and therefore need to acquire nutrients from the external environment. The diseases caused by fungi are called mycoses. These infections vary greatly in their manifestations but tend to present with subacute or chronic features, often relapsing over time. Acute disease, such as that produced by many viruses and bacteria, is less common with fungal infections.

STRUCTURE

Presence of a nucleus, mitochondria, and endoplasmic reticulum

*** Fungal cell wall distinguishes from mammalian cells**

*** Ergosterol, not cholesterol, makes up cell membrane**

The fungal cell has many typical eukaryotic features, including a nucleus with a nucleolus, nuclear membrane, and linear chromosomes (**Figure 42–1**). The cytoplasm contains a cytoskeleton with actin microfilaments and tubulin-containing microtubules. Ribosomes and organelles, such as mitochondria, endoplasmic reticulum, and the Golgi apparatus, are also present. Fungal cells have a rigid cell wall external to the cytoplasmic membrane, which differentiates them from mammalian cells. In addition to the cell wall, another important difference from mammalian cells is the sterol composition of the cytoplasmic membrane. In mammalian cells, the dominant membrane sterol is cholesterol; in fungi, it is ergosterol. Fungi are usually haploid in their DNA content, although diploid nuclei are formed through nuclear fusion in the process of sexual reproduction. Interestingly, the generation of polyploid/aneuploid nuclei is a strategy used by some fungi to generate genetic diversity as a response to cell stress, such as antifungal therapy.

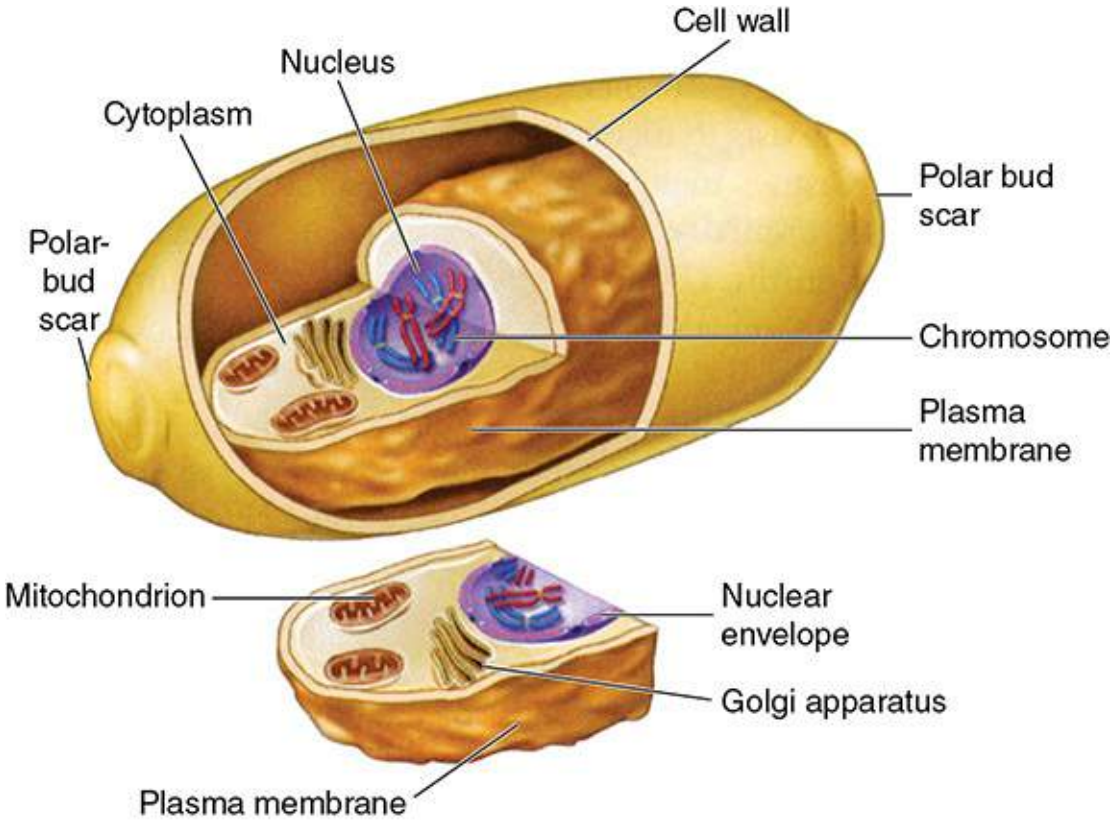

FIGURE 42–1. A yeast cell showing the cell wall and internal structures of the fungal eukaryotic cell plan. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Cell wall mannan linked to surface proteins

Chitin and glucans give rigidity to cell wall

The chemical structure of the cell wall in fungi is markedly different from that of bacterial cells in that it does not contain peptidoglycan, glycerol, teichoic acids, or lipopolysaccharide. In their place are complex polysaccharides such as **mannans, glucans,** and **chitins** in close association with each other and with structural proteins (**Figure 42–2**). Mannoproteins are composed of mannose-based polymers (mannan) linked to various proteins embedded in the external structural matrix of the cell wall. Mannoproteins are very important since antibodies are readily developed against these molecules on the cell surface. The potential variations in the composition and linkages of the mannan side chains allow fungi to generate a complex and adaptable cell surface to avoid easy immune detection by an infected host. The identification of different antibodies directed against specific mannoproteins also allows laboratories to "serologically" distinguish between individual strains within a fungal species.

The alpha- and beta-glucans are polymers of glucose found abundantly throughout the cell wall. Additionally, chitin, composed of long chains of *N*-acetylglucosamine, provides rigid structural support to the fungal cell in a manner analogous to the chitin in crab shells or cellulose in plants. In addition to their structural roles, these cell wall carbohydrates serve complex cell functions, often simultaneously activating and inhibiting various arms of the host immune response.

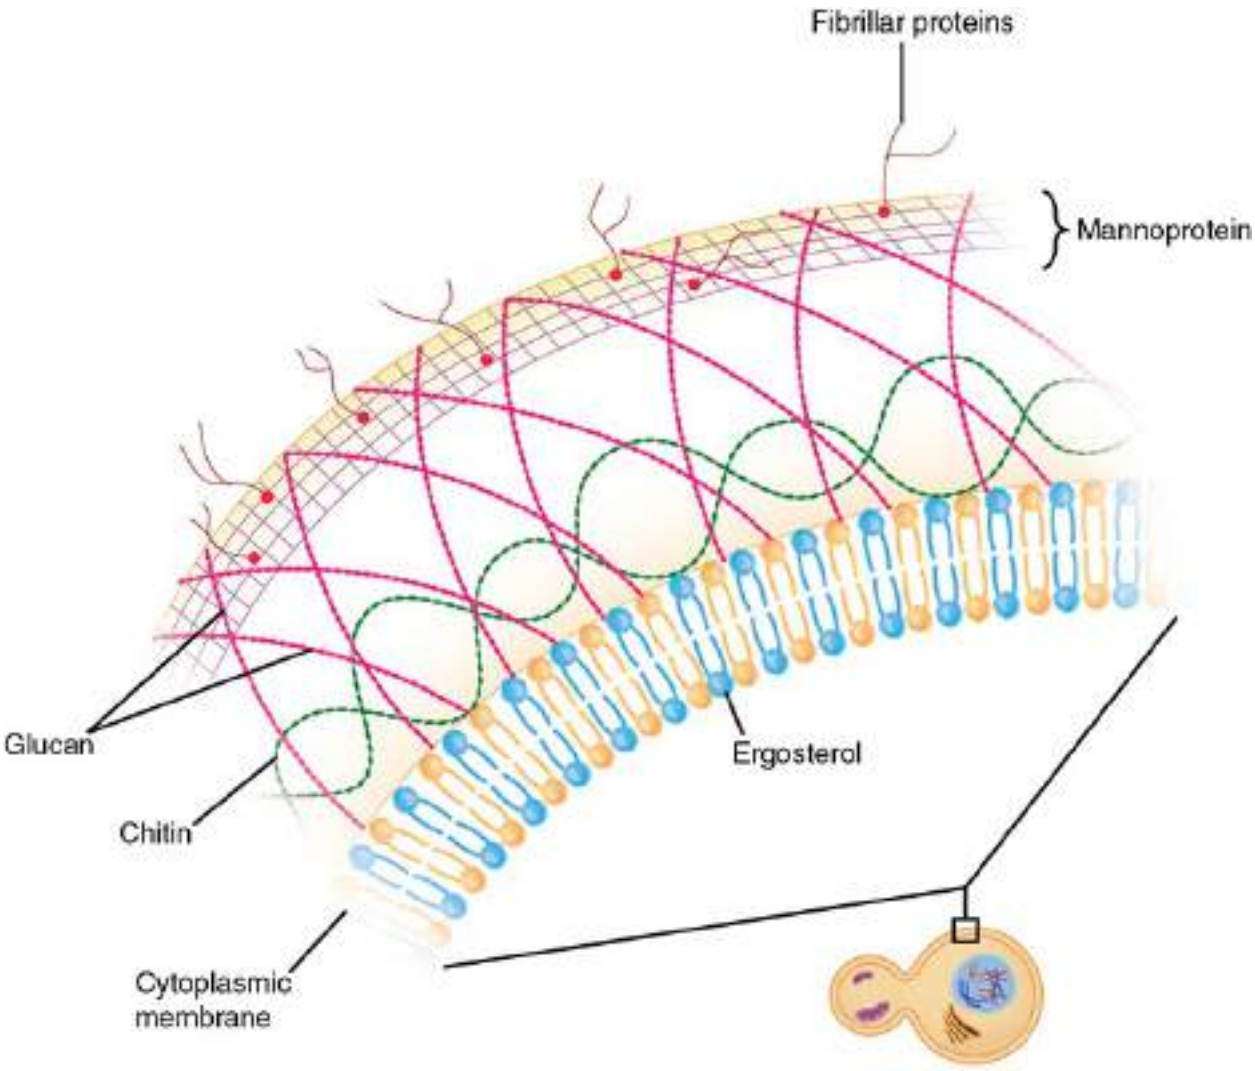

FIGURE 42–2. The fungal cell wall. The overlapping mannan, glucan, chitin, and protein elements are shown. Proteins complexed with the mannan (mannoproteins) extend beyond the cell wall.

METABOLISM

Heterotrophic metabolism uses available organic matter

In contrast to plants, fungi lack chloroplasts and photosynthetic energy-producing mechanisms. Therefore, fungi must acquire nutrients from exogenous sources. Metabolic diversity among fungi is great, but most are able to grow with very simple carbon and nitrogen sources. In nature, nutrients for free-living fungi are derived from decaying organic matter. Most fungi are strict aerobes, although some can grow under anaerobic conditions.

• FUNGAL MORPHOLOGY AND GROWTH

Vary in size from single cells to multicellular mushrooms

The size of fungi varies immensely. A single cell without transverse septa may range from bacterial size (2-4 μm) to a macroscopically visible structure. The morphologic forms of growth vary from colonies superficially resembling those of bacteria to some of the most complex, multicellular, colorful, and beautiful structures seen in nature. Mushrooms are an example of the potential higher structural differentiation among fungi.

Mycology, the science devoted to the study of fungi, has various terms to describe the morphologic components that comprise these structures. The terms and concepts that must be mastered can be limited by considering only the fungi of medical importance and accepting some simplification.

YEASTS AND MOLDS

Fungal forms include *yeasts* (single cells) and *molds* (elongated, filamentous hyphae)

Fungi that cause human infections can be broadly divided based on their morphological forms. **Yeasts** are fungi that primarily grow in a round cellular form. **Molds** are fungi that primarily grow as filamentous, tube-like structures called hyphae (**Figure 42–3A** and **B**). Although it is useful to consider this basic distinction based on cell shape, it is important to remember that some fungi can transition between yeast-like and hyphal morphologies. Often, this plasticity of shape is directly related to pathogenesis since different forms may be better suited for different microenvironments. The yeasts tend to have the simplest cellular forms, reproducing by a process of asexual budding, constriction, and cell separation similar to many bacteria.

FIGURE 42–3. Yeast and mold forms of fungal growth. A. This oval yeast cell is budding to form a daughter cell. Scars from prior cell separations can be seen on other parts of the cell. **B.** The mold form is highly variable. Here tubular stalks called conidiophores arising from hyphae (not seen) bear a "Medusa head" crop of reproductive conidia. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Fungi may also grow through the development of **hyphae** (singular, hypha), which are tube-like extensions of the cell with thick, parallel walls. As the hyphae extend, they form an intertwined mass called a **mycelium.** Most molds form hyphal **septa** (singular, septum), which are cross-walls perpendicular to the cell walls, dividing the hypha into subunit cells (**Figure 42–4**). The structure of these septa varies among species and may contain pores and incomplete walls that allow movement of nutrients, organelles, and nuclei between adjacent cells. Some species, including some human pathogens, form septae that are very distant from each other. Because their microscopic appearance, therefore, suggests a single, continuous hyphal cell, these particular species are often called "aseptate" molds. In both septate and aseptate hyphae, multiple nuclei are often present in each cell.

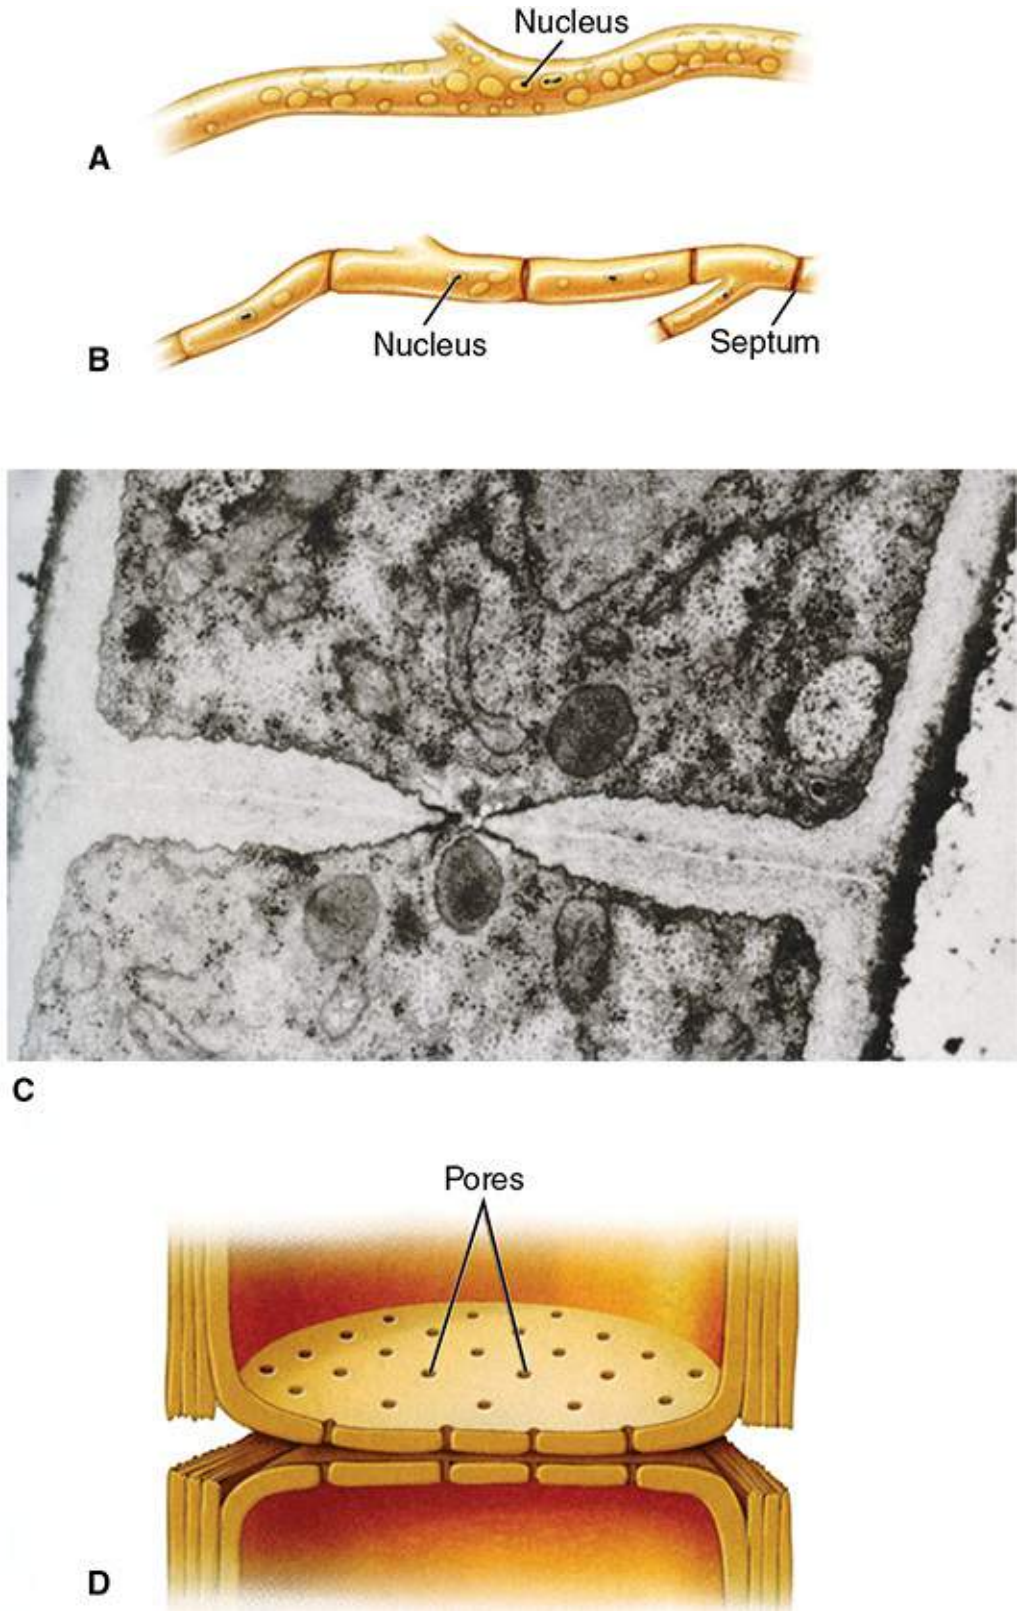

FIGURE 42–4. Hyphae. A. Nonseptate hyphae with multiple nuclei. **B.** Septate hyphae divide nuclei into separate cells. **C.** Electron micrograph of septum with a single pore. **D.** Multipore septum structure within fungal hyphae. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*,

7th ed. New York, NY: McGraw Hill; 2008.)

*** Molds produce septate or aseptate hyphae**

Aerial mycelium bears reproductive conidia or spores—the basis for species identification

*** Pseudohyphae are elongated yeast-like cells**

A portion of the mycelium (vegetative mycelium) usually grows into the medium or organic substrate (eg, soil) and functions like the roots of plants as a collector of nutrients and moisture. The more visible surface growth may assume a fluffy character as the mycelium becomes aerial. The hyphal walls are rigid in order to support this extensive, intertwining network. Different molds often have unique sexual and asexual structures associated with their hyphae (**Figure 42–5A-D**). These sexual structures are often unique to each species, allowing microbiology laboratories to distinguish among molds based on their morphological features. Some fungi also form **pseudohyphae,** which are actually elongated yeast cells growing end-to-end. Therefore, pseudohyphae are distinguished from true hyphae by having recurring bud-like constrictions and less rigid cell walls.

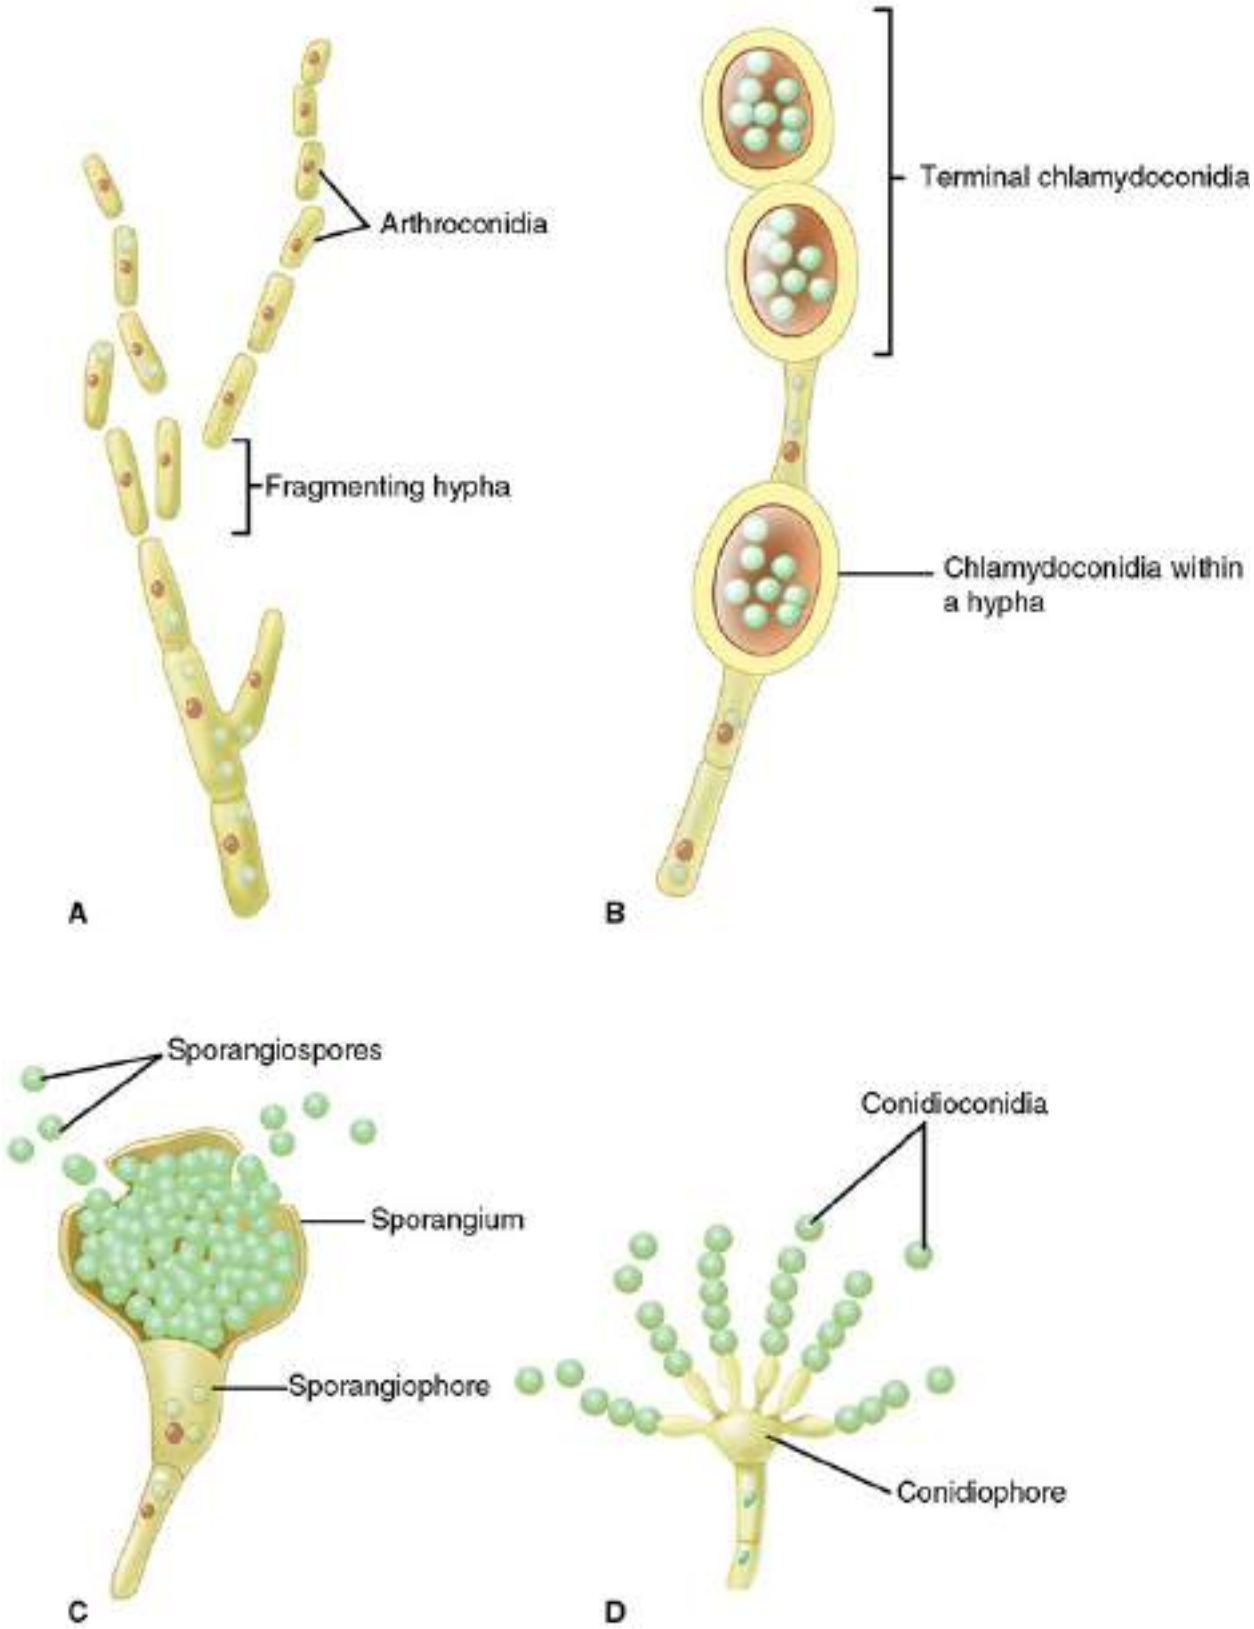

FIGURE 42–5. Asexual mold forms. A. Arthroconidia develop within the hyphae and eventually break off. **B.** Chlamydoconidia are larger than the hyphae and develop with the cell or terminally. **C.**

Sporangioconidia are borne terminally in a sporangium sac. **D.** Simple conidia arise directly from a conidiophore. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

DIMORPHISM

Although many fungi tend to grow as either yeasts or molds, some species can transition between morphological forms depending on environmental conditions. These species are known as **dimorphic fungi.** Many fungi, including the most common human fungal pathogen *Candida albicans*, display a striking ability to modify their cellular shape and structure in order to adapt to new environments. These morphological transitions are often very important for the pathogenesis of human infections.

Dimorphism: growth of a fungus in either a yeast or mold form

In thermally dimorphic fungi, temperature triggers a shift between phases

A distinct group of human pathogens are the **thermally dimorphic fungi**, shifting from yeast-like to hyphal growth based on temperature. These fungal species tend to grow in the mold form in their environmental reservoir as well as when incubated in culture at ambient temperatures. However, they convert to a yeast-like growth form in the mammalian host or when incubated in culture at 37^{o}C. Importantly, the conidia produced in the mold phase may be infectious and serve to disseminate the fungus during growth in the environment.

Dimorphism reversible, linked to virulence

Fungal dimorphism in fungi is reversible, a feature that distinguishes it from developmental processes such as embryogenesis seen in higher eukaryotes. The importance of the dimorphism in fungal virulence has been demonstrated in several fungi, including *C albicans* and *Histoplasma capsulatum*. Strains that are locked in one growth phase are often markedly reduced in their ability to produce disease and persist in the host.

CLASSIFICATION

Fungal classification has historically relied upon observable cellular characteristics such as the septation of hyphae and the appearance of the sexual

structures. However, nucleic acid sequence-based and protein-based classification methods are becoming more common, allowing fungi to be grouped by genetic and biochemical relatedness. Molecular classification techniques have also demonstrated that several microbial species are actually fungi despite having few fungal growth characteristics (eg, *Pneumocystis* species and Microsporidia).

Taxonomy based on visual identification of fungal features, genome sequencing, protein identification

Fungi have historically been organized into five phyla: Ascomycota, Basidiomycota, Zygomycota, Chytridiomycota, and Glomeromycota. The medically important genera fall mostly within the Ascomycota, with a few in Basidiomycota, and Zygomycota, as shown in **Table 42-1**.

TABLE 42–1 Classification of medically important fungi

GENUS	TYPICAL GROWTH	SEPTATION[a]	PHYLUM
Superficial Fungi			
Epidermophyton	Mold	+	Ascomycota
Microsporum	Mold	+	Ascomycota
Trichophyton	Mold	+	Ascomycota
Subcutaneous Fungi			
Sporothrix	Dimorphic	+	Ascomycota
Opportunistic Fungi			
Aspergillus	Mold	+	Ascomycota
Candida	Dimorphic	+	Ascomycota
Mucor	Mold	–	Zygomycota
Rhizopus	Mold	–	Zygomycota
Pneumocystis	Cysts[b]		Ascomycota
Systemic Fungi			
Blastomyces	Dimorphic	+	Ascomycota
Coccidioides	Dimorphic	+	Ascomycota
Histoplasma	Dimorphic	+	Ascomycota
Cryptococcus	Yeast		Basidiomycota

[a]For those that form hyphae.
[b]Tissue forms but does not grow in culture.

Medical grouping organized by biologic behavior in humans

Systemic fungi infect previously healthy persons

The grouping of medically important fungi used in the following chapters is based on the types of tissues they parasitize and the diseases they produce, rather than on the principles of basic mycologic taxonomy. The **superficial** fungi, such as the dermatophytes, cause indolent lesions of the skin and its appendages, commonly known as ringworm and athlete's foot, without typically spreading to deeper tissues. The **subcutaneous** pathogens characteristically cause infection through the skin, followed by subcutaneous or lymphatic spread. The **opportunistic** fungi are those found in the environment or in the resident flora that produce disease primarily in immunocompromised hosts. The **systemic** pathogens are the most virulent fungi and may cause serious and progressive systemic disease in previously healthy persons. These fungal species are not found in the human microbiota. Although their major potential is to produce deep-seated visceral infections and systemic spread (systemic mycoses), they may also produce superficial infections as part of their disease spectrum or as the initiating event. As with all clinical classifications, overlaps and exceptions occur. In the end, the interplay between host and microorganism defines the disease.

chapter 43

Pathogenesis and Diagnosis of Fungal Infections

We all have regular contact with fungi. They are so widely distributed in our environment that thousands of fungal spores are inhaled or ingested every day. Some species are so well adapted to humans that they are common members of the microbiota. Despite this ubiquity, clinically apparent systemic fungal infections are uncommon. However, systemic fungal infections pose some of the most difficult diagnostic and therapeutic problems in infectious disease, particularly among immunocompromised patients. The purpose of this chapter is to provide an overview of the pathogenesis and immunology of fungal infections. Details relating to specific fungi are provided in Chapters 45 to 47.

• GENERAL ASPECTS OF FUNGAL DISEASE EPIDEMIOLOGY

Environmental conidia inhaled

* Some endemic to geographic regions

Fungal infections are most often acquired from the external environment. One common mechanism of infection is by the inhalation of conidia generated from environmental molds. Some of these fungi are ubiquitous, whereas others are restricted to specific **endemic** areas, geographic regions whose climate favors their growth. Many fungi produce disease only after they are accidentally injected past the skin/mucosal barrier, especially in immunocompromised patients. Other pathogenic fungi have more sophisticated means of tissue penetration and invasion. Infection can result from systemic invasion by a fungal species that is typically an endogenous member of the resident flora, such as that seen with systemic candidiasis (**Figure 43–1**).

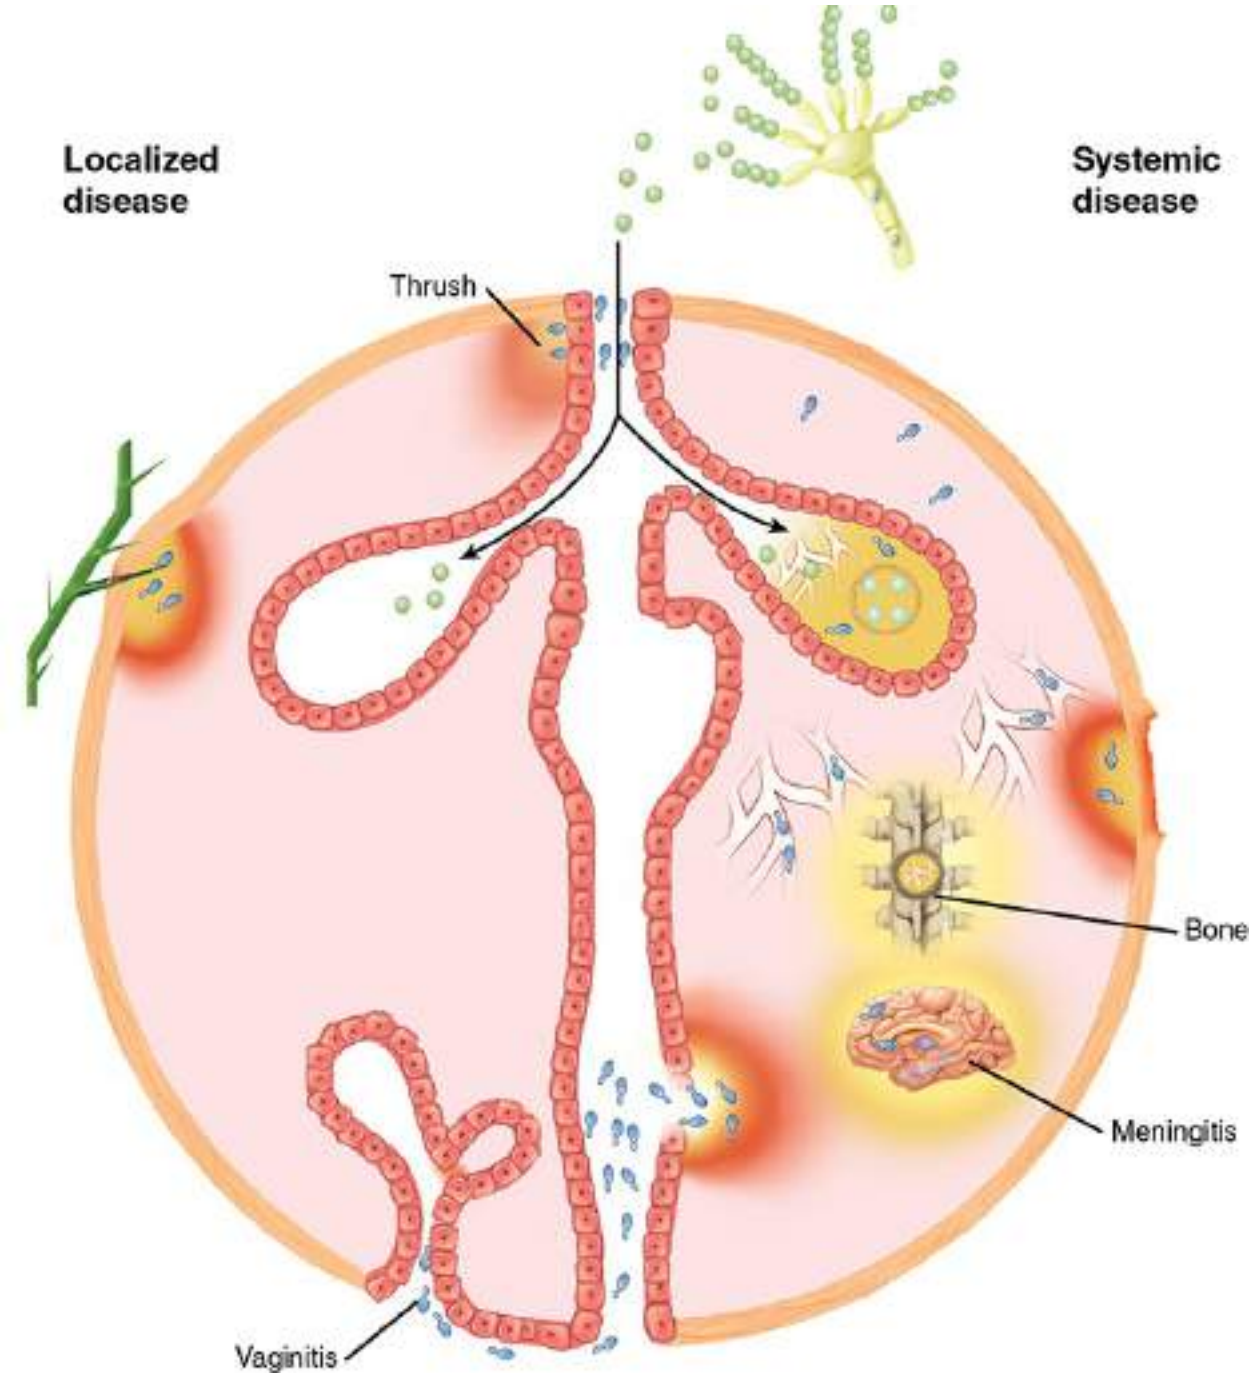

FIGURE 43–1. Fungi system view. Localized disease (*left*) is caused by local trauma or the superficial invasion of flora resident on the oropharyngeal (thrush), gastrointestinal, or vaginal mucosa. Systemic fungal disease (*right*) most often begins with inhalation of conidia followed by dissemination to other sites.

PATHOGENESIS

Fungi have mechanisms for adherence and invasion

Most fungi are opportunists

Compared with bacterial, viral, and parasitic disease, less is known about the pathogenic mechanisms and virulence factors involved in fungal infections. Analogies to bacterial diseases come closest because of similarities in microbial adherence to mucosal surfaces, invasion into deeper tissue layers, production of extracellular compounds, and interaction with phagocytes (**Figure 43–2**). In general, the principles discussed in Chapter 22 also apply to fungal infections. Most fungi are opportunists, causing serious disease only in individuals with impaired host defense systems. Only a few fungi are able to cause disease in previously healthy persons.

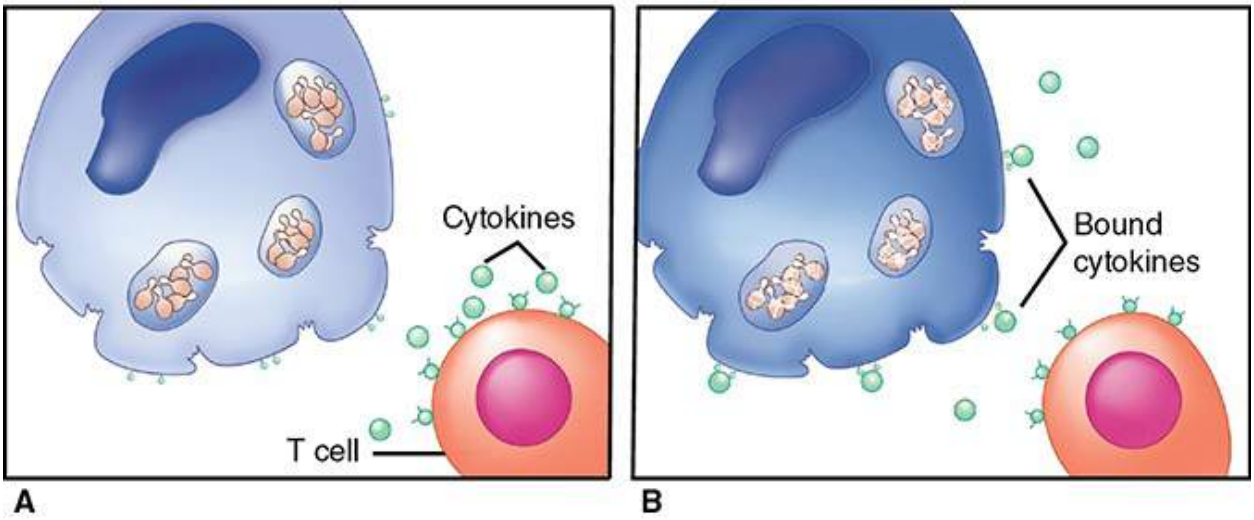

FIGURE 43–2. Immunity to fungal infections. A. Pathogenic fungi are able to survive and multiply slowly in nonactivated macrophages. **B.** When macrophages are activated by cytokines from T cells, the growth is restricted and the fungi digested.

▪ Adherence

Adherence is mediated by fungal adhesins to host cell receptors

Several fungal species, particularly the yeasts, are able to colonize the mucosal surfaces of the gastrointestinal and female genital tracts. It has been shown experimentally that the ability to adhere to buccal or vaginal epithelial cells is associated with both colonization and virulence. Within the genus *Candida*, the species that best adhere to epithelial cells are those most frequently isolated from clinical infections. Adherence usually requires surface adhesins on the fungus and a receptor on the epithelial cell. In the case of *Candida albicans*, mannoprotein components extending from the cell wall have been implicated as

specific adhesins, interacting with host fibronectin and other components of the extracellular matrix. Other fungal/host binding mediators have been identified, and this process can help to explain why certain tissue are targeted by specific fungal pathogens. For example, the neuropathogen *Cryptococcus neoformans* displays a unique interaction with proteins on the endothelium of the brain microvasculature, perhaps explaining how this species specifically invades the central nervous system.

▪ Invasion

Introduced through breaks in skin

Conidia may bypass airway defenses

Passing an initial surface barrier—skin, mucous membrane, or respiratory epithelium—is an important step for most successful pathogens. Some fungi are introduced through mechanical breaks. For example, *Sporothrix schenckii* infection typically follows a traumatic injury to the skin. Fungi that initially infect the lung must produce conidia small enough to be inhaled past the upper airway defenses. For example, arthroconidia of *Coccidioides immitis* (2-6 µm) can remain suspended in air for a considerable period of time, their size allowing efficiency delivery to the terminal bronchioles to initiate pulmonary coccidioidomycosis.

Invasion may involve enzymes

Dimorphic fungi change to more invasive form

Triggered by temperature and possibly other cues, dimorphic fungi from the environment undergo a metabolic shift similar to the heat shock response, completely changing their morphology to a more invasive form. Invasion directly across mucosal barriers by the endogenous yeast *C albicans* is similarly associated with a morphologic change, the formation of hyphae. For this species, the ability to transition between yeast-like and hyphal forms allows it to effectively penetrate tissue, form adherent biofilms, and disseminate to distant sites. Extracellular enzymes (eg, proteases, elastases) are also associated with the advancing edge of the hyphal form of *Candida* species, as well as with the invasive forms of many of the dimorphic and other pathogenic fungi.

▪ Injury

No classic exotoxins

Injury due to inflammatory responses of host

There are many mechanisms of tissue injury during fungal infection. Although many fungi produce secondary metabolites and **mycotoxins** in the environment, most of these extracellular toxins do not appear to be directly related to pathogenesis in human infections. Cell surface components contributing to host damage, analogous to the endotoxin of Gram-negative bacteria, are lacking in most fungi. Moreover, only the most immunocompromised patients, such as those with neutropenia, appear to have extensive injury due to direct fungal destruction of the surrounding tissue. In contrast, the injury experienced by the host during most fungal infections seems to be due primarily to the immune response against the infecting microorganism. As the immune system attempts to clear the fungal pathogens, there is often collateral damage to the host.

IMMUNITY

▪ Innate Immunity

Healthy persons have effective innate immunity to most fungal infections, especially the opportunistic molds. This resistance is mediated by the professional phagocytes (neutrophils, macrophages, and dendritic cells), the complement system, and pattern recognition receptors. Important receptors recognizing fungal elements include lectin-like structures on phagocytes (eg, dectin-1) that bind glucans on fungal cells, as well as Toll-like receptors (TLR2, TLR4). In most instances, neutrophils and alveolar macrophages are able to kill the conidia of fungi if they reach the tissues.

Most fungi are readily killed by neutrophils

Fungal species that cause human infections have developed strategies to avoid immune recognition and to thwart various aspects of immune-mediated clearance. The polysaccharide capsule of *C neoformans* shields immunogenic epitopes on the cell surface from being sensed by pattern recognition receptors and complement proteins. Moreover, capsule material secreted by the cryptococcal cell specifically inhibits the function of many immune cells. Similarly, *C albicans* is able to bind complement components in a way that interferes with phagocytosis. As the thermally dimorphic fungi convert to the

pathogenic yeast-like state, they too become more resistant to killing by phagocytes because of changes in surface structures subject to pattern recognition.

Pathogenic fungi resist phagocytic killing

In addition to preventing immune recognition, many fungal pathogens are also able to survive once sensed and engulfed by immune cells. The yeast-to-hyphal transition by *C albicans* favors its escape from phagocytic immune cells. As the hyphae of the thermally dimorphic fungus *C immitis* convert to the spherule (tissue) phase, they also become resistant to phagocytic killing because of their size and surface characteristics. Some fungi produce substances such as melanin, which interfere with oxidative killing by phagocytes. The yeast forms of *Histoplasma capsulatum* and *C neoformans* are adapted to live and multiply within macrophages by interfering with lysosomal killing mechanisms.

▪ Adaptive Immune Response

T-cell–mediated responses of primary importance

Progressive disease in immunocompromised

A recurrent theme with fungal infections is the importance of an intact immune response in preventing infection and progression of disease. The small number of species that are able to cause clinically apparent infection are usually cleared from the host, most often through a combination of the innate activity of neutrophils and through the development of an adaptive, T_H1-mediated immune response. Progressive, debilitating, or life-threatening fungal infections are commonly associated with depressed or absent cellular immune responses.

▪ Humoral Immunity

Antibodies may not correlate with resistance

Opsonizing antibody effective for some yeast

Antifungal antibodies can be detected at some time during the course of almost all fungal infections, but the appearance of antibodies does not necessarily correlate with antifungal resistance. In coccidioidomycosis, for example, high titers of *C immitis*-specific antibodies are associated with dissemination and a

worsening clinical course; antibody titers decrease as the infection is cured. In contrast, antibodies directed against the *C neoformans* capsule may actually contribute to the cell-mediated clearance of this encapsulated yeast from the site of infection. Antibody may also play a role in control of *C albicans* infections by enhancing fungus–phagocyte interactions.

Cellular Immunity

Systemic disease with deficiencies in neutrophils and T_H1 immunity

Considerable clinical and experimental evidence points toward the importance of cellular immunity in the resolution of fungal infections. Most patients with invasive mycoses have neutropenia, defects in neutrophil function, or depressed T_H1 immune responses. These can result from factors such as steroid treatment, hematologic malignancies, transplantation, and AIDS.

Fungi escaping neutrophils grow in macrophages

A basic schema for fungal-host interactions is illustrated in Figure 43–2. When hyphae or yeast cells of the fungus reach deep tissue sites, they are either killed by neutrophils or resist destruction by one of the antiphagocytic mechanisms described earlier. Surviving cells continue to grow slowly within the host in their tissue-adapted fungal forms (spherules for *C immitis*, hyphae for *Aspergillus fumigatus*, intracellular yeasts for *C neoformans* and *H capsulatum*). The growth of these invasive forms may be slowed or killed by phagocytes such as neutrophils and macrophages. In healthy persons, the extent of infection is minimal, and any symptoms are instead caused by the host inflammatory response.

Immune defects lead to progressive disease

Everything awaits the specific adaptive immune response to the invader. In fungal infections, antigen-presenting cells such as dendritic cells and macrophages help to activate adaptive immune response, including antifungal antibody production and T_H1-mediated cellular immunity. Defects that disturb this cycle lead to progressive disease. To the extent that they are known, the specifics of these reactions are discussed in the following chapters.

LABORATORY DIAGNOSIS

▪ Direct Examination

KOH digests tissue, but not fungal wall

Calcofluor white enhances detection by staining fungal chitin

Fungi can often be identified by directly observing their distinctive morphologic features on direct microscopic examination of infected pus, fluids, or tissues. The simplest method is to mix a clinical specimen, such as skin scrapings, with a 10% solution of potassium hydroxide (KOH) on a microscope slide under a coverslip. The strong alkali digests the tissue elements (epithelial cells, leukocytes, debris) but not the rigid cell walls of either yeasts or molds. After digestion of the material, the fungi can be observed under the light microscope with or without staining (**Figure 43–3**). Direct examinations can be aided by the use of calcofluor white, a dye that binds to polysaccharides in cellulose and chitin. Under ultraviolet light, calcofluor white fluoresces, enhancing detection of fungi in fluids or tissue sections. A few yeasts including *C albicans* can be visualized using the Gram stain (Gram positive).

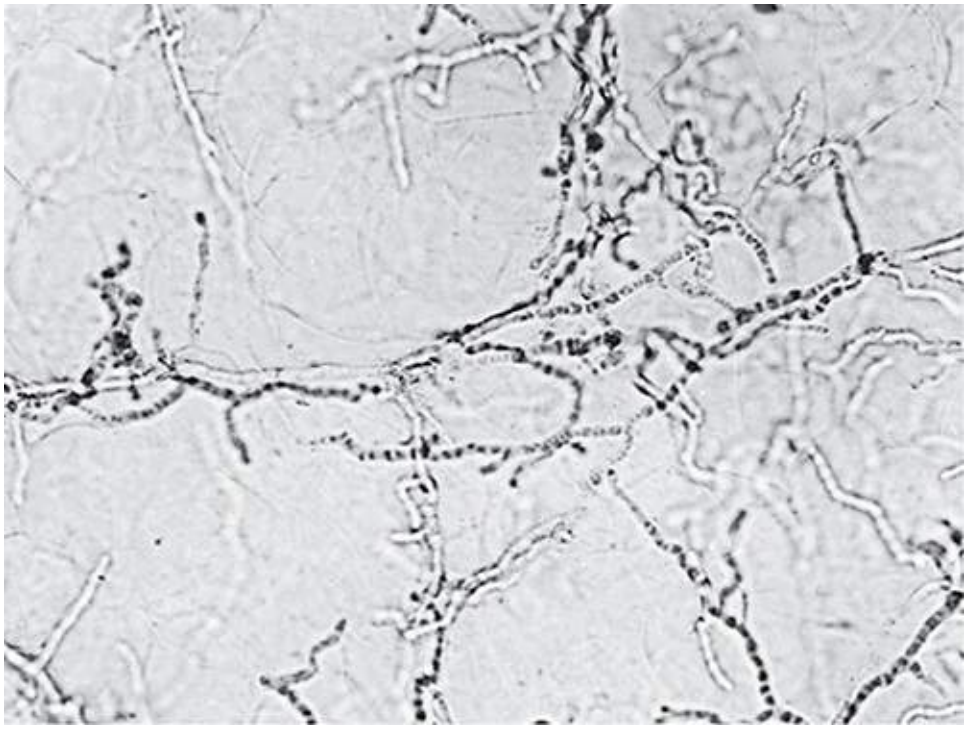

FIGURE 43–3. KOH (potassium hydroxide) preparation. Scalp scrapings from a suspected ringworm lesion have been mixed with 10% KOH and viewed under low power. The skin has been dissolved,

revealing tubular branching hyphae.

Often visible in H&E preparations

Silver stains enhance detection

Histopathologic examination of tissue biopsy specimens is widely used to diagnose fungal infections and shows the relation of the organism to tissue elements and host responses (blood vessels, phagocytes, granulomatous reactions). Most fungi can be seen in sections stained with the basic hematoxylin and eosin (H&E) method used in histology laboratories (**Figure 43–4**). Specialized staining procedures such as silver impregnation methods are frequently used because they stain almost all fungi strongly, but only a few tissue components (**Figure 43–5**). The pathologist should be alerted to the possibility of fungal infection when tissues are submitted because fungal-specific stains are not used routinely.

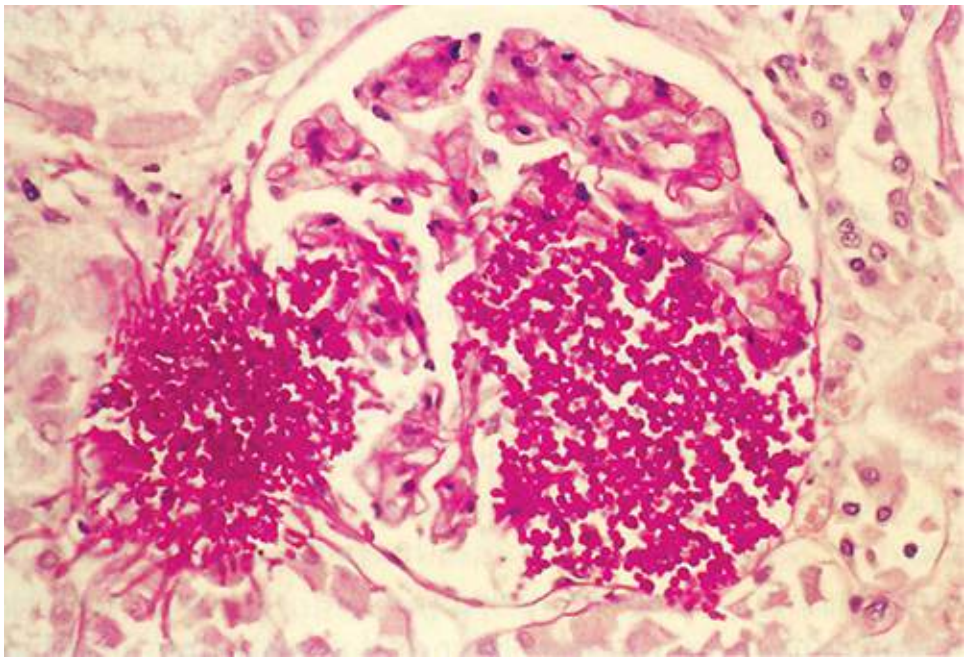

FIGURE 43–4. Disseminated candidiasis. *Candida albicans* (stained red by H and E stain) has invaded a kidney glomerulus. Most cells are in the yeast form, but some hyphae are seen at the lower left. FIGURE 43–5. Fusarium invasion. The branching septate hyphae are stained black by this silver stain. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases.* Stamford CT: Appleton & Lange; 1997.)

▪ Culture

Culture simple but slow

Selective media enhance isolation

Fungi can be grown by methods similar to those used to isolate bacteria. The growth of many fungal species occurs readily on enriched bacteriologic media commonly used in clinical laboratories (eg, blood agar and chocolate agar). Many fungal cultures, however, require days to weeks of incubation for initial growth; bacteria present in the specimen grow more rapidly and may interfere with isolation of a slow-growing fungus. Therefore, the culture procedures of diagnostic mycology are designed to favor the growth of fungi over bacteria and to allow incubation to continue for a sufficient time to isolate slower growing strains.

Sabouraud's agar optimal for many fungi

The most commonly used medium for cultivating fungi is Sabouraud's agar, which contains only glucose and peptones as nutrients. Its pH is 5.6, which is optimal for growth of dermatophytes and satisfactory for growth of many other

fungi. Most bacteria fail to grow, or grow poorly, on Sabouraud's agar. A wide variety of media are used for isolating specific fungi, many of which use either Sabouraud's medium or brain-heart infusion as their base.

Selective media make use of antimicrobials

Cultures are incubated at 30°C

Blood agar or other types of enriched bacteriologic media are used when pure cultures are expected, such as sub-culturing yeasts from blood cultures. These media can be made more fungal-selective by the addition of antibacterial antibiotics such as chloramphenicol and gentamicin. Cycloheximide, an antimicrobial that inhibits some saprophytic fungi, is sometimes added to Sabouraud's agar to prevent overgrowth of contaminating molds from the environment, particularly for skin cultures. However, media containing these selective agents cannot be relied on exclusively because they can interfere with growth of some pathogenic fungi or because the "contaminant" may be producing an opportunistic infection. For example, cycloheximide inhibits *C neoformans*, and chloramphenicol may inhibit the yeast forms of some dimorphic fungi. In contrast to most pathogenic bacteria, many fungi grow best at 25°C to 30°C, and temperatures in this range are used for primary isolation. Paired cultures incubated at 30°C and 35°C may be used to demonstrate dimorphism.

Yeasts identified biochemically

Once a fungus is isolated from a clinical sample, identification procedures often depend on whether the growing fungus is a yeast or a mold. Historically, yeasts have been identified to the species level by biochemical tests analogous to those tests used for bacteria. The observation of specific fungal structures such as pseudohyphae is also diagnostically useful among the yeasts. More recently, biochemical assessments using mass spectroscopy have been increasingly used for microbial identification.

Molds identified by morphology, culture features

Molds are most often identified by the morphology of their conidia and conidiophores. Other features such as the size, texture, and color of the colonies help characterize molds, but without demonstrating conidiation they are not sufficient for identification. Conidium production may not occur for days or

weeks after the initial growth of the mold. It is similar to waiting for flowers to bloom, and it can be frustrating when the result has immediate clinical application. Similar to yeasts, mass spectroscopy-based identification of mold species is likely to complement morphological assessments.

Temperature variation induces dimorphism

DNA probes more rapid

It is desirable, but not always possible, to demonstrate the yeast and mold phases with dimorphic fungi. In some cases, this result can be achieved with parallel cultures at 30°C and 35°C. The tissue form of *C immitis* is not readily produced *in vitro*. Demonstration of dimorphism has become less important with the development of specific DNA probes for the major systemic pathogens. These probes are rapid and can be applied directly to the mycelial growth of the readily grown mold phases of these fungi.

▪ Antigen and Antibody Detection

Serologic tests useful for some fungi

Antigen detection shows promise

Serum antibodies directed against a variety of fungal antigens can be detected in patients infected with those agents. These tests are most helpful for determining prior exposure to various fungi, and they are rarely useful for diagnosing acute infections, except for *C immitis* in which antibody levels often correlate with extent of infection. Immunoassays to detect fungal antigens attempt to identify fungal-specific components including mannans, mannoproteins, glucans, chitin. Two of these tests are extremely sensitive and specific for systemic infection: (1) the *C neoformans* capsular polysaccharide antigen test (cryptococcal antigen) and (2) the *H capsulatum* surface antigen test (*Histoplasma* antigen). Serum antigen tests for *Aspergillus* species (galactomannan) and other fungal pathogens (β-D-glucan) are less sensitive and specific for diagnosing infection but can be useful in some cases. PCR-based assays also offer promise for nonculture-based identification of fungal nucleic acid in clinical samples.

chapter 44

Antifungal Agents and Resistance

Many antifungals are too toxic for use

Compared with antibacterial agents, relatively few antimicrobials are available for treatment of fungal infections. Many substances with antifungal activity have proven to be unstable, to be toxic to humans, or to have undesirable pharmacologic characteristics, such as poor diffusion into tissues. Newer antifungal agents target fungal-specific cellular features and demonstrate lower toxicity than older drug classes.

Treatment is needed for invasive fungal infections in immunocompromised persons

Many fungal infections are self-limiting and require no therapy. However, there are also circumstances in which either topical or systemic antifungal agents are used. Superficial mycoses are often treated with topical therapy, limiting toxicity to the host. Invasive or systemic fungal infections that are not controlled by the host's immune system often require the prolonged use of systemic antifungals. Given that most of the patients with these infections also have underlying immunosuppression, invasive mycosis can be among the most difficult of all infectious diseases to treat successfully. The characteristics of currently used antifungal agents are summarized in **Table 44-1**. They are also discussed in the text that follows in relation to their target of action, as illustrated in **Figure 44–1**.

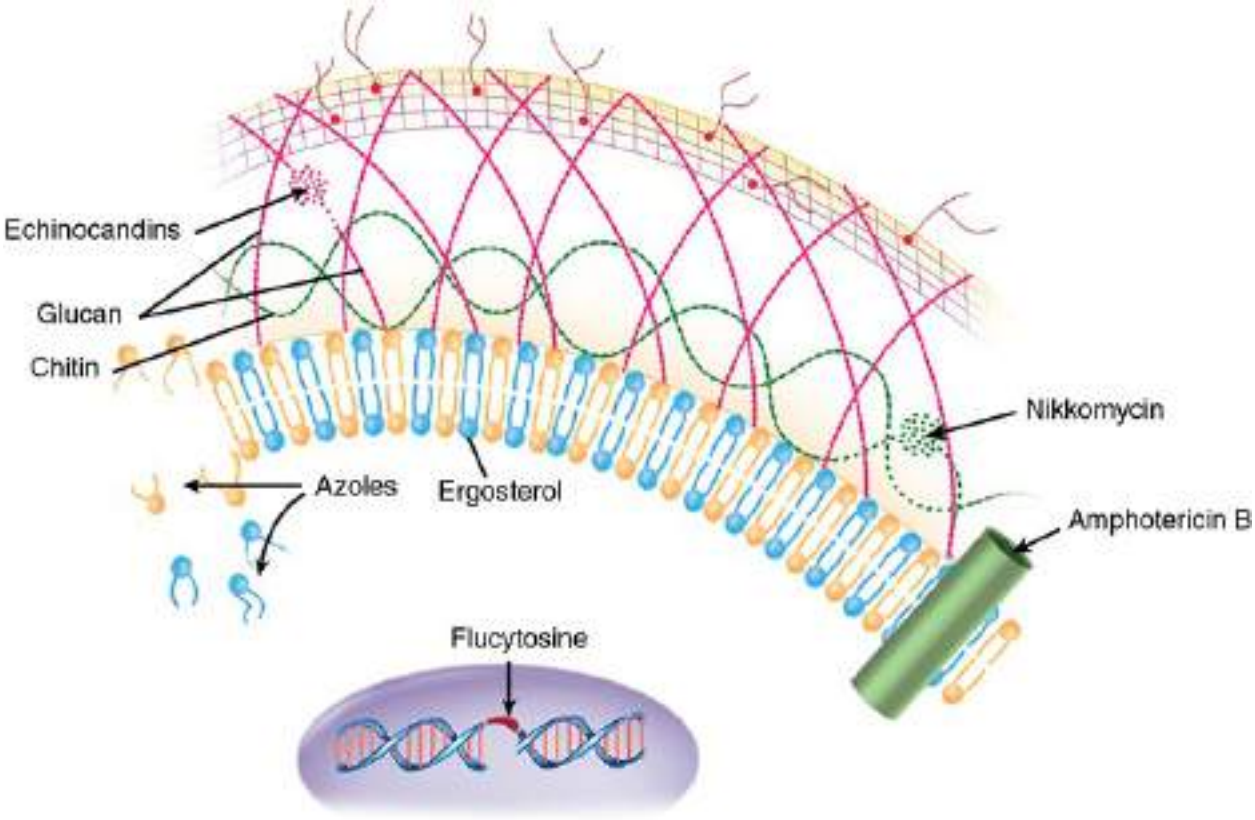

FIGURE 44–1. Sites of action of antifungal agents. This figure demonstrates the cellular targets of the major antifungal agents: (1) cell wall (echinocandins and nikkomycin—an experimental chitin synthase inhibitor), (2) cell membrane (azoles, amphotericin B), and (3) nucleic acid synthesis (flucytosine).

TABLE 44–1 Features of Antifungal Agents

AGENT	ACTION	RESISTANCE	ROUTE	CLINICAL USE
Polyenes				
Nystatin	Cell membrane pores	Sterol modification	Topical	Most fungi
Amphotericin B	Cell membrane pores	Sterol modification	Intravenous	*Aspergillus, Candida, Cryptococcus, Histoplasma, Sporothrix, Coccidioides, Zygomycetes*
Azoles				
Fluconazole	Ergosterol synthesis (demethylase)	Efflux, demethylase alteration, overproduction of target[a]	Oral, intravenous	*Candida, Cryptococcus, Histoplasma,*[c] *Coccidioides*[c]
Itraconazole	Ergosterol synthesis (demethylase)	Efflux, demethylase alteration, overproduction of target[a]	Oral, intravenous	*Aspergillus, Sporothrix, Candida, Blastomyces, Histoplasma, Coccidioides*
Voriconazole	Ergosterol synthesis (demethylase)		Oral, intravenous	*Candida, Aspergillus,* some saprophytic molds
Posaconazole	Ergosterol synthesis (demethylase)		Oral, intravenous	*Candida, Aspergillus* (prophylaxis), Zygomycetes
Isavuconazole	Ergosterol synthesis (demethylase)		Oral, intravenous	*Candida, Aspergillus* (prophylaxis), Zygomycetes
Clotrimazole	Ergosterol synthesis (demethylase)		Topical	*Candida,* dermatophytes
Ketoconazole	Ergosterol synthesis (demethylase)		Topical	*Candida,* dermatophytes
Miconazole	Ergosterol synthesis (demethylase)		Topical	*Candida,* dermatophytes
Allylamines				
Terbinafine	Ergosterol synthesis (squalene epoxidase)	?Efflux	Oral, topical	Dermatophytes
Flucytosine (5-FC)				
	DNA synthesis, RNA transcription	Permease or modifying enzymes[b] mutation	Oral	*Candida* and *Cryptococcus*[d]
Echinocandins				
Caspofungin	Glucan synthesis (β-glucan synthase)	Altered synthase	Intravenous	*Candida, Aspergillus*
Micafungin	Glucan synthesis (β-glucan synthase)	Altered synthase	Intravenous	*Candida, Aspergillus*
Anidulafungin	Glucan synthesis (β-glucan synthase)	Altered synthase	Intravenous	*Candida, Aspergillus*
Griseofulvin	Microtubule disruption	Unknown	Oral	Dermatophytes
Potassium iodide	Unknown	Unknown	Oral	*Sporothrix schenckii*

5-FC, 5-Flucytosine.
[a]Most work is with fluconazole and *Candida*; other azoles are to be assumed to be similar.
[b]Cytosine deaminase and uracil phosphoribosyltransferase (the enzymes that modify 5-FC to active forms).
[c]Itraconazole generally preferred.
[d]Only in combination with amphotericin B owing to developing resistance.

• ANTIFUNGAL AGENTS

CYTOPLASMIC MEMBRANE

▪ Polyenes

*** Amphotericin B binds ergosterol, forms membrane channels**

Cross-reactivity with mammalian sterols basis for toxicity

The polyenes **nystatin** and **amphotericin B** are lipophilic and bind to ergosterol, the dominant sterol in the cytoplasmic membrane of fungal cells. Sterol-binding by the polyenes has many adverse effects on the fungal cell, including the formation of annular channels that penetrate the membrane and lead to leakage of essential small molecules from the cytoplasm and cell death. Their binding affinity for the ergosterol in fungal membranes is not completely specific, cross-reacting with mammalian sterols such as cholesterol. This cross-binding is the basis for the considerable toxicity that limits their use. Almost all fungi are susceptible to amphotericin B, and the development of resistance is rare.

Amphotericin B must be infused in suspension

Therapy titrated against toxicity

At physiologic pH, amphotericin B is insoluble in water and must be administered intravenously as a colloidal suspension. It is not absorbed from the gastrointestinal tract. Infusion is commonly followed by chills, fever, headache, and dyspnea. The major limitation to amphotericin B therapy is the toxicity created by its affinity for mammalian as well as fungal membranes. The most serious toxic effect is renal dysfunction, observed in virtually every patient receiving a prolonged therapeutic course. Experienced clinicians learn to titrate the dosage for each patient to minimize the nephrotoxic effects. For obvious reasons, use of amphotericin B is limited to progressive, life-threatening fungal infections. In such cases, despite its toxicity, it retains a prime initial position in treatment and is often followed by the use of a less toxic agent. Preparations that complex amphotericin B with lipids have been used as a means to limit toxicity. The even greater toxicity of nystatin limits its use in topical preparations.

▪ Azoles

Inhibit enzyme crucial for synthesis of membrane ergosterol

The azoles are a large family of synthetic organic compounds, which include members with antibacterial, antifungal, and antiparasitic properties. Their activity is based on inhibition of the enzyme (14 α-demethylase) responsible for conversion of lanosterol to ergosterol, the major sterol of the fungal cell

membrane. This enzyme inhibition results in ergosterol depletion and lanosterol accumulation, thereby leading to defective fungal membranes. All antifungal azoles have the same basic mechanism of action. The differences among them are in avidity of enzyme binding, pharmacology, and side effects. Azoles can also affect the precursors of some hormones and may therefore cause endocrinological side effects, restricting their use in pregnancy.

Azoles less nephrotoxic than amphotericin B

Divided between yeast-active and mold-active agents

The systemic azoles are generally grouped based on antifungal spectrum. **Fluconazole** is primarily active against yeasts, including many *Cryptococcus* and *Candida* species. In contrast, newer azole compounds have extended activity against molds such as *Aspergillus* species, as well as the thermally dimorphic fungi (eg, *Coccidioides*, *Blastomyces*, *Histoplasma*). These mold-active azoles include **itraconazole, voriconazole, posaconazole,** and **isavuconazole**. Most of these agents can be given orally or parenterally. Although generally well tolerated, the antifungal azoles can cause varying degrees of liver toxicity. Additionally, all systemic azoles can adversely affect cardiac myocyte repolarization and therefore prolong the QTc interval on an EKG, placing patients at increased risk for cardiac arrhythmias. Among the systemic azoles, isavuconazole has the least potential for QTc prolongation. **Ketoconazole**, **clotrimazole,** and **miconazole** are available in over-the-counter topical preparations for superficial mycoses.

▪ Allylamines

Terbinafine inhibits ergosterol synthesis

The allylamines are a group of synthetic compounds that act by inhibition of an enzyme (squalene epoxidase) in the early stages of ergosterol synthesis. The allylamine group includes **terbinafine**, available in oral and topical forms for the treatment of dermatophyte (ringworm) infections.

CELL WALL SYNTHESIS

The unique chemical nature of the fungal cell wall, with its interwoven layers of mannans, glucans, and chitin (Figure 44–1), makes it an ideal target for

chemotherapeutic attack. The echinocandins, which block glucan synthesis, are now in widespread clinical use due to their potent antifungal effect and comparatively low adverse effect profile. Other cell wall-active antifungals are in preclinical development.

▪ Echinocandins

Inhibit enzyme crucial for glucan synthesis

Indications for *Candida, Aspergillus*

Echinocandins inhibit a glucan biosynthetic enzyme (β-1,3-D-glucan synthase) required for the synthesis of a structural cell wall carbohydrate of many fungi. Echinocandin administration, therefore, causes morphologic distortions and osmotic instability in yeasts and molds, similar to the effect of β-lactams on bacteria. The first such agent to be licensed was **caspofungin,** which has activity against *Candida* and *Aspergillus.* Although highly active against many *Candida* species, the echinocandins tend to be used as second-line agents for invasive aspergillosis. *Cryptococcus neoformans* and the thermally dimorphic fungi, whose cell wall glucans have a slightly different structure, are more tolerant of echinocandins. Therefore, echinocandins should not be used as primary therapy for these infections. Since there are no similar glucans in humans, echinocandin toxicity is minimal. Newer echinocandins, **micafungin** and **anidulafungin,** have the same mode of action and a similar spectrum of antifungal activity.

NUCLEIC ACID SYNTHESIS

▪ Flucytosine

5-FC inhibits RNA and DNA synthesis

5-Fluorocytosine (flucytosine/5-FC) is an analog of cytosine, one of the pyrimidine bases in both DNA and RNA. It is a potent inhibitor of nucleic acid synthesis. 5-FC requires a permease to enter the fungal cell, where its metabolites interfere with DNA synthesis and RNA transcription.

Active against yeasts but not molds

Resistance develops if used alone

Flucytosine is well absorbed after oral administration. It is active against most clinically important yeasts, including *Candida albicans* and *C neoformans*, but it has little activity against molds or dimorphic fungi. The frequent development of mutational resistance during therapy limits its application to mild yeast infections or its use in combination with amphotericin B for cryptococcal meningitis. The primary toxic effect of flucytosine is a reversible bone marrow suppression that can lead to neutropenia and thrombocytopenia. This effect is dose related and can be controlled by drug monitoring.

OTHER ANTIFUNGAL AGENTS

Microtubule disruption interferes with cell division

Active against dermatophytes

Griseofulvin is a product of one of the *Penicillium* species of molds. Griseofulvin is actively taken up by susceptible fungi and acts on the microtubules and associated proteins that make up the mitotic spindle. It interferes with cell division and possibly other cell functions associated with microtubules. Griseofulvin is absorbed from the gastrointestinal tract after oral administration and concentrates in the keratinized layers of the skin. It is active only against the agents of superficial mycoses. Clinical effectiveness has been demonstrated for many causes of dermatophyte infection, but the response is slow. Prolonged therapy may be required.

Iodide inhibits *Sporothrix*

Potassium iodide is the oldest known oral chemotherapeutic agent for a fungal infection. It is effective only for cutaneous sporotrichosis. Its activity is somewhat paradoxical because the mold form of the etiologic agent, *Sporothrix schenckii*, can grow on medium containing 10% potassium iodide. The pathogenic yeast form of this dimorphic fungus appears to be susceptible to molecular iodine.

• RESISTANCE TO ANTIFUNGAL AGENTS

DEFINITION OF RESISTANCE

Fungal resistance similar to bacteria

Fungal MICs labor intensive

The concepts, definitions, and laboratory methods described in Chapter 23 for bacterial resistance are generally applicable to fungi. Quantitative susceptibility is determined by measuring the minimal inhibitory concentration (MIC) of a drug under conditions that favor the growth of fungi. The wide range of growth rates and diversity of growth forms (yeast, hyphae, conidia) in the various fungi have added technical variables to testing, but standardized methods are now available. Comparison of MICs with drug pharmacology allows classification of fungi as susceptible or resistant, but these results do not yet predict clinical outcome with the same certainty they do with bacteria. Because of its specialized nature, the availability of antifungal susceptibility testing is restricted to major centers and reference laboratories.

MECHANISMS OF RESISTANCE

Many of the same resistance mechanisms observed in bacteria are also found in fungi. Fungi tend to primarily inactivate drug activity using efflux pumps and by altering their biosynthetic pathways. In contrast to bacteria, fungi do not make hydrolytic enzymes to inactivate antibiotics to the same extent as bacteria. In part this may be due to the reduced ability for horizontal gene transfer between species.

▪ Polyene Resistance

Amphotericin B resistance rare

Because amphotericin B binds directly to the ergosterol in the fungal cell membrane, the only means to resist this action is to change the membrane sterol composition. Therefore, only a few rare fungal species are intrinsically resistant to amphotericin B.

▪ Flucytosine Resistance

Multiple enzyme mutations cause flucytosine resistance

5-FC requires a permease for entry into the cell and then multiple enzymes to modify it to the active metabolites that inhibit nucleic acid synthesis. Mutation in

any one of these enzymes renders the drug ineffective. It is one of the few antimicrobials in which emergence of resistance is predictable *during* therapy of an acute infection. This is the reason that its use is mostly limited to combination therapy with other antifungals.

▪ Azole Resistance

Azole pumped out by efflux pumps

Enzyme target altered

There are several mechanisms by which fungi can become resistant to the azoles. The most well-characterized mechanism is through the induction of efflux pumps that transport the drug out of the cell. Some pumps act on all azoles, and others act on only one. Fungal species can also alter the subunits of the demethylase enzyme by mutation, effectively decreasing the affinity of the azole for its enzyme target. Multiple mutations can have an additive effect.

Demethylase enzyme upregulated or bypassed

Additionally, some fungi are able to decrease the effect of the azoles by increasing the production of the drug target. Some azole-resistant strains of *Candida* and *Cryptococcus* species actually duplicate regions of their genome to increase the number of copies of the demethylase-encoding genes. This results in the requirement of higher concentrations of the azole drug to inhibit fungal growth. Some azole-resistant strains have also been shown to accomplish ergosterol synthesis by an alternate pathway, thus bypassing the azole target enzyme. Of particular concern is the widespread agricultural use of azole fungicides in many countries. This practice may result in the transfer of azole resistance mechanisms to medically important fungi as azole resistance increases among environmental isolates.

▪ Echinocandin Resistance

Mutant glucan synthetase

Resistance to echinocandins has significantly increased in recent years. One resistance mechanism is an altered target. Mutations in subunits of the glucan synthetase have been correlated with increases in MIC more than a thousand-fold.

SELECTION OF ANTIFUNGALS

As with all chemotherapy, the selection of antifungal agents for treatment of superficial, subcutaneous, and systemic mycoses involves balancing expected efficacy against toxicity. The factors to be considered are the following: (1) the threat of morbidity or mortality posed by the specific infection, (2) the immune status of the patient, (3) the toxicity of the antifungal, and (4) the probable activity of the antifungal agent against the fungus. In the case of superficial mycoses, the risks of appropriate therapy are small, and various topical agents may be safely used. At the other extreme, an immunocompromised patient will most likely be treated aggressively with systemic agents for proven or even suspected systemic fungal infection. Since cultures and susceptibility tests may not be available at the time of presumptive diagnosis, the decisions regarding which agents to use are often made and sustained on an empiric basis. Even when guided by *in vitro* testing, treatment failures are common, particularly in highly immunocompromised patients, emphasizing the importance of the immune system in preventing and clearing systemic fungal infections.

KEY CONCLUSIONS

- Topical antifungal therapy can often be used for superficial infections, but invasive infections require systemic therapy.
- Antifungal agents act on several fungal cell targets, including the cell membrane (polyenes and azoles), the cell wall (echinocandins), and nucleic acid synthesis (flucytosine).
- Amphotericin B resistance is rare among fungi, but its use is limited by toxicity, especially nephrotoxicity.
- Azoles are frequently divided into those with activity primarily against yeasts (fluconazole) and those with expanded activity against molds (itraconazole, voriconazole, posaconazole, isavuconazole).
- Echinocandins are well-tolerated systemic antifungals that are most frequently used for infections due to *Candida* species, and as secondary agents for aspergillosis.
- Flucytosine is active against many yeasts, but resistance can develop during therapy if used as a single agent.

chapter 45

The Superficial and Subcutaneous Fungi: Dermatophytes, *Malassezia*, *Sporothrix*, and Pigmented Molds

Epidermophyton species • *Microsporum* species • *Trichophyton* species • *Malassezia furfur* • *Hortaea werneckii* • *Sporothrix schenckii* • *Fonsecaea* species • *Phialophora* species • *Cladophialophora* (*Cladosporium*) species

The least invasive of the pathogenic fungi are the dermatophytes and other superficial fungi that are adapted to the keratinized outer layers of the skin. Subcutaneous fungi go a step farther by extending infection to the tissue beneath the skin but rarely invading deeper structures (**Table 45-1**).

TABLE 45–1 Agents of Superficial and Subcutaneous Mycoses

FUNGAL GROWTH				
FUNGUS	IN LESION	IN CULTURE (25°C)	INFECTION SITE	DISEASE
Dermatophytes				
Microsporum canis	Septate hyphae	Mold	Hair,[a] skin	Ringworm
Microsporum audouinii	Septate hyphae	Mold	Hair[a]	Ringworm
Microsporum gypseum	Septate hyphae	Mold	Hair, skin	Ringworm
Trichophyton tonsurans	Septate hyphae	Mold	Hair, skin, nails	Ringworm
Trichophyton rubrum	Septate hyphae	Mold	Hair, skin, nails	Ringworm
Trichophyton mentagrophytes	Septate hyphae	Mold	Hair, skin	Ringworm
Trichophyton violaceum	Septate hyphae	Mold	Hair, skin, nails	Ringworm
Epidermophyton floccosum	Septate hyphae	Mold	Skin	Ringworm
Other superficial fungi				
Malassezia furfur[b]	Yeast (mycelia)[c]	Yeast	Skin (pink to brown)[d]	Pityriasis (tinea) versicolor
Hortaea werneckii[e]	Septate hyphae, ellipsoidal cells	Yeast (mold)	Skin (brown–black)[d]	Tinea nigra
Trichosporon cutaneum	Septate hyphae	Mold	Hair (white)[a]	White piedra
Piedraia hortae	Septate hyphae	Mold, ascospores	Hair (black)[a]	Black piedra
Subcutaneous fungi				
Sporothrix schenckii	Cigar-shaped yeast (rare)	Mold	Subcutaneous, lymphatic spread	Sporotrichosis
Fonsecaea pedrosoi	Muriform body[f]	Mold	Wart-like foot lesions	Chromoblastomycosis
Phialophora verrucosa	Muriform body[f]	Mold	Wart-like foot lesions	Chromoblastomycosis
Cladophialophora (Cladosporium) carrionii	Muriform body[f]	Mold	Wart-like foot lesions	Chromoblastomycosis

[a]Specimens fluoresce under ultraviolet light.

• SUPERFICIAL FUNGI

DERMATOPHYTES

OVERVIEW

Dermatophytoses are superficial infections of the skin and its appendages. Common names for these infections include ringworm (**Figure 45–1**), athlete's foot, and jock itch. They are caused by species of three genera collectively known as dermatophytes. These fungi are highly adapted to the nonliving, keratinized tissues of nails, hair, and the stratum corneum of the skin. The source of infection may be humans, animals, or the soil.

FIGURE 45–1. Ringworm. The ring-like lesions on this forearm are due to advancing growth of *Trichophyton mentagrophytes*. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

MYCOLOGY

* *Epidermophyton, Microsporum,* and *Trichophyton* major genera

The three genera of medically important dermatophytes (literally, skin-plants) are *Epidermophyton, Microsporum,* and *Trichophyton* (Table 45-1). Most dermatophyte infections are diagnosed and treated as a clinical syndrome since determining the causative species will not usually affect therapeutic choices.

DERMATOPHYTE DISEASE

CLINICAL CAPSULE

Dermatophytoses are slowly progressive eruptions of the skin and its appendages. Although often unsightly, they are not typically painful or life-threatening. The manifestations vary depending on the site of infection and vigor of the host response, but they often involve erythema, induration, itching, and scaling. The most familiar name is “ringworm,” describing the annular shape of the advancing edge of this cutaneous infection.

*** Transmission requires contact with intact or detached skin or hair**

Transmission can occur after close contact with an infected person or animal. However, exposure to detached skin scales or hair containing the fungal elements (fomites) may also result in new infections. Dermatophyte transmission has been described in many shared spaces, including locker room floors, barbershops, hotel carpets, and movie theater/airplane seats. However, health care workers do not need to take special precautions beyond handwashing after contact with an infected patient.

PATHOGENESIS

Initial infection through skin breaks

Fungal growth, skin desquamation determine outcome

Dermatophytoses begin when the infecting fungus comes in contact with skin, especially if there are minor breaks in the skin integrity. Detached hair and skin scales containing dermatophytes can remain infectious for months in the environment. Once the stratum corneum is penetrated, the organism can proliferate in the keratinized layers of the skin, with a variety of proteinases helping to establish infection. The course of the infection depends on many factors: the anatomic location, the degree of skin moisture, the dynamics of skin growth and desquamation, the speed and extent of the inflammatory response, and the infecting species. For example, if the organism grows very slowly in the stratum corneum and if skin turnover by desquamation is rapid, the infection will probably be short-lived and cause minimal signs and symptoms. Inflammation tends to increase desquamation rates and helps to limit infection, whereas immunosuppressive agents such as topical corticosteroids decrease shedding of the keratinized layers and tend to prolong infection. Invasion of any deeper structures is extremely rare.

Poor inflammatory response leads to chronic infection

Most dermatophyte infections are self-limited. However, those infections in which fungal growth rates and skin desquamation are balanced, and in which the inflammatory response is poor, tend to become chronic. The lateral spread of infection and its associated inflammation produce the characteristic sharp advancing margins that were once believed to be the burrows of worms. This characteristic is the origin of the common English name **ringworm,** as well as the Latin term *tinea* (worm), which is often applied to the clinical forms of the disease (Figure 45–1).

Hair shaft penetrated and broken

Infected nails thickened, dislodged

Infection may spread from skin to other keratinized structures, such as hair and nails, or may invade them primarily. The hair shaft is penetrated by hyphae (**Figure 45–2**), which extend either exclusively within the shaft (endothrix) or both within and outside the shaft (ectothrix). The end result is damage to the hair shaft structure, which often breaks off. Loss of hair at the root and plugging of the hair follicle with fungal elements may result. Invasion of the nail plate causes a hyperkeratotic reaction, which dislodges or distorts the nail (**onychomycosis**).

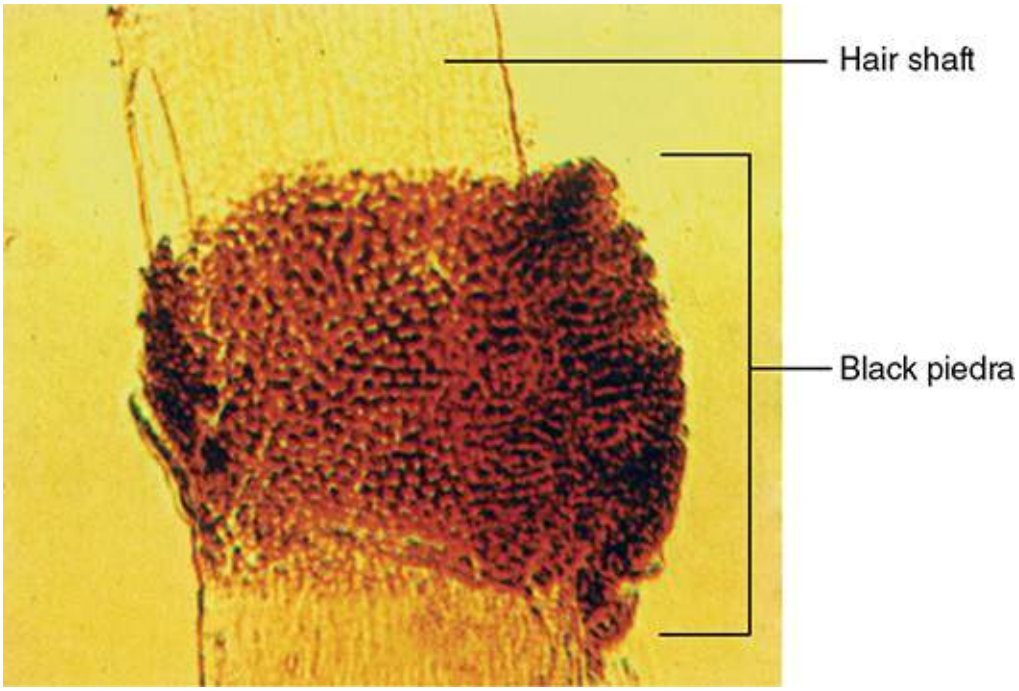

FIGURE 45–2. Black piedra. Note invasion by *Piedraia hortae* both within (endothrix) and outside

(ectothrix) the hair shaft. Dermatophyte invasion would be similar. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Widespread infection with T-lymphocyte defects and *T rubrum*

Occasionally, dermatophyte infections become chronic and widespread. This progression has been related to both host and organism factors. Approximately half of these patients have underlying diseases affecting their immune responses or are receiving treatments that compromise T-lymphocyte function. These chronic infections are particularly associated with *Trichophyton rubrum*, to which both normal and immunocompromised persons appear to be hyporesponsive. Interestingly, the clinical manifestations of these infections are largely due to delayed-type hypersensitivity responses rather than from direct effects of the fungus on the host.

DERMATOPHYTOSES: CLINICAL ASPECTS

MANIFESTATIONS

* *Involved skin site defines type of "tinea"

Dermatophyte infections range from inapparent colonization to chronic progressive eruptions that last months or years, causing considerable discomfort and disfiguration. Dermatologists often give each infection its own "disease" name based on the Latin name for the anatomic site at which the infection is found. For example, these names include *tinea capitis* (scalp; **Figure 45–3A**), *tinea pedis* (feet, athlete's foot), tinea manuum (hands), *tinea cruris* (groin), *tinea barbae* (beard, hair), and *tinea unguium* (nail beds). Skin infections otherwise not included in this anatomic list are called *tinea corporis* (body). There are certain clinical, etiologic, and epidemiologic differences among these syndromes, but they are basically the same disease in different locations. The primary differences among etiologic agents that infect different sites are shown in Table 45-1.

FIGURE 45–3. Tinea capitis. A. Ringworm of the scalp with superficial lesions and loss of hair. **B.** Close-up using an ultraviolet lamp (Wood's light) reveals fluorescing hair fragments. The culture grew *Microsporum audouinii*. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

Scalp infection leads to itching, hair loss

Tinea capitis. Infection of hair and the scalp begins with an erythematous papule around the hair shaft, which progresses to scaling of the scalp, and discoloration/fracture of the shaft. Spread to adjacent hair follicles progresses in a ring-like fashion, leaving behind broken, discolored hairs, and sometimes black dots where the hair is absent but the infection has invaded the follicle. In most cases, symptoms beyond itching are minimal, but the degree of inflammatory response markedly affects the clinical appearance and, in rare cases, can cause constitutional symptoms.

* Skin infection favors moist areas, skin folds

Other sites. Skin lesions on other parts of the body begin in a similar manner and enlarge to form sharply delineated erythematous patches with central clearing (nearly normal skin appearance in the center). Multiple lesions can fuse to form unusual geometric patterns on the skin. Lesions may appear in any location, but they are particularly common in moist, sweaty skin folds. Obesity and the wearing of tight apparel increase susceptibility to infection in the groin and beneath the breasts. Another form of infection, which involves scaling and splitting of the skin between the toes, is commonly known as **athlete's foot**. Again, excessive moisture and maceration of the skin provide the mode of entry.

*** Hyperkeratosis can dislodge the nail plate**

Nail bed infections first cause discoloration of the subungual tissue, followed by hyperkeratosis and discoloration of the nail plate. Progression of infection causes disfigurement of the nail but few symptoms until the nail plate is so dislodged or distorted that it exposes or compresses adjacent soft tissue. All dermatophyte infections provide a potential site of entry for skin bacteria, predisposing to more acute and painful lesions around the nail, or to more extensive bacterial cellulitis.

Why is it especially important to aggressively treat tinea pedis in patients with diabetes mellitus?

DIAGNOSIS

KOH mounts demonstrate hyphae

Some species fluoresce under UV light

The goal of diagnostic procedures is to distinguish dermatophytoses from other causes of skin inflammation. Infections caused by bacteria, other fungi, as well as noninfectious disorders (eg, psoriasis and contact dermatitis) may have similar features. The most important step of fungal detection is microscopic examination of material taken from the lesions. Potassium hydroxide (KOH) or calcofluor white preparations of skin scrapings from the advancing edge of a dermatophyte lesion often demonstrate septate hyphae. Examination of infected hairs reveals hyphae and arthroconidia penetrating the hair shaft. Some species of dermatophyte fluoresce when exposed to ultraviolet (UV) light, and selection of hairs for examination can be aided by the use of a UV (Wood's) lamp (Figure 45–3B).

Culture is used when KOH preparations are negative

Mild infections with typical clinical findings and positive KOH preparations are often not cultured because clinical management is not influenced significantly by the identity of the etiologic species. Suspected dermatophyte

infections with negative KOH preparations, especially those that fail to respond to empiric antifungal therapy, often require culture. The same material used for direct examination can be cultured for isolation of the offending dermatophyte (**Figure 45–4**).

FIGURE 45–4. Large boat-shaped macroconidia of *Microsporum gypseum*. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

TREATMENT AND PREVENTION

Topical terbinafine or azoles usually sufficient

Systemic antifungal agents used in refractory cases

Dermatophyte infections can usually be prevented simply by observing general hygiene measures. When they occur, many local skin infections resolve without specific antifungal therapy. Those that do not resolve may be treated with topical terbinafine or azoles (miconazole, ketoconazole). More extensive skin infections, especially those involving the scalp, often require systemic therapy with griseofulvin, itraconazole, or oral terbinafine, often combined with topical therapy. Nail infections are especially difficult to cure, likely due to the slow turnover of the infected nail and poor penetration of antifungal agents. Therapy

for nail infections must be continued over weeks to months, and relapses may occur. Keratolytic agents (Whitfield's ointment) may be useful for reducing the size of hyperkeratotic lesions.

Think ▸▸ Apply 45-1: Many chronic changes occur in the skin of the feet of patients with diabetes mellitus. Due to diabetes-associated microvascular changes, the skin can become thin and dystrophic. Also, diabetes-associated peripheral neuropathy can prevent diabetic patients from noticing microtrauma to the skin that occurs during daily activity. Together, these changes predispose many diabetic patients to develop bacterial cellulitis of the lower extremities. This condition is more likely if the skin barrier is compromised by tinea pedis, allowing bacteria ready access to deeper skin layers.

▪ Other Superficial Mycoses

M furfur requires lipids for growth

Pityriasis (tinea) versicolor is a very common superficial fungal infection of the skin. It is characterized by discrete patches of either hypopigmentation or hyperpigmentation, especially on the skin of the torso and upper arms. These lesions are associated with some scaling but minimal induration. Pityriasis versicolor is most commonly caused by fungi of the genus *Malassezia*, especially *Malassezia furfur*. These fungal species are common components of the skin microbiome, but they are present more abundantly in the setting of clinical infection. In scrapings of infected skin, they appear as clusters of budding yeast cells mixed with hyphae. *Malassezia* species grow in the yeast form in culture media enriched with lipids.

H werneckii causes superficial pigmented lesions of hands and feet

Tinea nigra, another superficial skin infection, is characterized by brown to black macular lesions, usually on the palms or soles. There is little associated inflammation or scaling, and skin architecture is well preserved since the infection is confined to the stratum corneum. This feature distinguishes tinea nigra from other pigmented lesions such as melanomas, which tend to change

the lines and markings of the skin. This infection is caused by melanized, black-pigmented fungi ("dematiaceous" fungi) such as *Hortaea werneckii*, commonly found in soil and other environmental sites. Scrapings of the lesion show brown- to black-pigmented septate hyphae.

Black or white piedra infections of the hair shaft

Piedra is an infection of the hair characterized by black or white nodules attached to the hair shaft. White piedra (caused by *Trichosporon cutaneum*) infects the shaft in a hyphal form that can fragment into component buds. Black piedra (caused by *Piedraia hortae*) grows as branched hyphae in the hair shaft (Figure 45–2).

SUBCUTANEOUS FUNGI

Many fungal pathogens can produce subcutaneous lesions as part of their disease spectrum. However, those considered here are introduced traumatically through the skin, with infection typically limited to subcutaneous tissues, lymphatic vessels, and contiguous tissues. These fungi rarely spread to distant organs. The diseases they cause include *sporotrichosis*, *chromoblastomycosis*, and *mycetoma*. Only sporotrichosis has a single specific etiologic agent, *Sporothrix schenckii*. Chromoblastomycosis and mycetoma are clinical syndromes with multiple fungal etiologies.

SPOROTHRIX

SPOROTHRIX SCHENCKII

Mold forms convert to cigar-shaped yeasts during infection

Sporothrix schenckii is a dimorphic fungus that grows as a cigar shaped, 3- to 5-mm yeast in tissues and in culture at 37°C. The mold, which grows in cultures incubated at 25°C, is presumably the infectious form in nature.

SPOROTRICHOSIS

OVERVIEW

Sporothrix schenckii is widely present in soil and other organic matter. Sporotrichosis begins with injection of the organism's conidia into the subcutaneous tissue, typically by a thorn prick or splinter in the hand. *Sporothrix schenckii* induces a slowly progressive infection that follows the lymphatic drainage from the original site (lymphangitis). Superficial ulcers may occur, but the infection rarely involves deeper structures.

EPIDEMIOLOGY

*** Inoculated by gardener, farmer trauma**

Sporothrix schenckii is a ubiquitous saprophyte particularly found in hay, moss, soil (including potting soil), and decaying vegetation, as well as the surfaces of various plants. Infection is acquired by traumatic inoculation of the fungus through the skin, often affecting gardeners, farmers, and rural laborers.

SPOROTRICHOSIS: CLINICAL ASPECTS

MANIFESTATIONS

Skin papule ulcerates

*** Lymphatic involvement creates multiple lesions**

Skin lesions due to *S schenckii* begin as painless papules developing a few weeks to a few months after inoculation. Its location can usually be explained by occupational exposure, most often involving the hand. The initial papule enlarges slowly and eventually ulcerates, leaving an open sore. Pustular or firm nodular lesions may appear around the primary site of infection or at other sites along the lymphatic drainage route (**Figure 45–5**). The spread of infection along

lymphatic channels is so characteristic for this infection that lymphangitic progression of any infection is often referred to as having a “sporotrichoid” appearance. Ulcerated lesions can become chronic, and multiple ulcers develop if the disease is untreated. Symptoms are directly related to the local areas of infection. Constitutional signs and symptoms in sporotrichosis are rare.

FIGURE 45–5. Sporotrichosis. A. This infection began on the finger and has started to spread up the lymphatic channels of the arm, leaving satellite lesions behind. If untreated, these lesions will evolve into ulcers. **B.** A more advanced case beginning with inoculation in the foot. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

DIAGNOSIS

Direct microscopic examination for *S schenckii* is usually unrewarding because there are too few organisms to detect readily with KOH preparations. Even specially stained biopsy samples and serial sections are usually negative, although the presence of a histopathologic structure, the asteroid body, is suggestive. This structure is composed of *S schenckii* yeast cells surrounded by amorphous eosinophilic “rays.” Definitive diagnosis depends on culture of infected pus or tissue. The organism grows within 2 to 5 days on all commonly used mycology media. Identification requires demonstration of both the typical conidia and of dimorphism.

TREATMENT AND PREVENTION

Potassium iodide replaced by itraconazole

Historically, cutaneous sporotrichosis was treated with a saturated solution of

potassium iodide (SSKI) administered orally. Itraconazole is now preferred for all forms of disease, with oral terbinafine and SSKI as alternatives. Pulmonary and systemic infections may require the additional use of amphotericin B. Eradication of the environmental reservoir of *S schenckii* is not usually practical.

• CHROMOBLASTOMYCOSIS

Multiple species produce wart-like pigmented lesions in tropics

Chromoblastomycosis is a chronic form of skin infection caused by multiple species of pigmented saprophytic fungi, also known as melanized or "dematiaceous" fungi. Disease caused by *Fonsecaea*, *Phialophora*, and *Cladophialophora* (*Cladosporium*) species typically occurs on the foot or leg, the sites of skin inoculation by the fungus. Primary lesions appear as papules that develop into scaly, wart-like structures, usually under the feet. Fully developed lesions have been likened to the tips of a cauliflower. Extension occurs through painless, slowly progressive satellite lesions. The organisms are found in the soil of endemic areas, and most infections occur in individuals who work barefoot. Disseminated infections due to the dematiaceous molds are uncommon, observed almost exclusively in highly immunocompromised patients. In these patients, certain pigmented molds have a predilection for infecting the central nervous system. Therefore, in highly immunocompromised patients, the isolation of a pigmented mold from a clinical specimen cannot necessarily be ignored as a contaminant.

Brown pigmented bodies seen in chromoblastomycosis

The outstanding mycologic feature in chromoblastomycosis is the presence in histological sections of brown-pigmented, thick-walled, multiseptate, 5 to 12 mm globose structures called muriform bodies. Branching septate hyphae may also be demonstrated in KOH preparations of tissue scrapings. In culture these fungi grow as darkly pigmented molds. Surgery and antifungal therapy have been used in treatment, but cure rates of advanced disease are disappointing. Itraconazole and other mold-active azoles are the systemic antifungal agents most frequently used for this infection.

• MYCETOMA

Mycetoma is the clinical term for a chronic, disfiguring infection associated with prior trauma to the foot. This infection is caused by varied microorganisms, with more than a dozen fungi described as potential etiologies. Bacterial species such as actinomycetes and *Nocardia* species (Chapter 28) may produce a similar disease. The typical clinical appearance of mycetoma is that of massive induration with draining sinuses. Some of the fungi that cause mycetoma are geographically widespread. Most cases, however, occur in the tropics, probably because the chronically damp, macerated skin of the feet among those who go barefoot. An illustrative case of mycetoma occurred in a college rower in Seattle; he was the only member of his shell who insisted on rowing barefoot.

*** Massive inflammatory lesions of feet with draining sinuses**

Multiple species involved

Trauma to bare feet injects fungi

Once infection is established, treatment of mycetoma is difficult, often requiring combined surgical and antimicrobial therapy depending on the causative microbe. Mycetomas cause by environmental molds may demonstrate hyphae in biopsied tissue. However, these fungal elements may be difficult to demonstrate because of a tendency to form microcolony granules. The definitive diagnosis of the etiological agent often requires culture of infected tissue.

SUMMARY

- Superficial fungal infections are frequently self-limited and can often be treated with topical antifungal therapy.
- Dermatophytes infect the superficial, keratinized layers of the skin.
- Dermatophyte infections are generally diagnosed as a clinical syndrome, named for the infected body site (eg, tinea capitis, tinea pedis).
- Nail infections caused by dermatophytes are especially difficult to cure.
- Pityriasis (tinea) versicolor, caused by *M furfur*, manifests as patches of hypo- or hyper-pigmented lesions of the skin of the torso and proximal extremities.
- Sporotrichosis begins by inoculation of the skin with soil or plant material, and often spreads along regional lymphatics as nodules and ulcers.

CLINICAL CASE

Head Bump

A 4-year-old boy was taken by his mother to the family doctor for evaluation of a 2-month history of a slowly growing “bump” on the back of his head. The boy had no other siblings or any pets at home. He attended a day care center each weekday. Examination revealed a happy, alert child in no distress. A raised, scaling lesion 3.5 cm in diameter with a few pinpoint pustules was present on the posterior scalp. A KOH preparation of material from the lesion was negative. A fungal culture of material from the lesion was later positive for a fungus with numerous microconidia and macroconidia typical of *Microsporum* species.

QUESTIONS

1. What is the most likely source of this child's infection?

A. Parents
B. Child at day care center
C. Animal
D. Insect
E. Food

2. What is the human niche where this organism proliferates best?

A. Fibronectin
B. Macrophages
C. M cells
D. Keratin

3. What additional examination might have revealed this infection while the child was in the doctor's office?

A. X-ray
B. Serologic test
C. Ultraviolet light
D. Biopsy
E. DNA probe

ANSWERS

1. **(B)**
2. **(D)**
3. **(C)**

chapter 46

The Opportunistic Fungi: *Candida*, *Aspergillus*, the Zygomycetes, and *Pneumocystis*

Candida albicans • *Candida glabrata* • *Candida krusei* • *Candida tropicalis* • *Candida parapsilosis* • *Candida auris* • *Aspergillus fumigatus* • *Absidia species* • *Rhizopus species* • *Mucor species* • *Pneumocystis jirovecii*

The "opportunistic fungi" are usually found as members of the resident human microbiota or on decaying matter in the environment. With the breakdown of host defenses, they can cause infections ranging from skin/mucous membrane involvement to life-threatening, systemic disease. The most common opportunistic infections are caused by two species: the yeast *Candida albicans*, a common inhabitant of the gastrointestinal and genital microbiota; and the mold *Aspergillus fumigatus* which is widespread in the environment. *Pneumocystis*, a frequent cause of pneumonia in AIDS patients, is an unusual fungus that used to be considered a parasite on morphologic grounds. However, it too is a frequent colonizer of the human respiratory tract. The diseases caused by these opportunistic fungi are summarized in **Table 46-1**.

TABLE 46–1

ORGANISM	TISSUE	CULTURE AT 37°C	SOURCE	INFECTION
Candida	Yeast (hyphae)[a]	Yeast	Endogenous	Skin, mucous membranes, urinary tract, disseminated
Aspergillus	Hyphae (septate)	Mold	Environment	Lung, disseminated
Zygomycetes[b]	Hyphae (nonseptate)	Mold	Environment	Rhinocerebral, lung, disseminated
Pneumocystis	Elliptical spores	None[c]	Unknown	Pneumonia

[a]Less common feature; pseudohyphae are produced as well.
[b]Common genera include *Absidia*, *Mucor*, *Rhizopus*.
[c]Has not been grown in culture.

• *CANDIDA*

MYCOLOGY

* *C albicans* morphologies: yeast, hyphae, and pseudohyphae

Candida species grow in multiple morphologic forms, most often as a budding yeast. *C albicans* is also able to form hypha-like structures triggered by changes in conditions such as temperature, pH, and available nutrients. When observed in their initial stages of germination from the yeast cell, these nascent hyphae resemble sprouts and are called "germ tubes" (**Figure 46–2A**). Most *C albicans* strains produce germ tubes when incubated in the presence of serum, allowing a rapid means of distinguishing this species from other *Candida* species. Other elongated forms with restrictions at regular intervals are called **pseudohyphae** because they lack the parallel walls and septation of true hyphae. Germ tube–negative strains may be further identified biochemically or reported as "yeast not *C albicans*," depending on their apparent clinical significance.

CANDIDIASIS

OVERVIEW

Candidiasis occurs in localized and disseminated forms. Localized disease often presents as erythema and white plaques in moist skinfolds (diaper rash/intertrigo) or on mucosal surfaces (oral thrush). It may also cause the itching and thick white discharge of vulvovaginitis. *Candida* bloodstream and urinary tract infections (UTIs) are especially common among hospitalized patients with intravenous and urinary catheters. Deep tissue and disseminated infections are limited almost exclusively to the immunocompromised.

EPIDEMIOLOGY

* Infections from endogenous flora entering deep tissues via intravascular devices

C albicans is present in the microbiota of 30% to 50% of healthy persons, especially common in the oropharyngeal, gastrointestinal, and female genital tracts. Most infections, even those occurring in hospitalized patients, are thought

to arise from one's own resident species. However, transmission and new acquisition of *Candida* colonization can occur by direct mucosal contact with others (eg, through sexual intercourse). Other factors that increase the risk of *Candida* infections include invasive procedures, indwelling intravascular devices, and the prolonged use of antibacterial agents.

PATHOGENESIS

Transitions between yeast and hyphae important for invasion, dissemination

Switch triggered by environment

The ability of *Candida* species to change between the yeast and hyphal forms is strongly associated with its pathogenic potential, and these different morphological forms are likely required for different phases of candidiasis (**Figure 46–1**). In histologic preparations, hyphal structures are seen during *Candida* invasion, either superficially into the mucosa or within deep tissues (Figure 46–3). However, systemic dissemination in the bloodstream most likely occurs by smaller yeast-like forms. Therefore, it is the plasticity between yeast and hyphal forms, rather than one morphology or the other, that results in the ability of *C albicans* to so effectively colonize and infect the host (**Figure 46–4**). The yeast-hyphal switch can be controlled *in vitro* by the manipulation of a wide variety of environmental conditions (serum, pH, temperature, amino acids). Various sensors and signaling pathways for morphogenesis have been described, including those in which *C albicans* induces its own morphological change by directly altering the local pH.

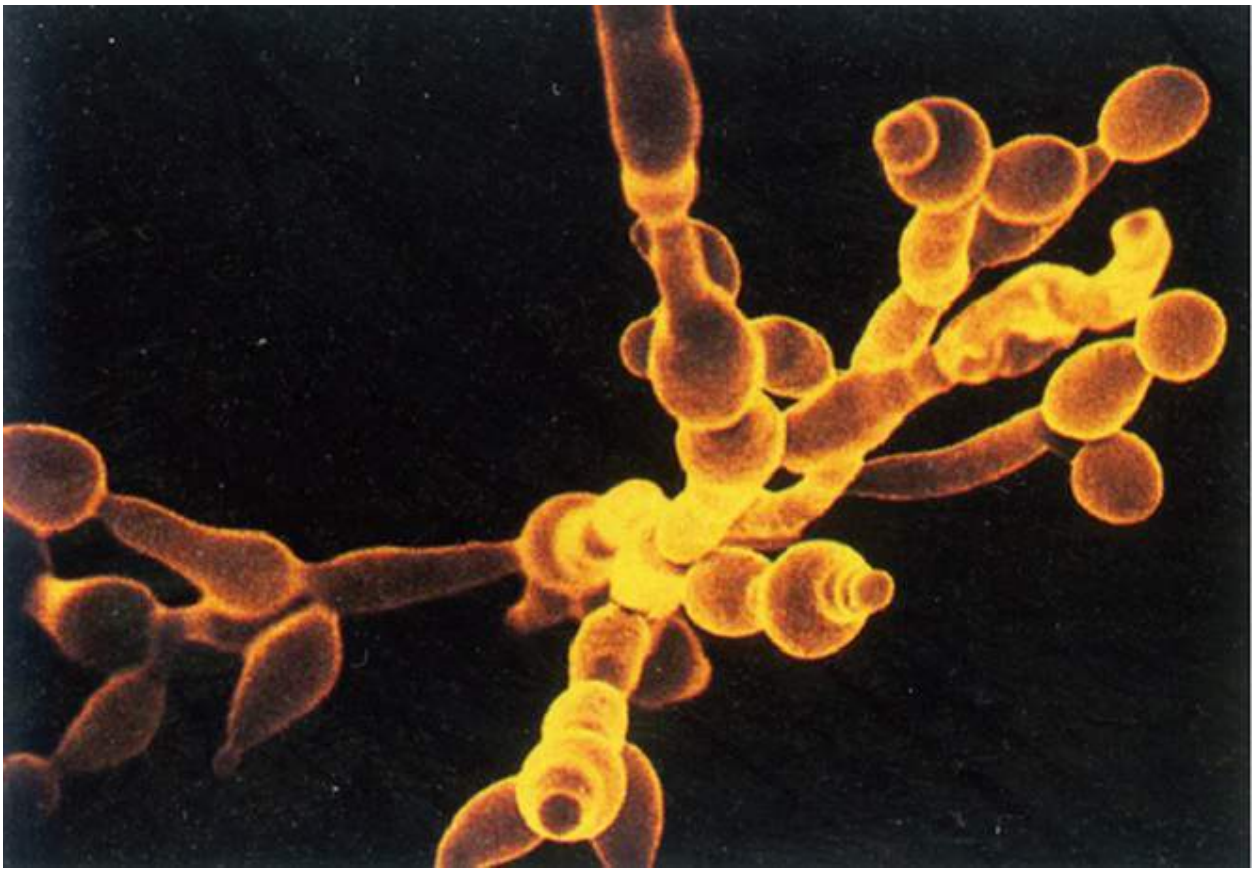

FIGURE 46–1. ***Candida albicans.*** This scanning electron micrograph demonstrates dimorphism with both yeast-like cells and hyphae. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

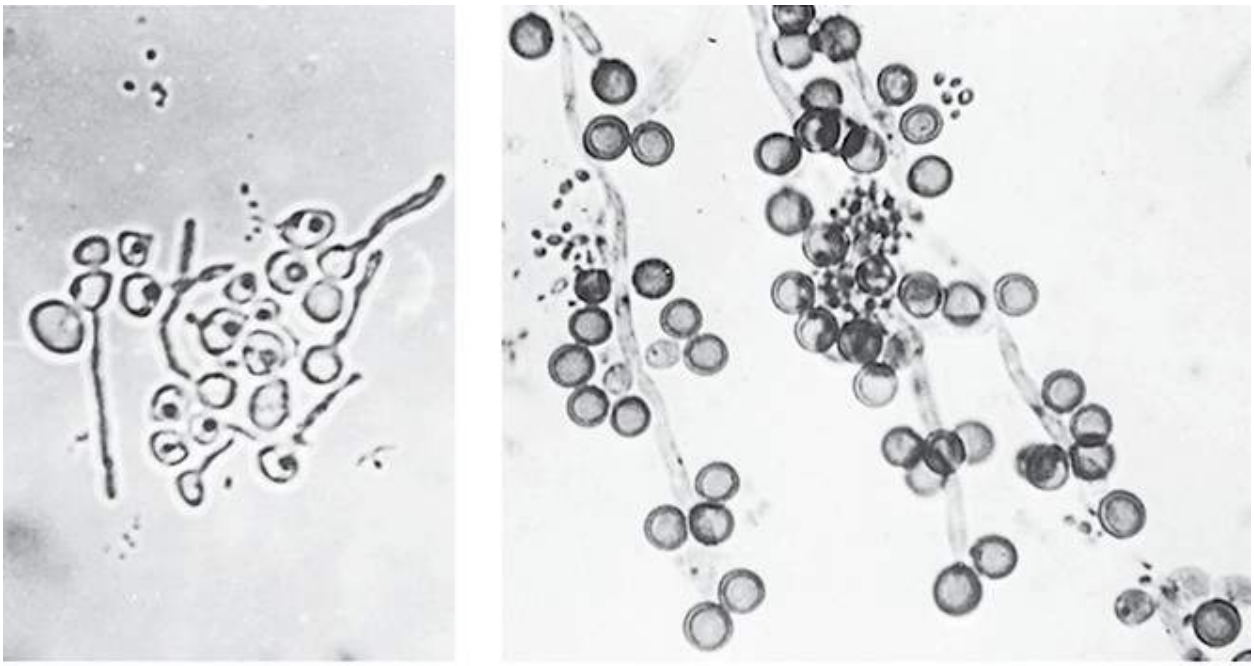

FIGURE 46–2. ***Candida albicans.*** **A.** When incubated at 37°C and in the presence of serum, *C albicans* rapidly forms elongated hyphae called germ tubes. **B.** On specialized media, *C albicans* forms thick-walled chlamydoconidia, which differentiate it from other *Candida* species.

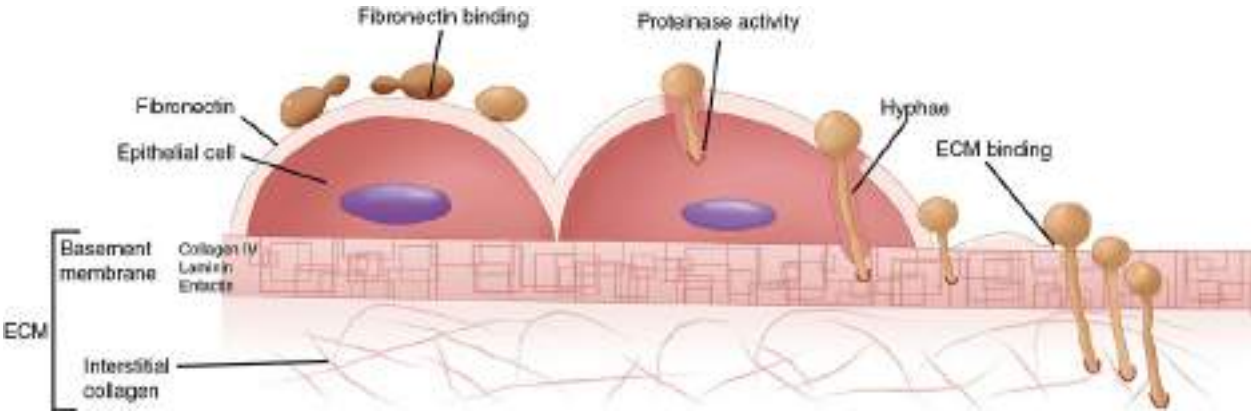

FIGURE 46–3. **Pathogenesis of *Candida albicans* infections.** Proposed mechanisms of *C albicans* attachment and invasion are shown. Surface glycoproteins on the yeast may bind to fibronectin covering the host epithelial cell, or to elements of the extracellular matrix (ECM) when the epithelial surface is disrupted. Invasion is associated with formation of hyphae and production of proteinases, which may digest tissue elements.

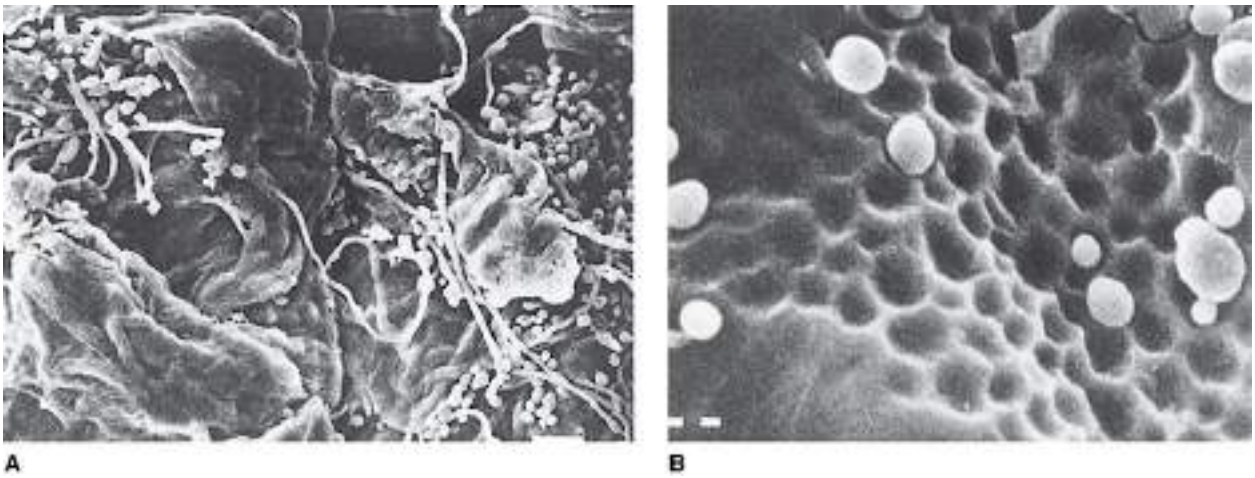

FIGURE 46–4. Invasiveness of *Candida albicans*. Two features of *C albicans* invasiveness are seen in these scanning electron micrographs taken from experiments with murine corneocytes. **A.** Both yeast-like and hyphal elements are present. The filamentous elements spread over the surface and invade the cell cuticle. **B.** A *C albicans* strain that produces a protease is seen producing cavity-like depressions in the cell surface. This activity could play a role in invasion of host tissue. (Reproduced with permission of Ray TL, Payne CD: Scanning electron microscopy of epidermal adherence and cavitation in murine candidiasis: a role for Candida acid proteinase, *Infect Immunol* 1988;Aug;56(8):1942–1949.)

Fungal biofilms adhere to surfaces and inhibit immune cell function and antifungal penetration

One of the most important pathogenic features of *C albicans* is its ability to form biofilms. These complex structures include yeast and hyphal forms of the fungus along with host-derived proteins. Once formed, the biofilm strongly adheres to components of the extracellular matrix (ECM) as well as to plastics. Neither host immune cells nor antifungal agents are able to penetrate *Candida* biofilms well, making this structure an important source of microbial persistence during infection. In a very practical sense, fungal biofilms that develop on prosthetic surfaces (eg, intravenous catheters, prosthetic joints, prosthetic heart valves) are almost impossible to sterilize without device removal.

Antimicrobials, immunosuppression increase risk

Disruptions provide access to ECM

Many factors predispose to both local and invasive *Candida* infections. Antibacterial therapy reduces microbial competition on mucosal surfaces and increases the relative abundance of *C albicans* within the microbiota. Alterations in innate immunity (eg, leukopenia or corticosteroid therapy) or adaptive immunity (eg, AIDS) are important contributing factors to systemic and mucosal

candidiasis. Additionally, anatomic disruptions of the skin and mucosa may enhance the invasion process by exposing *Candida* binding sites in the ECM, and by allowing direct access to deeper tissues. Biofilm formation on medical devices also contributes to fungal persistence in this host. Diabetes mellitus predisposes to *C albicans* infection, possibly due to greater production of surface mannoproteins in the presence of high glucose concentrations.

IMMUNITY

As a mucosal colonizer, *C albicans* is in continuous contact with epithelial cells and innate immune effectors. At this interface, the epithelial cells secrete potent antifungal peptides, such as candidalysin, that nonspecifically inhibit fungal growth. These mucosal lining cells are also the initiators of more specific antifungal immunity mediated by the binding of host receptors (EphA2, EGFR/Her2, E-cadherin) to fungal surface features such as β-glucans and Als adhesin proteins. These receptor-ligand interactions result in NF-kB and MAP kinase-mediated activation of proinflammatory cytokines and chemokines leading to the recruitment of macrophages, polymorphonuclear neutrophils (PMNs), and Th17 cells. These latter cells also induce further antimicrobial peptides such as β-defensins.

Epithelial cells secrete antifungal peptides

Th17 immunity mediator of protection

Many immunodeficiency syndromes involving T-lymphocyte dysfunction result in severe mucocutaneous candidiasis, emphasizing the importance of this arm of the immune system in defense against mucosal *Candida* infections. For example, patients with AIDS develop frequent episodes of oral and esophageal candidiasis, suggesting that protection against mucosal infections involves CD4-mediated immune responses.

Host pattern recognition receptors identify fungal surface features, activate immunity

Systemic candidiasis is most frequently a disease involving device biofilms and the disruption of protective anatomic barriers. Once introduced into distant sites through the bloodstream, *C albicans* cells are readily recognized by innate immune cells such as neutrophils and resident macrophages. This occurs through

the recognition of fungal surface components such as β-glucans by host pattern recognition receptors, including dectin-1. Innate humoral elements, including complement proteins, play an important role in enhancing fungal cell phagocytosis and recruiting additional immune cells to local sites of infection. Anti-*Candida* antibodies are readily detected in most people, but their role in preventing and clearing established infections is less well defined than cellular defenses.

CANDIDIASIS: CLINICAL ASPECTS

MANIFESTATIONS

*** White mucosal plaque called thrush**

*** Vaginitis may be recurrent**

Superficial invasion of the mucous membranes by *C albicans* produces a white, cheesy plaque that is loosely adherent to the mucosal surface. Oral lesions, called **thrush,** occur on the tongue, palate, and other mucosal surfaces as ragged white patches (**Figure 46–5**). Scraping the fungal plaque with a tongue blade will reveal varying degrees of underlying mucosal invasion and inflammation, helping to differentiate this infectious process from other causes of superficial oral films. Similarly, **vulvovaginal candidiasis** presents with a thick, curd-like vaginal discharge and itching. Although many women have at least one episode of vulvovaginal candidiasis in a lifetime, a small proportion suffers chronic, recurrent infections.

FIGURE 46–5. Thrush. The white plaques on this AIDS patient's tongue are caused by *Candida albicans*. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.

* Macerated skin a common site of infection

Superficial *C albicans* infections also occur in skin folds and other areas in which wet, macerated skin surfaces are opposed. For example, one type of diaper rash is caused by *C albicans* (**Figure 46–6A**). Other infections of the skinfolds and appendages occur in association with recurrent immersion in water (eg, dishwashers). The initial lesions are erythematous papules or confluent areas of erythema, tenderness, and skin fissures. Infection usually remains confined to the chronically irritated area with adjacent "satellite" lesions.

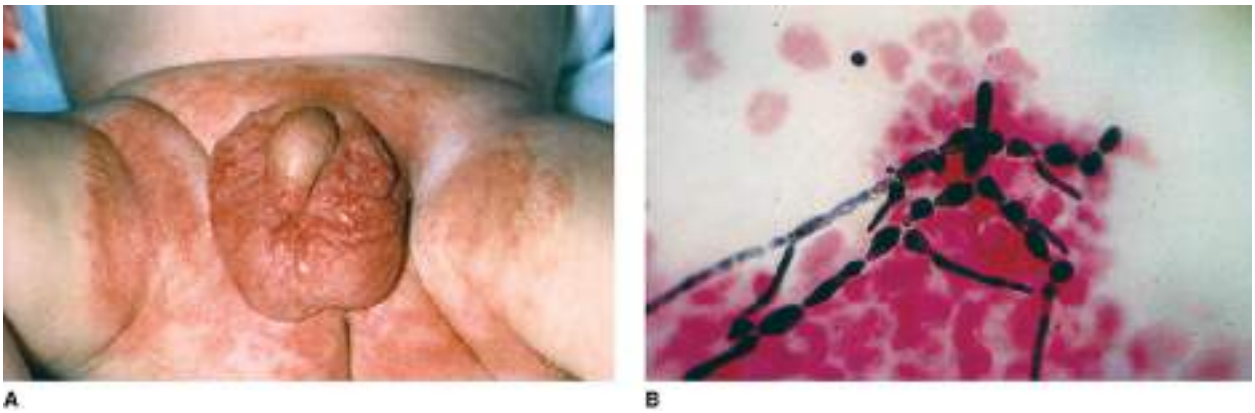

FIGURE 46–6. ***Candida albicans*** **skin infection. A.** This rash is preceded by chronically damp skin in the diaper area. **B.** This Gram stain demonstrates yeast cells and pseudohyphae. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

Rarely, chronic and relapsing *Candida* infections occur in patients with a specific defect in T_H1 immune defenses. This condition, known as **chronic mucocutaneous candidiasis (CMC)**, manifests with recurrent severe skin and mucosal lesions. With time, patients with CMC experience considerable skin disfigurement. Although lesions may become extensive, they usually do not result in fungal dissemination.

Chronic mucocutaneous candidiasis is associated with specific T-cell defects

In contrast, most people live their entire lives in constant contact with *C albicans* but without developing symptomatic infections. This observation largely reflects the ability of normal hosts to effectively control the growth of this fungus. However, *Candida* colonization without associated symptomatic inflammation may also represent a clinical example of immunologic tolerance—to be able to be exposed to a microorganism without developing an excessive immune response. Therefore, it is possible that a subset of patients with frequent episodes of symptomatic candidiasis (eg, recurrent vulvovaginal candidiasis) actually fails to appropriately suppress an over-exuberant immune reaction to resident fungi, as opposed to defects controlling microbial growth.

* Esophagitis, intestinal candidiasis similar to thrush

Inflammatory patches similar to those in thrush may also develop in the esophagus and upper GI tract. These lesions occur most frequently in immunocompromised patients and are characterized by painful swallowing or

substernal chest pain. Extensive ulcerations, scarring, and occasionally perforation of the esophagus may ensue.

In addition to infection of mucosal surfaces, Candida infection often involve the urinary tract. Ascending infections may produce cystitis, pyelonephritis, renal abscesses, or expanding fungus ball lesions in the renal pelvis. Patients with urinary catheters, kidney transplants, or other types of chronic urinary devices are at risk for these infections.

UTIs ascending or hematogenous

Disseminated candidiasis associated with high mortality

Endophthalmitis appears as white cotton-like retinal lesions

Disseminated infections are the most serious forms of candidiasis, associated with a very high attributable mortality. These infections occur most frequently in hospitalized patients, and the fungus often gains access to the bloodstream through disruptions of the skin (eg, burns, intravascular catheters), alteractions of the GI tract (eg, intestinal perforations, abdominal surgery), or prosthetic devices colonized with *Candida* biofilms. Once in the bloodstream, *Candida* species can infect many organs, including the kidneys, brain, and heart valves. Patients with candidemia typically have fever and a sepsis-like syndrome. However, these symptoms are generally not sufficiently characteristic to suggest *C albicans* over bacterial pathogens. Importantly, disseminated candidiasis frequently involves the eye. *Candida* **endophthalmitis** has the characteristic funduscopic appearance of a white cotton ball expanding on the retina or floating free in the vitreous humor. Endophthalmitis and infections of other eye structures can lead to blindness, and ocular complications must be considered in cases of disseminated candidiasis.

- **What specific interventions might limit the incidence of mucosal candidiasis (oral thrush and vaginal candidiasis) in immunologically normal hosts?**
- **What specific interventions might limit the incidence of candidemia in hospitalized patients?**

DIAGNOSIS

KOH and Gram smears show yeast and hyphae

Readily grown in routine culture

Exudate or epithelial scrapings examined by KOH preparations (Figure 46–6B) demonstrate abundant budding yeast cells; if associated hyphae/pseudohyphae are present, the infection is almost certainly caused by *C albicans. C albicans* is readily isolated in culture from clinical specimens including blood. Cultures from respiratory specimens, such as sputum, run the risk of contamination from yeasts present in the normal oropharyngeal flora.

Deep organ involvement is difficult to prove without a direct aspirate or biopsy. However, *Candida* species often grow in routine blood cultures, and every episode of candidemia must be carefully evaluated for evidence of dissemination, endophthalmitis, and involvement of prosthetic devices.

TREATMENT

*** Topical nystatin or azoles for superficial lesions**

*** Amphotericin B, fluconazole, and echinocandins for invasive disease**

C albicans is usually susceptible to amphotericin B, nystatin, flucytosine, the echinocandins, and the azoles. Superficial infections are generally treated with topical nystatin or azole preparations. Measures to decrease moisture and chronic trauma are important adjuncts in treating *Candida* skin infections. All *C albicans* infections may also require addressing predisposing conditions. For example, removal of an infected catheter, control of diabetes, or optimizing underlying medical conditions can be important aspects of the complete treatment of infection. Systemic therapy with amphotericin B, echinocandins, or azoles is required for disseminated or deep tissue infections. The choice of treatment is often guided by speciation and antifungal susceptibility testing. Fluconazole has been effective treatment for CMC and recurrent mucosal infections, although antifungal resistance can develop with the prolonged use of this agent.

Think ▸▸ Apply 46-1: Many cases of oral thrush could be prevented by limiting unnecessary antibacterial use, avoiding the associated disruption of the mucosal microbiota that predisposes to yeast overgrowth. Candidemia can be limited by minimizing unnecessary intravenous and urinary catheter use in hospitalized patients. In healthcare settings, adherence to good hand-hygiene limits spread from person to person.

OTHER CANDIDA SPECIES

*** Hospitalization increases risk for non-*albicans Candida***

*** *C glabrata, C krusei, C auris* often resistant to azoles**

Candida species other than *C albicans* can produce very similar infections to those described above, especially disseminated and UTI. However, these non-albicans *Candida* species are isolated almost exclusively from patients with nosocomial infections. Antibiotic use, wounds, and prosthetic devices predispose hospitalized patients to infections with diverse *Candida* species. Some species, such as *C glabrata, C krusei*, and *C auris* display increased levels of resistance to the azole antifungals. Therefore, these species may selectively colonize patients previously treated with azoles. Other *Candida* species, including *C tropicalis* and *C parapsilosis*, are often more susceptible to standard antifungals, but they are also isolated mostly from hospitalized patients, perhaps arising from the altered microbiota resulting from the hospital environment. Nosocomial transmission of *Candida* species may occur with poor adherence to proper handwashing and other infection control practices.

• *ASPERGILLUS*

MYCOLOGY

Species are distinguished based on arrangement of conidia on the

conidiophore

Aspergillus species are rapidly growing molds that are frequently isolated from the environment and thus are common causes of infections in patients with severe immune compromising conditions. Both in culture and during infection, *Aspergillus* species grow as branching **septate hyphae**. With prolonged culture in the laboratory, fruiting bodies develop as sites of spore (conidia) formation. Individual species are identified based on differences in the structure of the **conidiophore** and the arrangement of the **conidia**. (**Figure 46–7A–C**). The most common cause of infections in humans is *A fumigatus*, but others species, such as *A flavus, A niger,* and *A terreus* may less frequently cause human disease. For all of these species, fluffy colonies appear in 1 to 2 days; by 5 days, hyphal growth may cover an entire culture plate.

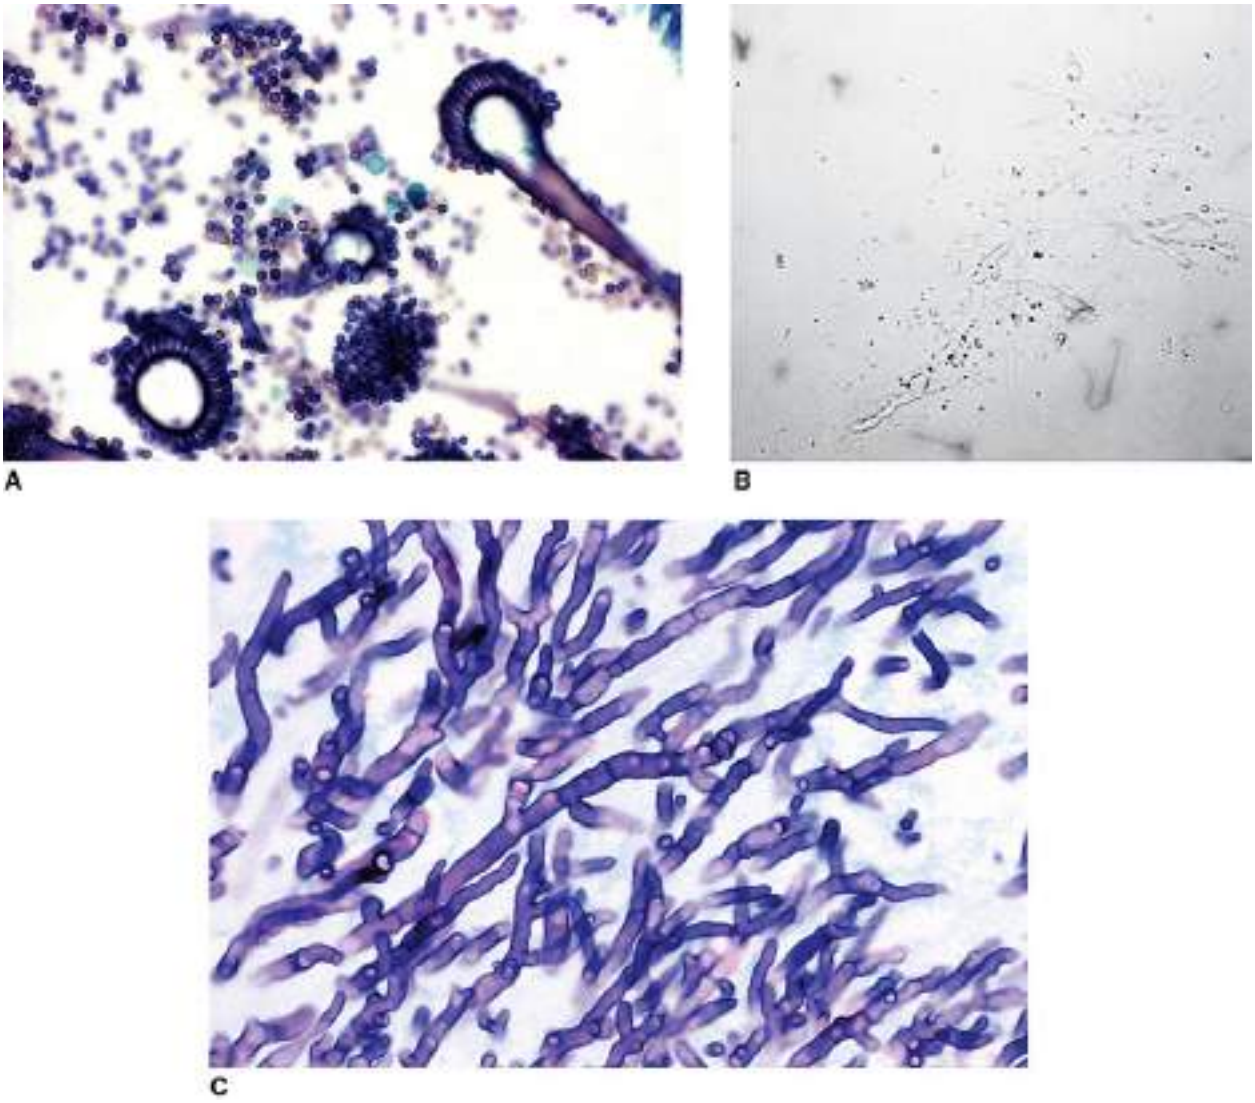

FIGURE 46–7. ***Aspergillus*. A.** This asexual conidium-forming structure is characteristic of *Aspergillus* species. The conidia are borne at the end of the finger-like extensions at the end of the conidiophore. These structures are rarely produced *in vivo*. **B.** This tissue aspirate mixed with KOH shows branching, septate hyphae. **C.** Histologic sections also show branching, septate hyphae, but because the conidia shown in A are not seen, the findings are not diagnostic of *Aspergillus*. (A and C, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

• ASPERGILLOSIS

OVERVIEW

Invasive aspergillosis occurs in highly immunocompromised persons, often rapidly resulting in death. Patients at highest risk for this infection typically have prolonged neutropenia due to treatments for hematological malignancies, or perhaps those undergoing hematopoietic stem cell transplantation. Most infections are acquired by inhaling infectious spores from the environment. Fever and a dry cough may be the only clinical signs of early aspergillosis, even before lung consolidation is demonstrated radiologically. Finding definitive evidence for *Aspergillus* infections is challenging. Therefore, many patients are treated empirically for this condition when suspicious lung infiltrates are observed in the setting of profound immunosuppression.

EPIDEMIOLOGY

Conidia may be spread through air ducts in hospital units

Aspergillus species are widely distributed in nature and throughout the world. They seem to adapt to a wide range of environmental conditions, and the heat-resistant conidia provide a good mechanism for dispersal. Like bacterial spores, the fungal conidia survive well in the environment, and human infection is most commonly caused by inhalation. Outbreaks of pulmonary aspergillosis in hospitals have been traced to fungal spores transmitted through air ducts, emphasizing the potential for environmental acquisition of infection. Similarly, building construction and remodeling have also been associated with increased frequency of *Aspergillus* infections. Hospital wards with highly immunocompromised patients often use specialized air filtration devices to limit patient exposure to these environmental fungi.

PATHOGENESIS

Inhaled conidia reach terminal airways

Once inhaled, *Aspergillus* conidia are small enough to readily reach the terminal airways and alveoli. However, the resident innate immune cells are able to suppress the germination of these cells into growing hyphae. Therefore, lung infections due to *Aspergillus* species are exceeding rare in people with normal immune systems. Host factors favoring *Aspergillus* growth include anatomic abnormalities of the lungs (eg, bronchiectasis, severe emphysema) and immunosuppression (neutropenia, lung transplantation).

IMMUNITY

*** Alveolar macrophages kill conidia**

*** PMNs attack hyphae**

Macrophages, particularly pulmonary alveolar macrophages, are the first line of defense against inhaled *Aspergillus* conidia, phagocytosing and killing them prior to germination. For the conidia that survive and germinate, PMNs become the primary defense. They are able to attach to the growing hyphae, generate an oxidative burst, and secrete reactive oxygen intermediates. Patients with AIDS rarely develop pulmonary or disseminated aspergillosis, suggesting that adaptive, T-cell mediated immunity is less important than innate immune mechanisms in controlling and preventing this infection. Antibodies to *Aspergillus* fungal elements are formed during infection, but their protective value is incompletely defined.

ASPERGILLOSIS: CLINICAL ASPECTS

MANIFESTATIONS

Aspergillus infections typically present in one of four major ways, with the clinical findings completely dependent on the immune status of the host. These clinical presentations include: (1) *Aspergillus* pneumonia, (2) disseminated aspergillosis, (3) allergic respiratory disease, and (4) aspergilloma (fungus ball).

Aspergillus pneumonia. As the main site of fungal cell entry into the body, the lung is the primary organ involved in most cases of aspergillosis. Although

innate immune responses in the lung are usually able to clear *Aspergillus* spores as they are inhaled, anatomic and immune defects can allow this fungus to grow and establish infection. Patients with severe forms of emphysema and bronchiectasis, including those with cystic fibrosis, have regions of anatomic abnormalities within their lungs that offer protected sites for fungal germination and growth. Resident lung macrophages and neutrophils are less effective at controlling fungal growth in these regions of scarring and tissue destruction within the airways and lung parenchyma. In the presence of an intact immune system, the infection is unable to deeply penetrate into the surrounding lung tissue or to disseminate. However, this smoldering infection can result in symptoms of chronic bronchopneumonia, with flares of cough and worsening respiratory function.

*** Pulmonary aspergillosis in immunocompromised patient highly invasive**

In contrast, patients with severe defects of immunity, such as solid-organ transplantation or neutropenia, can develop a progressive and immediately life-threatening pneumonia due to *Aspergillus* species. This rapidly progressive infection does not require prior lung anatomic abnormalities, and it emphasizes the importance of the innate immune system in preventing fungal colonization and growth. During invasive pulmonary aspergillosis, the fungal hyphae penetrate intact lung tissue and blood vessels, leading to local necrosis (Figure 46–7C). Symptoms include fever, cough, hemoptysis, and respiratory failure. Rapidly progressive lung infiltrates are often observed radiographically. Untreated, this infection quickly leads to death. Even in the presence of antifungal therapy, cure of this infection often requires restoration of immune function (eg, recovery from neutropenia, reduction of transplant immunosuppression). When feasible, surgical debridement of infected tissue combined with antifungals may favor patient survival.

Disseminated aspergillosis. Once a primary *Aspergillus* infection is established in an immunocompromised patient, the fungus can disseminate through the bloodstream to affect any organ system in the body. The most dreaded site of spread is the central nervous system. The symptoms of disseminated infection will depend on the organs affected. However, changes in mental status, or other specific organ dysfunction, should always prompt a thorough clinical investigation in immunosuppressed patients. isseminated aspergillosis carries a high mortality rate. Therefore, much effort has gone into developing rapid

diagnostic and preventive strategies in neutropenic patients, since delays in the treatment of invasive aspergillosis (IA) are associated with worse survival.

Allergic respiratory disease. As ubiquitous components of the air, fungal spores are typically captured by mucus present in our respiratory tract. In patients with allergic tendencies, the accumulation of excessive mucus in the airways may provide a growth substrate for inhaled fungi. After germinating, these fungal elements are not able to invade the underlying respiratory tissue, nor are they able to disseminate from this initial growth site. However, as potent allergens, the fungi may induce a cycle of progressive inflammation, creating enhanced mucinous substrate for fungal growth. The growth of environmental *Aspergillus* species in the sinuses and larger airways can cause chronic allergic symptoms in susceptible patients. Allergic sinus disease due to fungi is thought to be an especially common cause of chronic sinusitis.

Allergic disease marked by eosinophilia and specific anti-*Aspergillus* IgG

Treated with antiallergy therapy and not antifungals

Of note, children with severe forms of asthma are especially prone to develop a condition known as allergic bronchopulmonary aspergillosis (ABPA), characterized by eosinophilia, symptomatic asthma flares, cough, and respiratory distress. Anti-*Aspergillus* antibodies can often be detected in the bloodstream. During flares of ABPA, fleeting infiltrates may be seen on chest radiographs. These infiltrates do not reflect invasive fungal disease, but rather extensive inflammation due to the allergic reaction to fungal antigens. This condition is treated with antiallergy therapy (eg, inhaled/systemic corticosteroids, antihistamines, immunotherapy) rather than antifungals.

Fungus ball in lung cavities can injure surrounding blood vessels, cause hemoptysis

Aspergilloma (fungus ball). Patients with prior lung infections can develop pulmonary scarring and cavities. Historically, this was especially common in patients with old, healed pulmonary tuberculosis. Fungal spores that found their way into these cavities were often able to grow into macroscopic fungal colonies. These “balls” of fungal hyphae appear radiographically as round regions of consolidation inside of old lung cavities. Unable to penetrate into the

surrounding tissues, these fungus balls nonetheless are often able to induce mechanical trauma to the wall of the lung cavity. Patients with aspergillomas therefore often experience recurrent episodes of hemoptysis. If large blood vessels are present near these cavities, life-threatening bleeding can occur. Antifungal therapy may help some patients with this condition. However, cavity removal or catheter-guided embolization of involved lung vessels may be required for recurrent hemorrhages due to aspergillomas.

DIAGNOSIS

Direct aspirate or biopsy often required

Serodiagnosis useful for allergic disease

Antigen testing helpful in neutropenic patients

Aspergillus can often be isolated and identified in cultures of infected tissue. The diagnostic problem is distinguishing *Aspergillus* contamination and colonization from invasive disease. However, the isolation of a pathogenic *Aspergillus* species from a susceptible host with a consistent clinical setting is highly suggestive of IA. The diagnosis often requires invasive techniques such as lung biopsy or bronchoalveolar lavage (BAL). Fungal growth from infected material is demonstrated by the presence of branching, septate hyphae (Figure 46–7B and C). Infrequently, the complete fruiting bodies are produced *in vivo*, creating a striking and diagnostic histologic picture (Figure 46–7A). Serological demonstration of anti-*Aspergillus* antibodies may be helpful in suggesting allergic aspergillosis, but they have little value in defining invasive disease. Immunoassays detecting circulating *Aspergillus* antigens (galactomannan, glucans) are also helpful, especially when used serially in neutropenic patients to detect preclinical infections.

Why would rapid and noninvasive diagnostic tests be important advances for invasive aspergillosis?

TREATMENT AND PREVENTION

*** Mold-active azoles, amphotericin B, echinocandins, and surgery**

The mold-active azoles are the preferred treatments for IA. Echinocandins and amphotericin B are alternatives. No regimen is considered highly effective because the mortality rate of invasive disease is high; therefore, azoles are often used as prophylactic agents in susceptible patients. Surgical removal of infected tissue is sometimes helpful, even in the brain. Construction of rooms with filtered air has been effective in reducing exposure to environmental conidia.

• ZYGOMYCETES AND ZYGOMYCOSIS/MUCORMYCOSIS

***Absidia, Rhizopus,* and *Mucor* soil saprophytes**

*** Immunocompromised hosts infected**

Zygomycosis (mucormycosis) refers to infection with the zygomycete fungi, including *Absidia*, *Rhizopus*, and *Mucor* species. These fungi are ubiquitous decomposers in soil and are commonly found growing on bread and many other foods. Infections are most common in patients with neutropenia. Zygomycetes occasionally cause disease in persons with diabetes mellitus (especially those with frequent episodes of diabetic ketoacidosis) and in immunosuppressed patients receiving corticosteroid therapy.

Think ▸▸ Apply 46-2: Due to the devastated immune system of most patients with IA, this infection can progress rapidly, leading to patient death. Culture-based diagnostic tests are rarely positive in this infection, perhaps due to poor access to adequate specimens. Patients with neutropenia (low neutrophils) are also frequently thrombocytopenic (low platelets), making clinicians hesitant to biopsy infected tissue due to concerns for hemorrhage. Delays in diagnosis and treatment of IA are associated with poor survival.

Pulmonary disease similar to other fungi

Sinus infections can erode to the brain

Similar to aspergillosis, pulmonary or rhinocerebral mucormycosis is acquired by inhalation of conidia from the environment. The pulmonary form has clinical findings similar to those of other fungal pneumonias, with dense pulmonary consolidation. In rhinocerebral mucormycosis, the infecting fungi penetrate the mucosa of the nose, paranasal sinuses, or palate, often resulting in ulcerative lesions. Once beyond the mucosa, they progress through tissue, nerves, blood vessels, and fascial planes, potentially reaching the base of the brain. This clinical syndrome typically begins with sinus symptoms and headache, rapidly progressing to orbital cellulitis, cranial nerve palsy, vascular thrombosis, coma, and death.

* Large ribbon-like, aseptate hyphae seen in tissues

The pathologic findings in mucormycosis are distinctive: zygomycetes all show ribbon-like, **nonseptate (aseptate) hyphae** in tissue which are so large that their branch points can be difficult to visualize (**Figure 46–8**). As with *Aspergillus* infections, tissue biopsies are usually necessary to demonstrate the invasive hyphae, unless they can be seen on scrapings from palatal or nasal ulcers. For reasons that are unclear, cultures are sometimes negative, even those from tissue containing characteristic hyphae. Therapy involves control of underlying disease (eg, recovery from neutropenia, treatment of hyperglycemia) and high-dose antifungal therapy (lipid-associated amphotericin B, selected azoles). Surgical debridement is the most important intervention favoring survival and cure of infection.

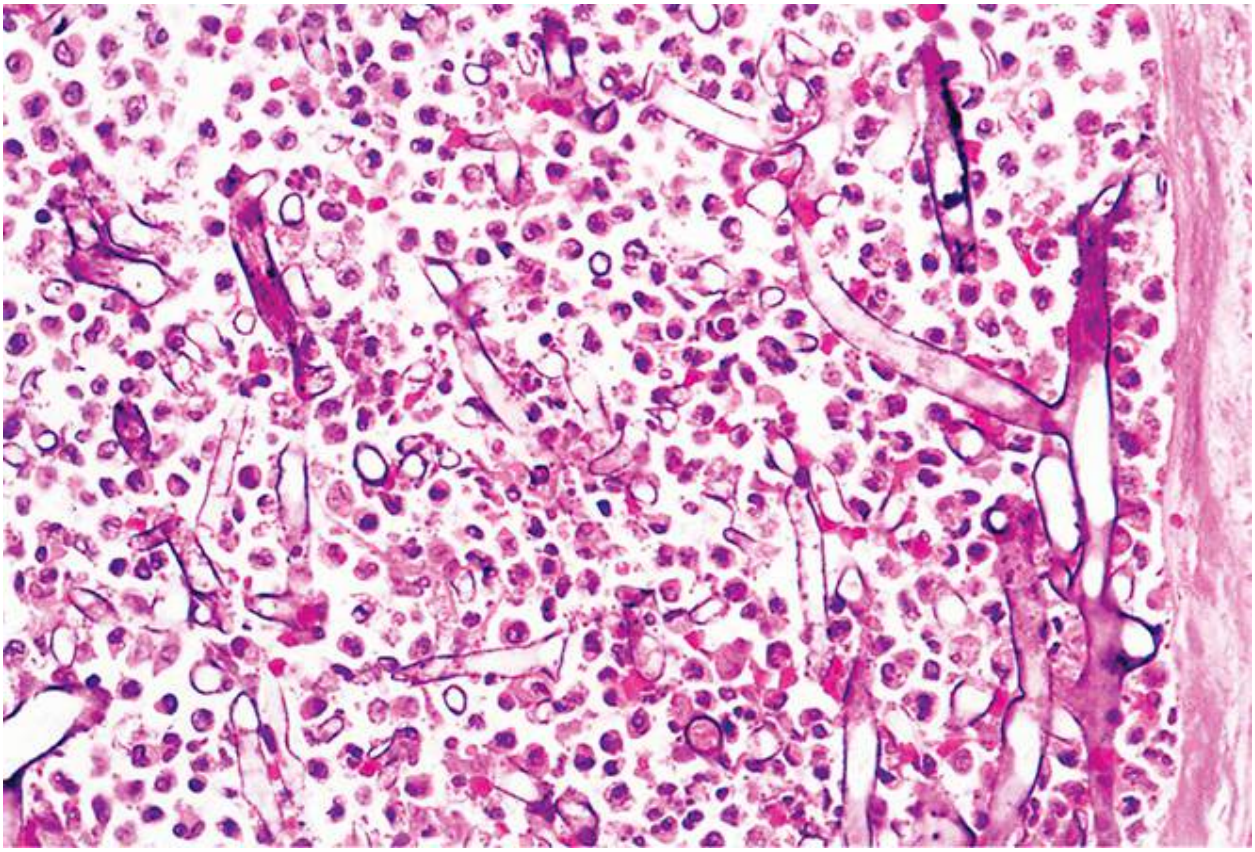

FIGURE 46–8. Zygomycosis. This zygomycete has invaded a blood vessel. Note the ribbon-like hyphae without septation. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

• *PNEUMOCYSTIS*

Pneumocystis jirovecii is a ubiquitous colonizer of the human airway. It does not cause infections in most people, but it can cause a lethal pneumonia in immunocompromised persons, particularly those with AIDS. The more familiar name to many clinicians, *P carinii,* is now used for a *Pneumocystis* species found in rats. *P jirovecii* has not been grown in culture and was long considered a parasite rather than a fungus based on the morphology of forms seen in infected tissue.

MYCOLOGY

Life cycle is deduced from static images

Because it has not been possible to cultivate *Pneumocystis*, our knowledge about its basic biology is limited. Observations rest on the study of organisms purified from infected lungs and genomic analysis of *Pneumocystis* DNA. The *Pneumocystis* "life cycle" is deduced from static images seen in infected tissues. The observed stages include delicate 5 to 8 μm cystic structures (**Figure 46–9**). The trophic form is bounded by a cell wall and cytoplasmic membrane that enclose a nucleus and several mitochondria. As the precyst matures, the nuclei divide to form eight "spores" within the original structure to form the cyst. The spores have an eccentric nucleus, a nucleolus, and a single mitochondrion in the cytoplasm. No filamentous form has been observed.

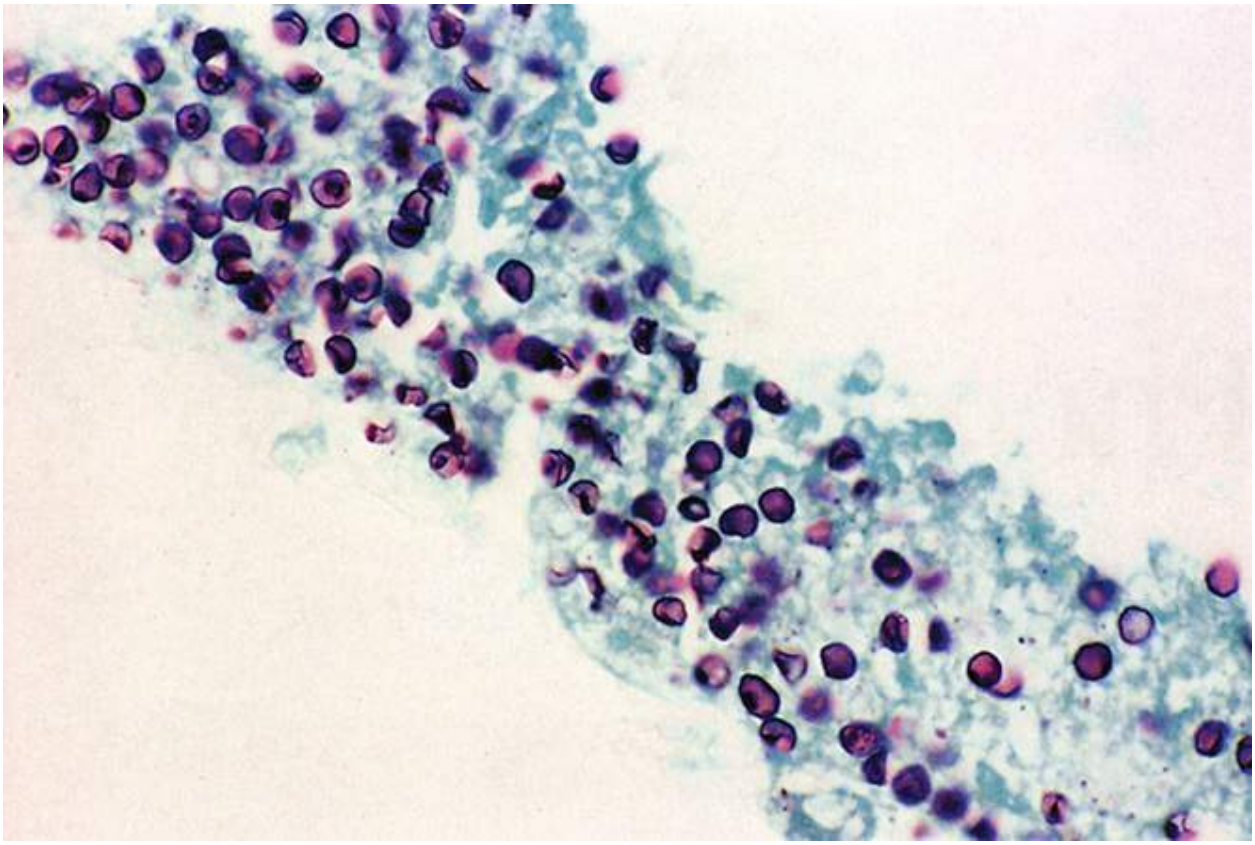

FIGURE 46–9. *Pneumocystis* pneumonia. A methenamine silver stain of material from an infected lung reveals folded cysts, some of which contain comma-shaped spores. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

PNEUMOCYSTOSIS

OVERVIEW

Pneumocystis pneumonia is an opportunistic infection with nonspecific initial symptoms, including fever or malaise. Respiratory symptoms come later with nonproductive cough and shortness of breath. Radiographs reveal symmetric alveolar pulmonary infiltrates, which spread outward from the hilar regions. Untreated progressive hypoxia can lead to death in a 3- to 4-week period. The observation of an increased incidence of *Pneumocystis* pneumonia in the early 1980s was one of the first clinical clues to the identification of HIV/AIDS.

EPIDEMIOLOGY

Worldwide distribution in humans and animals

Airborne transmission probable

Lung colonization with *Pneumocystis* species occurs worldwide in humans and in a broad spectrum of animal life. Exposure is nearly ubiquitous; specific antibodies are present in most children by the age of 4. The reservoir and mode of transmission remain unknown, but laboratory rodents acquire *Pneumocystis* colonization with the first breaths of life. Perhaps due to low organism burden, *Pneumocystis* is not typically observed in the respiratory tract of asymptomatic persons. However, its frequent presence in the human lung was suggested by nucleic acid amplification techniques in over half of asymptomatic victims of automobile accidents. Among HIV-infected individuals, the strains involved in second and third episodes of *Pneumocystis* infection are frequently antigenically different, suggesting frequent reacquisition of new strains.

* PCP is a complication of immunodeficient states

* AIDS patients are at high risk

Before the AIDS pandemic, *Pneumocystis* pneumonia (PCP) occurred sporadically among infants with congenital immunodeficiencies and in older children and adults as a complication of immunosuppressive therapy. Now AIDS has become the most common predisposing condition, and PCP is often a presenting manifestation of late-stage HIV infection. In fact, before the development of effective chemoprophylactic regimens (see Treatment and Prevention), PCP occurred in approximately 50% of all AIDS patients at the time of initial diagnosis.

PATHOGENESIS

Low CD4 counts increase the risk in AIDS

Pneumocystis is an organism of low virulence, which seldom produces disease in a host with normal T-lymphocyte function. In experimental animals, progressive infection can be initiated with starvation or corticosteroid administration. In AIDS patients, the risk of developing pneumocystosis increases dramatically once the CD4+ T-lymphocyte count has fallen below 200 cells/mm^3. Concurrent viral, bacterial, fungal, and protozoan infections are found frequently in humans with PCP, suggesting that *Pneumocystis* may require the presence of another microbial agent for its multiplication.

Alveoli filled with foamy exudate

Histologically, PCP is characterized by alveoli filled with desquamated alveolar cells, monocytes, organisms, and fluid, producing a distinctive foamy, honeycombed appearance (**Figure 46–10**). Hyaline membranes suggestive of ARDS may be present. *Pneumocystis* is not easily visualized by routine histological strains, but its presence is more apparent by methenamine silver or similar silver-containing stains.

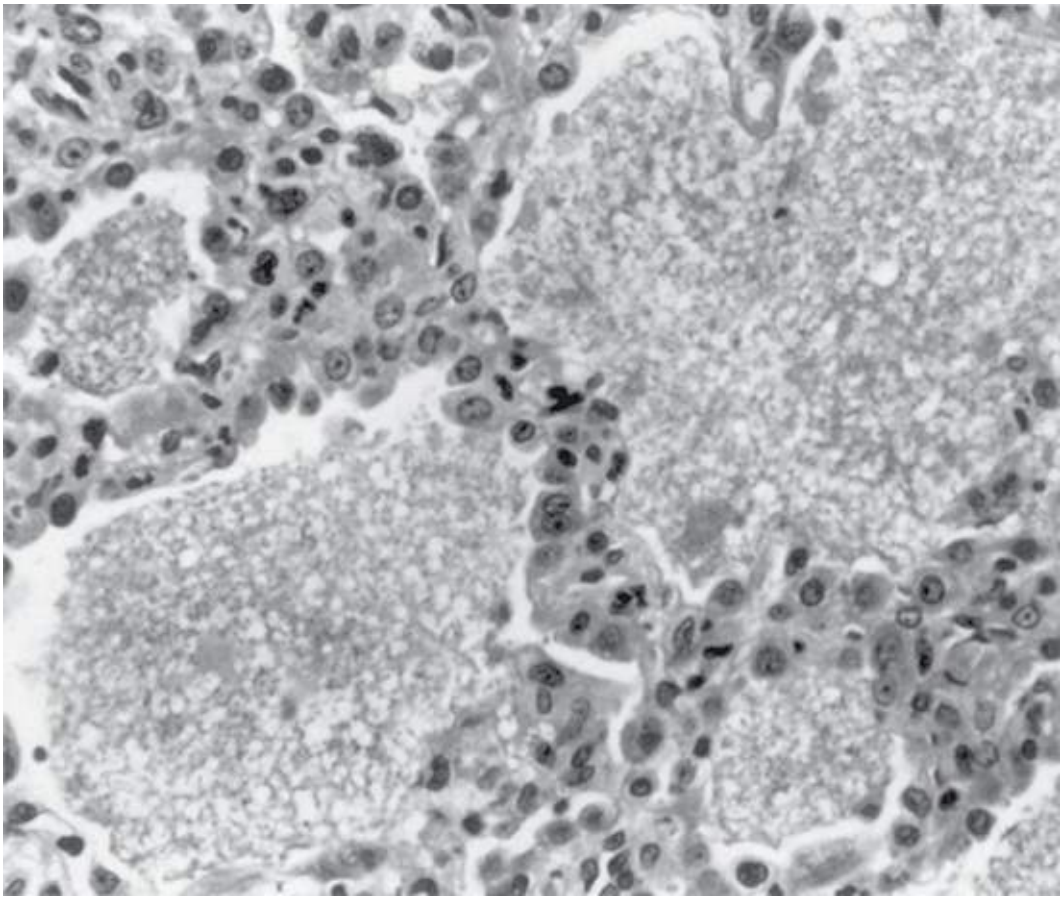

FIGURE 46–10. Lung biopsy specimen from *Pneumocystis* pneumonia, showing "foamy" contents of alveoli. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

IMMUNITY

Activated macrophages and cytokines mediate CMI

The nature of the immunodeficiencies in patients with pneumocystosis points to the primacy of T_H1 immune responses in resolution of infection with *Pneumocystis.* Alveolar macrophages are the first line of defense, with activated macrophages and CD4+ lymphocytes playing essential roles in the resolution of the infection.

PNEUMOCYSTOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Diffuse pneumonitis with insidious onset**

Nonproductive cough, dyspnea, and cyanosis develop later

Alveolar infiltrates spread out from the hila

In the immunocompromised host, the disease presents as a progressive, diffuse pneumonitis. Illness may begin after discontinuation or a decrease in the dose of corticosteroids or, in the case of acute lymphocytic leukemia, during a period of remission. These observations suggest that the immune response to the organism results in many of the symptoms accompanying the infection. In infants and patients with AIDS, symptom onset is typically insidious, and the clinical course is often 3 to 4 weeks in duration. Fever is mild or absent. In older persons and patients who have previously been on high doses of corticosteroids, the onset can more abrupt. In both populations, the cardinal manifestations are progressive dyspnea and tachypnea; cyanosis and hypoxia eventually supervene. A nonproductive cough is present in 50% of all patients. Lung infiltrates on chest radiographs typically spread out symmetrically from the hilar regions of the lungs, eventually affecting most of the lung. Occasionally, unilateral infiltrates, coin lesions, lobar infiltrates, cavitary lesions, or spontaneous pneumothoraces are observed. Pleural effusions are uncommon. Clinical and radiographic abnormalities are generally accompanied by a decrease in arterial oxygen saturation, diffusion capacity of the lung, and vital capacity. Death occurs by progressive hypoxia.

Extrapulmonary lesions seen in AIDS

Lesions outside the lung were rarely seen before the AIDS epidemic, but they now appear with some regularity in this patient population. The sites most often involved are lymph nodes, bone marrow, spleen, liver, eyes, thyroid, adrenal glands, gastrointestinal tract, and kidneys. The extrapulmonary clinical manifestations range from incidental autopsy findings to progressive multisystem disease.

DIAGNOSIS

Diagnostic yield from sputum low

BAL best of invasive procedures

Definite diagnosis of pneumocystosis depends on finding organisms of typical morphology in appropriate specimens. Because the pathologic process is alveolar rather than bronchial, the organisms are not readily seen in expectorated specimens such as sputum. The diagnostic yield is much better from specimens obtained by more invasive procedures. Of these, BAL gives the best results with the least morbidity. Percutaneous needle aspiration of the lung, transbronchial biopsy, and open lung biopsy, though somewhat more sensitive techniques, are accompanied by more complications, including pneumothorax and hemothorax.

*** Silver and other stains readily demonstrate *Pneumocystis***

DNA amplification from BAL, a means of diagnosis

Pneumocystis can be demonstrated by a variety of staining procedures. The standard stain is methenamine silver (Figure 46–9), but direct fluorescent antibody (DFA) method, if available, is slightly more sensitive. Laboratories often perform a rapid stain (Wright, Giemsa, Papanicolaou) first and confirm by methenamine silver or DFA later. Detection of *Pneumocystis* DNA in BAL fluid by polymerase chain reaction is also routinely used in many clinical laboratories. The detection of fungal antigens in the blood, such as beta-D glucan, supports the diagnosis.

To prevent missed diagnoses, should tests for PCP be routinely added to standard clinical microbiological panels used to evaluate respiratory samples from all patients with pneumonia?

TREATMENT AND PREVENTION

*** TMP-SMX is treatment of choice**

The fixed combination of trimethoprim and sulfamethoxazole (TMP-SMX) is the treatment of choice for all forms of pneumocystosis. It is administered orally or intravenously for 14 to 21 days. Patients with AIDS often receive the longer course because they start with a higher organism burden, respond more slowly,

and suffer relapse more often. Unfortunately, patients with AIDS have a high incidence of adverse effects to TMP-SMX, particularly the sulfonamide component. This requires the use of other antimicrobials (eg, clindamycin, primaquine, dapsone) alone or in combination with trimethoprim. The use of adjunctive corticosteroids in hypoxic patients with PCP results in improved survival, likely due to prevention of an excessive immune reaction to dying microbes.

Chemoprophylaxis prevents PCP in AIDS

Prophylaxis. Low-dose administration of TMP-SMX has been shown to significantly decrease the incidence of PCP in high-risk patients and prevents relapse in patients with AIDS. This chemoprophylaxis is indicated for patients who have CD4+ lymphocyte counts lower than 200/mm^3, unexplained fever, or a previous episode of PCP. Chemoprophylaxis for PCP is also used in solid-organ transplant patients immediately after transplantation and during treatment for allograft rejection.

Think ▸▸ Apply 46-3: Clinicians should maintain a high index of suspicion for PCP in patients with known or suspected defects in cell-mediated immunity (AIDS, transplant patients). This infection is exceedingly uncommon in immunocompetent patients, limiting the effectiveness of general screening for PCP in most cases of pneumonia.

KEY CONCLUSIONS

Candida

- *Candida albicans* is a commensal yeast-like fungus in the normal, human mucosal microbiota.
- Growing in both yeast and hyphal forms, *C albicans* can form nearly impenetrable biofilms on prosthetic material, as well as causing mucosal and disseminated infections.
- Certain *Candida* species are resistant to specific antifungals. Therefore, the particular *Candida* isolate causing systemic infections should be identified to the species level.

- Bloodstream infections due to *Candida* species are very common in hospitalized patients. When present, consider potential sources (eg, IV catheters, intestinal lesions) as well as potential distant sites of spread (eg, retina).

Aspergillus

- Invasive aspergillosis (IA) occurs most commonly in patients with defective neutrophils.
- Immediate antifungal therapy and surgical debridement are important interventions when IA is considered or recognized in immunocompromised patients.
- Environmental controls and prophylactic antifungal therapy may decrease the incidence of IA for selected patient populations (eg, hematopoietic stem cell transplant patients).

Mucormycosis/zygomycosis

- Environmental molds such as the zygomycetes can cause destructive sinus infections in patients with poorly controlled diabetes mellitus.
- Pulmonary infections occur in highly immunocompromised patients and have a high mortality, often requiring combination of antifungal therapy and surgical debridement.

Pneumocystis

- PCP occurs in patients with profound defects in CD4+ lymphocyte function.
- Specific prophylactic therapy will often help to prevent PCP in susceptible patients.
- In addition to antimicrobial therapy, adjunctive corticosteroids may decrease mortality in severe cases of PCP by limiting immune-mediated damage during antimicrobial treatment.

CLINICAL CASE

A Budding Blood Culture

A 71-year-old woman was admitted with a recurrence of poorly differentiated squamous cell carcinoma of the cervix. She underwent extensive gynecologic surgery (excision of the organs of the anterior pelvis) and was maintained postoperatively on broad-spectrum intravenous antibiotics. The woman had a central venous catheter placed on the day of the surgery.

Beginning 3 days postoperatively, the patient had temperatures of 38.0°C

to 38.5°C, which persisted without a clear source. Multiple blood cultures grew a yeast-like fungus. When incubated in serum, these round fungal cells sprouted long tubes with parallel sides.

QUESTIONS

1. Which organism is most likely to be identified in this patient's blood culture?

A. *Candida albicans*
B. *Candida glabrata*
C. *Aspergillus*
D. *Mucor*
E. *Pneumocystis*

2. What feature of the organism might have facilitated its infection in these circumstances?

A. Mannoprotein
B. Glucan
C. Germ tube formation
D. Biofilm formation
E. Sporocytes

3. Which is the probable origin of the infecting agent?

A. Animals
B. Hospital air
C. Medical devices
D. Patient's flora
E. Healthcare workers

Answers

chapter 47

The Systemic Fungal Pathogens: *Cryptococcus, Histoplasma, Blastomyces, Coccidioides, Paracoccidioides*

Cryptococcus neoformans/Cryptococcus gattii • *Histoplasma capsulatum* • *Blastomyces dermatitidis* • *Coccidioides immitis/Coccidioides posadasii* • *Paracoccidioides brasiliensis*

The fungi discussed in this chapter cause a variety of infections, each ranging in severity from subclinical to progressive, debilitating disease. Some of these species are dimorphic, growing in the infectious mold form in the environment but switching to a round, yeast-like form in infected tissues. They differ from the opportunistic fungi in their ability to cause disease in previously healthy persons. However, the most serious infections still occur in patients with compromised immune systems. With the exception of *Cryptococcus neoformans*, each of these fungi is predominantly restricted to geographic niches corresponding to the environmental habitats of the mold form of the species. None of these infections is transmitted from human to human. The major features of the systemic pathogens are summarized in **Table 47-1**.

TABLE 47–1 Features of Systemic Fungal Pathogens

ORGANISM	GROWTH: CULTURE AT 25°C	GROWTH: CULTURE AT 37°C	TISSUE	SOURCE	PRIMARY DISEASE	DISSEMINATED DISEASE
Cryptococcus neoformans, C gattii	Encapsulated yeast	Encapsulated yeast	Encapsulated yeast	Environment, worldwide	Pneumonia	Chronic meningitis
Histoplasma capsulatum	Mold, tuberculate macroconidia[a]	Small yeast	Small intracellular yeast[b]	Environment, U.S. Midwest[d]	Pneumonia, hilar adenopathy	RES enlargement
Blastomyces dermatitidis	Mold[a]	Yeast		Environment, U.S. Midwest[e]	Pneumonia	Skin and bone lesions
Coccidioides immitis, C posadasii	Mold, arthroconidia	(Spherules)[c]	Spherules	Environment, Sonoran desert[c,f]	Valley fever	Pneumonia, meningitis, skin, bone
Paracoccidioides brasiliensis	Mold	Yeast, multiple blastoconidia		Environment, Latin America	Pneumonia	Mucocutaneous, RES

RES, reticuloendothelial system (lymph nodes, liver, spleen, bone marrow).
[a]Micoconidia are formed but are not distinctive.
[b]Typically multiple yeast within macrophages.
[c]Ecologic "islands" are found throughout the Americas.
[d]Ecologic islands are found worldwide.
[e]It is difficult to grow the spherule phase in culture.
[f]In the United States and includes parts of Arizona, California, Nevada, and western Texas.

• *CRYPTOCOCCUS*

CRYPTOCOCCUS NEOFORMANS AND *CRYPTOCOCCUS GATTII*

Cryptococcus species were first isolated from environmental sources more than a century ago, and they are now recognized as important human pathogens, especially in the setting of HIV infection. The most important clinical manifestation of cryptococcal disease is a life-threatening meningitis in immunocompromised patients.

Two pathogenic *Cryptococcus* species and multiple varieties

Found throughout the world, *Cryptococcus* species grow as a budding yeast 4 to 6 μm in diameter. The most characteristic feature of these cells is a large polysaccharide **capsule** (**Figure 47–1**), often extending the overall diameter of these cells to 25 μm or more. Cryptococcal species are basidiomycetes, a group of fungi that includes the mushrooms as well as many agricultural pathogens. The *Cryptococcus* genus contains two pathogenic species complexes, *C neoformans* and the more recently recognized *Cryptococcus gattii*.

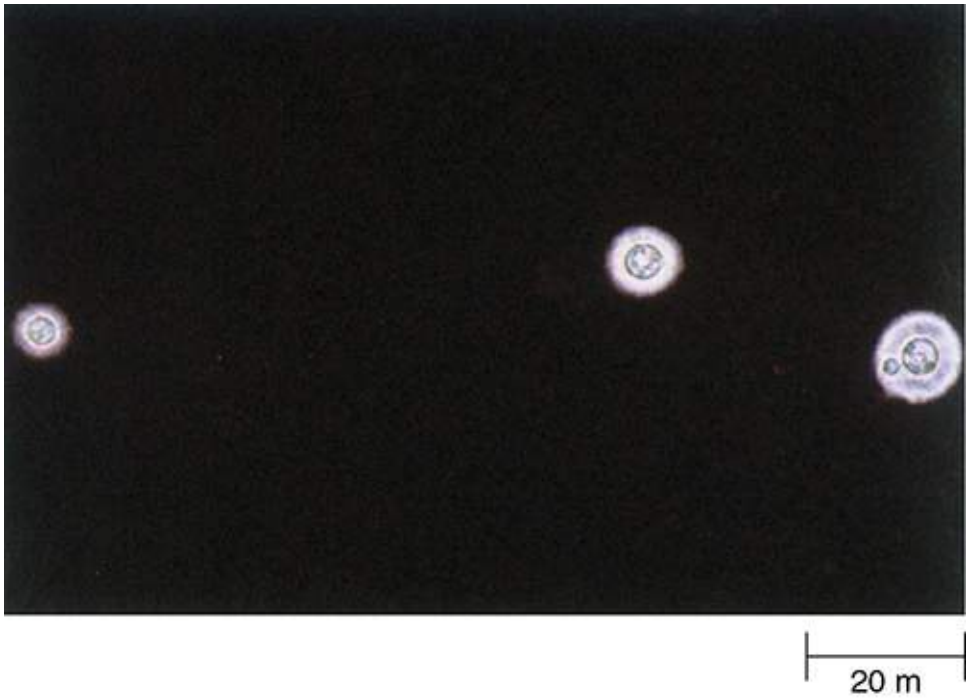

FIGURE 47–1. ***Cryptococcus neoformans*.** This India ink preparation was made by mixing cerebrospinal fluid containing cryptococci with India ink. The yeast cells can be seen within the clear space caused by the large polysaccharide capsule excluding the ink particles. Note that the one on the right is budding. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

An encapsulated yeast cell is diagnostic for *Cryptococcus* species

The cryptococcal capsule is a unique feature among pathogenic fungi, composed of a complex polysaccharide polymer. The major components of the capsule are glucuronoxylomannan and glucuronoxylomannogalactan, together referred to as **GXM.** Capsule production is repressed under environmental growth conditions, and it is stimulated by human physiologic conditions and in culture on some laboratory media. Capsular material is also secreted into the surrounding environment, serving to suppress the activity of nearby immune cells. GXM is so potently immunosuppressive that it has been used to treat autoimmune conditions such as rheumatoid arthritis in experimental trials.

CRYPTOCOCCOSIS

CLINICAL CAPSULE

Cryptococcus species are yeasts distinguished by a surrounding capsule. The primary disease caused by cryptococci is a chronic meningitis. The clinical onset is slow, even insidious, with low-grade fever and headache progressing to altered mental state and seizures. In the cerebrospinal fluid (CSF) and in tissues, the inflammatory response is often remarkably muted. Most patients who develop this infection have some obvious form of immune compromise, although some show no demonstrable immune defect.

EPIDEMIOLOGY

Cryptococcus neoformans can be isolated from environmental samples throughout the world, particularly in soil contaminated with bird droppings and decaying vegetable matter. The infectious form is felt to be either desiccated yeast cells or sexual basidiospores stirred up from these sites and subsequently inhaled. The less common species *C gattii* was once felt to be restricted to tropical and subtropical areas, but it has recently been isolated from patients and the environment near the US Pacific Northwest (British Columbia, Washington, Oregon). Person-to-person transmission has not been documented, with most cases likely resulting from reactivation of dormant foci of remote infections, similar to tuberculosis (TB).

*** Associated with soil and bird droppings**

Inhaled yeasts, basidiospores initiate infection

Cases of symptomatic cryptococcal infections in immunologically normal people are very rare, although it is well known that most people are exposed to this fungus early in childhood. This suggests that cryptococcal species are well controlled by the immune system after initial infection. Cryptococcosis in immunocompromised patients occurs primarily in those with defects in CD4+ T-lymphocyte function, particularly in patients with AIDS in whom it is the most common systemic fungal infection. Recent data estimated that more than 200,000 deaths occur each year in AIDS patients due to this infection. In countries with well-developed antiretroviral therapy programs, the incidence of cryptococcal disease has markedly declined in recent years. However, this infection remains an important clinical issue in other immunocompromised populations. Life-threatening disease can occur in patients with no known immune defects, although many clinicians believe that poorly characterized

immune disorders may explain the majority of these infections.

PATHOGENESIS

*** "Crypto" is immunologically "hidden" behind its capsule**

*** Circulating GXM interferes with immune function**

After being inhaled, *Cryptococcus* cells reach the alveoli, where production of the polysaccharide capsule is the prime determinant of virulence. The capsule is antiphagocytic and has various other immunomodulating effects, such as downregulation of cytokines, interference with antigen presentation, inhibition of leukocyte migration, misdirection of specific antibody responses, and delaying the development of T_H1 immune responses. *C neoformans* produces sufficient capsule that the GXM is readily detected in the blood and other body fluids. Therefore, the immune regulatory effects of the released capsule polysaccharide may act both locally and systemically.

Melanin provides oxidative protection in macrophages

The affinity of *C neoformans* for the central nervous system (CNS) is striking. Proposed explanations include crossing the blood–brain barrier inside macrophages (Trojan horse model) and the ability of laccase to convert the abundant catecholamines in the CNS to melanin. Similar to other neuropathogens, *C. neoformans* has components on its cell surface may help to target this microbe to the CNS by specific interactions with proteins on the endothelial cells of the brain microvasculature.

CRYPTOCOCCOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Meningitis insidious and chronic**

*** Course more rapid with AIDS**

*** Untreated CNS infection fatal**

Meningitis is the most commonly recognized form of cryptococcal disease. Unlike bacterial infections of the CNS, cryptococcal meningitis usually has a slow, insidious onset with relatively nonspecific findings until late in its course. Common presenting symptoms include intermittent headache, irritability, dizziness, and difficulty with complex cerebral functions, appearing over weeks or months. Behavioral changes have sometimes been mistaken for psychoses. Fever is usually, but not invariably, present. Seizures, cranial nerve defects, and papilledema may appear later in the clinical course, as may dementia and decreased levels of consciousness. A more rapid course may be seen in AIDS patients. Historically, as many as 5% to 15% of untreated patients with AIDS developed symptomatic cryptococcal infections. Although the onset of illness may be subacute, cryptococcal infection of the CNS is usually fatal if not recognized and treated.

Like many other pathogenic fungi that enter the host through the lung, most initial pulmonary infections are minimally symptomatic. Infections can be truly clinically inapparent, or they may manifest as a self-limited respiratory illness. However, cryptococcal pneumonia can be progressive and severe in immunocompromised patients. In either case, no clinical findings are sufficiently specific to suggest the etiology.

Dissemination of infection occurs almost exclusively in immunocompromised patients, sometimes targeting the skin and bones. Classically, cryptococcal skin lesions are papular or nodular, often with a central umbilication, and remarkable for their lack of inflammation. The diagnosis is sometimes made when lesions are biopsied as suspected neoplasms.

Pneumonia often asymptomatic

CNS involvement varies with species

There are differences in the disease spectrums of the two *Cryptococcus* species. *C gattii* is more likely to produce symptomatic pulmonary infections and less likely to invade the CNS. *C gattii* infection has also been described more frequently in patients with no definable immunological defect. In the CNS, *C gattii* may cause more localized lesions (cryptococcomas) as opposed to the diffuse meningoencephalitis typical of *C neoformans*.

DIAGNOSIS

Increased intracranial pressure common

Cells, glucose depression in CSF may be minimal

India ink preparation shows encapsulated yeasts

Typical CSF findings in cryptococcal meningitis are increased intracranial pressure, pleocytosis (usually >100 white blood cells/mm^3) with predominance of lymphocytes, and depression of glucose levels. In some cases, one or all of these findings may be absent, yet cryptococci are still isolated on culture. Encapsulated yeast cells (diagnostic of *C neoformans* infection) are demonstrable in CSF in approximately 50% of cases by mixing centrifuged CSF sediment with **India ink** and examining the mixture under the microscope (Figure 47–1). Experience is necessary to avoid confusion of lymphocytes with cryptococci. *C neoformans* stains poorly with routine histologic stains; thus, it is easily missed unless special fungal stains are used (**Figure 47–2**).

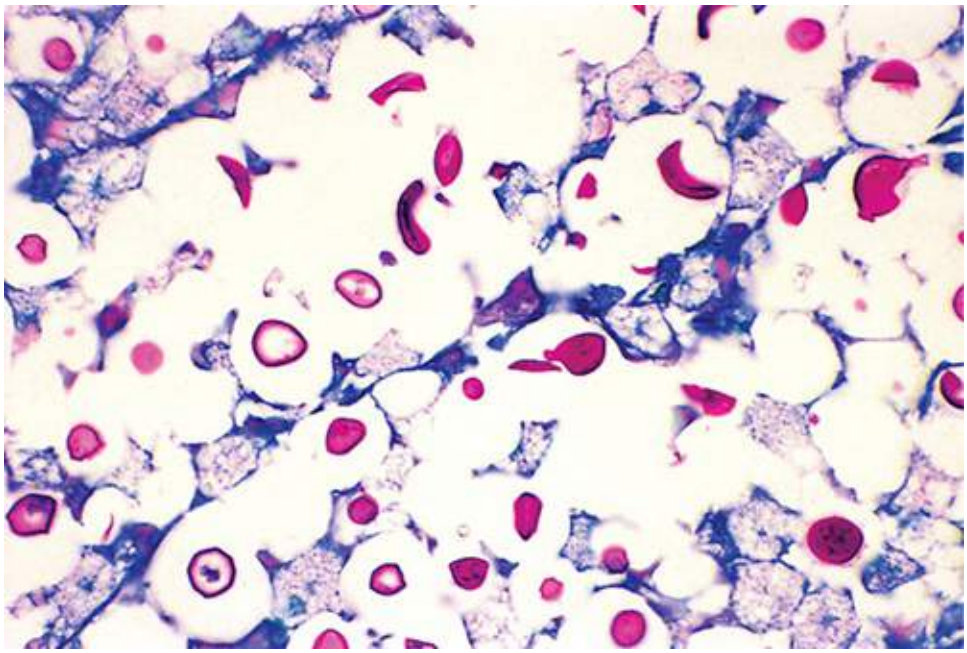

FIGURE 47–2. Cryptococcal meningitis. The *C neoformans* cells are stained red by this PAS (periodic acid-Schiff) stain. The capsule is not stained but is creating the halo around the organisms. Note the lack of inflammatory cells. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Cryptococci may be few

*** GXM detectable in CSF and serum**

For the isolation of *C neoformans* by culture, the volume of CSF sampled is important. The number of organisms present may be small enough to require a substantial volume of fluid (>30 mL) to yield a positive culture. The detection of cryptococcal capsular antigen in the CSF is the most sensitive and specific way to make the diagnosis of cryptococcal meningitis. This test can also be performed on serum where it is especially useful in diagnosing infection in immunocompromised patients due to higher levels of circulating organisms. The cryptococcal antigen test is performed by latex agglutination or enzyme immunoassay (EIA), and its quantitation has prognostic significance. A rising antigen level can indicate progression, and a declining titer is a favorable sign.

TREATMENT

Amphotericin B and flucytosine used in combination

Fluconazole for non-CNS infections

Lumbar puncture assesses intracranial pressure

The primary treatment for serious cryptococcal infections includes induction therapy with amphotericin B plus flucytosine, followed by an extended consolidation course with fluconazole. Although 75% of persons with meningitis respond to this treatment, many patients suffer relapses after antifungal therapy is stopped, requiring repeated courses of therapy. In patients with AIDS-associated cryptococcosis, reconstitution of the immune system with antiretroviral therapy is very important to prevent recurrent infection. One-half of patients with a microbiological cure have some kind of residual neurologic damage. The management of CNS cryptococcosis also involves addressing elevated intracranial pressure when present, often with serial lumbar punctures or CSF shunting procedures. Azoles alone can often be used in non-CNS disease; therefore, it is very important to perform lumbar punctures and CSF analysis in all patients with cryptococcal infections to determine if the CNS is involved.

• *HISTOPLASMA*

HISTOPLASMA CAPSULATUM

Histoplasma capsulatum is one example of a thermally dimorphic fungus **(Figure 47–3B)**, microorganisms that change growth form depending on the ambient temperature. Common features of this group of fungi include the fact that most are restricted to particular geographic locations (**regions of endemicity**). Additionally, these fungi establish initial infection by the inhalation of environmental spores. Immune competent patients typically spontaneously resolve infections due to these fungi, but they can become chronic or disseminated.

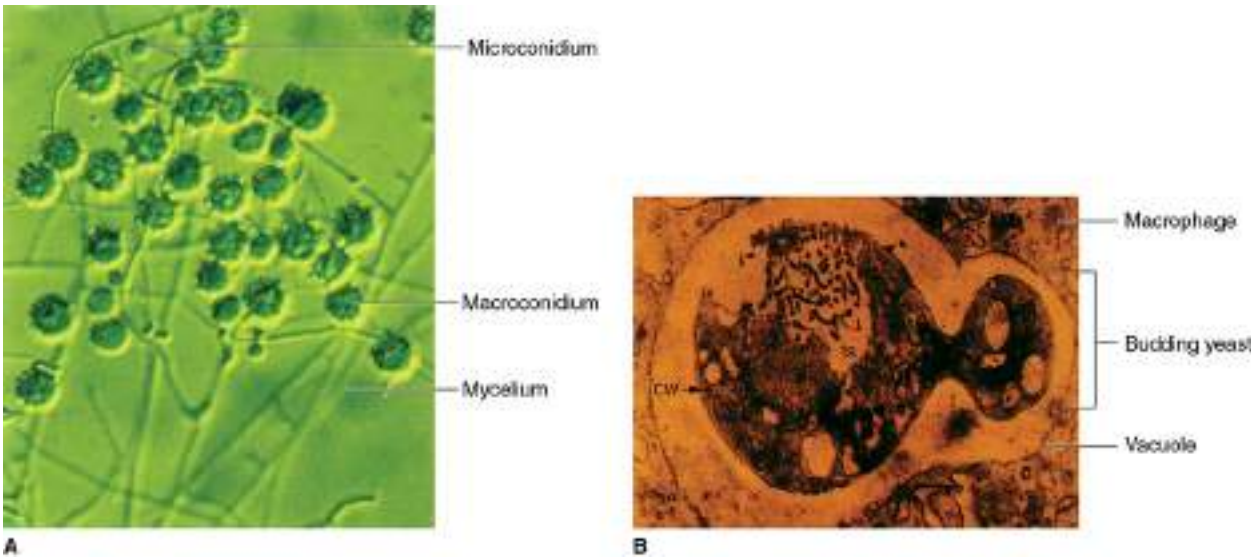

FIGURE 47–3. Histoplasma capsulatum. A. Mold phase with hyphae, microconidia, and tuberculate macroconidia. **B.** A yeast cell is multiplying (note budding) within a macrophage phagocytic vacuole. (Reproduced with permission from Willey JM: *Prescott, Harley, & Klein's Microbiology*, 7th ed. New York, NY: McGraw Hill; 2008.)

H capsulatum grows in a round, yeast-like phase in tissue and in cultures incubated at 37°C. However, when incubated at lower temperatures, such as those most commonly encountered in the environment, *Histoplasma* species grow as a filamentous mold where it is a saprophyte in soil.

HISTOPLASMOSIS

OVERVIEW

Histoplasma capsulatum is a thermally dimorphic fungus that can be isolated from the soil in specific endemic areas. After infection, patients are usually asymptomatic or experience a self-limited illness characterized by fever and cough. During this initial infection, a pulmonary infiltrate and hilar adenopathy may or may not be evident on a radiograph, complicating the initial diagnosis. Progressive infections show extension in the lung or enlargement of lymph nodes, liver, and spleen.

EPIDEMIOLOGY

Microconidia infectious

Mold grows in soil with bird droppings

*** High prevalence in central United States**

H capsulatum is particularly prevalent in certain temperate, subtropical, and tropical zones, and endemic areas are present in all continents of the world except Antarctica. The largest and best-defined area of endemicity is the U.S. region drained by the Ohio and Mississippi rivers (**Figure 47–4**). More than 50% of the residents of states in this area have radiologic evidence of previous infection. In some locales, up to 90% demonstrate delayed-type hypersensitivity to *Histoplasma* antigens, suggesting that they have been infected at some point in the past. Point source outbreaks of histoplasmosis have occurred after the inhalational of large amounts of fungi following disturbances of bird roosts, bat caves, and soil at construction sites. Persons in endemic areas whose employment (agriculture, construction) or avocation (spelunkers) brings them in contact with aerosolized microconidia are at increased risk. Disease is more common in men, but there are no other known genetic differences in susceptibility.

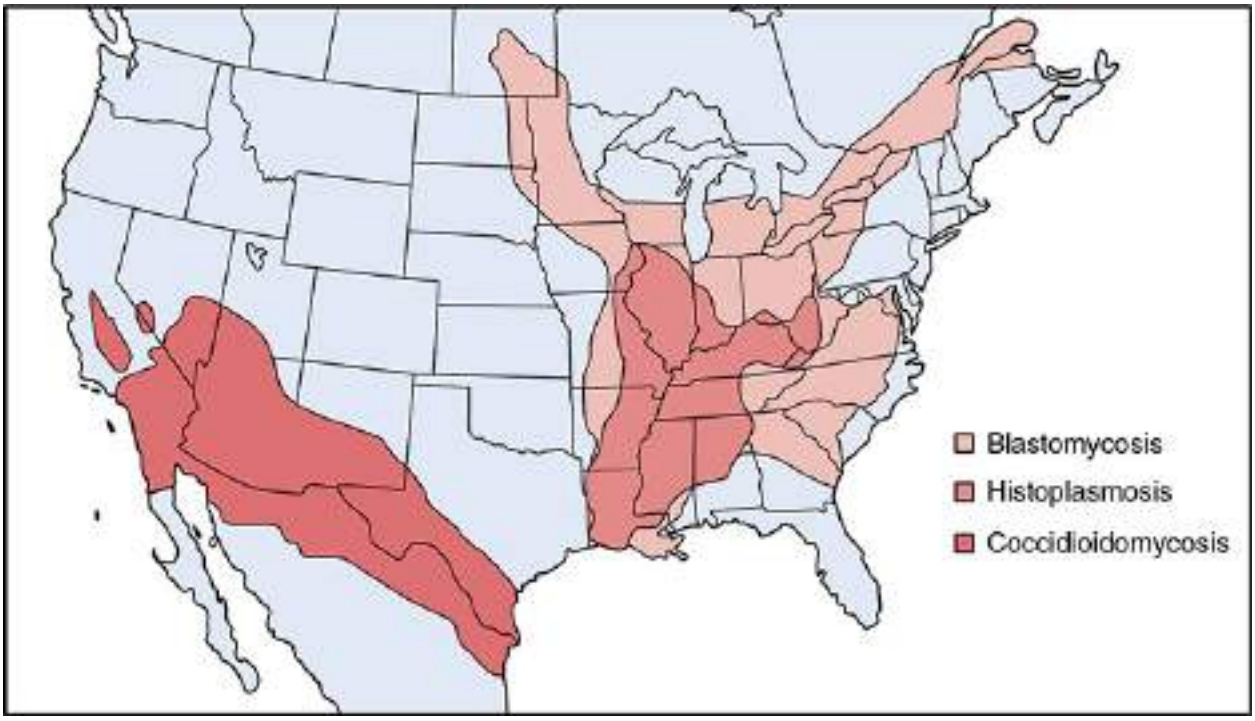

FIGURE 47–4. Geographic distribution of systemic fungal infections in the United States.

PATHOGENESIS

* Reticuloendothelial system focus of infection

Once infection is established, *H capsulatum* cells live primarily in the lymph nodes, spleen, bone marrow, and other elements of the reticuloendothelial system. This is an example of a microorganism that has adapted to intracellular growth within phagocytic macrophages. Other examples include *M tuberculosis* and *C neoformans*. Like TB and cryptococcosis, the initial infection with *H capsulatum* occurs in the lungs after inhalation of infectious conidia. These fungal spores convert to the yeast form after germinating in the host.

* Lymphatic spread and reactivation similar to TB

The initial pulmonary infection of histoplasmosis generally spreads to regional lymph nodes, resulting in a primary focus of paired lung/lymphatic lesions similar to the Ghon complex of TB. Also like TB, most cases never advance beyond the primary stage, leaving only a calcified node and pulmonary calcifications as evidence of prior infection. As in TB, viable fungal cells may remain in these old lesions and reactivate later, particularly if the person

becomes immunocompromised.

* Granulomas in liver, spleen, bone marrow

Pathologically, histoplasmosis is characterized by granulomatous inflammation with associated necrosis. Even with special fungal stains, *H capsulatum* may be difficult to detect within these infected foci, making a precise pathological diagnosis challenging. Extrapulmonary spread of histoplasmosis occurs primarily in immunocompromised patients, primarily involving the reticuloendothelial system with resulting enlargement of the liver and spleen. In patients with compromised immunity, numerous organisms within macrophages may be found in these organs, in lymph nodes, bone marrow, or even peripheral blood (**Figure 47–5**).

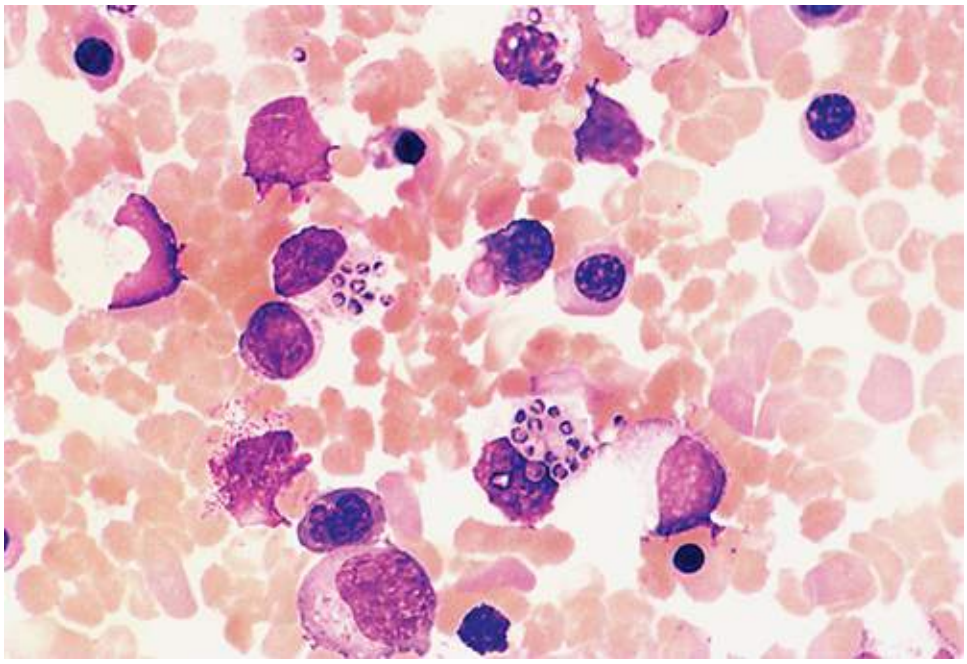

FIGURE 47–5. *Histoplasma capsulatum*. This peripheral blood smear shows two monocytes with multiple organisms filling their cytoplasm. Note the size of the yeast cells, which is very small for fungi. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

HISTOPLASMOSIS: CLINICAL ASPECTS

MANIFESTATIONS

Most cases asymptomatic or only fever, cough

*** Pulmonary disease shows cavities, weight loss**

Most cases of *H capsulatum* infection in normal hosts are minimally symptomatic, often causing mild fever and cough for a few days or weeks. Mediastinal lymphadenopathy and subtle pulmonary infiltrates may be seen on X-rays. More severe cases are most often characterized by chills, malaise, chest pain, and more extensive lung infiltrates, all of which usually resolve without specific therapy. Most people who resolve the primary infection have scattered calcified pulmonary granulomas as radiographic evidence of healed histoplasmosis. Rarely, residual pulmonary nodules may continue to enlarge over a period of years, causing a differential diagnostic problem with pulmonary neoplasms. Progressive pulmonary disease can mimic pulmonary TB, with sputum production, night sweats, weight loss, and even the development of lung cavities. The clinical course of pulmonary histoplasmosis may infrequently be chronic and relapsing, with symptoms lasting for several months to years.

*** Dissemination involves RES, mucous membranes, adrenal glands**

Disseminated histoplasmosis generally appears as a nonspecific febrile illness in an immunocompromised patient, with enlargement of reticuloendothelial organs. Populations at particular risk for developing disseminated histoplasmosis include patients with advanced AIDS as well as those being treated with tumor necrosis factor-alpha inhibitors. The CNS, skin, gastrointestinal tract, and adrenal glands may also be involved. Painless ulcers on mucous membranes are a common clinical finding; however, given their painless nature, these lesions must be actively sought by clinicians in order to help make the diagnosis. The course of disseminated histoplasmosis is typically chronic, with manifestations that depend on the organs involved. For example, chronic bilateral adrenal failure (Addison disease) may develop when the adrenal glands are affected.

DIAGNOSIS

Blood and bone marrow examination require special stains

In most forms of pulmonary histoplasmosis, the diagnostic yield of direct examinations or culture of sputum is low. In disseminated disease, blood culture

or biopsy samples of a reticuloendothelial organ are the most likely to contain *Histoplasma*. Of these cultures, bone marrow culture has the highest yield. Because of their small size, the yeast cells are difficult to see in potassium hydroxide (KOH) preparations, and their morphology is not sufficiently distinctive to be diagnostic. Specimens must therefore be examined carefully under high magnification. Selective fungal stains such as methenamine silver demonstrate the organism but may not differentiate it from other yeasts. Hematoxylin and eosin (H&E)-stained tissue or Wright-stained bone marrow often demonstrates the organisms in their intracellular location in macrophages (Figure 47–5). Identification of culture isolates requires demonstration of the typical conidia and dimorphism. Nucleic acid probes have been developed for culture confirmation.

*** ID of polysaccharide in blood and urine by EIA aids in diagnosing disseminated infection**

Antibodies can be detected during and after infection, but their diagnostic usefulness in endemic areas is limited by false-negative results and cross-reactions with blastomycosis. Rising antibody titers are suggestive of dissemination or relapse. The histoplasmin skin test has been useful in the past to document prior exposure, but the reagents are no longer commercially available. Isolation of the fungus in culture or clear histologic demonstration is often necessary to establish a firm diagnosis of histoplasmosis. The diagnosis of disseminated infection has been greatly aided by the development of a commonly used EIA detecting a *Histoplasma* polysaccharide antigen. This test can be performed on blood or urine samples, and it detects more than 90% of cases of disseminated disease.

TREATMENT

*** Amphotericin B and itraconazole treatments of choice, particularly for disseminated infection**

Primary infections and localized lung lesions usually resolve without treatment. For mild disease localized to the lung, a systemic azole such as itraconazole is commonly used. For more severe or disseminated disease, initial therapy with amphotericin B is often followed by longer-term therapy with itraconazole. Azoles can be effective in an endemic area for prophylaxis of persons with a high risk of disease, including AIDS patients with low CD4 counts and other

immunocompromised patients. The echinocandin class of antifungals is decidedly less effective, and these agents should not routinely be used for histoplasmosis.

Patients with immunocompromising disorders (eg, patients with progressive AIDS, patients receiving anti-tumor necrosis alpha therapy) are at high risk for developing life-threatening complications from invasive infections due to pathogenic fungi. Can you suggest minimally invasive testing strategies that might identify patients with subclinical infections due to these fungi and who are therefore at risk for serious complications with progressive immunosuppression?

• *BLASTOMYCES*

BLASTOMYCES DERMATITIDIS

*** Yeast cells have broad-based buds (rule of "B's")**

Mold similar to *Histoplasma*

Blastomyces dermatitidis is a dimorphic fungus with some characteristics similar to those of *Histoplasma*. This fungus grows in yeast-like phase in tissues and in cultures incubated at 37°C. The yeast cells are typically larger (8-15 mm) than those of *H capsulatum*, with broad-based buds (blastoconidia) and a thick wall (**Figure 47–6**). The mold phase appears in culture at 25°C.

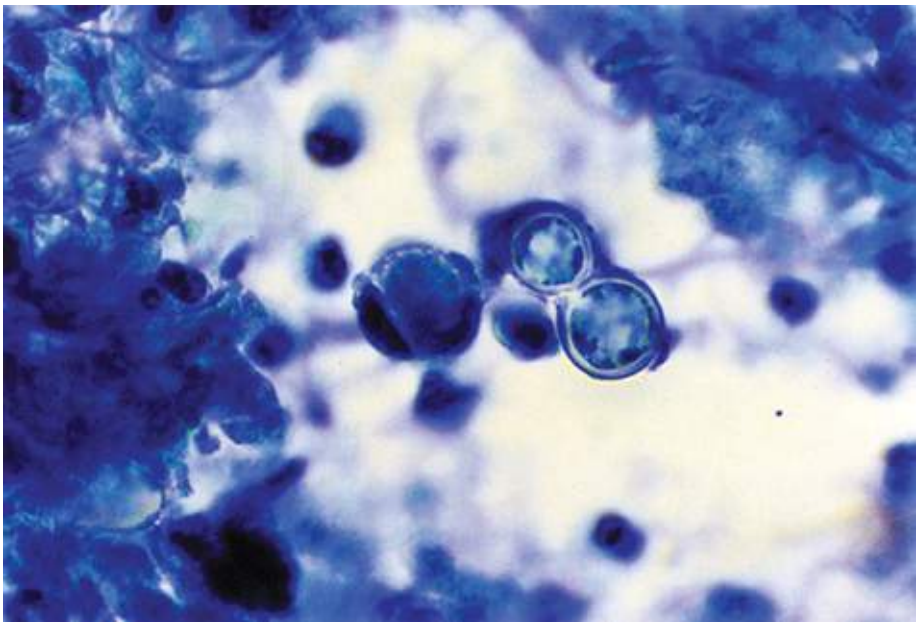

FIGURE 47–6. ***Blastomyces dermatitidis.*** Large thick-walled yeast cells are shown in this sputum. Note how the blastoconidia retain a broad attachment to the mother cell before separating. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases.* Stamford CT: Appleton & Lange; 1997.)

BLASTOMYCOSIS

CLINICAL CAPSULE

Blastomyces dermatitidis is a thermally dimorphic fungus similar to *Histoplasma*. Many clinical features of blastomycosis are similar to histoplasmosis. During initial infection, most patients are asymptomatic or have self-limited mild fever and cough. Chronic infections of the lung infrequently occur. Skin lesions are the most common manifestation of disseminated disease. Unlike histoplasmosis, the reticuloendothelial system is not involved.

Think ▸▸ Apply 47-1: Patients with late-stage AIDS or other forms of immunosuppression can have subclinical infections due to pathogenic fungi that become clinically evident with time.

Minimally invasive tests for fungal antigens, such as urine or blood tests for *Cryptococcus* or *Histoplasma* antigens, have been used to identify these infected but asymptomatic patients in order to effectively direct antifungal therapy before serious complications develop.

EPIDEMIOLOGY

* Geographic distribution similar to *Histoplasma*

Blastomycosis is most commonly observed in geographic regions that overlap with those for histoplasmosis. In North America, this includes the upper Midwestern states and regions around the Great Lakes (Figure 47–4), but infections have been reported in Africa, the Middle East, and Europe as well. A specific skin test for blastomycosis is not routinely available, thus limiting epidemiological mapping of the endemic areas. Unlike histoplasmosis, the causative agent of blastomycosis, *Blastomyces dermatitidis*, is not strongly associated with bird or bat habitats. It is assumed that inhalation of environmental microconidia is the means of infection, as is the case for most endemic fungal pathogens.

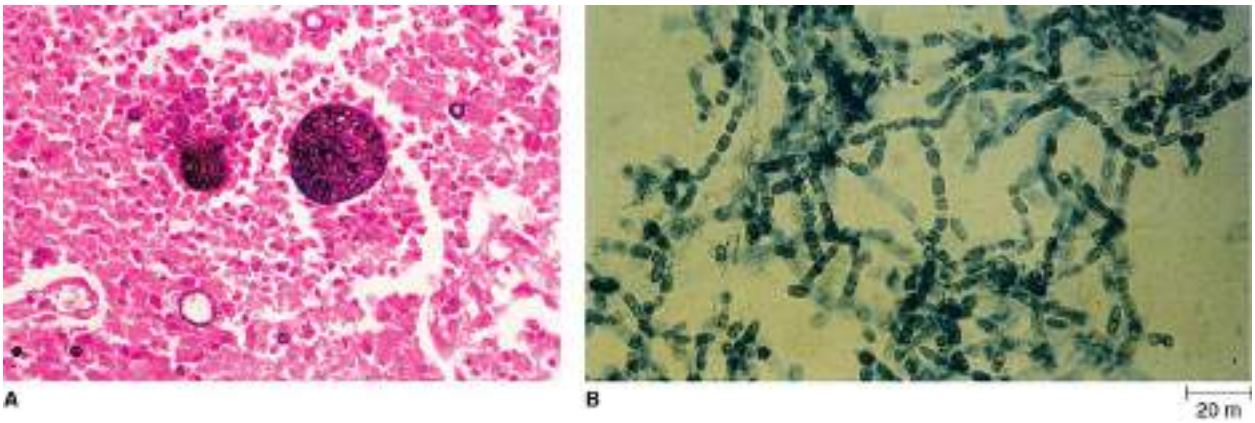

FIGURE 47–7. ***Coccidioides immitis*. A.** Lung tissue with a large thick-walled spherule containing multiple endospores. The smaller spherule to its left has ruptured releasing endospores. **B.** Mold phase in which alternate cells have differentiated to form barrel-shaped arthroconidia. (A, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997. B, Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

BLASTOMYCOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Pulmonary blastomycosis similar to other mycoses**

*** Skin lesions on exposed surfaces, often grouped microabscesses**

*** GU tract/prostate frequently involved**

Because mild cases of blastomycosis are difficult to diagnose, most infections are only recognized if they progress to more advanced or disseminated stages of the disease. Pulmonary infection is evidenced by cough, sputum production, chest pain, and fever. Hilar lymphadenopathy may be present, as may nodular pulmonary infiltrates with alveolar consolidation. This nonspecific clinical picture may mimic a pulmonary tumor, TB, or some other form of chronic pneumonitis. In contrast to histoplasmosis, mucous membrane lesions are rarely observed in blastomycosis. Instead, lesions develop more commonly on exposed skin, often as “grouped microabscesses.” Given the chronicity of many untreated cases of cutaneous blastomycosis, the associated extensive necrosis and fibrosis may produce considerable disfigurement. Bone infection has features similar to those of other causes of chronic osteomyelitis. The urinary and genital tracts are the most commonly affected visceral sites; the prostate is especially prone to infection.

DIAGNOSIS

KOH and biopsy show budding yeast

Culture takes weeks, conidia not distinctive

Direct demonstration of typical large yeasts with broad-based buds (blastoconidia) in KOH preparations of infected tissue is the most rapid means of diagnosis (Figure 47–6). Biopsy specimens also have a high yield, and the organisms are visible in histopathology samples stained with either H&E or special fungal stains. *Blastomyces dermatitidis* grows in the clinical microbiology laboratory on routine fungal media, but cultures may take as long

as 4 weeks. Conidia are not particularly distinctive, and demonstration of thermal dimorphism and typical yeast morphology is essential to avoid confusion with other fungi. A DNA probe is particularly useful in differentiating cultures from *Histoplasma*. Serological tests are available but are less sensitive than those for other fungal pathogens.

TREATMENT

Amphotericin B and azoles effective

As with histoplasmosis, itraconazole and other mold-active azoles may be used for mild to moderate disease. Amphotericin B is indicated for more serious or disseminated infections. Fluconazole or voriconazole may be used in meningitis. As with other systemic mycoses, response to treatment is slow, and relapse is common.

• *COCCIDIOIDES*

COCCIDIOIDES IMMITIS AND COCCIDIOIDES POSADASII

Dimorphism with unique spherule

*** Spherules form and release endospores**

Coccidioides species are dimorphic fungi commonly encountered within North America in the desert regions of the southwestern United States and northern Mexico. In contrast to *Blastomyces* and *Histoplasma* species that grow in the body as budding yeast-like cells, the tissue form of *Coccidioides* species is a large (12-100 μm), round-walled **spherule** (**Figure 47–7A**). This structure is quite distinctive and unique among the pathogenic fungi. Its formation takes place in a process illustrated in **Figure 47–8.** The spherule eventually ruptures, releasing 200 to 300 endospores (**Figure 47–9**), each of which can differentiate into another spherule.

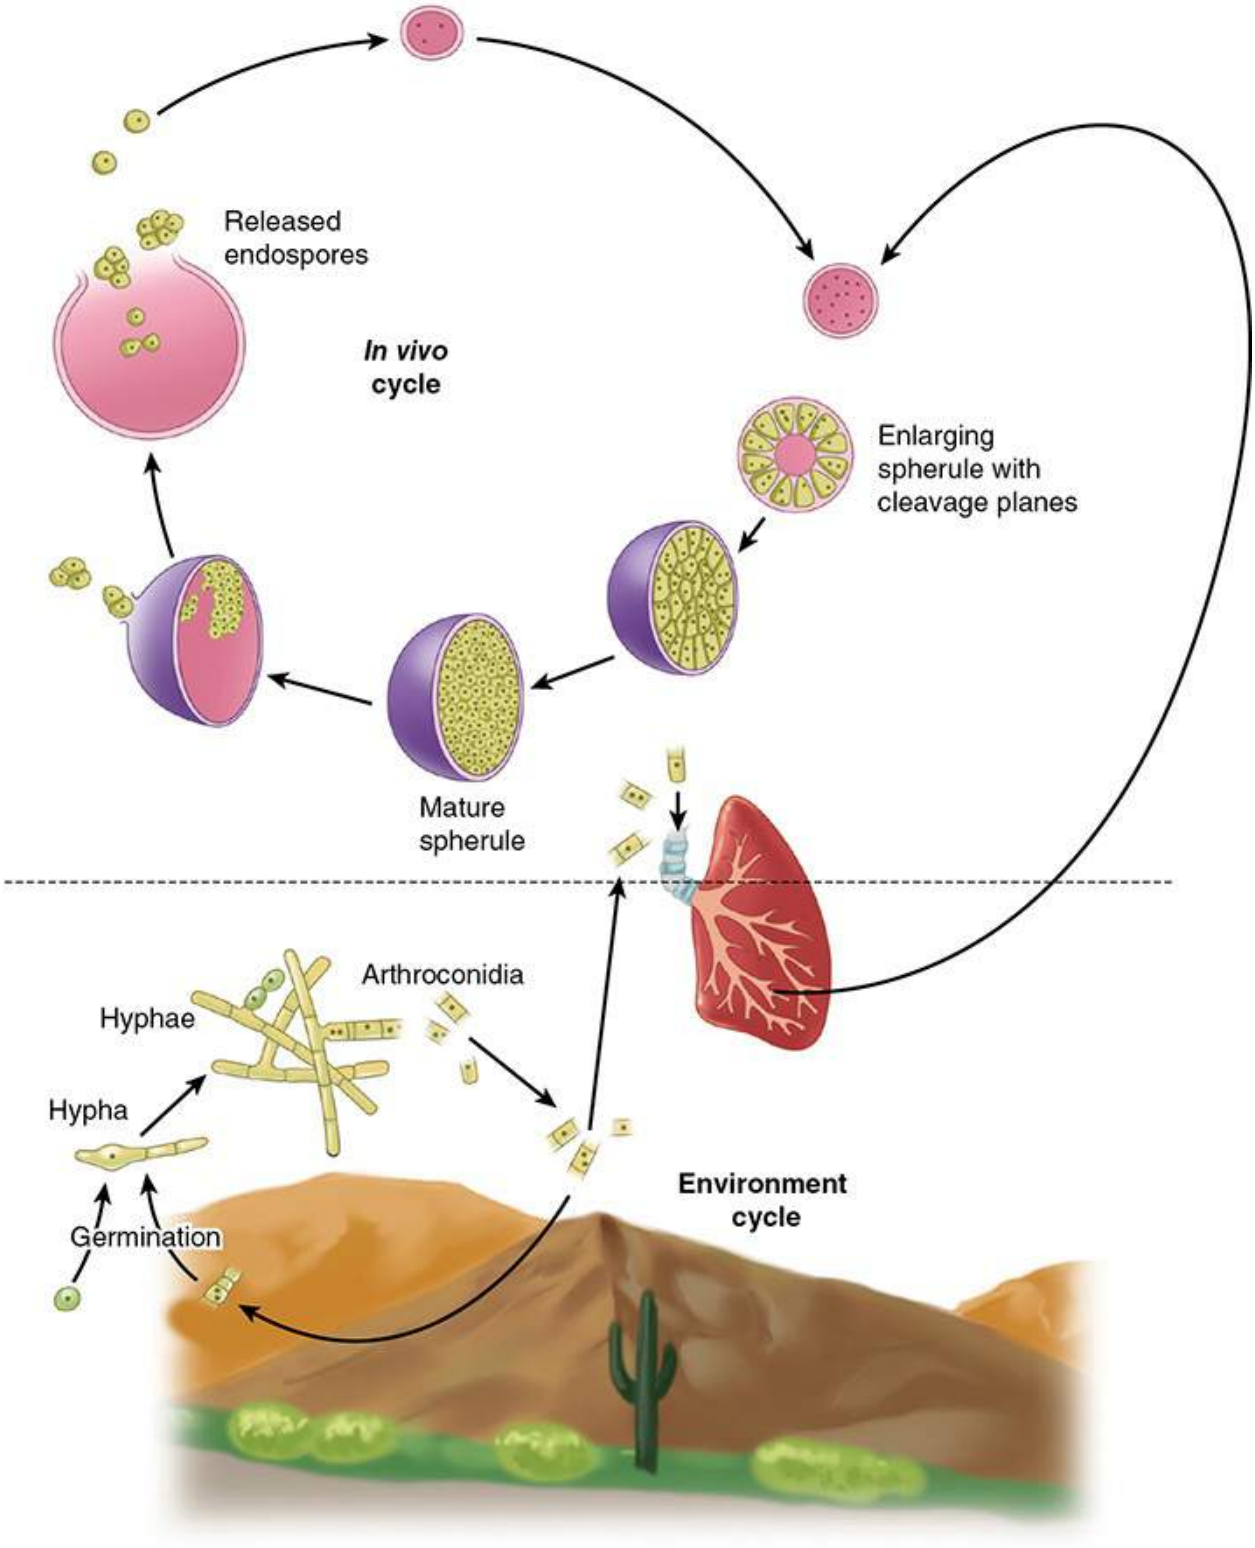

FIGURE 47–8. Life cycle of *Coccidioides immitis*. The nature cycle takes place in desert climates with modest rainfall. Hyphae differentiate into arthroconidia, which break loose and may be suspended in the air. Soil disruptions and wind facilitate spread and the probability of inhalation into human lungs. In the human host environment, *in vivo* differentiation produces cleavage planes and eventually huge spherules. The

spherules rupture, releasing endospores, which can then repeat the *in vivo* cycle.

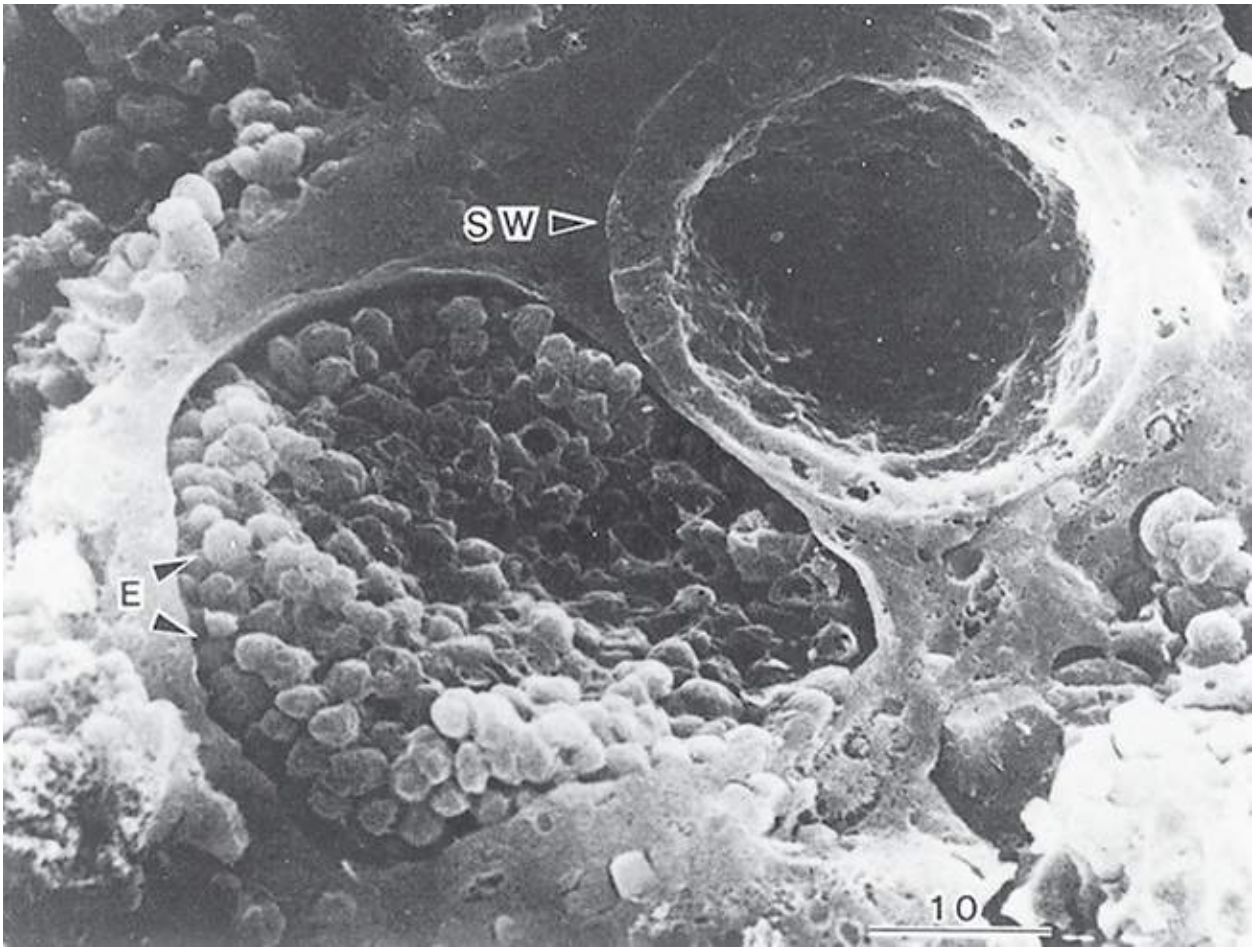

FIGURE 47–9. ***Coccidioides immitis.*** This electron micrograph of infected mouse lung shows a spherule filled with endospores (E) and one that has discharged its endospores into the surrounding tissue. Note the thickness of the spherule wall (SW). (Reproduced with permission from Drutz DJ, Huppert M: Coccidioidomycosis: factors affecting the host-parasite interaction, *J Infect Dis* 1983; Mar;147(3):372-390.)

COCCIDIOIDOMYCOSIS

EPIDEMIOLOGY

OVERVIEW

Coccidioides species are thermally dimorphic fungi endemic in parts of the American West. Acute primary infection with *C immitis* is most often asymptomatic, but it can manifest as a complex of symptoms called “Valley Fever” by residents of the endemic areas. Valley Fever includes fever, malaise,

dry cough, joint pains, and sometimes a rash. Red, inflamed nodules on the extremities (erythema nodosum) are suggestive of Valley Fever. Disseminated forms of the disease can involve the bones, joints, skin, and a progressive chronic meningitis.

* Restricted to Sonoran Desert

High proportion of locals infected

Coccidioidomycosis is the most geographically restricted of the systemic mycoses because *C immitis* grows only in the alkaline soil of semiarid climates known as the Lower Sonoran life zone (Figure 47–4). These areas are characterized by hot, dry summers, mild winters with few freezes, and annual rainfall of about 10 inches during brief rainy seasons. Ecologic "islands" with these conditions are found scattered throughout Central and South America. The primary endemic zones in the United States are in Arizona, Nevada, New Mexico, western Texas, and the arid parts of central and southern California. Three unrelated cases in the eastern half of Washington State could give this zone its most northern extension. The area between the Cascade and Rocky Mountains is also dry and arid, but prolonged winter freezes make it less hospitable for *Coccidioides* species. Persons living in the endemic areas are at high risk of infection, and positive skin test rates of 50% to 90% occur in long-time residents of highly endemic areas. Coccidioidomycosis is not transmissible from person to person.

Infection cannot typically be acquired without at least visiting an endemic area, although some interesting examples have been recorded in which the endemic zone itself "paid a visit" and resulted in infections. In 1978, a storm originating in Bakersfield, California (endemic zone), carried a thick cloud of dust all the way to San Francisco. This weather event was followed by cases of coccidioidomycosis in persons who had never left the Bay Area. Similarly, infection in a patient who had never left the southeastern United States was epidemiologically associated with exposure to preprocessed cotton grown in Arizona.

* Considered potential bioweapon

Coccidioides immitis is also a notorious cause of infection in laboratory workers. The high infectivity of cultured arthroconidia has caused it to be classified as a significant biohazard and potential bioweapon.

IMMUNITY

* Progressive disease in AIDS or cell-mediated immunity defects

Lifelong immunity to coccidioidomycosis clearly develops in most of those who become infected. This immunity is associated with strong polymorphonuclear leukocyte and T_H1-mediated responses to coccidioidal antigens. In most cases, a mixed inflammatory response is associated with early resolution of the infection and development of a positive delayed-type hypersensitivity skin test. Progressive disease is associated with weak or absent cellular immunity and loss of delayed-type hypersensitivity to coccidioidal antigens. The disease progresses when cell-mediated immunity and consequent macrophage activation do not develop. Such immune deficits may be a result of disease (AIDS) or immunosuppressive therapy, but progressive coccidioidomycosis may infrequently occur in persons with no known immune defects.

* Antibody levels inversely related to disease progression

Humoral mechanisms are not known to play a major role in immunity to coccidioidomycosis. In fact, *C immitis* is resistant to complement-mediated killing, and levels of complement-fixing antibody are inversely related to the process of disease resolution. Persons with minimal objective indications of tissue involvement (eg, lesions, radiographs) have strong T-lymphocyte responses to *C immitis* antigens and little if any detectable anti-*Coccidioides* antibody. Those with disseminated disease and absent cellular immunity have high titers of antibody. Thus, the levels of antibody seem to indicate the degree of antigenic stimulation rather than any known contribution to resolution of the infection (**Figure 47–10**).

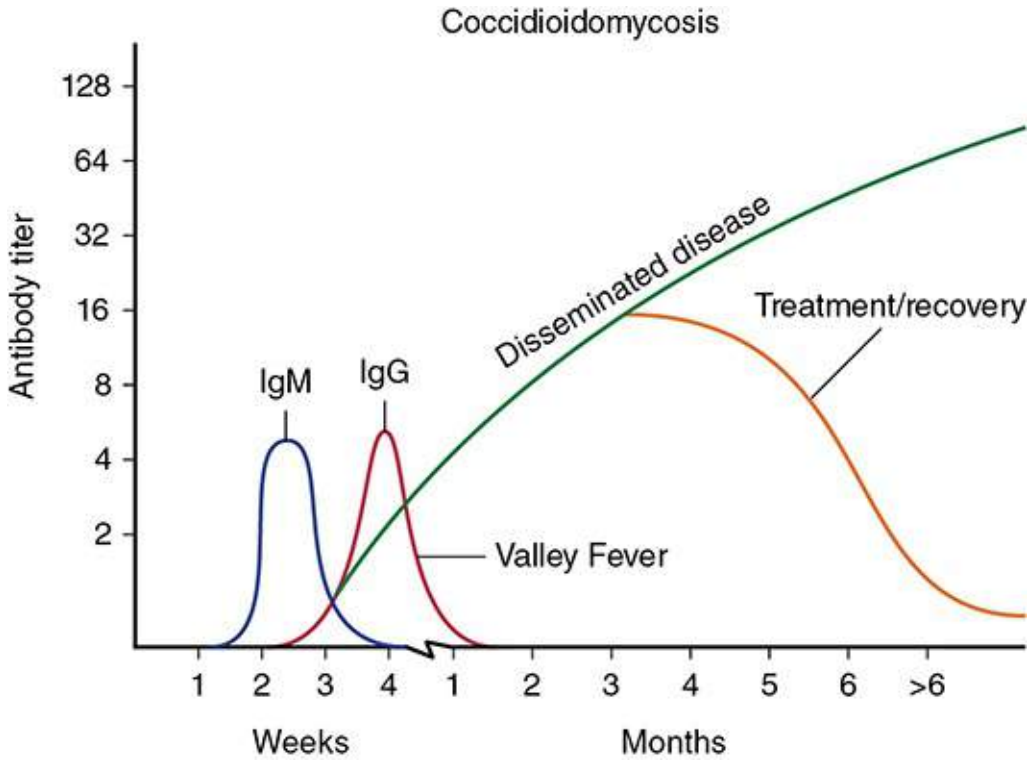

FIGURE 47–10. Serologic tests in coccidioidomycosis.

COCCIDIOIDOMYCOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Valley Fever usually self-limiting**

*** Erythema nodosum common in women**

Disseminated disease less than 1%

More than 50% of those infected with *C immitis* experience no symptoms, or the disease is so mild that it cannot be recalled when evidence of infection (serology, skin test) is discovered. Others develop malaise, cough, chest pain, fever, and arthralgia 1 to 3 weeks after infection. This illness, dubbed **Valley Fever** by the local San Joaquin Valley residents, lasts 2 to 6 weeks with few distinctive findings. The chest X-ray is usually clear or shows only hilar adenopathy. Red, inflamed skin nodules, known as erythema nodosum, may occur during the course of initial infection, particularly on the extremities, and most frequently in

women. In most cases, all clinical symptoms of Valley Fever resolve spontaneously, but often only after considerable discomfort and loss of productivity. In more than 90% of cases, there are no pulmonary residua. A small number of cases progress to a chronic pulmonary infection characterized by cavity formation and a slowly relapsing course that extends over years. Less than 1% of all primary infections and 5% of symptomatic cases disseminate to foci outside the lung.

*** Genetic factors, immune status predict dissemination**

*** Meningitis is chronic**

There is a well-recognized but poorly understood predisposition to chronic infections among distinct patient populations. Disseminated disease is more common in men, as well as people from areas of the world in which malaria is hyperendemic. The genetic determinants of this association have not yet been elucidated. Given the importance of CD_4-mediated immunity in controlling coccidioidomycosis, patients with AIDS or transplants are also at particular risk for disseminated infection. Evidence of extrapulmonary infection almost always appears in the first year after infection. The most commonly involved sites are bones, joints, skin, and the CNS. Coccidioidal meningitis develops slowly with gradually increasing headache, fever, neck stiffness, and other signs of meningeal irritation. The CSF findings are similar to those in TB and other fungal causes of meningitis, such as *C neoformans*. Mononuclear cells predominate in the cell count, but substantial numbers of neutrophils and eosinophils are often present. If untreated, the disease is slowly progressive and fatal.

DIAGNOSIS

Direct observation of spherules diagnostic

With enough persistence, direct examination of infected tissue can reveal diagnostic forms of *C immitis*. The thick-walled spherules are so large and characteristic (Figure 47–7A) that they are difficult to miss in wet mounts (KOH, calcofluor) or biopsy sections. Skin and visceral lesions are most likely to demonstrate spherules; however, these fungal forms are rarely seen in the CSF. Spherules released into expectorated sputum are often small (10-15 mm) and

immature without well-developed endospores, thus difficult to visualize. In contrast, spherules stain well in histologic sections of infected tissue using either H&E or special fungal stains.

CSF culture difficult

Laboratory infection risk

Culture of *C immitis* from sputum, visceral lesions, or skin lesions is not difficult, but must be undertaken only by those with experience and proper biohazard protection. Cultures of CSF are positive in less than half the cases of meningitis. Laboratories must be warned of the possibility of coccidioidomycosis to ensure diagnosis and prevent inadvertent laboratory infection.

TREATMENT

Primary disease treated only with risk factors

Amphotericin B, azoles with progression

Primary coccidioidomycosis is self-limited, and no antifungal therapy is indicated except to reduce the risk of dissemination in patients with risk factors, such as immunocompromise and pregnancy. Itraconazole is preferred for acute or progressive pulmonary disease, with fluconazole as an alternative agent. Disseminated, extrapulmonary infection may require amphotericin B. Fluconazole is often favored as treatment for meningitis because of its enhanced CSF penetration. In cases of refractory meningitis, amphotericin B may be infused directly into the CSF. Unlike other forms of the disease that can be treated for cure, coccidioidomycosis involving the CNS often requires lifelong therapy.

• *PARACOCCIDIOIDES BRASILIENSIS*

Yeast with multiple blastoconidia in ulcerative lesions

Paracoccidioides brasiliensis is the cause of paracoccidioidomycosis (South American blastomycosis), a disease limited to tropical and subtropical areas of

Central and South America. The organism is a dimorphic fungus, the most noteworthy feature of which is the production of multiple blastoconidia from the same cell. Characteristic 5 to 40 μm cells covered with budding blastoconidia may be seen in tissue or in yeast-phase growth at 37°C. This structure has a morphology reminiscent of a ship's steering wheel, often referred to as a "Captain's wheel" when seen in tissue. The disease manifests primarily as chronic mucocutaneous or cutaneous ulcers. The disfiguring ulcers spread slowly and develop a granulomatous mulberry-like base. Regional lymph nodes, reticuloendothelial organs, and the lungs may also be involved.

Strong predilection for men

Paracoccidioidomycosis has a striking predilection for men, despite skin test evidence that subclinical cases occur at the same rate in both sexes. This may be related to the experimental observation that estrogens but not androgens inhibit conversion of mold-phase conidia to the yeast phase. Treatment is with sulfonamides, amphotericin B, and, more recently, the azole compounds.

KEY CONCLUSIONS

- Remember the "C's" of *Cryptococcus neoformans*
- *C*apsule
- *C*D4 cell dysfunction predisposes to symptomatic infection
- *C*NS infections are most common
- *C*ryptococcal antigen is the most sensitive diagnostic test
- The thermally dimorphic fungi each have distinctive tissue forms
- *Histoplasma*—small, budding yeasts
- *Blastomyces*—broad-based budding yeasts
- *Coccidioides*—spherule with endospores
- Infections due to the thermally dimorphic fungi:
- begin after inhalation of infectious particles
- cause a minimally symptomatic initial lung infection in most people
- can disseminate, especially in immunocompromised patients
- Histoplasmosis can mimic tuberculosis with a primary lung infection, granulomatous inflammation, and dissemination in macrophages
- Blastomycosis disseminated disease often manifests as chronic skin lesions
- Coccidioidomycosis can cause a chronic and fatal meningitis

- Paracoccidioidomycosis causes disfiguring skin and mucosal lesions, especially in men

CASE STUDY

A Forgetful Farmer

A 64-year-old farmer was hospitalized because of “progressive dementia.” He had been in excellent health and working full time, never having left the state of Montana. Two months before admission, he became uncharacteristically careless and forgetful, and he was increasingly unable to perform his work on the farm. Neither he nor his family noticed other symptoms, except for a chronic frontal headache of 1 month duration.

Physical examination revealed a well-developed man who did not appear ill. His blood pressure, pulse, and respiratory rate were normal, and his temperature was 99.2°F. The rest of the examination was normal except for mild nuchal rigidity, disorientation to time and place, and marked confusion. A complete blood count was normal, and an HIV serological test was negative.

Lumbar puncture revealed clear CSF with an opening pressure of 250 mm; 100 white blood cells (92% lymphocytes); protein of 85 mg% and glucose of 45 mg% (concomitant blood sugar was 90 mg%). Gram stain of the CSF was negative.

QUESTIONS

1. If this is a case of fungal meningitis, the most likely etiologic agent is:

A. *Candida albicans*
B. *Cryptococcus neoformans*
C. *Histoplasma capsulatum*
D. *Coccidioides immitis*
E. *Paracoccidioides brasiliensis*

2. If blood and CSF cultures for bacteria, mycobacteria, and fungi are negative, what test is most likely to reveal the diagnosis?

A. GMX antigen detection
B. GMX antibody detection
C. Germ tube test
D. Silver stain
E. *Coccidioides immitis* IgG

3. What is the most common route of primary infection for this pathogenic microorganism?

A. Inoculation
B. Ingestion
C. Insect vector
D. Inhalation
E. Animal bite

Answers

1. (B)

2. (A)

3. (D)

Most cases of cryptococcal meningitis/meningoencephalitis occur in patients with defined defects of immunity, such as late-stage HIV infection. However, this infection has been described in otherwise immunocompetent patients, presenting with chronic and progressive CNS symptoms. *C neoformans* is the most common cause of fungal meningitis. *C immitis* can infrequently cause meningitis, but travel to

endemic areas is required for infection. *P brasiliensis* is endemic to regions in Central and South America. Detection of the GXM component of the cryptococcal capsule is the most sensitive test for this infection. Like many fungal pathogens, *C neoformans* typically enters the body through the lungs by inhalation.

Part V

Pathogenic Parasites

Paul Pottinger • Charles R. Sterling

chapter **48**

Parasites—Basic Concepts

The discipline of Medical Parasitology encompasses a broad spectrum of organisms belonging to the kingdoms Protista and Animalia that include diverse phylogenetic groupings such as the subkingdoms Protozoa and Metazoa, respectively. The latter include the trematodes, cestodes (Platyhelminthes), and nematodes (Nemathelminthes). Although often quite dissimilar, many parasites do share some important traits. They are opportunists by nature and exploit environmental niches and lifestyles within their hosts that suit their individual needs. Many have high prevalence rates, given the right set of circumstances, and may cause significant morbidity and mortality. All have exceedingly complex life cycles. The purpose of this chapter, and Chapters 49 and 50 that follow, is to lay a foundation of basic definitions and concepts that hopefully will aid the student in better understanding the specific diseases that will be described in succeeding chapters.

DEFINITION

*** Eukaryotic, single-celled Protozoa and multicellular, macroscopic helminths**

Majority are commensalistic

*** Disease-producing species usually obligate parasites**

Within the context of this section of the book, the term **parasite** refers to organisms that are physiologically dependent upon their host for survival and belong to the major taxonomic groupings mentioned earlier: Protozoa, Platyhelminthes, and Nemathelminthes. **Parasitism,** however, denotes a relationship in which one organism, the parasite, usually benefits at the expense of the other, the host. Protozoa are microscopic, single-celled eukaryotes with a membrane-bound nucleus and organelles. Helminths, comprising both

Platyhelminthes and Nemathelminthes, in contrast, are macroscopic, multicellular worms possessing differentiated tissues and complex organ systems; they vary in length from more than 1 m to less than 1 mm. The majority of both Protozoa and helminths are free living, play a significant role in the ecology of the planet, and seldom inconvenience the human race. The less common disease-producing species are typically **obligate** parasites, dependent on vertebrate hosts, arthropod hosts, or both for their survival. Most parasites are perfectly happy living in a **commensalistic** relationship with their host, producing little or no injury. Of importance to us are those that disturb this relationship, leading to pathogenesis and, occasionally, to death of both the host and parasite.

SIGNIFICANCE OF HUMAN PARASITIC INFECTIONS

Major cause of disease and death worldwide

The relative infrequency of parasitic infections in the temperate societies of the industrialized world with strict sanitation has sometimes led to the parochial view that knowledge of parasitology has little relevance for physicians practicing in these areas. In spite of this view, parasites such as *Toxoplasma gondii*, *Cryptosporidium* spp., *Giardia*, *Trichomonas vaginalis*, and *Enterobius vermicularis* thrive in our midst. Many others pose risks as imported agents and our medical communities are continuously challenged to both identify and treat them. In addition, the continuing presence of parasitic disease among the impoverished, immunocompromised, sexually active, and peripatetic segments of industrialized populations means that most physicians throughout the world regularly encounter those pathogens. Parasitic diseases remain among the major causes of human misery and death in the world today and, as such, are important obstacles to the development of economically less favored nation (**Table 48-1**). Moreover, political, socioeconomic, and medical instabilities in several parts of the world have combined to produce a dramatic recrudescence of several parasitic diseases with important consequences to both the United States and the developing world.

TABLE 48–1 **Estimated Prevalence of Parasitic Infections**

DISEASE	ESTIMATED POPULATION AFFECTED
Amebiasis	10% of world population
Annual deaths	120,000
Giardiasis	>200 million
Trichomoniasis	>200 million
Malaria	300 million
Population at risk	3 billion
Annual deaths	<1 million
Leishmaniasis	12 million
African trypanosomiasis	
Population at risk	50 million
New cases per year	100,000
Annual deaths	5000
American trypanosomiasis	15 million
Population at risk	65 million
New cases per year	60,000
Schistosomiasis	207 million
Population at risk	600 million
Annual deaths	0.5–1.0 million
Clonorchiasis and opisthorchiasis	13.5 million
Paragonimiasis	2.1 million
Fasciolopsiasis	10 million
Filiariasis	128 million
Onchocerciasis	18 million
Dracunculiasis	<25,000
Ascariasis	1.3 billion
Hookworm	1.3 billion
Trichuriasis	0.9 billion
Strongyloidiasis	35 million
Enterobius vermicularis	400 million
Cestodiasis	65 million

*** Resistance of malaria to chemotherapeutics**

*** Resistance of insect vectors to insecticides**

* Increases in imported malaria

Currently, about half of the world's population lives in areas where malaria transmission could or does occur; of these, approximately 200 to 300 million experience new cases annually, with many individuals being infected more than once during any given year. About 400,000 people, predominantly children living in Sub-Saharan Africa, die of malaria each year. *Plasmodium falciparum*, the deadliest of the malarial organisms and responsible for cerebral malaria, has developed resistance to several categories of antimalarial agents, and resistant strains are now found throughout Southeast Asia, parts of the Indian subcontinent, Southeast China, large areas of tropical America, and tropical Africa. Disturbingly, this parasite is developing increased resistance to artemisinin, the current frontline drug in the treatment of malaria. Although several new drugs are in development, it could take years before they reach the public that needs them the most. Growing resistance of the anopheline mosquito vectors of malaria to the less toxic and less expensive insecticides has resulted in a cutback of many malaria control programs. On top of that, many mosquito vectors of malaria are changing their habits, perhaps in response to our efforts to control them. In countries such as India, Pakistan, and Sri Lanka, where eradication efforts had previously interrupted parasite transmission, the disease incidence has increased 100-fold in recent years. In tropical Africa, the intensity of transmission has been greatly reduced largely due to the compliant use of insecticide-impregnated bed nets. Presently, approximately 2000 cases of imported malaria are reported to the Centers for Disease Control and Prevention. Most of these are the result of individuals traveling to malarious areas and not being compliant in taking prophylactic medicines.

Amebic infections in 10% of world

Entamoeba spp., many of which are strictly commensalistic, are intestinal Protozoa that infect about 50% of the world's population, with rates varying substantially depending on sanitary conditions. The pathogenic *Entamoeba* has historically been thought of as *Entamoeba histolytica* and it is estimated that up to 10% of the world's population harbor this parasite. A noninvasive species, *Entamoeba dispar*, which is morphologically similar to *E histolytica* has been recognized and probably accounts for 90% of all reported *E histolytica*-like infections. The invasive *E histolytica*, which is morphologically identical to *E dispar*, produces amebiasis, a disease characterized by intestinal ulcers and liver abscesses. Rates up to 4% are seen in the United States. It is more commonly

seen in areas of the world with poor sanitation, but occurs in the United States as well, particularly in institutions for the mentally retarded and among migrant workers and some male homosexuals.

*** Trypanosomiasis produces disease, limits food supplies**

In the poor, rural areas of Latin America, *Trypanosoma cruzi* infects an estimated 8 million individuals, leaving many with the characteristic heart and gastrointestinal lesions of Chagas disease that characterize the chronic phase of this disease. An estimated 300,000 people who have immigrated from endemic areas live with this parasite in the United States. This parasite has a large reservoir host population, including many animals that live in peridomestic situations. This disease is transmitted by triatomine bugs that have also been found to be infected with *T cruzi* in the United States. In Africa, from the Sahara Desert in the north to the Kalahari in the south, related organisms, belonging to subspecies of the ancestral *Trypanosoma brucei*, cause one of the most lethal of human infections, sleeping sickness. Animal strains of this same organism limit food supplies by making the raising of cattle economically unfeasible over vast areas of the African continent. A large part of this latter problem is influenced by the activity of the vectors, members of the tsetse fly genus *Glossina*.

Leishmaniasis cutaneous or disseminated

Leishmaniasis, a disease produced by an intracellular protozoan and transmitted by sandflies of the genus *Phlebotomus*, is found in parts of Europe, Asia, Africa, and Latin America. Clinical manifestations range from a self-limiting skin ulcer, known as oriental sore, through the mutilating mucocutaneous infection of espundia, to a highly lethal infection of the reticuloendothelial system (kala-azar).

*** Worm infections spread by irrigation projects**

In 1947, in an article entitled “This Wormy World,” Stoll estimated that between the Tropic of Cancer and the Tropic of Capricorn, there were many more intestinal worm infections than people. The prevalence was judged to be far lower in temperate climates. The most serious of the helminthic diseases, schistosomiasis, affects an estimated 140 million individuals in Africa, Asia, and the Americas. These infections tend to be very chronic and persons with heavy worm burdens develop bladder, intestinal, and liver disease, which may

ultimately result in death. The pathology accompanying schistosomiasis is largely the result of immune responses directed against eggs that get trapped in various tissues. Unfortunately, the disease is frequently spread because of rural development schemes involving irrigation projects. Egypt, Sudan, Ghana, and Nigeria have seen significant increases in the incidence of the disease in these areas due to extension of the snail vectors into new areas, often mitigating the economic gains of the development program itself.

Intestinal nematodes infect one-fourth of the world's population

The parasitic nematodes *Ascaris lumbricoides*, hookworms, and *Trichuris* infect more than 1.5 billion people. Collectively they account for tremendous morbidity that is manifest as reduced growth rates among children, iron deficiency, and anemia. *Ascaris* females can produce up to 250,000 extremely environmentally resistant eggs per day!

Larval tapeworm infections are a far more serious threat to human health than infections with adult tapeworms. This is exemplified by infection with the cysticercus of *Taenia solium*, which frequently results in neurocysticercosis. Another larval tapeworm infection caused by *Echinococcus granulosus* results in hydatid cyst disease in humans. An endemic pocket of this disease exists in the four corners area of the United States.

*** Filariasis produces swellings and blindness**

Larval and adult nematode infections cause serious illness. Two closely related filarial worms, *Wuchereria bancrofti* and *Brugia malayi*, which are endemic in Asia and Africa and transmitted by many species of mosquitoes, interfere with the flow of lymph and can produce grotesque swellings of the legs, arms, and genitals. Another filarid, transmitted by black flies, produces onchocerciasis (river blindness) in millions of Africans and Americans, leaving thousands blind.

Multiple parasitic diseases in United States

Toxoplasmosis, giardiasis, trichomoniasis, cryptosporidiosis, and pinworm (enterobiasis) infections are five cosmopolitan parasitic infections well known to American physicians. Toxoplasmosis, a protozoan infection of cats, infects possibly one-half of the world's human population. Although it is usually asymptomatic, infection acquired in utero may result in abortion, stillbirth,

prematurity, or severe neurologic defects in the newborn. Asymptomatic infection acquired either before or after birth may subsequently produce visual impairment. Immune suppression, such as caused by HIV infection and immunosuppressive therapy may reactivate latent infections, producing severe encephalitis.

CLASSIFICATION, FORM, AND FUNCTION

▪ Protozoa

Classification

The classification schemes for the Protozoa seem to be evolving even quicker than the organisms themselves. Within the context of this book a classification scheme used by classical parasitologists in textbooks has been adopted. It is based largely on light and electron microscopy and modes of locomotion, but considers current evolutionary thinking based on comparative genetics. Within the context of this scheme, the Protozoa are considered a subkingdom within the kingdom Protista.

The subkingdom Protozoa includes the following phyla: Sarcomastigophora, including the flagellates and amebas; Apicomplexa, including malaria parasites, *Cryptosporidium* and *Toxoplasma*; Microsporidia, including the microsporidia; and Ciliophora, including the ciliates (**Table 48-2**).

TABLE 48–2 Classification of Protozoan Parasites

Kingdom—Protista
- Subkingdom—Protozoa
  - Phylum—Sarcomastigophora
    - Subphylum—Mastigophora
      - Genera—*Leishmania, Trypanosoma, Giardia, Trichomonas* and *Dientamoeba*
    - Subphylum—Sarcodina
      - Genera—*Entamoeba, Acanthamoeba,* and *Naegleria*
  - Phylum—Apicomplexa
    - Genera—*Plasmodium, Toxoplasma, Cryptosporidium, Cyclospora, Isospora, Sarcocystis,* and *Babesia.*
  - Phylum—Microsporidia
    - Genera—*Enterocytozoon* and *Encephalitozoon*
  - Phylum—Ciliophora
    - Genus—*Balantidium*

The Sarcomastigophora are an extremely diverse group including true

flagellates of the subphylum Mastigophora and parasites such as those belonging to the genera *Leishmania*, *Trypanosoma*, *Giardia*, *Trichomonas*, and *Dientamoeba.* Mastigophorans include those that are obligate intracellular parasites (*Leishmania*), parasites of the blood vascular system (*Trypanosoma*), intestinal track (*Giardia*), or genital–urinary track (*Trichomonas*). The subphylum Sarcodina can also be found within this phylum and include the important genera *Entamoeba*, *Acanthamoeba*, and the ameba–flagellate *Naegleria*.

The Apicomplexa also represent a diverse group of organisms that have been placed together phylogenetically because of the presence of complex apical organelles in life cycle stages responsible for cellular invasion. All are obligate intracellular parasites for most of their life cycles. Parasites in this taxonomic grouping include members of the genera *Plasmodium, Toxoplasma, Cryptosporidium, Cyclospora, Isospora, Sarcocystis,* and *Babesia.*

The Microsporidia include an opportunistically important group of parasites called the microsporidia. Many infections in this group are seen in immunocompromised patients with the more important genera being *Enterocytozoon* and *Encephalitozoon*. The Ciliophora include a single genus, *Balantidium*, which is only occasionally encountered in humans.

Form and Function

Protozoa range in size from slightly more than 1 to more than 100 μm. They are single-celled organism and have a true membrane-bound nucleus. The nucleus contains clumped or dispersed chromatin and a central nucleolus or **karyosome.** The shape, size, and distribution of the nucleus can be useful in distinguishing protozoan species from one another.

Endoplasm contains nutrients

Ectoplasm has organelles of locomotion

The cytoplasm is frequently divided into an inner endoplasm and a thin outer ectoplasm. The granular **endoplasm** is concerned with nutrition and often contains food reserves, contractile vacuoles, and undigested particulate matter. The **ectoplasm** may be organized into specialized organelles of locomotion. In some species, these organelles appear as blunt, dynamic extrusions known as pseudopods. In others, highly structured thread-like cilia or flagella arise from intracytoplasmic basal bodies. Flagella are longer and less numerous than cilia and possess a structure and a mode of action distinct from those seen in

prokaryotic organisms.

Many Protozoa are facultative anaerobes

*** Nutrients engulfed by phagocytosis or pinocytosis**

Most parasitic Protozoa are heterotrophic and must assimilate organic nutrients. This assimilation is accomplished by engulfing soluble or particulate matter in digestive vacuoles, processes termed **pinocytosis** and **phagocytosis,** respectively. In some species, food is ingested at a definite site, the peristome or cytostome. Food may be retained in special intracellular reserves, or vacuoles. Undigested particles and wastes are extruded at the cell surface by mechanisms that are the reverse of those used in ingestion. The intracellular location of many of these parasites means that host cells may have to be modified to accommodate for transport and assimilation of nutrients. This is especially true among the apicomplexans and parasites like *Leishmania*. Many parasitic protozoans are facultative anaerobes in their definitive host (*E histolytica* and *Giardia* are excellent examples). The African trypanosomes must switch from an inefficient anaerobic to a more efficient mode of aerobic respiration when they take up residence in their vector. This is accomplished by profound changes that take place within the kinetoplast–mitochondrial complex of these organisms. The malaria parasite *P falciparum* has been found to complete its development within the microaerophilic environment of postcapillary venules. This discovery now allows investigators to extensively cultivate this parasite *in vitro*. Some parasitic Protozoa are amitochondriate and utilize specialized organelles such as mitosomes (*Giardia*) or hydrogenosomes (*T vaginalis*) where terminal events of electron transfer in anaerobic respiration occur.

Reproduction usually by binary fission

Protozoa form cysts as survival form

Survival is ensured by fastidious reproductive and protective techniques. Reproduction in many parasitic protozoans is accomplished primarily by simple binary fission. In one phylum of Protozoa, the Apicomplexa, a cycle of multiple fission (schizogony) alternates with a period of sexual reproduction (sporogony). A similar mode of reproduction is seen in the microsporidia although somewhat modified. Many Protozoa, when exposed to an unfavorable milieu, become less active metabolically and secrete a cyst wall capable of protecting the organism

from physical and chemical conditions that would otherwise be lethal. In this form, the parasite is better equipped to survive passage from host to host in the external environment. *Giardia, Entamoeba, Naegleria, Cryptosporidium, Cyclospora,* and others are all capable of forming environmentally protective cysts or oocysts. The microsporidia produce spores. Immunoevasive mechanisms described in later chapters also contribute to survival of these parasites within the host.

▪ Helminths

Classification

As for the Protozoa, the classification of helminth parasites is ever changing. The scheme used in this book is a more classical one and readily accepted and understood by most parasitologists. Accordingly, the various helminth groups discussed are placed into distinct phyla within the subkingdom Metazoa of the kingdom Animalia, which includes all multicellular organisms. These phyla include the Platyhelminthes with the important classes Trematoda (flatworms) and Cestoidea (tapeworm), the Nemathelminthes, or roundworms, and the Acanthocephala, or thorny-headed worms (**Table 48-3**).

TABLE 48–3 Classification of Helminth parasites

Kingdom—Animalia
- Subkingdom—Metazoa
  - Phylum—Platyhelminthes
    - Class—Trematoda
      - Genera—*Schistosoma, Fasciola, Fasciolopsis, Clonorchis,* and *Paragonimus*
    - Class—Cestoidea
      - Genera—*Diphyllobothrium, Taenia, Echinococcus,* and *Hymenolepis*
  - Phylum—Nemathelminthes
    - Genera—*Trichuris, Trichinella, Capillaria, Strongyloides, Necator, Ancylostoma, Ascaris, Toxocara, Wuchereria, Brugia,* and *Onchocerca*
  - Phylum—Acanthocephala
    - Genus—*Macracanthorhynchus*

The class Trematoda includes important parasites belonging to the genera *Schistosoma*, *Fasciola*, *Fasciolopsis*, *Clonorchis*, and *Paragonimus.* Cestoidea includes the tapeworm parasitic genera *Diphyllobothrium*, *Taenia*, *Echinococcus*, and *Hymenolepis*.

The Nemathelminthes include important parasites belonging to the genera *Trichuris*, *Trichinella*, *Capillaria*, *Strongyloides*, *Necator*, *Ancylostoma*, *Ascaris*,

Toxocara, *Wuchereria*, *Brugia*, and *Onchocerca*.

The Acanthocephala contains only one genus, *Macracanthorhynchus*, considered to be of occasional importance to humans.

Form and Function

All helminths are multicellular organisms. The Trematoda vary in size from a few millimeters to several inches and are usually flat in shape. They all are invested in a tegument that is organized as a multicellular syncytium. Absorption of nutrients and excretion of wastes occur across the tegument. They are acoelomate with a body filled with parenchymal tissue. Embedded within this tissue are an incomplete digestive tract composed of ceca and the reproductive organs of both sexes. The schistosomes are an exception to this, have separate sexes, and are tubular in shape. Trematodes usually possess two suckers which help them to locomote and anchor to host tissue. Most trematodes have complex life cycles involving snails as a required first intermediate host in which asexual multiplication of larval stages takes place. Larval stages called cercaria emerge from snail and may either directly penetrate the final definitive host (the schistosomes), or encyst openly in the environment or within a second intermediate host (all other parasitic trematodes).

The Cestoidea, or tapeworms, have a flattened, ribbon-like body, or strobila, composed of segments called proglottids. Like the trematodes, they are invested in a tegument and are acoelomate with proglottids filled with parenchymal tissue. Each proglottid serves as an individual reproductive unit harboring both sets of male and female reproductive organs and are classified as being immature, mature, or gravid (egg filled). At the anterior end of the worm is a scolex (head region) that may or may not be armed with hooks. This body region is anchored to host tissue. Tapeworms continuously produce proglottids, which may be shed individually (apolysis) or as a chain once the eggs are released (anapolysis). They also possess a primitive nervous system that links the scolex to the proglottids. Tapeworms have complex life cycles that vary tremendously and will be discussed in chapters that follow. Infections by larval tapeworms usually result in greater pathogenesis to the host than infection by adult tapeworms. This is true of infections caused by *Diphyllobothrium latum*, *T solium*, *E granulosus*, and *Echinococcus multilocularis.*

The Nemathelminthes, or nematodes, have a cylindrical fusiform body and a tubular alimentary tract that extends from the mouth at the anterior end to the anus at the posterior end. They are invested in a tough cuticle that must be shed as they go through molts to become adults. They are considered as

pseudocoelomate organisms with a body cavity filled with fluid. These worms possess only longitudinal muscles that allow them to flex and put pressure on internal organs so they can function. The sexes are separate, and the male worm is typically smaller than the female. An unusual feature in males is that sperms are ameboid and not flagellated. A variety of reproductive modes are used by these worms including oviparity (egg laying), ovoviviparity (egg followed by larval birth in utero), and parthenogenesis. First larval stages are considered as L_1 upon hatching and molt four times to become adults. Life cycles vary tremendously within this group from being direct (*Trichuris*), indirect, and complex (*Strongyloides*), to those requiring an intermediate host (all filarial parasites). These life cycles will be discussed in chapters to follow. Helminth parasites are nourished by ingestion (nematodes) or absorption (trematodes and cestodes) of the body fluids, lysed tissue, or intestinal contents of their hosts. Carbohydrates are rapidly metabolized, and the glycogen concentration of the worms is high. Respiration is primarily anaerobic, although larval offspring frequently require oxygen. A large part of the energy requirement is devoted to reproductive needs. The daily output of offspring can be as high as 200,000 for some worms.

Protection from the host's digestive and body fluids is afforded by the tegument or cuticle and the secretion of enzymes. Some worms, such as the schistosomes, can protect themselves from immunologic attack by the incorporation of host antigens into their tegument. The life span of the adult helminth is often measured in weeks or months, but some, such as the hookworms, filariae, and flukes, can survive within their hosts for decades, producing chronic infections with attendant morbidity or mortality.

HOST TYPES AND TRANSMISSION PATTERNS

Parasites usually encounter one or more hosts during their life cycles, but the one host they must visit is the **definitive host.** This is the host in which the parasite reaches sexual maturity. Many protozoa do not have a sexual stage of the life cycle, in which case, if there is more than one host type in the life cycle, the more evolved host is usually considered the definitive host. Purists would argue that the mosquito is the definitive host for malaria because the sexual union of gametes occurs in that host, yet for this book, the definitive host is considered to be man. If some development of a parasite occurs in another host, then that host is considered an **intermediate host.** Snails are intermediate hosts for schistosome parasites and tsetse flies for most African trypanosomes. For one

parasite, *Trichinella*, the same host is both a definitive and intermediate host because sexually active adult worms reside in the intestinal tract and the first-stage larvae are nurtured within muscle cells of the same host. Snail and tsetse fly intermediate hosts may also be considered **vectors.** However, there can be vectors in which no development takes place. Such a vector is then considered a **mechanical vector.** Such a host can also be referred to as a **paratenic** or **transport host.** Flies are considered transport hosts for *Giardia*, *Cryptosporidium,* and *E histolytica.* For many parasites there are also **reservoir hosts.** Such a host is a reservoir of infection from which other hosts can be infected. The East African trypanosomes have many ungulate species as reservoir hosts. These animals are considered as definitive hosts as well.

Some parasites, such as *Cryptosporidium hominis* and *Cyclospora cayetanensis* are highly **host specific.** In these cases, humans are the only hosts. *Cryptosporidium parvum,* on the other hand, is a zoonotic species with many animals serving as reservoirs from which man can become infected. *Trichinella*, mentioned earlier, is an example of a parasite that has loose host specificity. Any carnivorous animal can serve as a host for this parasite.

Parasitic infections that are transmissible from animals to humans are considered **zoonotic.** Many parasitic infections considered in the following chapters fall into this category. Those transmissible from humans to humans or back to animals are considered **anthroponotic.** *Cryptosporidium hominis* is readily transmissible from humans to humans, and some of the primate malarias encountered in South America are thought to have arisen from human malarias brought to the new world after colonization. Transmission patterns that only involve animals are considered **enzootic.** If a transmission pattern occurs in association with man, it is considered **synanthropic.** Many parasitic infections fall into this pattern of transmission. Transmission patterns may also involve life cycles occurring away from man and these usually involve animal hosts and are considered **sylvatic.** *Echinococcus granulosus* has a synanthropic cycle involving dogs, sheep, and man, and a sylvatic cycle involving deer and coyotes or moose and wolves.

▪ Single-Host Parasite Life Cycle Examples

As is evident from the previous discussion, many parasites require but a single host species for the completion of their life cycles. The method by which the parasite is transmitted from individual to individual within that species is determined in large part by its viability in the external environment and, in the case of helminths, by the conditions required for the maturation of eggs or

offspring. The mode of transmission, in turn, determines the social, economic, and geographic distribution of the parasite. A few examples are described in **Table 48-4.**

TABLE 48–4 Transmission and Distribution of Four Representative Parasites

ORGANISM	INFECTIVE FORM	MECHANISM OF SPREAD	DISTRIBUTION
Trichomonas vaginalis	Trophozoite	Direct (venereal)	Worldwide
Entamoeba histolytica	Cyst/trophozoite	Direct (venereal)	Worldwide
	Cyst	Indirect (fecal–oral)	Areas of poor sanitation
Ascaris lumbricoides	Egg	Indirect (fecal–oral)	Areas of poor sanitation
Plasmodium falciparum	Sporozoite	*Anopheles* mosquito	Tropical and subtropical areas

* Transmission by direct sexual contact

The protozoan *T vaginalis* does not produce a protective cyst form. Although its active or trophozoite form is relatively hardy, it can survive only a few hours outside of its normal habitat, the human genital tract. Thus, for all practical purposes, transmission requires the direct genital contact of sexual intercourse. Thus, trichomoniasis is cosmopolitan, occurring wherever human hosts engage in sexual activity with multiple partners.

* Fecal–oral transmission common for intestinal parasites

Another protozoan, *E histolytica*, inhabits the human gut and produces hardy **cysts** that are passed in the stool. Transmission occurs when another individual ingests these cysts. Like *T vaginalis*, the organism can be passed by direct physical contact, in this case by oral–anal sexual activity. This mode of transmission, in fact, accounts for the high incidence of amebic infections in male homosexuals. Unlike *T vaginalis*, however, the cysts can survive for prolonged periods in the external environment, where they may eventually contaminate food or drinking water. Thus, in environments such as mental institutions, where the level of personal hygiene is low, or in populations in which methods for the sanitary disposal of human wastes are not available, amebiasis is common.

Infectivity develops in soil

The intestinal helminth *A lumbricoides* illustrates still another transmission pattern. In this infection, highly resistant eggs are passed in the human stool. Unlike the situation with *E histolytica* described previously, the eggs are not

immediately infective but must incubate in soil under certain conditions of temperature and humidity before they are fully embryonated and infectious. Thus, this parasite cannot be transmitted directly from host to host. The organism spreads only when indiscriminate human defecation results in deposition of eggs on soil and subsequent exposure of that soil to the climatic conditions required for embryonation of the eggs. For this reason, *Ascaris* infections are most prevalent in areas of the tropics and subtropics and are associated with poor sanitation.

▪ Multiple-Host Parasite Life Cycle Examples

Multiple hosts may be involved

Definitive and intermediate hosts

A few Protozoa and many helminths require two or more host species in their life cycle. As stated previously, to avoid confusion, it is customary to refer to the species in which the parasite reproduces sexually as the definitive host and that in which asexual reproduction or larval development takes place as the intermediate host. When there is more than one intermediate host, they are known simply as the first and second intermediate hosts. In some cases, such as that of *Taenia saginata*, the beef tapeworm, both host species are vertebrates; humans serve as the definitive host and cattle as the intermediate host. Among parasites that inhabit the blood and tissues of humans, it is more common for a blood-feeding arthropod to serve as a second host and as the transmitting vector. An example is malaria, in which the causative *Plasmodium* is transmitted from person to person by the bite of an infected female mosquito of the genus *Anopheles.* As mentioned previously, people argue whether mosquito or man is the definitive host as the sexual union of gametes occurs in the mosquito.

chapter 49

Pathogenesis and Diagnosis of Parasitic Infection

PATHOGENESIS

The pathogenesis of both protozoan and helminthic disease is highly variable. Many factors contribute to this variability and included among them may be parasite size, induced injury, reproductive potential, nutritional requirements (including metabolites or toxins produced), niche selection (often influenced by individual life cycles and migration patterns through the host), and last, but not the least, immunologic consequences of infection.

Parasite size may or may not be a predictor of pathogenesis. Many of the parasitic Protozoa, including those that cause malaria (*Plasmodium*), African sleeping sickness (*Trypanosoma brucei* subspecies), Chagas disease (*Trypanosoma cruzi*), and leishmaniasis (*Leishmania*), are among the smallest and most pathogenic. The giant cestode, *Diphyllobothrium latum*, can reach sizes exceeding 10 m, yet produces a pernicious anemia due to vitamin B12 competition with the host in less than 1% of the infected individuals. *Ascaris lumbricoides*, which can grow up to a foot in length can cause severe intestinal blockage if enough worms are present. The larval hydatid cyst of the tapeworm *Echinococcus granulosus* can achieve considerable size if given long enough to grow and can put tremendous pressure on organs it may be found within.

Parasite-induced injury frequently results from parasite invasion of host tissues. Hookworms, *Strongyloides* and *Trichuris*, repeatedly probe the intestinal or colon lining, promoting and inducing extensive, immunologically mediated inflammatory responses. In these cases, worm burden determines the extent of the pathogenesis. The egg laying of schistosome parasites determines the pathology of this infection as many eggs get trapped in tissues in their attempt to leave the host. The result is extensive inflammation and eventual fibrosis of affected tissues.

The reproductive potential of parasites varies considerably. Protozoa

generally have short generational times. In large part, this is due to the asexual nature of their reproduction for much of their life cycles. Rates vary from several hours (African trypanosomes) to several days (malaria). This can place tremendous pressure on host resources with attendant consequences. Helminthes, however, are usually incapable of reproducing within their definitive hosts, so overall worm burden becomes a greater determinant of pathogenesis. This, in turn, will depend on how many eggs, or larvae, initiated the infection. An exception is encountered in *Trichinella*, in which fertile females residing within the intestinal lining give birth to larvae that migrate to the musculature.

Nutritional requirements among parasites vary tremendously, although most tend to be facultative anaerobes. All *Trypanosoma* spp. metabolize carbohydrates from their host, but the metabolites are fermentation-like end products of pyruvate that can affect endothelial linings within the host. Malaria parasites of the genus *Plasmodium* ultimately have rather synchronous infections and produce byproducts of metabolism, including insoluble hemozoin, which when released from infected cells trigger a rise in proinflammatory cytokines that cause fever and impair the functioning of macrophages. Hookworms, because of their voracious appetite and wasteful digestive methods, deplete the iron in the host, resulting in severe anemia if the worm burden is great enough. Hookworms, and many of their allies, also produce powerful enzymes to help predigest what they take in. These enzymes help produce inflammatory responses. *Entamoeba histolytica* and *Trichomonas vaginalis* produce enzymes that help mediate **contact-dependent cytotoxicity** reactions. In the case of *E histolytica*, this helps the parasite establish extraintestinal sites of infection. In one interesting case, the death of filarial parasites or their larvae in a definitive host also releases mutualistic endosymbionts. These are felt to contribute to inflammatory responses seen in such infections as those caused by *Onchocerca volvulus* and resulting in river blindness.

Where the parasite resides, or migrates during establishment in the host, can also be a strong determinant of pathogenesis. Many helminth parasites undergo an obligatory migration through the bloodstream that brings them in contact with lung tissue. This required migration often results in Loeffler syndrome that manifests as an intense eosinophilic inflammatory response. Larval stages of *Taenia solium* are frequently encountered in brain tissue, resulting in neurocysticercosis. Parasites such as *Toxocara canis* may be unable to complete full development in humans, but larvae try to migrate through tissues, causing visceral larval migrans. Many more examples will be expanded upon in chapters that follow.

* Immunopathologic mechanisms contribute to parasitic diseases

Finally, there can be numerous immunologic consequences of infection that help promote pathogenesis. Antigen, antibody, and complement complexes combine to cause excessive anemia and glomerulonephritis in African trypanosomiasis. Allergic reactions play a major role in the cutaneous reactions to invading hookworm, *Strongyloides*, and schistosome larvae (ground itch, swimmers' itch). Transient pneumonias induced by the pulmonary migration of *Ascaris* and other nematode larvae (Loeffler syndrome), nocturnal paroxysms of asthma in some patients with filariasis (tropical pulmonary eosinophilia), and the shock, asthma, and urticaria that follow rupture of a hydatid cyst are all immunologically mediated. The latter frequently results in anaphylaxis. Cardiac damage in Chagas disease is thought, at least in part, to reflect immune-induced inflammatory responses, or perhaps autoimmune-related phenomena. Immune complex diseases are seen in schistosomiasis (Katayama syndrome) and malaria (nephrosis). The granulomatous reaction to schistosomal eggs is the result and antibody-dependent, cell-mediated cytotoxic (ADCC) responses. The entire clinicopathologic spectrum of manifestations arising from leishmanial infections appears to be caused by differences in the ability of cell-mediated immune responses to function properly.

IMMUNITY AND IMMUNE EVASION

Immune response vigorous but often ineffective

The large size, complex structure, varied metabolic activity, and synthetic prowess of most parasites provide their human host with an intense antigenic challenge. Generally, the resulting immunologic response is vigorous, but its role in modulating the parasitic invasion differs significantly from that in viral and bacterial infections. It is apparent from the chronic course and frequent recurrences typical of many parasitic diseases that complete acquired resistance resulting in sterile immunity is often absent. Immunity does, however, frequently serve to moderate the intensity of the infection and its associated clinical manifestations. In fact, clinical recovery and resistance to reinfection in some instances require the persistence of viable organisms at low concentration within the body of the host (**premunition = infection immunity**). An excellent example of this is seen in patients infected with *Toxoplasma gondii*.

All those immune responses generally exercised against the more primitive

viral and bacterial microorganisms, including **innate responses,** driven by the complement system, dendritic cells and natural killer cells, and **adaptive (acquired) responses,** driven by antibodies, cytokines (lymphokines), cytotoxic T lymphocytes, activated macrophages, memory cells, and ADCC mechanisms, have been shown to play a part in modulating parasitic infection.

Innate immune responses are usually immediate, less specific, and evolutionarily considered older than adaptive responses. Innate responses often depend on pattern recognition molecules leading to the destruction of bound organisms by complement activation and phagocytosis. Receptor engagement and activation are often critical to further involvement by adaptive responses. One example of innate responses manifests against parasite infections including those seen against malaria. The innate immune response to malaria involves multiple mechanisms, but rarely results in clearance of the parasite. Like other protozoan parasites, *Plasmodium falciparum* induces the production of IFN-γ by NK cells and subsequent phagocytosis of free parasites by macrophages. NK cells themselves can also lyse parasite-infected erythrocytes. Complicating the picture, improper activation of innate immune mechanisms during malaria may contribute to the disease. For instance, activation of the complement system is a common finding in human malaria, but excessive complement activation appears to be associated with an increased risk of cerebral malaria and severe malarial anemia in children. Likewise, iron sequestration mediated by hepcidin, another innate immune response against malaria, may also worsen anemia by decreasing erythropoiesis.

Overall, parasites are very capable of resisting host innate defenses. Adaptive responses, therefore, are critical in attempts by the host to control such infections and include both humoral and cell-mediated responses. As already noted, they are usually not perfect.

All elements of immune response mobilized

Antibodies are one line of defense against parasites. They play roles in opsonization, neutralization, complement activation, and ADCC adaptive responses. Antibodies are largely responsible for eliminating populations of trypanosomes from infected individuals. Interestingly, these antibodies are not formed as a result of classical immune stimulation, instead, the antigenic signal coming from the trypanosomes consists of T-independent antigens that can directly stimulate B cells to form antibody. In this case, the antibody is not the classical IgG but IgM. Although this is useful in eliminating the dominant population of trypanosomes present, another wave of parasites arises because of

antigenic variation. Antibodies, if present in high enough concentration, can neutralize sporozoites and merozoites of malaria, thereby preventing them from invading their target host cells, hepatocytes, and red blood cells. Antibody generation against malarial sporozoites using attenuated and recombinant vaccines is currently undergoing multiple pilot clinical trials in developing countries where malaria is endemic. Complement activation does not usually result in direct parasite killing. In fact, many protozoan parasites have evolved mechanisms to avoid complement-mediated killing. Instead, complement appears to play a role in cell-mediated and especially ADCC responses against parasites.

*** IgE response to worms attracts eosinophils**

Eosinophils release toxic protein

On invasion of tissue, many helminths, and the schistosomes in particular, stimulate the production of IgE, the Fc portion of which binds to mast cells and basophils. Interaction of the antibody with parasitic antigen triggers the release of histamine and other mediators from the attached cells. These may injure the worm directly or, by increasing vascular permeability and stimulating the release of chemotactic factors, may lead to the accumulation of other cells and IgE antibodies capable of initiating antibody-dependent, cell-mediated destruction of the parasite. This is augmented by complement. The specific killer cell involved is often the eosinophil. These cells attach by their Fc receptor site to IgE antibody-coated parasites and degranulate, releasing a major basic protein that is directly toxic to the worm.

Cellular immunity is likewise important as an adaptive response. It is a hallmark of cutaneous *Leishmania tropica* infections. Skin lesion biopsies show the presence of lymphocytes and macrophages working in synergy to contain parasites. Activated macrophages are quite capable of destroying engulfed leishmanial parasites. However, defects in this type of cooperation can be seen in leishmanial infections that result in mucocutaneal leishmaniasis. Lesions containing these parasites contain plenty of macrophages, but few or no lymphocytes.

Cytotoxic T cells, or CD8+ T cells, play an important part in response to many protozoan infections. These cells not only produce INF-γ but can also produce TNF-α, and recently have been shown to produce IL-17. Collectively, all the cytokines have been shown to have varying roles for protective responses in toxoplasmosis, malaria, Chagas disease, and leishmaniasis.

Many cellular responses also work in consort with antibody responses to assist in modulating parasitic infections. An excellent example of this is seen in the case of many nematode infections such as *Trichinella*, *Ancylostoma*, *Necator*, and *Strongyloides*, where intimate association with intestinal tissue is an integral part of the life cycle. Such interactions lead to inflammatory responses that are the result of antigen signaling through the Peyer patches, movement of cells to mesenteric lymph nodes, and clonal expansion of both T and B cells that migrate back to the intestinal epithelium to promote inflammatory responses that depend on both antibody and cell-mediated constituents. The whole idea of inflammation in this instance is to produce an environment inhospitable for the worms or to induce worm expulsion as in the case of *Trichinella*.

Protozoa escape phagosome, prevent phagosome/lysosome fusion, avoid destruction

Many parasites are capable of evading host immune responses. The strategies used vary considerably and allow the parasite to successfully propagate and spread to other hosts. If immune responses were completely successful in eliminating parasites, parasites would no longer be a problem. However, if all parasites killed their hosts, transmission would be interrupted. What good is a dead host to a parasite? The techniques by which parasites have been shown to evade the consequences of the host's specific adaptive responses are numerous. Included among them are seclusion within immunologically protected areas of the body, continual alteration of surface antigens (antigenic variation), molecular mimicry, and active evasion or suppression of the host's effector mechanisms. Several protozoa are shielded from the host defenses by virtue of their intracellular location. Some have even found ways to avoid or survive the normally lethal environment of the macrophage, a first-line defense cell normally intent on destroying pathogens it encounters. *T cruzi*, for example, escapes from phagosomes into the cytoplasm early during host infection. *T gondii* inhibits the fusion of phagosomes with lysosomes, thus preventing phagolysosome formation. *Leishmania* species, capable of neither of these feats, are resistant to the action of lysosomal enzymes and survive in macrophage phagolysosomes. Once macrophages have been activated to sufficient levels; however, the tables are somewhat turned on these parasites.

*** Outer covering of parasite may provide protection from host defenses**

In the examples given above, *T cruzi* and *T gondii* have alternate mechanisms for escaping host responses. They do so by becoming intracellular in cell types not normally involved in immune responsiveness. The gut lumen is perhaps the largest immunologic sanctuary within the body, because, unless the integrity of the intestinal mucosa is breached by injury or inflammation, this barrier protects lumen-dwelling parasites, many of which are surrounded by a protective tegument, or cuticle, from most of the effective humoral and cellular immune mechanisms of the host, allowing survival and the opportunity to reproduce.

*** Antigenic shifts occur in parasites**

*** Trypanosomal variation outpaces immunologic response**

Variants of trypanosomes selected from preexisting repertoire

Most immune effector mechanisms are directed against the surface antigens of the parasite, and alteration of these antigens may blunt the immunologic attack. Many parasites undergo developmental changes within their hosts that are generally accompanied by alterations in surface antigens. Immune responses directed at an early developmental stage may be totally ineffective against a later stage of the same parasite. Such stage-specific immunity is very evident in malaria because different life cycle stages express different antigens and even give rise to different types of responses. The issue of stage-specific immunity in malaria is further compounded by species-specific immunity. No wonder we still do not have a totally effective vaccine against this disease. Even more intriguing is the ability of some parasites to vary the antigenic characteristics of a single developmental stage. The trypanosomes that cause African sleeping sickness circulate in the bloodstream coated with a thick glycoprotein surface coat. The development of humoral antibody to this coating results in the elimination of parasites from the blood expressing the dominant surface coat. However, within this dominant population of parasites are a few that have undergone antigenic variation and produced a new variant surface glycoprotein coat. This less dominant population gives rise to the next dominant population and this process repeats itself over and over. Over 1000 variant types can arise via this process. The process is genetically and not immunologically driven. The expression of individual genes from this large genetic repertoire is controlled by the sequential transfer of a duplicate copy of each gene to an area of the parasite genome responsible for gene expression. Continued antigenic variation, unfortunately,

causes host immunosuppression with attendant consequences.

Antigenic shedding, masking with host antigens

Several protozoan and helminthic pathogens are thought to be capable of neutralizing antibody-mediated attack by shedding and, later, regenerating specific surface antigens. Adult schistosomes, in addition, may immunologically hide from the host by masking themselves with host blood group antigens and immunoglobulins and through a process known as molecular mimicry by which they produce substances that are transported to their tegument that mimic substances naturally found within the host.

*** Destroy immunologic mediators**

*** Cause immune suppression**

Cuticle resists immune effectors

Several parasites can destroy or inactivate immunologic mediators. Tapeworm larvae produce anticomplementary chemicals, and *T cruzi* splits the Fc component of attached antibodies, rendering it incapable of activating complement. Several protozoa, most notably *T brucei* species that are responsible for African sleeping sickness, induce polyclonal B-cell activation leading to the production of nonspecific immunoglobulins and eventual exhaustion of the antibody-producing capacity of the host. This and other protozoa can produce nonspecific suppression of both cellular and humoral effector mechanisms, also enhancing the host's susceptibility to a variety of unrelated secondary infections. Patients with disseminated leishmaniasis display a specific inability to mount a cellular immune response to parasitic antigens in the absence of evidence of generalized immunosuppression. Finally, the thick, tough cuticle of many adult helminths renders them impervious to immune effector mechanisms designed to deal with the less robust microbes.

DIAGNOSIS

Diagnosing parasitic infections can test the limits of the best physicians and diagnostic laboratories. Many of these infections are not frequently encountered in most of the industrialized world, as they are elsewhere, and many laboratories do not routinely handle requests to diagnose such infections. In addition,

personnel may be poorly trained to adequately diagnose these infections.

Consider indigenous, imported infections

The continuous arrival of travelers and immigrants from endemic areas, and the fact that parasitic infections may at times be life-threatening, necessitates consideration of these diseases in differential diagnoses. Unfortunately, the clinical manifestations of parasitic infections are highly varied, often mimic other disease conditions, and are seldom sufficiently characteristic to raise this possibility in the clinician's mind. It is incumbent upon the physician to ask questions related to travel history, food and liquid intake, activities, exposure to biting insects, etc, to raise the possibility that the individual might have acquired a parasitic disease.

*** Morphologic demonstration primary diagnostic**

Once considered, an appropriate diagnostic test must be ordered. Typically, diagnosis rests on the demonstration and morphologic identification of the parasite or its progeny in the stool, urine, sputum, blood, or tissues of the human host.

A routine blood differential may raise the specter of such an infection. Eosinophilia has been recognized as an important clue to the diagnosis of parasitic disease. However, this phenomenon is characteristic only of helminthic infection, and even in these cases it is frequently variable. Eosinophilia, which presumably reflects an immunologic response to the complex foreign proteins possessed by worms, is most marked during tissue migration. Once migration ceases, the eosinophilia may decrease or disappear entirely.

*** Stool concentration for intestinal parasites**

In intestinal infections, an O&P or ova and parasite examination may suffice. This may involve concentration procedures such as floatation or sedimentation, followed by a wet mount or stained smear, or both, of the stool sample. Some parasites, such as *Giardia*, however, may be passed in the feces intermittently or in fluctuating numbers and repeated specimens are needed to confirm infection. Occasionally, specimens other than stool must be examined. In the case of small bowel infections, such as giardiasis and strongyloidiasis, aspirates of the duodenum or a small bowel biopsy may be required to establish the diagnosis. Similarly, the recovery of large bowel parasites such as *E histolytica* and

Schistosoma mansoni may require proctoscopy or sigmoidoscopy, with aspiration or biopsy of suspect lesions. Eggs of pinworms (*Enterobius*) may be found on the perianal skin and require recovery using a specialized scotch tape application technique.

Blood and tissue parasites require timing

Parasites dwelling within the tissue and blood of the host are more difficult to identify. Direct examination of the blood is useful for the detection of malarial parasites, *Leishmania*, trypanosomes, and filarial progeny (microfilariae). The concentration of organisms in the bloodstream may fluctuate, however, and require the collection of multiple specimens over several days. Both wet mount and stained preparations of thin and thick blood smears (see Chapter 51) are used. Timing of blood collection is important in diagnosing filarial infections because they may display marked periodicity. Lung flukes and occasionally other helminths discharge their offspring in the sputum and may be found there with appropriate concentration techniques. In others, larvae can be recovered with skin (onchocerciasis) or muscle (trichinosis) biopsy.

Serologic tests available for some parasites

In some infections, parasite recovery is uncommon. Immunodiagnostic and nucleic acid hybridization techniques provide diagnostic alternatives for these situations. Although tests for circulating antibodies have long been available for many parasitic diseases, they have often lacked sensitivity and specificity. The replacement of crude, antigenically complex parasitic extracts with purified homologous antigens, together with the adaptation of highly reactive test systems, has significantly increased the sensitivity and specificity of such tests. Currently, reliable serologic procedures are available for amebiasis, cysticercosis, echinococciasis, paragonimiasis, schistosomiasis, strongyloidiasis, toxocariasis, toxoplasmosis, and trichinosis. More will undoubtedly follow in the near future.

Antigen detection becoming available

Techniques for the detection of parasitic antigens in blood, body fluids, tissues, and excreta also have been developed. Commercial immunofluorescent and immunosorbent kits for *T vaginalis* (genitourinary fluids), *E histolytica*, *Giardia*, and *Cryptosporidium* (feces) are now commonly found in clinical

laboratories. Less generally available are systems for the detection of malaria antigens in blood and *T gondii* in tissue.

* Molecular methods used increasingly

Even with many recent advances, the acknowledged limitations of both microscopic and serologic techniques in diagnosing parasitic infections have stimulated a widespread interest in resorting to gene amplification techniques to affect a more sensitive and specific diagnosis of these infections. The advent of the polymerase chain reaction (PCR) in its various formats has had a tremendous impact on detecting many parasite infections. Highly specific probes are available for the detection of malaria, Chagas disease, the African trypanosomes, leishmaniasis, toxoplasmosis, cryptosporidiosis, schistosomiasis, cysticercosis, and the etiologic agents of lymphatic filariasis. In some instances, PCR can be multiplexed and conducted in real time (RT-PCR). This permits the simultaneous detection of several parasites from one sample. The probes for many of these parasites have demonstrated sensitivities that match or exceed those of traditional techniques. The major limitations of PCR probes as diagnostic tools largely relate to the technical aspects of the hybridization procedure and, with time, will undoubtedly be overcome.

chapter 50

Antiparasitic Agents and Resistance

OVERVIEW

Most parasitic infections can be treated. Generally, drugs are effective against either protozoa or helminths, but not both. Some are well tolerated, while others are toxic or unpleasant for the patient. Antiparasitic resistance is a much more important issue in protozoan infections than helminth infections due to the worms' more complex and slow life cycles. All providers should be familiar with the medications covered here.

Antiparasitic agents among first antimicrobials

Parasites have been with us throughout human history, and the use of natural remedies to treat these infections date to antiquity. Quinine-containing extracts of cinchona tree bark were used to treat malaria hundreds of years ago. In China, a recipe for malaria treatment using Qinghaosu tea was recorded by Ge Hong centuries earlier. Based on what we now know about the chemistry of these natural products, both remedies had a firm biochemical basis for their effectiveness. By 1930, chemically synthesized drugs had been marketed for the treatment of malaria, trypanosomiasis, and schistosomiasis.

Newer antiparasitics broader spectrum, less toxic

In spite of the introduction and explosive increase in the number and variety of antibacterials, antiparasitic medications have lagged far behind. Most antibacterials are ineffective against parasites, which share eukaryotic characteristics of their hosts. Most antiparasitics were only partially effective, toxic, and required prolonged or parenteral administration. In time, newer antiparasitics were developed that overcame many of these problems. Their numbers are still limited, and only recently have their safety and efficacy begun to match those of their antibacterial equivalents.

Treatment programs difficult in emerging economies

Antiparasitic drug use and development have been shaped to a significant degree by the concentration of parasitic diseases in impoverished areas of the world. Community-based public health measures aimed at interrupting pathogen transmission—such as provision of sanitary facilities, clean water supplies, and insecticide-treated bed nets—are often beyond the means of tightly constrained local budgets. Consequently, the major burden of mitigating the impact of parasitic illnesses in endemic areas often falls on clinical officers or community health workers who, operating in remote and under-resourced conditions, must examine, diagnose, and treat sick patients with whom they may have only fleeting contact. Given these realities, optimal therapy for parasitic infections requires drugs that are effective in a single oral dose, easily administered, safe enough to be dispensed with limited medical supervision, sufficiently inexpensive to be widely used, and at low risk of accelerating drug resistance. Few such agents exist. Pharmaceutical companies, faced with the enormous costs of drug development and approval, have been reluctant to expend capital they are unlikely to recover. Public–private partnerships, cofinanced and operated by philanthropic organizations, industry, and academia, provide an exciting model that may yield the next wave of effective treatment for parasitic infections.

STRUCTURE AND ACTION

Most antiparasitics are synthetic

With few exceptions, antiparasitic agents have been synthesized de novo rather than developed from naturally occurring substances. Most are relatively simple and often contain benzene or other ring structures.

* Differential toxicity based on uptake, metabolic factors

It is believed that most antiprotozoan drugs interfere with nucleic acid synthesis or, less commonly, with carbohydrate metabolism. Antihelminthics, on the other hand, apparently act by compromising the worm’s glycolytic pathways or neuromuscular function. In most cases, the parasite and host cells have functionally equivalent target sites. Differential toxicity is achieved by preferential uptake, metabolic alteration of the drug by the parasite, or differences in the susceptibility of functionally equivalent sites in parasite and host.

*** Acquired resistance involves reduced uptake**

As has been the case for antibacterial agents, the impact of many antiprotozoan agents has been compromised by the development of resistance in the parasite. This seems to have resulted from mutation and selection in the face of intensive drug use. The mechanisms responsible have been studied for only a few parasites, but appear to be related to reduced uptake or increased efflux of the drug.

DRUGS FOR PROTOZOAN INFECTIONS

As with bacteria, most protozoa are usually harmless. However, certain protozoa may cause disease, and for them the goal of treatment is to achieve a full microbiological cure.

▪ Antimalarial Quinolines

*** Quinine and analogs active against malaria**

Cinchona bark was used in Europe for the treatment of malaria beginning in the 1600s. Its active ingredient is a quinoline alkaloid called **quinine.** Synthesis of new quinolines was stimulated by the interruption of quinine supplies during the World War I and World War II and, after 1961, by the growing impact of drug-resistant falciparum malaria in several areas of the world. Among the most effective agents are those that share the double-ring structure of quinine.

Accumulate, block heme metabolism

Current analogs fall into three major groups: 4-aminoquinolines (including **chloroquine**), 8-aminoquinolines (including **primaquine**), and 4-quinolinemethanols (including **mefloquine**). All of them selectively destroy intracellular parasites by accumulating in parasitized host cells. Most of these agents appear to inhibit heme polymerase, leading to the buildup of toxic hemoglobin metabolites within the malarial parasite.

*** Suppress malarial infection in RBCs**

*** 8-aminoquinolones cure by treating liver**

Quinine, chloroquine, and mefloquine concentrate in parasitized erythrocytes

and rapidly destroy the erythrocytic stage of the parasite that is responsible for the clinical manifestations of malaria. Thus, these agents can be used either prophylactically to prevent clinical symptoms or therapeutically to terminate an acute attack. They do not concentrate in tissue cells, and thus organisms sequestered in sites outside the erythrocytes, particularly the liver, survive and may later reestablish erythrocytic infection and produce a clinical relapse. In contrast, primaquine and tafenoquine accumulate in tissue cells, destroy hepatic parasites, and effect a full “radical” cure.

*** Chloroquine less effective**

*** Primaquine, tafenoquine may have hematologic toxicity**

Chloroquine phosphate was the most widely used antimalarial drug for decades. In the doses used for long-term malaria prophylaxis it was remarkably free of untoward effects. Unfortunately, its heavy use led to widespread resistance in *Plasmodium falciparum*, and thus it is no longer recommended for prevention or treatment of falciparum malaria in most parts of the world (see Resistance below). Primaquine phosphate, the 8-aminoquinoline used to eradicate persistent hepatic parasites, has toxic effects related to its oxidant activity. Methemoglobinemia and hemolytic anemia are particularly frequent in patients with glucose-6-phosphate dehydrogenase deficiency because they are unable to generate sufficient quantities of the reduced form of nicotinamide adenine dinucleotide to respond to this oxidant stress. Typically, the anemia is severe in patients of Mediterranean and Far Eastern ancestry and mild in patients of African ancestry. The newer drug tafenoquine carries the same potential risk but is taken more conveniently with a single dose rather than daily for 2 weeks with primaquine.

Quinine active against chloroquine-resistant malarial strains

Quinine is the oldest and most toxic of the quinolines. It is currently used for severe or complicated malaria only when artemisinin combination therapy is not available (see later). Quinidine, a less cardiotoxic optical isomer of quinine, is better tolerated but not readily available in the United States. Mefloquine, an oral 4-quinolinemethanol analog, originally displayed a high level of activity against most chloroquine-resistant parasites; however, mefloquine-resistant strains of *P falciparum* are now widespread in Southeast Asia and are present to a lesser degree in South America and Africa. Concerns regarding psychiatric side effects

of mefloquine have been generally overblown, but serve as another reason for the waning use of this medication.

Phenanthrenes active against multidrug-resistant malaria

Phenanthrene methanols are not in the strict sense quinine analogs. Nevertheless, they are structurally similar to this group of agents and, together with them, were discovered to have antimalarial activity during the World War II. **Halofantrine,*** the most effective of the group, is a blood schizonticide effective against both sensitive and multidrug-resistant strains of *P falciparum*. However, because of rare cases of fatal heart arrhythmias, it is not available in the United States. A related drug, **Lumefantrine,** is much safer, but is unreliable when dosed alone. It is always administered as a coformulation with artemisinins (see later).

▪ Artemisinin

Active against malaria, amoebas, *Schistosoma*

Concentrated in erythrocytes

*** ACT treatment of choice for falciparum malaria**

This natural extract of the plant *Artemisia annua* (qing hao, sweet wormwood) is a sesquiterpene lactone peroxide that is structurally distinct from all other known antiparasitic compounds. Extracts of qing hao were recommended for the treatment of fevers in China as early as AD 341; their specific antimalarial activity was defined by Chinese investigators in 1971. Although it has also been shown to be active against the free-living amoeba *Naegleria fowleri* and several trematodes, including *Schistosoma japonicum*, *Schistosoma mansoni*, and *Clonorchis sinensis*, its greatest impact to date has been in the treatment of malaria. Extensive investigations showed it to be schizonticidal for both chloroquine-sensitive and chloroquine-resistant strains of *P falciparum*. Several derivatives, among them **artemether** and **artesunate,** are significantly more active than the parent compound. All are concentrated in parasitized erythrocytes, where they decompose and release free radicals, which are thought to damage parasitic membranes. Artemisinin compounds act more rapidly than other antimalarial agents, stopping parasite development and preventing cytoadherence in falciparum malaria. Because of their relatively short half-life, they should be administered in coformulations with longer-acting agents such as

lumefantrine. This “artemisinin combination therapy (ACT)” is so safe and effective that it has become the standard of care for treatment of acute malaria worldwide. Unfortunately, resistance has been detected, especially among *P falciparum* isolates from the Thai–Myanmar border. Although depression of reticulocyte counts has been reported, these agents appear significantly less toxic than quinoline antimalarials. Because there is some evidence that they may possess teratogenic properties, they should be avoided in the first trimester of pregnancy if possible. They may be given orally, rectally (by suppository), or parenterally.

▪ Quinones

Atovaquone is a novel hydroxynaphthoquinone that shows promise in the treatment of malaria and toxoplasmosis. Its antiparasitic activity appears to result from the specific blockade of pyrimidine biosynthesis secondary to the inhibition of the parasite’s mitochondrial electron transport chain.

*** Atovaquone stable and active against malaria and toxoplasmosis**

Efficacy trials established its capacity to affect rapid clearance of parasitemia in patients with chloroquine-resistant falciparum malaria. Frequent parasitic recrudescences were eliminated when atovaquone was administered in combination with the folate antagonist **proguanil** (see later). This coformulation (**Malarone**) is popular in malaria prophylaxis because it is effective, well tolerated, and protects against liver infection, thus can be dosed for just a week following exposure. Atovaquone has also demonstrated activity against toxoplasmosis in patients with acquired immunodeficiency syndrome (AIDS). Unlike other antitoxoplasma agents, atovaquone is active against *Toxoplasma gondii* cysts as well as tachyzoites, suggesting that this agent may produce radical cure. Supporting this is the infrequency with which cessation of atovaquone treatment of toxoplasmic cerebritis in AIDS patients has resulted in relapse. Relapse after atovaquone treatment of the fungus *Pneumocystis jirovecii* in this same patient population appears similarly uncommon.

▪ Folate Antagonists

Sulfonamide and folate antagonists inhibit protozoa

Folic acid is a critical coenzyme for the synthesis of purines and ultimately DNA. In protozoa, as in bacteria, the active form of folic acid is produced *in vivo*

by a simple two-step process. The first step, the conversion of *para*-aminobenzoic acid to dihydrofolic acid, is blocked by sulfonamides. The second step, the transformation of dihydro- to tetrahydrofolic acid, is blocked by folic acid antagonists, which competitively inhibit dihydrofolate reductase. Used together with sulfonamides, folate antagonists may inhibit the growth of some protozoa.

*** Sulfonamides effective in *Toxoplasma* infections**

Trimethoprim, an inhibitor of dihydrofolate reductase, is used in combination with sulfamethoxazole to treat toxoplasmosis. Another folate antagonist, **pyrimethamine,** has a high affinity for sporozoan dihydrofolate reductase and has been particularly effective, when used with a sulfonamide, in the management of clinical malaria and toxoplasmosis. A third folate antagonist, **proguanil,** is commonly taken in combination with atovaquone for malaria prophylaxis. Acquired protozoal resistance to sulfonamides coformulated with folate antagonists has greatly diminished their effectiveness for malaria prevention and treatment.

Folate deficiency, sulfonamide toxicities occur during treatment

Folate antagonists may result in folate deficiency in individuals with limited folate reserves, such as newborns, pregnant women, and the malnourished. This is of greatest concern when large doses are used for prolonged periods, as in the treatment of acute toxoplasmosis. When folate antagonists are used with sulfonamides, the entire range of sulfonamide toxic effects may be seen. Patients with advanced AIDS may suffer an unusually high incidence of toxic side effects to trimethoprim–sulfamethoxazole.

▪ Nitroimidazoles

Metronidazole, a nitroimidazole, was introduced in 1959 for the treatment of trichomoniasis. Subsequently, it was found to be effective in the management of giardiasis, amebiasis, and a variety of infections produced by obligate anaerobic bacteria. Energy metabolism in all of them depends on the presence of low-redox–potential compounds, such as ferredoxin, to serve as electron carriers. These compounds reduce the 5-nitro group of the imidazoles to produce intermediate products responsible for the death of the protozoal and bacterial cells, possibly by alkylation of DNA. Resistance, though uncommon, has been noted in strains of *Trichomonas vaginalis* lacking nitroreductase activity.

Nausea, dysgeusia (taste perversion), and peripheral neuropathy are notable potential side effects.

Tinidazole, a newer nitroimidazole, appears to be both a more effective and better-tolerated antiprotozoal agent. Its greater lipid solubility improves cerebrospinal fluid levels and *in vitro* activity. Either drug can be used for trichomoniasis, invasive amebiasis, and giardiasis.

Active against protozoa at low-redox–potential

Benznidazole, another member of this drug family, is used for the treatment of Chagas disease. A related medication in the nitrofuran class, **nifurtimox,** is also used for this condition. Both may be toxic to the gastrointestinal and neurological systems and these treatments have limited efficacy in chronic Chagas. This disease is an important cause of morbidity and mortality in Latin America, and newer treatments are urgently needed.

▪ Nitazoxanide

Alternative option for giardiasis

A member of the thiazolide class, nitazoxanide provides an unusually broad spectrum of activity. It is effective not only against gastrointestinal protozoa such as giardia and amoeba, but in trials has also killed helminths such as human hookworm. In fact, it has demonstrated *in vitro* activity against certain anaerobic bacteria and even some viruses, although it is not used clinically for those purposes. In diarrhea due to giardia or cryptosporidium, for which it is approved in the United States, its mechanism seems to be interfering with the cell's electron transfer enzymes. Unfortunately, its clinical usefulness in cryptosporidiosis among immunocompromised patients is limited, and new medications for this condition are urgently needed.

▪ Eflornithine (Difluoromethylornithine)

Originally an anticancer drug

Active against West African sleeping sickness

Eflornithine is an enzyme-activated, irreversible inhibitor of ornithine decarboxylase (ODC). In mammalian cells, decarboxylation of ornithine by ODC is a mandatory step in the synthesis of polyamines, compounds thought to

play critical roles in cell division and differentiation. Originally developed as an antineoplastic agent, eflornithine proved ineffective in cancer chemotherapy trials. It was also marketed as a topical depilatory agent (anti hair growth). With the discovery that polyamines of *Trypanosoma* species were also synthesized from ornithine, eflornithine was successfully tested in the treatment of animal trypanosomiasis. It has been used to treat advanced cases of human West African sleeping sickness due to *T brucei gambiense*. However, it is not effective against the more virulent *T brucei rhodesiense*, it is dosed intravenously, and it remains expensive. Eflornithine appears to be cytostatic and requires an intact host immune system for maximum effect.

▪ Heavy Metals

Arsenic, antimonial compounds inactivate –SH groups

Toxicity based on enhanced uptake

*** Melarsoprol active against trypanosomiasis, but toxic**

Arsenic and antimonial compounds have been used for generations. They form stable complexes with sulfur compounds and probably exert their biologic effects by binding to sulfhydryl (–SH) groups. They are toxic to the host as well as to the parasite, and have their greatest impact on cells that are metabolically active such as neuronal, renal tubular, intestinal epithelial, and bone marrow stem cells. Their differential toxicity and therapeutic value are due to enhanced uptake by the parasite and its intense metabolic activity. However, significant host toxicity remains. Only one trivalent arsenical, **melarsoprol** (Mel B), is now used for African trypanosomiasis of the central nervous system, because of its penetration of the blood–brain barrier. Due to its toxicity, including a roughly 10% chance of fatal arsenic poisoning, it is used only when less toxic agents have failed or when the central nervous system is involved. Safer agents are urgently needed for this deadly disease.

*** Antimonials used only for leishmania infections**

Antimonial agents are now restricted to the management of leishmanial infections. Two pentavalent compounds, **sodium stibogluconate** (Pentostam) and **meglumine antimoniate**† (Glucantime), may be used for all forms of leishmaniasis. In disseminated visceral disease, prolonged therapy is usually

required, and relapses often occur. In localized cutaneous leishmaniasis, cure is usually achieved with a relatively brief course. Toxic side effects are similar to those of the arsenicals, although less severe. However, visceral leishmaniasis is usually treated using intravenous **amphotericin-lipid** formulations, which are typically used as antifungal medications. In fact, these drugs are being used more frequently for cutaneous leishmaniasis as well, where they are often effective and better tolerated than the antimonials.

▪ Miltefosine

Useful in visceral and cutaneous leishmaniasis, amebic encephalitis

A recent advance in antiprotozoal treatment is the introduction of **miltefosine.** This alkylphosphocholine compound belongs to the phospholipid family. It appears to target protein kinase B, a molecule involved in cellular apoptosis regulation. Blockade of protein kinase B seems to trigger programmed death of infected cells, including many strains of leishmania and free-living amoebas. And, it is dosed orally. As clinical experience grows with this medication, it seems to hold great promise for the treatment of these neglected infections.

KEY CONCLUSIONS

- Antiprotozoan medications act through a variety of mechanisms.
- Some are highly organism specific, while others have a broader spectrum.
- Older medications may be profoundly toxic; newer compounds are better tolerated.
- Resistance is of particular concern for the antimalarial drugs (see later).

DRUGS FOR HELMINTH INFECTIONS

The approach to treatment of most worm infections differs significantly from those applied to prokaryotic or protozoan infections. Helminths, with few exceptions, do not multiply within the human host, and severe infections usually require the repeated acquisition of infectious worms.

For gastrointestinal helminth infections, full eradication is not usually necessary. Interestingly, the intensity of gastrointestinal worm burden does not follow a normal distribution in human populations. Most infected persons harbor fewer than a dozen adult worms in the GI tract; a small minority of “wormy

persons" harbor very large worm numbers. Because there is a direct correlation between worm burden and clinical disease, only this minority suffers significant morbidity. Concentrating treatment on those few clinically ill patients could moderate the medical impact of a helminthic disease on the community at a cost dramatically lower than that required for mass treatment. Moreover, it is usually unnecessary to eradicate all gastrointestinal worms from treated patients; a significant decrease in the worm burden may be adequate to alleviate clinical symptoms. This can often be accomplished with entire affected populations by providing short, subcurative doses that further reduce cost and minimize the likelihood of drug toxicity. Because this approach can dramatically decrease the total community worm burden, the number of worm progeny shed into the environment is similarly reduced, and the transmission of the disease slowed or —rarely—eliminated entirely.

Worms treatment efforts concentrate on the most heavily parasitized

For tissue-invasive helminths, full cure is often the goal, although ironically medical treatment may be less effective than in GI infection. In some cases, adult tissue-invasive worms are more susceptible to therapy than immature forms, and in other cases the opposite is true. Even worse, dying tissue invaders may release antigens that lead to an undesired inflammatory state that endangers the patient.

Goal is reduced worm burden

Neither GI-dwelling nor tissue-invasive helminths have demonstrated considerable drug resistance, presumably because their reproduction happens over a longer period of time and because most of them complete their reproductive cycle outside the human host.

▪ Benzimidazoles

Broad-spectrum anthelmintics

As their name implies, the basic structure of benzimidazoles consists of linked imidazole and benzene rings. Unlike their antiprotozoal cousins discussed previously, the benzimidazoles are broad-spectrum anthelmintic agents. The prototype drug, **thiabendazole,** acts against both adult and larval nematodes. Soon after its introduction in the early 1960s, it was shown to be useful in the management of cutaneous larva migrans, trichinosis, and most intestinal

nematode infections. The mechanism by which it exerts its anthelmintic action is uncertain. It is known to inhibit fumarate reductase, an important mitochondrial enzyme of helminths. The primary mode of action, however, may derive from the known capacity of all benzimidazoles to inhibit the polymerization of tubulin, the eukaryotic cytoskeletal protein. Side effects are related to the gastrointestinal tract or liver, and rapidly resolve with the discontinuation of the drug. Hypersensitivity reactions, induced either by the drug or by antigens released from the damaged parasite, may occur. For this reason, thiabendazole has been replaced by newer, better-tolerated agents of the same class.

Blocks glucose uptake by adult and larval worms

Interferes with tubulin, microtubules

Mebendazole, a carbamate benzimidazole introduced in 1972, has a spectrum similar to that of thiabendazole, but also has been found to be effective against a number of cestodes, including *Taenia, Hymenolepsis*, and *Echinococcus*. It irreversibly binds to worm tubulin, thus interfering with the assembly of cytoplasmic microtubules, structures essential for glucose uptake. This results in glycogen depletion, cessation of ATP formation, and worm paralysis or death. Unlike thiabendazole, mebendazole is not well absorbed from the gastrointestinal tract and may owe part of its effectiveness against intestine-dwelling adult worms to its high concentrations in the human gut. It does not appear to affect glucose metabolism in humans, and toxicity is uncommon. Teratogenic effects have been observed in experimental animals; its use in infants and pregnant women is relatively contraindicated.

*** Albendazole better absorbed, broader spectrum**

Albendazole is a benzimidazole carbamate that is more highly absorbed and thus has a somewhat broader spectrum than that of its close relative, mebendazole. It demonstrates more activity against *Strongyloides stercoralis* and several tissue nematodes. In addition to the vermicidal (adult killing) and larvicidal (immature-form killing) properties that it shares with other benzimidazoles, it is ovicidal (egg killing), enhancing its effectiveness in tissue cestode infections such as echinococcosis and cysticercosis. Its activity against *Giardia*, one of the most common intestinal protozoa, makes it an appealing candidate for the treatment of polyparasitism. Although it shares the teratogenic potential of other benzimidazoles, it is otherwise extremely well tolerated.

Single-dose therapy is effective in the management of many intestinal nematode infections.

Triclabendazole is another benzimidazole with enhanced activity against hermaphroditic trematodes, especially Fasciola hepatica, the cause of sheep liver rot and human hepatic fascioliasis.

▪ Ivermectin

Influences nematode neurotransmitters

*** Activity against filariae**

*** Drug of choice for onchocerciasis**

Ivermectin is a member of the avermectin group: macrocyclic lactones produced as fermentation products of *Streptomyces avermitilis*. Structurally similar to the macrolide antibiotics, ivermectin is effective at extremely low concentration against a wide variety of nematodes and arthropods. It appears to induce neuromuscular paralysis by acting on a receptor of the parasite peripheral neurotransmitter, gamma-aminobutyric acid (GABA). In mammals, GABA is confined to the central nervous system, and because ivermectin does not cross the blood–brain barrier in significant concentration, it does not appear to produce significant untoward effects in the mammalian host. A derivative of avermectin B1, ivermectin was originally developed and marketed as a horse dewormer. However, its effect on human health has been tremendous. It is currently the drug of choice for the treatment and suppression of onchocerciasis and is dosed on a massive scale for that purpose in West Africa. It is also effective in the treatment of strongyloidiasis, filariasis, and certain GI helminth infections. It also has activity against ectoparasites, making it useful in the treatment of common syndromes such as head lice and scabies.

▪ Praziquantel

Loss of intracellular calcium in cestodes, trematodes

Used in mass therapy

Praziquantel, a heterocyclic pyrazinoisoquinoline, is an important anthelmintic, effective against a broad range of cestodes and trematodes, many of which are poorly responsive to previously available agents. It is given in one to three

doses. The drug is rapidly taken up by susceptible helminths, in which it appears to induce the loss of intracellular calcium, tetanic muscular contraction, and destruction of the tegument. The differential toxicity of this agent may be related to the inability of susceptible worms to metabolize the drug. Aside from transient, mild gastrointestinal symptoms, praziquantel appears remarkably free of side effects in humans. It is currently the drug of choice for the treatment of most trematode infections, including schistosomiasis, clonorchiasis, and opisthorchiasis. Its side effects are minor, and its overall high level of safety suggests that it may play a significant role in future worldwide mass therapy campaigns.

▪ Diethylcarbamazine

Use for microfilarial infections with caution

Diethylcarbamazine (DEC) is a derivative of piperazine, used to kill tissue-invasive helminths of the microfilarial family. It is believed to work via inhibition of arachidonic acid metabolism. DEC is usually well tolerated, and has even been added to cooking salt in areas endemic to lymphatic filariasis, in order to assist in disease control. On the other hand, it is so deadly to another microfilarial infection, onchocerciasis, that it is *avoided* in endemic areas to prevent severe allergic reactions triggered by overwhelming microfilaricidal action.

▪ Other Antiparasitic Agents

A number of antiparasitic agents, their properties, and their clinical uses are listed in **Table 50-1.**

TABLE 50–1 Miscellaneous Antiparasitic Agents

COMPOUND	DRUG CLASS	ROUTE	MECHANISM OF ACTION	CLINICAL USE	COMMENT
Amphotericin	Polyene	IV	Membrane disruptor	Leishmaniasis	Antifungal agent also harms *Leishmania* spp.
Benznidazole	Nitroimidazole	Oral	DNA binder	Acute Chagas disease	Bone marrow depression peripheral neuropathy, rash, itching
Bithionol	Phenol	Oral	Uncouples phosphorylation	Paragonimiasis	Not commercially available in the United States
Diethylcarbamazine	Piperazine	Oral	Neuromuscular paralysis	Filarial infections	Allergic reactions to filarial antigens
Diloxanide furoate	Acetanilide	Oral	Unknown	Intestinal amebiasis	Used only for asymptomatic carriers
Iodoquinol	Halogenated quinoline	Oral	Unknown	Intestinal amebiasis *Dientamoeba* infections	Related drug has caused optic atrophy
Miltefosine	Phospholipid	Oral	Protein kinase B inhibitor	Visceral and cutaneous leishmaniasis, amebic encephalitis	Only oral option for visceral leishmaniasis
Nifurtimox	Nitrofuran	Oral	Oxidative stress by production of free radicals	Acute Chagas disease	Toxicity, prolonged therapy, marginal effectiveness
Nitazoxanide	Nitrothiazolyl-salicylamide	Oral	Inhibits anaerobic metabolism	*Cryptosporidium*, *Giardia*	Occasional vomiting, abdominal pain, diarrhea
Paromomycin	Aminoglycoside	Oral	Similar to other aminoglycosides	Intestinal cryptosporidiosis	Not absorbed, marginal effectiveness
Pentamidine	Diamidine	IV	Binds DNA	Leishmaniasis trypanosomiasis	Toxic
Pyrantel pamoate	Tetrahydropyrimidine	Oral	Neuromuscular blockade; inhibits fumarate reductase	Pinworm infection, hookworm infection, ascariasis	Single-dose therapy
Spiramycin	Macrolide	Oral	Blocks protein synthesis	Toxoplasmosis	Used to treat pregnant women
Suramin	Sulfated naphthylamine	IV	Inhibits glycerophosphate oxidase and dehydrogenase	African trypanosomiasis onchocerciasis	Not effective in central nervous system disease Renal toxicity

IV, intravenous.

KEY CONCLUSIONS

- Anthelminthic drugs usually have a broad spectrum of activity.
- Most are very well tolerated.
- The goals of treatment may differ between GI-dwelling worms (where a few adult survivors are often well tolerated) and tissue-invasive worms (where full cure is more desirable).

ANTIPARASITIC RESISTANCE

*** *Plasmodium falciparum* resistance a major problem**

The major problem with antiparasitic resistance relates to *Plasmodium* species, specifically *P falciparum.* This organism divides asexually within the human host, under the selective pressure of drug treatment, thus fostering an environment in which drug-resistant mutants may be selected. The crisis of drug-resistant malaria is widespread throughout sub-Saharan Africa, Asia, and Latin America, but resistance has also appeared in other areas. The most common is chloroquine resistance, wherein the parasite reduces the amount of drug that accumulates in its digestive vacuoles. This involves mutations in a transport molecule of the digestive membrane called *P falciparum* chloroquine resistance transporter (PfCRT). This mutation is now the rule, rather than the exception, and chloroquine is only effective with acceptable reliability against *P falciparum* in areas of northern Latin America. Other parasite point mutations can similarly result in resistance to sulfadoxine–pyrimethamine and atovaquone–proguanil (the latter by mutations in the cytochrome b gene) and reduced susceptibility to mefloquine, quinine, and quinidine. Resistance to artemisinin combination therapy has emerged in Southeast Asia, and is of great concern globally; if this highly effective treatment class falls, we currently have no reliable, nontoxic drug to take its place.

Helminth resistance to antiparasitic agents has been less of a concern, although this may be due to the relatively lower use of this class of drugs, as well as the helminths' longer and more complex reproductive cycles. As antihelminthics are used more widely and intensively, in the long run, resistant populations may be selected.

*Not available in the United States.
†Not available in the United States.

Apicomplexa and Microsporidia

Plasmodium falciparum • *Plasmodium vivax* • *Plasmodium ovale* • *Plasmodium malariae* • *Plasmodium knowlesi* • *Babesia spp.* • *Toxoplasma gondii* • *Cryptosporidium spp.* • *Cyclospora cayetanensis* • *Isospora belli*

A man can be riddled with malaria for years on end, with its chills and its fevers and its nightmares, but if one day he sees that the water from his kidneys is black, he knows he will not leave that place again, wherever he is, or wherever he hoped to be.

—Beryl Markham: *West with the Night* (1942)

• APICOMPLEXA

When the paroxysms fall on even days, the crises will be on even days; and when the paroxysms fall on odd days, the crises will be on odd days. Furthermore, it is necessary that one know that if crises fall on days other than those mentioned above, there will be a relapse, and this may be deadly. But it is essential to pay attention and know at which times the crises will lead to death and in which to recovery, or during which is there tendency to fair better or worse.

—Hippocrates (Translated from the ancient Greek in his work—Epidemics)

GROUP CHARACTERISTICS

Intracellular protozoa alternate sexual, asexual cycles

The Apicomplexa are obligate intracellular protozoan parasites. The name of this group of parasites derives from the complex of organelles located at the apical end of parasite life cycle stages that are involved in penetrating cells. These

organelles include the rhoptries, micronemes, and associated microtubular complexes located in this region of the parasite. The Apicomplexa have alternating cycles of sexual and asexual reproduction. Asexual multiplication within the host occurs by a process of multiple fission termed schizogony. The nucleus of a trophozoite divides into several parts, forming a multinucleated schizont. The cytoplasm then condenses around each nuclear portion to form new daughter cells, or merozoites, which burst from their intracellular location to invade new host cells. After the completion of one or more of these asexual cycles, some merozoites differentiate into male and female gametocytes, initiating the sexual phase of the life cycle. In the case of malaria, the gametocytes reach maturity in the mosquito host and effect fertilization, forming a zygote, or motile ookinete. In other Apicomplexa, this process may occur in intestinal cells. The zygote then becomes an oocyst for these parasites. Sporozoites are formed within the oocyst by an asexual process of sporogony and when released, penetrate host tissue cells, and begin another asexual cycle as trophozoites. The only phase of this life cycle that is diploid is when the zygote is formed. All other stages in the life cycle are haploid. The general apicomplexan cell plan is illustrated in **Figure 51–1.**

Cause malaria, toxoplasmosis, cryptosporidiosis, cyclosporiasis, isosporiasis, and babesiosis

Two Apicomlexan infections, malaria and toxoplasmosis, are common diseases in humans; together, they affect more than one-third of the world's population and kill or deform perhaps one-half million neonates and children each year. *Cryptosporidium*, *Cyclospora*, and *Isospora* are Apicomplexa that can cause diarrhea, particularly in the immunocompromised. *Babesia*, a relative of malaria, and transmitted by ticks, is also a member of this group.

• *PLASMODIUM* SPP.

Of all infectious diseases there is no doubt that malaria has caused the greatest harm to the greatest number.

—Laderman, 1975

OVERVIEW

Plasmodium is a parasite species with a sexual cycle in mosquitoes and an asexual cycle in humans. Malaria is a febrile illness caused by a *Plasmodium* spp. infection of human erythrocytes. Malaria is transmitted by female mosquitoes of the genus *Anopheles*. Malaria infection is followed by a period of patency while the parasite develops in the liver and is species dependent. Patency begins with fevers that are accompanied by headache, chills, sweats, and malaise, and typically appear in paroxysmal episodes lasting hours and recurring for weeks. Fever episodes usually become synchronous and can be used to help in identifying the malarial species. Anemia may also be present. Cerebral malaria, caused by *Plasmodium falciparum*, is due to capillary blockage in the brain and can be fatal. Children suffer the greatest from this complication.

PARASITOLOGY

*** Sexual phase in mosquito, asexual in humans**

Five species infect humans

The plasmodia are Apicomplexa in which the sexual and asexual cycles of reproduction are completed in different host species. The sexual phase occurs within the gut of mosquitoes and results in the formation of a motile zygote, the ookinete. These arthropods subsequently transmit the parasite as sporozoites while feeding on a vertebrate host. Within the vertebrate, the plasmodia reproduce asexually, first in the liver and then in erythrocytes; they eventually burst from the erythrocyte and invade other uninvolved RBCs. This event

produces periodic fever and anemia in the host, a disease process known as malaria. Of the many species of plasmodia, five are known to infect humans and are considered here: *Plasmodium vivax, Plasmodium ovale, Plasmodium malariae, Plasmodium knowlesi*, and *Plasmodium falciparum*.

LIFE CYCLE OF MALARIAL PARASITES

This day relenting God
Hath placed within my hand
A wondrous thing; and God
Be praised. At his command,

Seeking his secret deeds
With tears and toiling breath,
I find thy cunning seeds,
O million-murdering Death.

I know this little thing
A myriad men will save,
O Death, where is thy sting?
Thy victory, O Grave?

—Sir Ronald Ross, August 22, 1897, in a poem to Sir Patrick Manson on the discovery of sporozoites in mosquito salivary glands.

*** Mosquito ingests gametocytes from human blood**

*** Sporozoites reach mosquito salivary glands**

The life cycle in the female *Anopheles* mosquito begins with the ingestion of male and female gametocytes from the circulation of a malaria-infected individual. In the gut of the mosquito, the gametocytes reach full maturation, are released from infected erythrocytes, and effect fertilization. The resulting zygote, an ookinete, is the only stage in the life cycle that is diploid, is motile, and penetrates the mosquito's gut wall, lodges beneath the basement membrane facing the mosquito's hemocoel, undergoes a postzygotic reduction division, and vacuolates to form an oocyst. Within this structure, thousands of sporozoites are formed by asexual division. The enlarging cyst eventually ruptures, releasing the sporozoites into the body cavity of the mosquito. Some penetrate the salivary glands, rendering the mosquito infectious for humans. The time required for the

completion of the cycle in mosquitoes varies from 1 to 3 weeks, depending on the species of insect and parasite as well as on the ambient temperature and humidity.

*** Humans infected by mosquito bite**

*** Infection of hepatocytes starts asexual cycle**

Sporozoites from the mosquito's salivary glands are injected into the human's subcutaneous capillaries when the female mosquito feeds. Within minutes and up to 1 hour, they attach to and invade liver cells (hepatocytes), a process mediated by a ligand present in the outer protein coat of the sporozoites (circumsporozoite protein). In *P vivax* and *P ovale* infections, some of the sporozoites enter a dormant state immediately after cell invasion to become hypnozoites. These stages are responsible for the **relapse** phenomenon seen in malarial infections caused by these species. In all malarial infections, the remaining sporozoites initiate exoerythrocytic schizogony, each producing about 2000 to 40,000 daughter cells, or merozoites, depending on the infecting species. After 1 to 2 weeks, the infected hepatocytes rupture, releasing merozoites into the general circulation.

*** Erythrocytic cycle begins with merozoite attachment to RBC**

*** Trophozoites multiply in RBCs, form new merozoites**

RBCs rupture, releasing merozoites to infect new RBCs

*** Dormancy causes relapses with *P vivax* and *P ovale***

The erythrocytic phase of malaria starts with the attachment of a released hepatic merozoite to a specific receptor on the RBC surface. After attachment, the merozoite releases substances from its apical organelles, the rhoptries, which affect red cell membrane fluidity resulting in invagination of the cell membrane and entry of the parasite into a parasitophorous vacuole. The intracellular parasite initially appears as a small ring-shaped trophozoite, which enlarges and becomes more active and irregular in outline. Within a few hours, nuclear division occurs, producing the multinucleated schizont. The cytoplasm eventually condenses around each nucleus of the schizont to form an intraerythrocytic cluster of 6 to 24 merozoite daughter cells. About 24 (*P knowlesi*), 48 (*P vivax*, *P ovale*, and *P falciparum*) to 72 (*P malariae*) hours after

initial invasion, infected erythrocytes rupture, releasing the merozoites and producing the first clinical manifestations of disease. The newly released merozoites invade other RBCs, where most repeat the asexual cycle. Other merozoites are transformed into sexual forms or gametocytes. These latter forms do not produce RBC lysis and continue to circulate in the peripheral vasculature until ingested by an appropriate mosquito. The recurring asexual cycles continue, involving an ever-increasing number of erythrocytes until the development of host immunity helps contain the erythrocytic cycle. The dormant hepatic sporozoites of *P vivax* and *P ovale* survive the host's immunologic attack and may, after a latent period of months to years, resume intrahepatic multiplication. This leads to a second release of hepatic merozoites and the initiation of another erythrocytic cycle, a phenomenon known as relapse. The life cycle of malarial parasites is summarized in **Figure 51–2** and variations in the differential characteristics of the parasites infecting humans are summarized in **Table 51-1.**

MORPHOLOGY OF ERYTHROCYTIC PARASITES

Morphology of the parasite and the infected RBCs vary by stage and species

The morphology of the stained intraerythrocytic *Plasmodium* parasites is shown in **Figure 51–3.** In stained smears, three characteristic features aid in the identification of plasmodia: Red nuclear chromatin; blue cytoplasm; and brownish-black malarial pigment, or hemozoin, consisting largely of a hemoglobin degradation product, ferriprotoporphyrin IX. The change in the shape of the cytoplasm and the division of the chromatin at different stages of parasite development are obvious. Gametocytes can be differentiated from the asexual forms by their large size and lack of nuclear division. Some of the infected erythrocytes develop membrane invaginations or caveolae–vesicle complexes, which are thought to be responsible for the appearance of the dark Schüffner dots or granules (see following text).

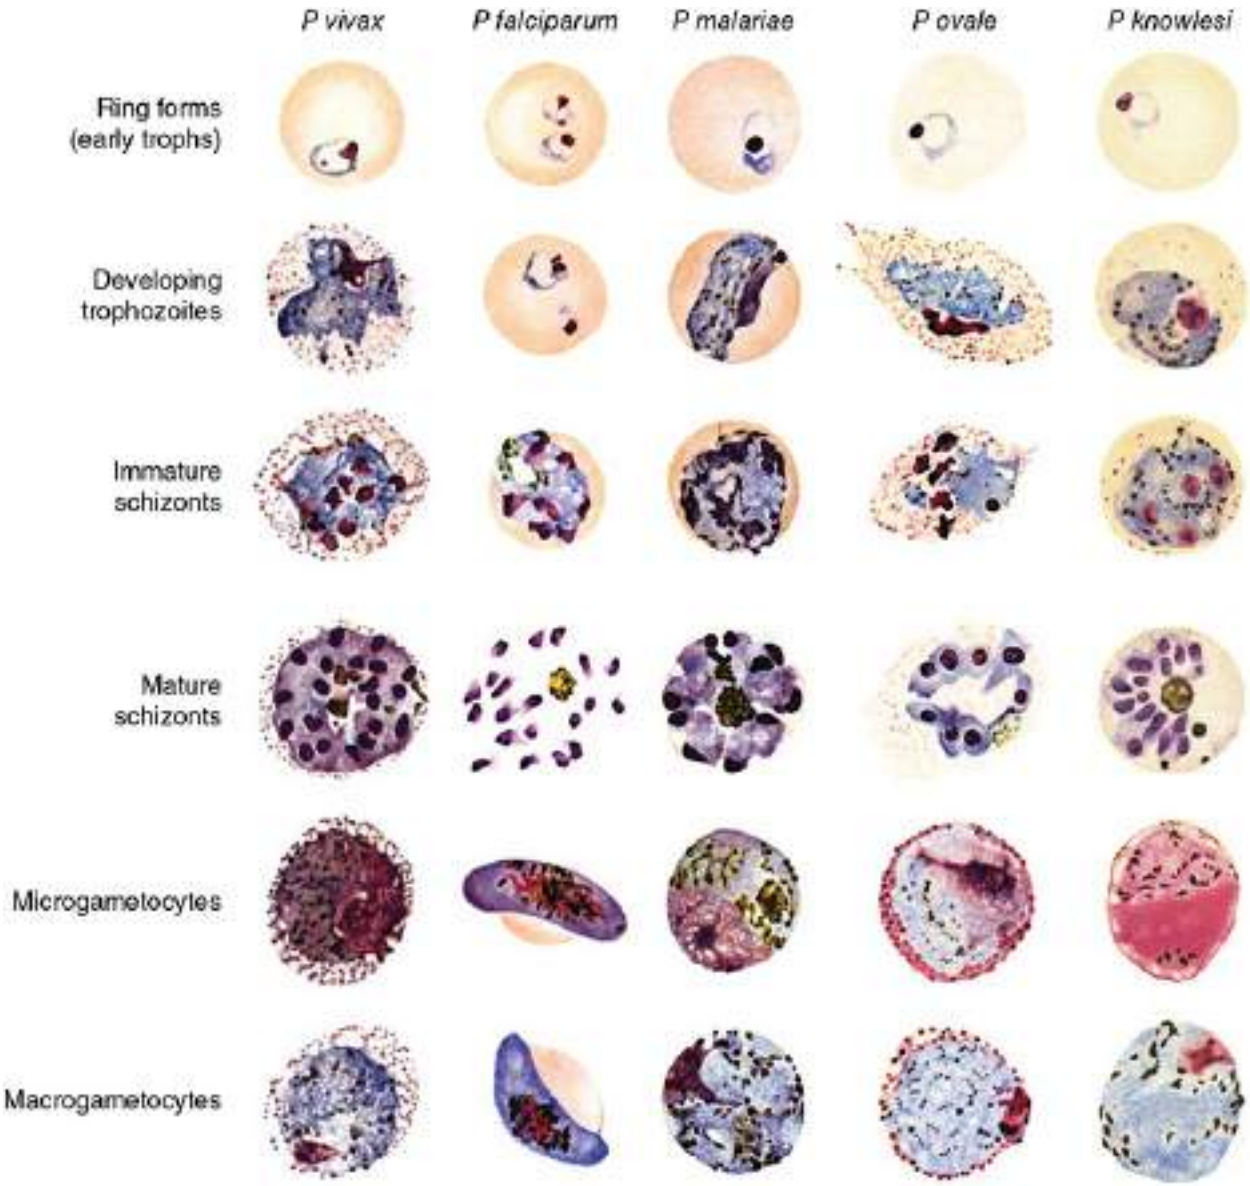

FIGURE 51–3. Drawings of erythrocytic stages of malarial parasites. Note that trophozoite and schizont forms of *Plasmodium falciparum* occur in visceral capillaries rather than in blood. Female gametophytes have morphologic differences from the male forms shown. (Reproduced with permission from Centers for Disease Control, Coatney GR, Collins WE, et al: *The Primate Malarias*. National Institutes of Health; 1971.)

Morphologic differences, primary means of diagnosis

The appearance of each of the five species of plasmodia that infect humans is sufficiently different to allow their differentiation in stained smears, although some similarities in some stages exist between the different species. The parasitized erythrocyte in *P vivax* and *P ovale* infections is pale and enlarged and contains numerous Schüffner dots. All asexual stages (trophozoite, schizont,

merozoite) may be seen simultaneously. Cells infected by *P ovale* are elongated and frequently irregular or fimbriated in appearance. In *P malariae* infections, the RBCs are not enlarged and contain no granules. The trophozoites often present as "band" forms, and the merozoites are arranged in rosettes around a clump of central pigment. In *P falciparum* infections, the rings are very small and may contain two chromatin dots rather than one. There is often more than one parasite per cell, and parasites are frequently seen lying against the margin of the cell. Intracytoplasmic granules known as Maurer dots may be present, but are often cleft shaped and fewer in number than Schüffner dots. Schizonts and merozoites of *P falciparum* are not present in the peripheral blood as they are sequestered in postcapillary venules. Gametocytes are large and banana shaped. *P knowlesi* shares many of the morphologic characteristics of *P malariae*, but can be distinguished from the latter by its fever cycle and diagnostically by using polymerase chain reaction (PCR). These characteristics are summarized in Table 51-1.

PHYSIOLOGY

Vary in ability to attack erythrocytes

Duffy antigen, glycoprotein A RBC receptors

Species of plasmodia differ significantly in their ability to invade subpopulations of erythrocytes; *P vivax* and *P ovale* attack only immature cells (reticulocytes), whereas *P malariae* attacks only senescent cells. During infection with these species, therefore, no more than 1% to 2% of the cell population is involved. *P falciparum*, in contrast, invades RBCs, regardless of age, and may produce very high levels of parasitemia and particularly serious disease. In part, these differences may be related to the known differences in the RBC receptor sites available to the individual *Plasmodium* species. In the case of *P vivax*, the site is closely related to the Duffy blood group antigens (Fy^a and Fy^b). Duffy-negative individuals, who constitute most people of West African ancestry, are therefore resistant to vivax malaria. RBC sialoglycoproteins, particularly glycoprotein A, have been implicated as the *P falciparum* receptor site.

* Sickle cell trait limits *P falciparum*

Hemoglobinopathies exert protection

Certain RBC genetic polymorphisms may also affect parasitism. The altered hemoglobin (hemoglobin S) associated with the sickle cell trait limits the intensity of the parasitemia caused by *P falciparum*, and thereby provides a selective advantage to individuals who are heterozygous for the sickle cell gene. Thus, the sickle cell gene, which would otherwise be disadvantageous, is common in populations living in malarious areas. Parasite growth appears to be retarded in RBCs heterozygous for hemoglobin S (SA) when they are exposed to conditions of reduced oxygen tension such as those which might be present in the visceral capillaries. These conditions cause the hemoglobin in infected cells to polymerize, rendering it unusable by the parasite. In essence, the parasite starves to death. Sickling may also render the erythrocyte more susceptible to phagocytosis or directly damage the parasite. A similar protective effect may be exerted by hemoglobins C, D, and E; thalassemias; and glucose-6-phosphate dehydrogenase (G6PD) or pyridoxal kinase deficiencies, because these abnormalities have also been found more frequently in malarious areas. The protection in these conditions may be related to the increased susceptibility of such RBCs to oxidant stress. In thalassemia, the protection may also be related in part to the production of fetal hemoglobin, which retards maturation of *P falciparum*, as well as an increased binding of antibodies to modified parasitic antigens (neoantigens) presenting on the surface of the erythrocytes.

Changes induced in erythrocyte

Endothelium binding causes microinfarcts

Once invasion has occurred, malaria parasites may induce several changes in the erythrocytic membrane. These include alteration of its lipid concentration, modification of its osmotic properties, and incorporation of parasitic neoantigens, rendering the RBCs susceptible to immunologic attack. *P vivax* and *P ovale* stimulate the production of caveolae–vesicle complexes, which are visualized as Schüffner dots in stained smears. In *P falciparum* infections, electron-dense elevated knobs or excrescences form on the RBC surface. These produce a strain-specific, high–molecular-weight adhesive protein (PfEMP1), which mediates binding to receptors on the endothelium of capillaries and postcapillary venules of the brain, placenta, and other organs, where they can produce obstruction and microinfarcts.

Metabolize anaerobically, synthesize own folate

Malarial parasites generate energy by the anaerobic metabolism of glucose. They appear to satisfy their protein requirements by the degradation of hemoglobin within their acidic food vacuoles, resulting in the formation of the malarial pigment (hemozoin) mentioned previously. It has been estimated that the average plasmodium destroys between 25% and 75% of the hemoglobin of its host erythrocyte. Unlike their vertebrate hosts, malarial parasites synthesize folates de novo. Thus, antifolate antimicrobials such as pyrimethamine are effective antimalarial agents.

GROWTH IN THE LABORATORY

Continuous *in vitro* cultivation of plasmodia in human erythrocytes was first achieved in 1976. More recently, the sporogonic cycle has been propagated in laboratory-reared mosquitoes. These twin developments provide new opportunities for studying the biology, immunology, and chemotherapy of human malaria. The most immediate impact of these advances has been on the introduction of methods for testing the sensitivity of *P falciparum* to chemotherapeutic agents. Ultimately, these developments will play critical roles in the generation of effective antimalarial vaccines.

MALARIA

EPIDEMIOLOGY

Distribution in tropical areas worldwide

Malaria has a worldwide distribution between 45°N and 40°S latitude, generally at altitudes below 1800 m. *P vivax* is the most widely distributed of the four species, and together with the uncommon *P malariae*, is found primarily in temperate and subtropical areas. *P falciparum* is the dominant organism of the tropics. *P ovale* is rare and found principally in Africa. *P knowlesi*, first recognized in humans in 1965, accounts for up to 70% of the infections recorded in some areas of Southeast Asia. It is also a zoonotic species, with long-tailed macaques being the dominant reservoir.

Manifestations muted with hyperendemicity

The intensity of malarial transmission in an endemic area depends on the density and feeding habits of suitable mosquito vectors and the prevalence of infected humans, who serve as parasite reservoirs. In hyperendemic areas (areas where more than half of the population is parasitemic), transmission is usually constant, and disease manifestations are moderated by the development of immunity. Mortality is largely restricted to infants and to nonimmune adults who migrate into the region and is primarily caused by *P falciparum*. When the prevalence of disease is lower, transmission is typically intermittent. In this situation, solid immunity does not develop, and the population suffers repeated, often seasonal, epidemics, the impact of which is shared by people of all ages.

Presently, an estimated 2 billion people live in malaria-endemic areas in 103 of the poorest countries of Africa, Asia, Latin America, and Oceania. Within these areas, malaria transmission has been reduced significantly over the last 15 years, largely as the result of the compliant use of insecticide impregnated bed nets (**Figure 51–4**). Still, many within these areas are thought to be carrying the malaria parasite at any given time. Approximately 400,000 individuals, primarily African children, die of malaria annually. Although endemic malaria disappeared from the United States decades ago, imported cases continue to be reported. An increase in international travel has resulted in an increase in the number of U.S. cases to approximately 1500 to 2000 annually as reported by the Centers for Disease Control and Prevention (CDC). Forty-five percent of the patients with imported malaria have acquired the disease in Africa, 30% in Asia, and 10% in the Caribbean or Latin America. Fifty percent of recent infections have involved American travelers: Nearly 60% of these acquired their infection in Africa. Climatologists and epidemiologists warn that global warming could enhance mosquito and therefore malaria transmission into areas where malaria was once endemic. Current vector distribution for malaria is shown in **Figure 51–5**.

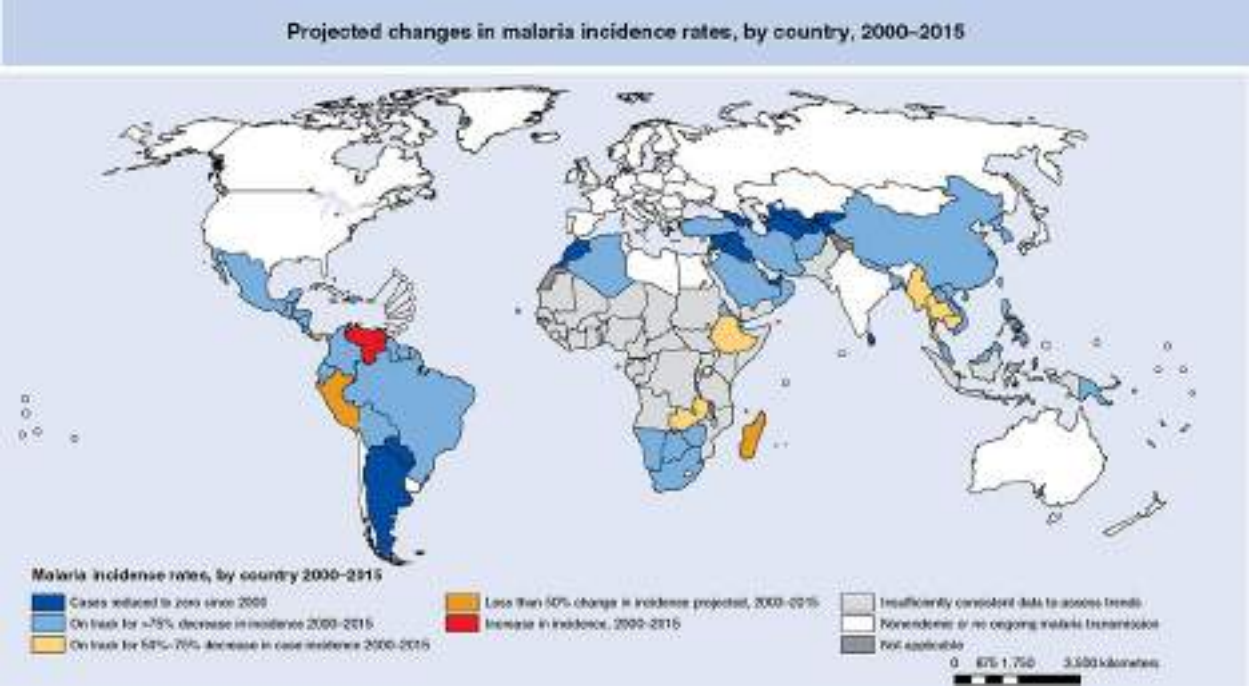

FIGURE 51–4. Worldwide changes in malaria incidence 2000-2015: http://www.who.int/gho/malaria/en/ Geographic distribution of malaria. (Data from Thacker SB, Parrish RG, Trowbridge FL. A method for evaluating systems of epidemiological surveillance, *World Health Stat Q* 1988;41(1):11–18.)

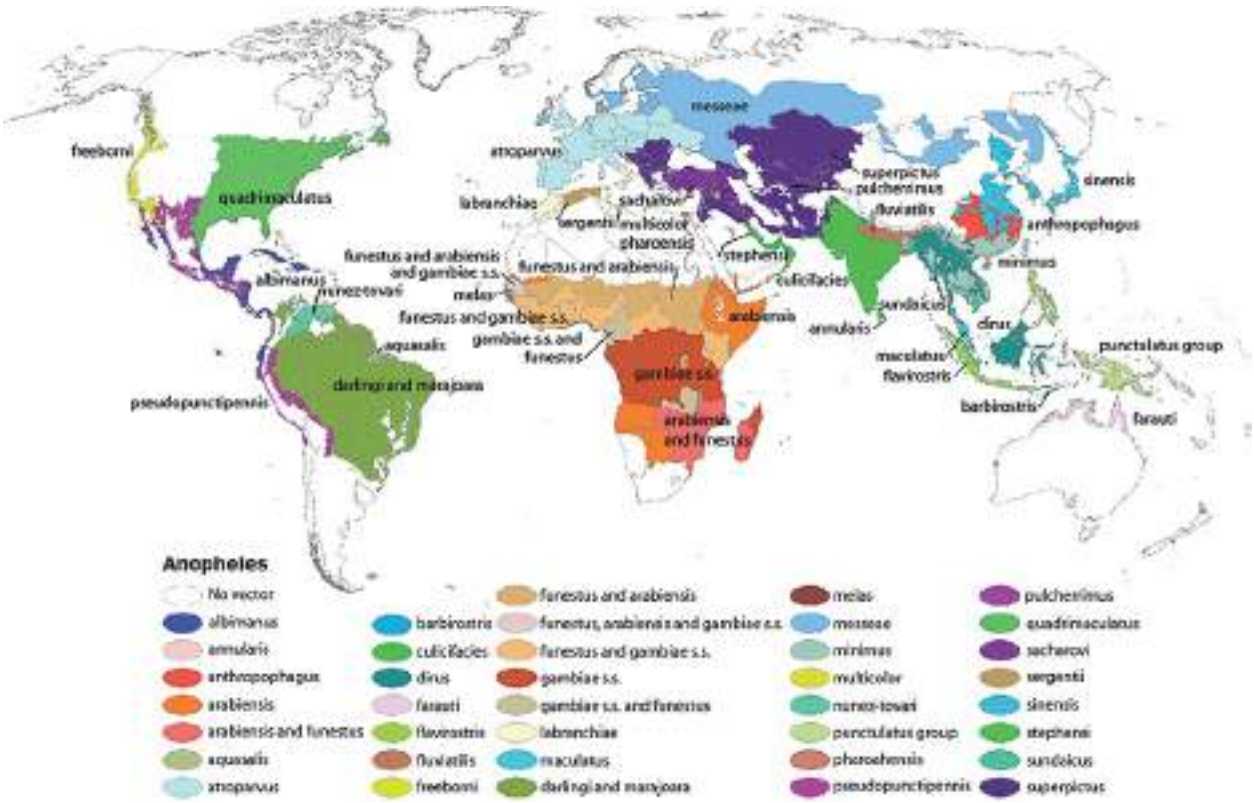

FIGURE 51–5. Current distribution of malaria vectors. (Reproduced with permission from Kiszewski A, Mellinger A, Spielman A, et al: A global index representing the stability of malaria transmission, *Am J Trop*

Med Hyg 2004 May;70(5):486–498.)

Malaria kills mostly children

Imported malaria months after travel

Clinical manifestations of malaria typically develop within weeks to months of arrival of cases in the United States; however, 25% of cases caused by *P vivax* are delayed beyond that time. Approximately 40% of imported cases and almost all associated fatalities have been caused by the virulent *P falciparum*. Tragically, most of these cases could have been prevented or successfully treated. Congenital malaria in infants born in the United States of mothers from malarious areas is occasionally observed. Infections transmitted by transfusions of whole blood, leukocytes, or platelets, or by organ transplantation are, fortunately, now unusual in this country due to the improved screening procedures of blood banks.

Anopheline mosquitoes capable of transmitting malaria are present throughout much of the United States. On rare occasions, malaria is transmitted from an imported case to individuals who have never traveled outside of the country.

There is a fear that the COVID-19 pandemic could raise malaria death rates due to a redistribution of resources.

PATHOGENESIS

The fever, anemia, circulatory changes, and immunopathologic phenomena characteristic of malaria are all the result of the erythrocytic cycle of the plasmodia. There are no clinical signs of infection associated with the liver phase of infection.

▪ Fever

*** Fever with RBC rupture**

*** Synchronization of replication causes cyclic fever**

Fever, the hallmark of malaria, appears to be initiated by the process of RBC rupture that leads to the liberation of a new generation of merozoites. It is possible that parasite-derived pyrogens are released at the time of red cell rupture; alternatively, the fever might result from the release of proinflammatory

cytokines such as interleukin-1 (IL-1) and/or tumor necrosis factor (TNF) from macrophages involved in the ingestion of parasitic or erythrocytic debris. Early in malaria, RBCs appear to be infected with malarial parasites at several different stages of development, each inducing erythrocyte destruction at a different time. The resulting fever is irregular and hectic. Because temperatures higher than 40°C destroy mature parasites, a single population eventually emerges, parasite replication is synchronized, and fever occurs in distinct paroxysms at 24-hour (*P knowlesi*), 48-hour (*P falciparum, P vivax, P ovale*) or, in the case of *P malariae,* 72-hour intervals. Periodicity is seldom seen in patients who are rapidly diagnosed and treated. Periodicity is also not always a hallmark of *P falciparum* infections. Fever-induced modifications to membrane architecture and infected-cell sequestration events are thought to play a role in disrupting periodicity in these infections. Sometimes, the fever in *P falciparum* infections can more or less be continuous.

▪ Anemia

Destruction of RBCs causes anemia

Massive intravascular hemolysis

Parasitized erythrocytes are phagocytosed by a stimulated reticuloendothelial system or are destroyed at the time of parasite-induced cell rupture, releasing toxic products. This not only results in destruction of infected cells but noninfected ones as well, resulting in an anemia that may be disproportionate to the degree of parasitism. Depression of marrow function, sequestration of erythrocytes within the enlarging spleen, and accelerated clearance of nonparasitized cells all appear to contribute to the anemia. So too might cytokine imbalances brought about by overstimulation of innate immune responses. Such imbalances can influence erythropoiesis. Intravascular hemolysis, though uncommon, may occur, particularly in *P falciparum* malaria. When hemolysis is massive, hemoglobinuria develops, resulting in the production of dark urine. This process in conjunction with malaria is known as **blackwater fever.**

▪ Circulatory Changes

Blood flow decreased to vital organs

The high fever results in significant vasodilatation. In falciparum malaria, vasodilatation leads to a decrease in the effective circulating blood volume and

hypotension, which may be aggravated by other changes in the small vessels and capillaries. The intense parasitemias of *P falciparum* is capable of producing comas and the adhesion of infected RBCs to the endothelium of visceral capillaries can impair the microcirculation and precipitate tissue hypoxia, lactic acidosis, and hypoglycemia. Although all deep tissues are involved, the brain is the most intensely affected resulting in what has been described as **cerebral malaria** (**Figure 51–6**).

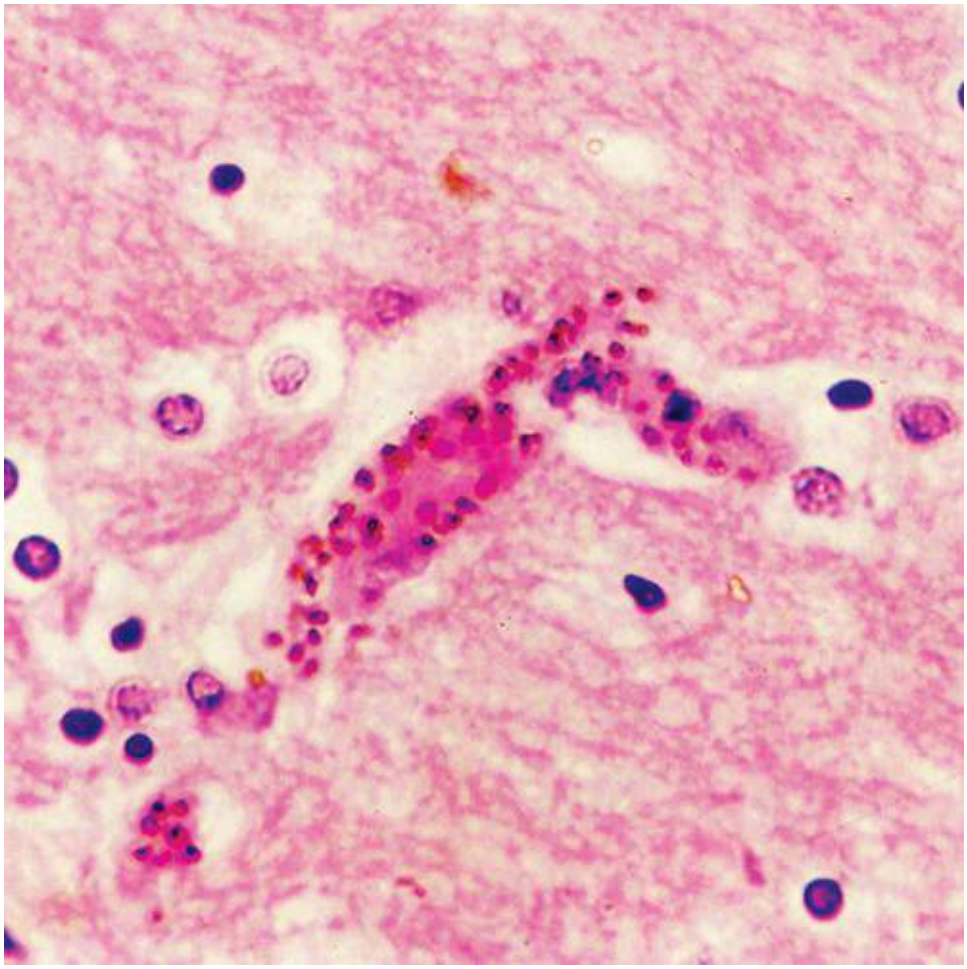

FIGURE 51–6. Central nervous system malaria. This small cerebral blood vessel is blocked with many parasitized erythrocytes adherent to the endothelium. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

▪ Cytokines

Elevated cytokines contribute to injury

Elevated levels of IL-1 and TNF are consistently found in patients with malaria.

Probably released at the time of parasite rupture from erythrocytes, these proteins are certainly an essential part of the host's immune response to malaria. By modulating the effects of endothelial cells, macrophages, monocytes, and neutrophils, they may play an important role in the destruction of the invading parasite. However, TNF levels increase with parasite density, and high concentrations appear harmful. TNF has been shown to cause upregulation of endothelial adhesion molecules; high concentrations might precipitate cerebral malaria by increasing the sequestration of *P falciparum*-parasitized erythrocytes in the cerebral vascular endothelium. Alternatively, excessive TNF levels might precipitate cerebral malaria by directly inducing hypoglycemia and lactic acidosis.

▪ Other Pathogenic Phenomena

Thrombocytopenia and nephritis

Thrombocytopenia is common in malaria and appears to be related to both splenic pooling and a shortened platelet lifespan. Both direct parasitic invasion and immune mechanisms may be responsible. There may be an acute transient glomerulonephritis in falciparum malaria and progressive renal disease in chronic *P malariae* malaria. These phenomena probably result from the host immune response, with deposition of immune complexes in the glomeruli.

IMMUNITY

* Immune response limits, does not eliminate infection

Once infected, the host quickly mounts a stage-, species-, and strain-specific immunologic response that typically limits parasite multiplication and moderates the clinical manifestations of disease, without eliminating the infection. A prolonged recovery period marked by recurrent exacerbations in both symptoms and number of erythrocytic parasites follows. Recrudescences are marked by periods in which the parasitemia drops below the threshold of detection, only to surge again. Fluctuations in immunity probably account for this phenomenon. With time, these recrudescences become less severe and less frequent, and eventually may stop altogether.

Antibody-mediated immunity important

The exact mechanisms involved in this recovery are uncertain. In simian and probably in human malaria, recovery is known to require the presence of both T and B lymphocytes. It is probable that the T lymphocytes act partially through their helper effect on antibody production. Some authorities have suggested that they also play a direct role through cytokine production by stimulating effector cells to release nonspecific factors capable of inhibiting intraerythrocytic multiplication. The B lymphocytes begin production of stage- and strain-specific antiplasmodial antibodies within the first 2 weeks of parasitemia. With the achievement of high levels of antibodies, the number of circulating parasites decreases. The infrequency with which malaria occurs in young infants has been attributed to the transplacental passage of such antibodies. It is uncertain whether they are directly lethal, act as opsonizing agents, or block merozoite invasion of RBCs. Antibody responses are also detectable against sporozoites and, because of this, much attention has been given to develop a vaccine against this parasite stage. Because sporozoites clear so quickly from the peripheral circulation, however, they may escape immune detection and all it would take is one to initiate hepatic schizogony resulting in blood stage infection. Antibodies against sporozoites have no effect on erythrocytic stages of infection.

Antigenic variation could play a role in persistence

In simian malaria, the parasite can undergo antigenic variation and thereby escape the suppressive effect of the antibodies. This antigenic variation leads to cycles of recrudescent parasitemia, but ultimately to production of specific antibodies to the variants, and cure. In *P falciparum* malaria, chronic infection is maintained through the insertion of highly polymorphic variant antigens that are inserted into the infected erythrocyte membrane. With *P falciparum*, the disease typically does not exceed 1 year, but with *P malariae* the erythrocytic infection can be extremely persistent, lasting in one case up to 53 years. How erythrocytic parasites circulating in numbers too small to be detected on routine blood films escape immunologic destruction remains a puzzle. In a closely related simian malaria, splenectomy results in rapid cure, suggesting that suppressor T lymphocytes in the spleen may play a protective role. In infection with *P vivax* and *P ovale*, latent hepatic infection may result in the discharge of fresh merozoites into the bloodstream after the disappearance of erythrocytic forms. This phenomenon, known as **relapse,** can maintain infection for 3 to 5 years or longer.

In almost all cases, immunity to malaria is usually short lived and does not result in a sterile immunity. Many individuals, living in areas where transmission

is sporadic, can be infected multiple times by the same species of parasite. A question often asked: if natural infection with malaria does not result in a lasting or sterile immunity, can a vaccine be developed that will?

MALARIA: CLINICAL ASPECTS

MANIFESTATIONS

Incubation prolonged by suppressants

The incubation period between the bite of the mosquito and the onset of disease is approximately 2 weeks. With *P malariae* and with strains of *P vivax* in temperate climates, however, this period is often more prolonged. Individuals who contract malaria while taking antimalarial suppressants may not experience illness for many months. In the United States, the interval between entry into the country and onset of disease exceeds 1 month in 25% of *P falciparum* infections and 6 months in a similar proportion of *P vivax* cases.

Malarial paroxysm: cold, hot, wet stages

The clinical manifestations of malaria vary with the species of plasmodia but typically include chills, fever, splenomegaly, and anemia. The hallmark of disease is the malarial paroxysm. This manifestation begins with a cold stage, which persists for 20 to 60 minutes. During this time, the patient experiences continuous rigors and feels cold. With the consequent increase in body temperature, the rigors cease and vasodilatation commences, ushering in a hot stage. The temperature continues to rise for 3 to 8 hours, reaching a maximum of 40°C to 41.7°C before it begins to fall. The wet stage consists of a decrease in fever and profuse sweating. It leaves the patient exhausted but otherwise well until the onset of the next paroxysm.

* Paroxysms when parasite replication synchronized

Typical paroxysms first appear in the second or third week of fever, when parasite replication within erythrocytes becomes synchronized. In falciparum malaria, synchronization may never take place, and the fever may remain hectic and unpredictable. The first attack is often severe and may persist for weeks in

the untreated patient. Eventually the paroxysms become less regular, less frequent, and less severe. Symptoms finally cease with the disappearance of the parasites from the blood.

* Cerebral falciparum malaria often lethal

In falciparum malaria, capillary blockage can lead to several serious complications. When the central nervous system is involved (cerebral malaria), the patient may develop delirium, convulsions, paralysis, coma, and rapid death. Acute pulmonary insufficiency frequently accompanies cerebral malaria, killing about 80% of those involved. When splanchnic capillaries are involved, the patient may experience vomiting, abdominal pain, and diarrhea with or without bloody stools. Jaundice and acute renal failure are also common in severe illness. These pernicious syndromes generally appear when the intensity of parasitemia exceeds 100,000 organisms per cubic millimeter of blood. Most deaths occur within 3 days.

DIAGNOSIS

* Thick and thin blood smears detect parasites

Malarial parasites can be demonstrated in stained smears of the peripheral blood in virtually all symptomatic patients. Typically, capillary or venous blood is used to prepare both thin and thick smears, which are stained with Wright or Giemsa stain and examined for the presence of erythrocytic parasites. Thick smears, in which erythrocytes are lysed with water before staining, concentrate the parasites and allow detection of very mild parasitemia. Nonetheless, it may be necessary to obtain several specimens before parasites are seen. Artifacts are numerous in thick smears, and correct interpretation requires experience. The morphologic differences among the five species of plasmodia may allow their speciation on the stained thin smear by the skilled observer.

Acridine orange stains, other methods available

Several attempts have been made to improve the standard thin and thick smear method. One such procedure involves acridine orange staining of centrifuged parasites in quantitative buffy coat (QBC) tubes. Although it is expensive, this requires a fluorescence microscope and permits less reliable parasite speciation; its rapidity and ease of use make it attractive to laboratories

that are only occasionally called on to identify patients with malaria. Simple, specific card antigen detection procedures are now available. The most widely used test, ParaSight F, detects a protein (HRP2) excreted by *P falciparum* within minutes. The test can be performed under field conditions and has a sensitivity of more than 95%. A second rapid test, OptiMAL, detects parasite lactate dehydrogenase, and, unlike ParaSight F, can distinguish between *P falciparum* and *P vivax*. Numerous PCR assays have also been developed for the laboratory diagnosis of malaria.

Serologic tests for malaria are offered at a few large reference laboratories but are used primarily for epidemiologic purposes. They are occasionally helpful in speciation and detection of otherwise occult infections. The recently completed sequencing of the malaria genome will lead to newer diagnostic methods.

TREATMENT

The indications for treatment rest on several factors. These include the severity of disease, the infecting species of *Plasmodium*, and the part of the world in which the infection was acquired. The immune status of the afflicted patient may also factor into this equation. The species and area of infection acquisition are likely to help determine if the parasite is resistant to any antimalarials or not. Falciparum malaria is potentially lethal in nonimmune individuals, such as new immigrants or travelers to a malarious area, and immunosuppressed indigenous individuals, such as pregnant women. These individuals must receive urgent treatment.

Need to destroy all forms of the parasite

The complete treatment of malaria requires the destruction of erythrocytic schizonts, hepatic schizonts, and erythrocytic gametocytes. The first terminates the clinical attack, the second prevents relapse, and the third renders the patient noninfectious to *Anopheles* and thus breaks the cycle of transmission. Unfortunately, no single drug accomplishes all three goals. The present strategy for the diagnosis and treatment of malaria is shown in **Figure 51–7.**

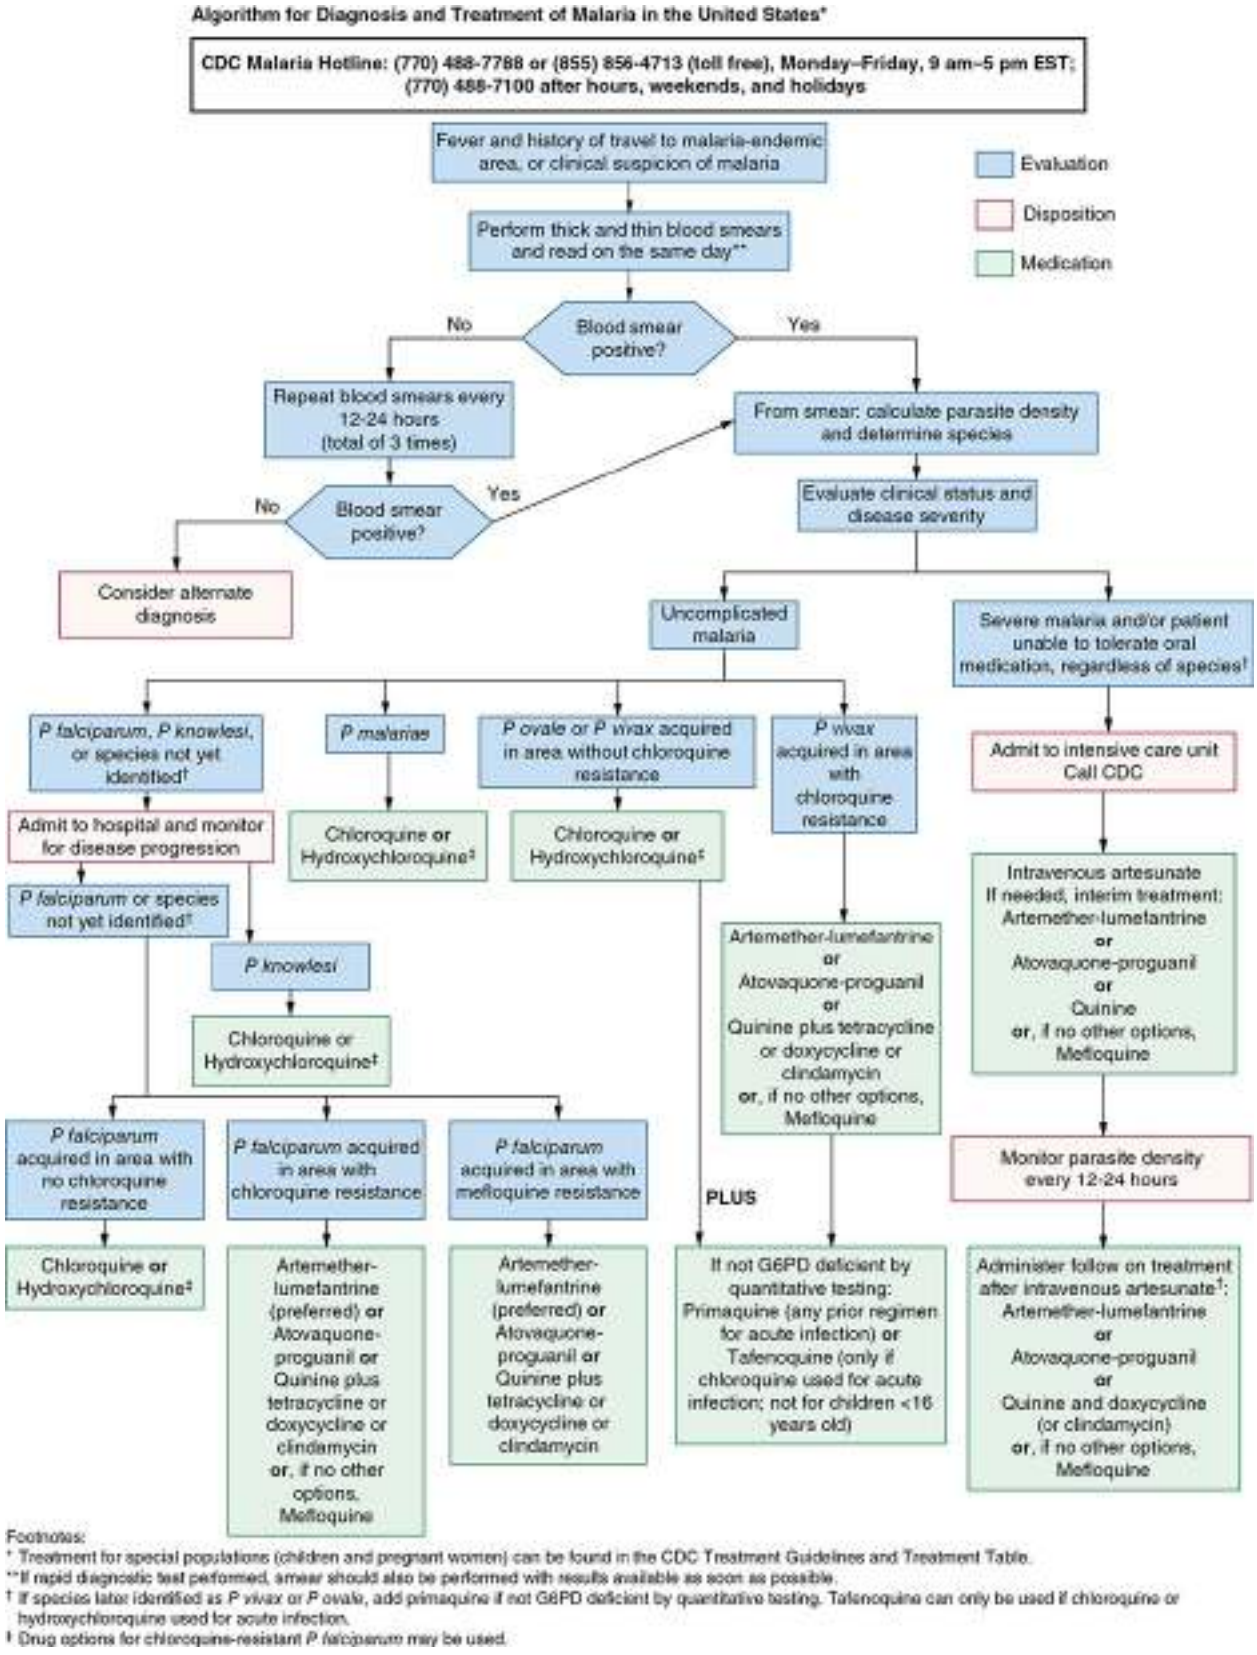

FIGURE 51-7. Algorithm for diagnosis and treatment of malaria in the United States. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human

Services. Algorithm for Diagnosis and Treatment of Malaria in the United States. May, 2020. https://www.cdc.gov/malaria/resources/pdf/Malaria_Treatment_Guidelines.pdf.)

▪ Termination of Acute Attack

Several agents can destroy asexual erythrocytic parasites. Chloroquine, a 4-aminoquinoline, has been the most commonly used. It acts by inhibiting the degradation of hemoglobin, thereby limiting the availability of amino acids necessary for growth. It has been suggested that the weak basic nature of chloroquine also acts to raise the pH of the food vacuoles of the parasite, inhibiting their acid proteases and effectiveness. When originally introduced, it was rapidly effective against all four species of plasmodia and, in the dosage used, free of serious side effects. However, chloroquine-resistant strains of *P falciparum* are now widespread in Africa and Southeast Asia; they are also found, though less frequently, in other areas of Asia and in Central America and South America. Chloroquine-resistant strains of *P vivax* have been reported from Papua New Guinea, India, and Pakistan, but overall remains poorly defined worldwide.

*** Chloroquine inhibits hemoglobin degradation**

*** Artemisinins prevent gametocyte development**

Other schizonticidal agents include quinine/quinidine, antifolate–sulfonamide combinations, mefloquine, halofantrine, and the artemisinins. Unfortunately, resistance to these agents is increasing, particularly in Southeast Asia. The artemisinins work by binding to proteins in many of the organism's key biochemical pathways. The artemisinins are also unique in their capacity to reduce transmission by preventing gametocyte development. Resistance to this latter first-line drug is increasing in areas of Southeast Asia.

*** Chloroquine, other resistance common with *P falciparum***

Strains of *P malariae*, *P ovale*, and *P vivax* (except for some acquired in the South Pacific and South America) remain sensitive to chloroquine and may be treated with this agent. *P vivax* infections acquired in New Guinea and Sumatra, however, should be assumed to be chloroquine-resistant and managed with mefloquine alone or in combination with other agents. *P falciparum* has now become variably resistant to all drug groups, including the artemisinin compounds.

Combination therapy necessary

There is a growing consensus that the most effective way to slow the further development of drug-resistant strains of *P falciparum* is to use one of the artemisinins in combination with quinine/quinidine, antifolate–sulfonamide compounds, mefloquine, or halofantrine.

▪ Radical Cure

*** Primaquine destroys hepatic schizonts of *P vivax* and *P ovale***

In *P vivax* and *P ovale* infections, hepatic schizonts persist and must be destroyed to prevent reseeding of circulating erythrocytes with consequent relapse. Primaquine, an 8-aminoquinoline, is used for this purpose. Some *P vivax* infections acquired in Southeast Asia and New Guinea fail initial therapy owing to relative resistance to this 8-aminoquinoline. Retreatment with a larger dose of primaquine is usually successful. Unfortunately, primaquine may induce hemolysis in patients with G6PD deficiency. Persons of Asian, African, and Mediterranean ancestry should thus be screened for this abnormality before treatment. Chloroquine destroys the gametocytes of *P vivax*, *P ovale*, and *P malariae* but not those of *P falciparum.* Primaquine and artemisinins, however, are effective for this latter species.

PREVENTION

▪ Personal Protection

*** Mosquito protection with screens and repellents**

*** Chemoprophylaxis considers resistance in area**

In endemic areas, mosquito contact can be minimized with the use of house screens, insecticide bombs within rooms, and/or insecticide-impregnated mosquito netting around beds. Those who must be outside from dusk to dawn, the period of mosquito feeding, should apply insect repellent and wear clothing with long sleeves and pants. In addition, it is possible to suppress clinical manifestations of infection, if they occur, with a weekly dose of chloroquine. In areas where chloroquine-resistant strains are common, an alternative schizonticidal agent should be used. Mefloquine, Malarone, or doxycycline are

usually preferred. The antifolate pyrimethamine plus a sulfonamide can be taken as well. However, use of this combination is occasionally accompanied by serious side effects, so it is recommended only when mefloquine- and doxycycline-resistant strains are present in the area, and then only for individuals residing in areas of intense transmission for prolonged periods of time. On leaving an endemic area, it is necessary to eradicate residual hepatic parasites with primaquine before discontinuing suppressive therapy.

▪ General

Reduce contact with and eradicate mosquitoes

Complete eradication has failed

Malaria control measures have been directed toward reducing the infected human and mosquito populations to below the critical level necessary for sustained transmission of disease. The techniques used include those mentioned previously, treatment of febrile patients with effective antimalarial agents, chemical or physical disruption of mosquito breeding areas, and residual insecticide sprays. An active international cooperative program aimed at the eradication of malaria resulted in a dramatic decline in the incidence of the disease between 1956 and 1968. Eradication was not achieved, however, because mosquitoes became resistant to many of the chemical agents used, and today malaria annually still infects 200 to 300 million inhabitants of Africa, Latin America, and Asia. Tropical Africa alone accounts for 100 million of the afflicted and for most of the 400,000 deaths that occur annually because of this disease. The long-term hope for progress in these areas now depends on the compliant use of existing and development of new technologies.

▪ Vaccines

Subunit vaccines fused with a hepatitis B protein have shown promise

Three advances in the last decade have produced the hope for the first time that an effective malaria vaccine might be within reach of medical science. The establishment of a continuous *in vitro* culture system and the successful propagation of malaria in laboratory-raised mosquitoes have provided the large quantities of parasite needed for antigenic analysis. Development of the hybridoma technique allowed the preparation of monoclonal antibodies with

which antigens responsible for the induction of protective immunity could be identified. Finally, recombinant DNA procedures enabled scientists to clone and sequence the genes encoding such antigens, permitting the amino acid structure to be determined and peptide sequences suitable for vaccine development to be identified. In 2012, a phase III clinical trial consisting of a protein fragment from the outer surface of *P falciparum*, fused with a hepatitis B virus protein, and combined with an immune adjuvant reduced episodes of both clinical and severe malaria in children aged 5 to 17 months by approximately 30%. This vaccine, named Mosquirix, has now been approved for a closely monitored vaccination program in Malawi, Ghana, and Kenya, targets the preerythrocytic stage of the disease and requires four injections. Overall efficacy is low and offers protection for no more than 4 years. The WHO does not recommend vaccinating young children under 1 year of age. Studies are continuing, with development of new adjuvants that may be even more potent. Hopefully, this may lead to vaccine strategies that are sorely needed throughout the developing world. Other attenuated sporozoite vaccines are currently in clinical trial.

As a physician, you have been asked to make recommendations to a student who comes from the western highland area of Kenya to do undergraduate work at Harvard, has experienced multiple episodes of malaria all through his childhood and teenage years, has not been home in 2 years, and wants to return to his home in Kenya for a 1-month visit before coming back to the United States to resume his education. What would you recommend?

KEY CONCLUSIONS

- Human malaria is transmitted only by female *Anopheles* mosquitoes.
- Malaria symptoms are preceded for a prepatent period involving multiplication of parasites in the liver.
- *Plasmodium vivax* and *ovale* can relapse due to dormant hypnozoites in the liver.
- *Plasmodium knowlesi* is a zoonotic malarial species.
- Malaria parasites eventually replicate in synchronous fashion, producing fevers at regular intervals. An exception to this is *Plasmodium falciparum* whose replication may be asynchronous.

- Cerebral malaria, due to *P falciparum*, can result in coma and death if not treated.
- Immunity to malaria is short lived and stage- and species-specific.
- Malaria is increasingly becoming resistant to drugs.
- Mosquitoes are increasingly becoming resistant to insecticides.

BABESIA SPP.

The genus *Babesia* is represented by species that are close relatives of malaria belonging to the order Piroplasmida. They are small parasites of the mammalian host RBCs and are transmitted by ticks. These parasites were the first shown to be transmitted by an arthropod intermediate host. The organism involved in this instance was *B bigemina*, the causative agent of redwater fever in cattle.

Babesia microti is one of the parasites of interest to human health. It was first reported from a patient on Nantucket Island, Massachusetts. Since then there have been hundreds of cases reported from New England and in the states of Wisconsin, Washington, and California. Hard ticks of the genus *Ixodes* are the principal vectors. These ticks are also capable of transmitting Lyme disease. Within the tick vector, the disease can also be transmitted between stages of development (transstadial transmission) or across generations through the ova (transovarial transmission). *Babesia divergens* is the primary species infecting humans in Europe. It is also transmitted by *Ixodes* ticks. Unlike malaria, *Babesia* only infects the RBCs of its human host. Resulting symptoms can be flu like with attendant symptoms of fevers, chills, sweats, etc; not too unlike malaria. Diagnosis is affected by finding the small piroplasms in blood smears **(Figure 51–8)**. Because they resemble malaria it is often necessary to send smears to a reference laboratory or to have serologic or PCR testing performed.

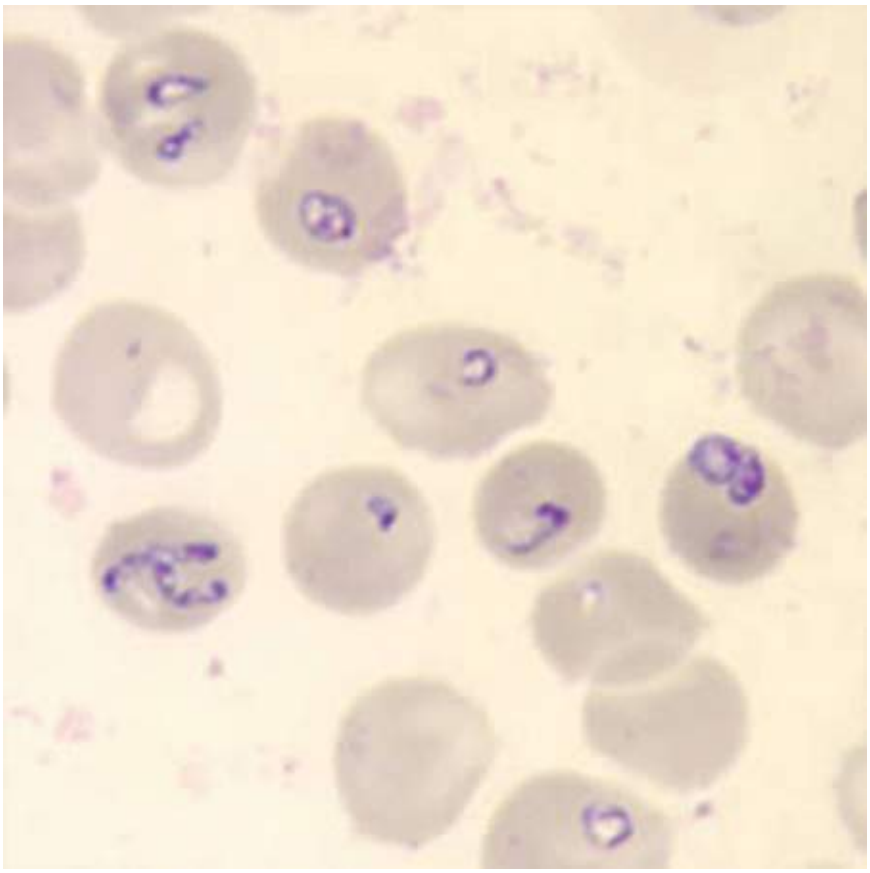

FIGURE 51–8. *Babesia* spp. in human blood. (Reproduced with permission from Centers for Disease Control and Prevention. U.S. Department of Health & Human Services. DPDx - Laboratory Identification of Parasites of Public Health Concern, Babesiosis. October, 2017.)

Patients usually respond well to treatment with a combination of quinine and clindamycin. Because these may be poorly tolerated, atovaquone plus azithromycin can also be used. Preventive measures include avoidance of areas known to be tick infected, using appropriate insecticides, wearing appropriate clothing, and performing daily tick inspections if one ventures into wooded areas where ticks live.

Think ▸▸ Apply 51-1: The western highland area of Kenya is endemic for *P falciparum* which causes almost all cases of malaria in the region. Because the student has not been home in 2 years, he most likely has lost all immunity to the disease. Because of this he will need to be on chemoprophylaxis for his visit to home. Recommended drugs include Mefloquine (helps arrest tissue phase development), Malarone (works against

erythrocytic stages of infection), or doxycycline (usually used in combination with another schizonticide, but shows action against both liver and blood stages). Each is useful, but some show more side effects than others. Patients should be informed of plus and minus uses for each.

KEY CONCLUSIONS

- *Babesia* spp. are transmitted to humans by hard ticks that also transmit Lyme disease.
- Symptoms of babesiosis closely resemble those of malaria without the cerebral involvement.
- Babesiosis is usually found in temperate zones where malaria is not endemic.

TOXOPLASMA GONDII

Overview

Toxoplasma gondii is an obligate intracellular parasite transmitted to humans from felines, but more commonly via infected meat products. *Toxoplasma* can infect most warm-blooded animals, both domestic and wild; it is thus the most cosmopolitan of parasites. Cats, however, are the only definitive hosts. Approximately 50% of the world population has been infected as defined serologically. In the United States, this rate is approximately 23%. In the overwhelming majority of persons, infection is chronic, asymptomatic, and self-limiting. Clinical disease manifests in three major forms: (1) self-limiting febrile lymphadenopathy; (2) highly lethal infection of immunocompromised patients, usually manifest as meningoencephalitis; and (3) congenital infection of infants, which may have fatal consequences.

PARASITOLOGY

Asexual and sexual cycles in felines

*** Human spread via fecal–oral route, ingestion of meat**

Like the plasmodia, *T gondii*, the cause of toxoplasmosis, is an obligate intracellular apicomplexan. It differs from *Plasmodium* in that both sexual and asexual reproductive cycles occur within the gastrointestinal tract of felines, the definitive host. The disease is transmitted to other host species by the ingestion of oocysts passed in the feces of infected felines, or through carnivorism from one infected host to another. The principal mode of transmission to humans is either via ingestion of oocysts from contaminated cat feces or via ingestion of meat products containing tissue cysts (bradyzoites). Transplacental transmission may also occur.

MORPHOLOGY

T gondii was first demonstrated in 1908 in the gondi, an African rodent, by Nicolle and Manceaux. Its name, derived from the Greek *toxo* (arc), is based on the characteristic shape of the organism. All strains of this parasite appear to be closely related antigenically. The major morphologic forms of the parasite are the oocyst, trophozoite, and tissue cyst (**Figure 51–9**).

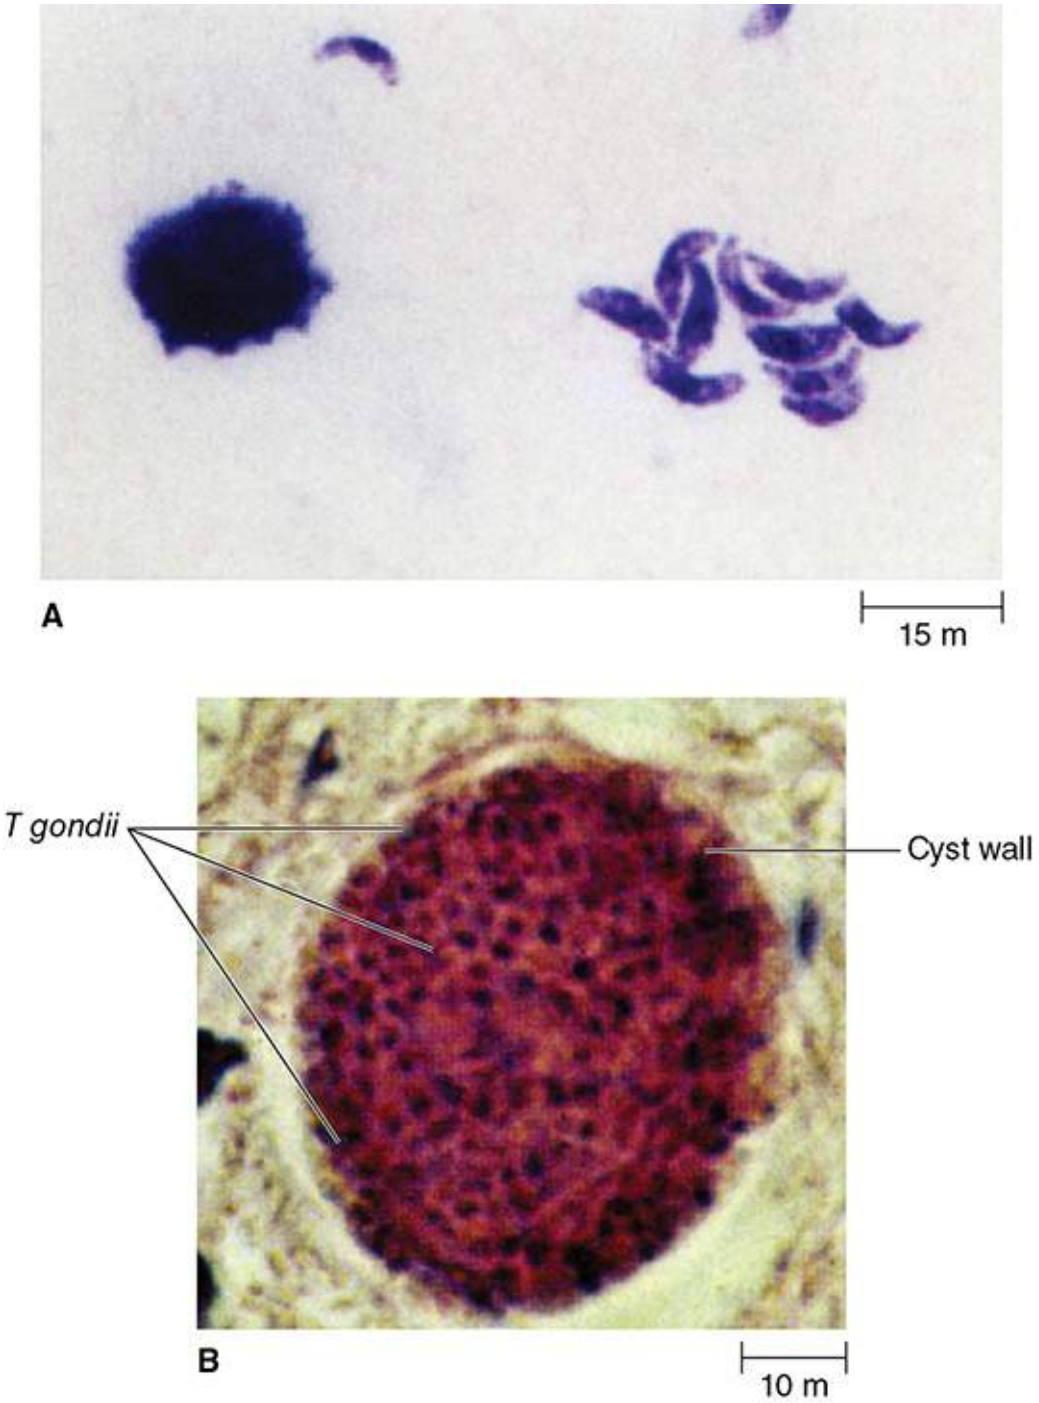

FIGURE 51–9. ***Toxoplasma gondii.*** **A.** Invasive trophozoite forms. **B.** Cyst in tissue. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

- **Oocyst**

  *** Tissue cysts killed by cooking**

The oocyst is ovoid, measures 10 to 12 µm in diameter, and possesses a thick wall that makes it resistant to most environmental challenges. It may be destroyed by heat higher than 66°C and by chemicals such as iodine and formalin. In its immature form, the center of the cyst lacks internal structure. With maturation, two sporocysts appear, and later four sporozoites may be discerned within each sporocyst. Sporulation does not occur at temperatures lower than 4°C or higher than 37°C. Complete sporulation may occur within 24 to 48 hours outside the host. This form is responsible for the fecal–oral route of transmission of the parasites from felines to other warm-blooded animals.

▪ Tachyzoite (Trophozoite)

The term “trophozoite” is used in its broadest sense to refer to the asexual proliferative forms responsible for cell invasion and clinical disease. In different stages of the asexual cycle, it is referred to by several other terms, including merozoite and **tachyzoite.** It is crescent or arc shaped, measures 3 by 7 µm, and can invade all nucleated cell types. Although tachyzoites are obligate intracellular organisms, they may survive extracellularly in a variety of body fluids for periods of hours to days. They cannot, however, survive the digestive activity of the stomach and, therefore, are not infective on ingestion.

▪ Tissue Cysts

Cysts measure 10 to 200 µm in diameter. The contained organisms, referred to as **bradyzoites,** are like tachyzoites, but are smaller and divide more slowly. Tissue cysts are resistant to digestive enzymes and, like oocysts, are infectious to the animal that ingests them. They survive normal refrigerator temperatures but are killed by freezing and thawing and by normal cooking temperatures.

LIFE CYCLE (FIGURE 51–10)

▪ Definitive Host

*** Infection in cat ileal cells**

*** Fusion of gametes leads to oocysts; shed in feces**

*** Sporulate in environment**

Sexual reproduction of *T gondii* occurs only in the intestinal tract of felines, most commonly in the domestic cat. Ingested parasites enter the epithelial cells

of the ileum by mechanisms like that of other apicomplexan parasites. Intracellularly, the trophozoites reside within a membrane-bound vacuole and undergo schizogony. With cell rupture, merozoites are released. The merozoites infect adjacent epithelial cells; they then repeat another asexual cycle or eventually differentiate into gametocytes, initiating sexual reproduction. Fusion of the mature male and female gametes leads to the formation of an oval, thick-walled oocyst that is then shed in the feces. In the typical infection, millions of these structures are released daily for 1 to 3 weeks. The oocysts are immature at the time of shedding and must complete sporulation in the external environment. In this process, two sporocysts, each containing four sporozoites, develop within each oocyst. The time required for sporulation typically takes 2 to 3 days, but may vary depending on the ambient temperature and moisture. Once mature, the resistant oocysts may remain viable and infectious for many months in soil.

▪ Intermediate Hosts

Oocysts, bradyzoites infect host orally

*** Sporozoites invade macrophages**

*** Cysts can persist for life**

Many animal species, including humans, are considered intermediate hosts for this infection. Infection may be acquired via ingestion of oocysts or via carnivorism of tissue-containing bradyzoites. After ingestion by a susceptible warm-blooded animal, sporozoites or bradyzoites are released from the disrupted oocyst or tissue and enter macrophages. Within these cells they are transported through the lymphohematogenous system to all organ systems. Survival within macrophages early in infections is because lysosomes are prevented from fusing with phagosomes containing the parasite. Continued intracellular division, termed endodyogeny results in the formation of 8 to 32 tachyzoites, which rupture from the macrophage and may invade any adjacent nucleated host cell to continue the asexual cycle. With the development of host immunity, many of the parasites are destroyed as macrophages become competent killers of the parasite. Within the cells of certain organs, particularly the brain, heart, and skeletal muscle, the trophozoites produce a membrane that surrounds and protects them: Within this tissue cyst, multiplication continues at a slower pace. Eventually, cysts that measure up to 200 μm in diameter are produced and contain more than 1000 bradyzoites. These cysts persist intact for the life of the host or rupture,

producing parasitologic relapse. If they are ingested by a carnivore, they survive the digestive enzymes and initiate infection in the new host. The persistence of cysts confers protection against superinfection. This is referred to as **premunition.**

TOXOPLASMOSIS

EPIDEMIOLOGY

▪ Prevalence and Distribution

Worldwide distribution among mammals and birds

Toxoplasmosis occurs in almost all mammals and many birds. Human infections are found in every region of the globe; in general, the incidence is higher in the tropics and lower in cold and/or arid regions. In the United States, the prevalence of positive serologic evidence for the disease increases with age. By adulthood, approximately 50% of individuals worldwide can be shown to have circulating antibodies against *T gondii*. Seroprevalence in cats may range from about 20% in countries like Japan, where cats are more likely to be kept indoors, to over 70% in some countries where cats are likely to live in rural areas or be feral.

▪ Transmission

Although it is known that humans may acquire toxoplasmosis in a variety of ways, data on their relative frequency are both meager and conflicting. It is likely that the route of transmission varies from population to population, and perhaps from age to age, within any given area. The most important transmission mechanisms of toxoplasmosis are discussed below.

Ingestion of Oocysts

*** Hazard to children by contact with contaminated areas**

Persons with felinophobia are inclined to believe that the deposition of oocysts in the feces of cats and their subsequent ingestion by the unsuspecting owner is the most common way in which humans acquire this important infection. Disease epidemics of toxoplasmosis associated with exposure to infected cats

have been reported. Unfortunately, data from studies relating the frequency of feline exposure to the prevalence of positive serologic tests are conflicting. Acutely infected cats shed oocysts for only a few weeks. It has been shown, however, that chronically infected felines can occasionally reshed oocysts, and prevalence studies have demonstrated that 1% of domestic cats excrete oocysts at any given time. The large number of these structures passed during active shedding and their prolonged survival in the external environment greatly enhance their chance of transmission. Particularly at risk are children at play, who may come in close contact with areas likely to be contaminated with cat feces, and adults responsible for changing a cat's litter box. It is also possible that insects can mechanically transfer oocysts to human food.

Ingestion of Tissue Cysts

*** Cysts present in meat**

Tissue cysts have been frequently demonstrated in meat produced for human consumption. They are most common in pork (25%) and mutton (10%) and less so in beef and chicken (<1%). Although such cysts are killed at normal (well-done) cooking temperatures, an impressive array of epidemiologic information links the handling and/or ingestion of raw or undercooked meat with serologic and, occasionally, clinical evidence of disease. Confounding these data is an Indian study that demonstrated no difference between meat eaters and vegetarians in the incidence of positive serologic tests.

Congenital

*** Transplacental transmission highest in third trimester**

Approximately 1 of every 500 pregnant women acquires acute toxoplasmosis, and approximately 10% to 20% of the involved women become symptomatic. Regardless of the clinical status of the infected mother, the parasite involves the fetus in 33% to 50% of all acute maternal infections. The risk of transplacental transmission is independent of the clinical severity of the disease in the mother but does correlate with the stage of gestation at which she is exposed. Fetal involvement occurs in 17% of first-trimester and 65% of third-trimester infections. Conversely, the earlier a fetal infection is acquired, the more severe it is likely to be. Overall, 20% of fetuses experienced severe consequences; a similar proportion develops mild disease. The remainder are asymptomatic.

Miscellaneous

* Transmitted by transfusions, organ transplants

In addition to causing congenital infection, tachyzoites have been responsible for disease transmission in several other situations, including laboratory accidents, transfusions of whole blood and leukocytes, and organ transplantation. Because tachyzoites may survive for several hours in body fluids or exudates of acutely infected humans, it is possible for infection to occur after contact with such materials.

PATHOGENESIS AND IMMUNITY

Dissemination in immunosuppressed subjects

In primary infection, the proliferation of tachyzoites results in the death of involved host cells, stimulation of a mononuclear inflammatory reaction, and parasite-specific antibody and cellular responses. In immunodeficient hosts, such as those with human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), latent infections reactivate and rapid organism proliferation ensues, producing numerous widespread foci of tissue necrosis. The consequences are most serious in organs such as the brain, where the potential for cell regeneration is limited.

Immunity primarily cell-mediated

In normal hosts, acute infection is rapidly controlled with the development of humoral and cellular immunity. Extracellular parasites are destroyed, intracellular multiplication is hindered, and tissue cysts are formed. Except for lysis of extracellular parasites by antibody and complement, cell-mediated immunity appears to play the principal role in this process, mediated in part by IL-2, interferon-α, and cytotoxic T cells. Immunity appears to be lifelong, most likely due to the persistence of the parasite in the tissue cysts. The cysts, which are found most frequently in the brain, retina, heart, and skeletal muscle, normally produce little or no tissue reaction. The suppression of cell-mediated immunity that accompanies serious illness, or the administration of immunosuppressive agents, may lead to the rupture of a cyst and the release of trophozoites. Their subsequent proliferation and the intense antibody reaction to their presence result in an acute exacerbation of the disease.

TOXOPLASMOSIS: CLINICAL ASPECTS

MANIFESTATIONS

In most patients, infection with *T gondii* is completely asymptomatic. Clinical manifestations, when they do appear, vary with the type of host involved. In general, they may be grouped into one of the three syndromes listed below.

▪ Congenital Toxoplasmosis

*** Infection in utero produces malformations, chorioretinitis, stillbirth**

Immune mechanisms are poorly developed in utero. Thus, a large proportion of fetal infections results in clinical illness. If the infection spreads to the central nervous system, the outcome is often catastrophic. Abortion and stillbirth are the most serious consequences. Liveborn children may demonstrate microcephaly, hydrocephaly, cerebral calcifications, convulsions, and psychomotor retardation. Disease of this severity is usually accompanied by evidence of visceral involvement, including fever, hepatitis, pneumonia, and skin rash. Infants infected with toxoplasmosis later in prenatal development demonstrate milder disease. Many appear healthy at birth but develop epilepsy, retardation, or strabismus months or years later. Probably the most common delayed manifestation of congenital toxoplasmosis is chorioretinitis. This condition, which is thought to result from the reactivation of latent tissue cysts, typically presents during the second or third decade of life as recurrent bouts of eye pain and loss of visual acuity. The lesions are usually bilateral but focal. If the retinal macula is not involved, vision improves as the inflammation subsides. *Toxoplasma gondii* accounts for 25% of all cases of granulomatous uveitis seen in the United States.

▪ Normal Host

Fever and lymphadenopathy can mimic infectious mononucleosis

The most common clinical manifestation of toxoplasmosis acquired after birth is asymptomatic localized lymphadenopathy. The cervical nodes are most frequently involved, but nontender enlargement of other regional groups,

including the retroperitoneal nodes, also occurs. At times, adenopathy is accompanied by fever, sore throat, rash, hepatosplenomegaly, and atypical lymphocytosis, thus mimicking the clinical and laboratory manifestations of infectious mononucleosis. Occasionally, the normal host develops severe visceral involvement, which may be manifested as meningoencephalitis, pneumonitis, myocarditis, or hepatitis. Chorioretinitis after postnatally acquired infection, though documented, is uncommon. Unlike congenitally acquired ocular disease, it occurs during midlife and is generally unilateral.

▪ Immunocompromised Host

Primary infection or reactivation can produce widespread disease

AIDS patients develop encephalitis

In the immunocompromised host, toxoplasmosis is a serious, often fatal disease. If primary infection is acquired while a patient is undergoing immunosuppressive therapy for malignancy or organ transplantation, widespread dissemination of the infection with necrotizing pneumonitis, myocarditis, and encephalitis may occur. More commonly, acute disease in this population results from the activation of chronic, latent infection by immunosuppressive therapy, or from the acquisition of a concurrent immunosuppressive infection, particularly AIDS. Encephalitis occurs in 50% of such cases and in more than 90% of fatal cases. Toxoplasmic encephalitis is particularly common in AIDS patients; it is seen in approximately 10% of those with circulating toxoplasma antibodies. As such, it is a major cause of morbidity and mortality in this patient population. Clinically, encephalitis may present as a meningoencephalitis, diffuse encephalopathy, or mass lesion. Acute toxoplasmosis has been seen as a result of organ transplantation in which immunosuppressive drugs were given to prevent organ rejection but resulted in a reactivation of latent cyst forms.

DIAGNOSIS

Demonstration in histopathologic specimens

The diagnosis of toxoplasmosis may be established by a variety of methods. In acute toxoplasmic lymphadenitis, the histologic appearance of the involved nodes is often pathognomonic. The trophozoite may be demonstrated in tissue with Wright or Giemsa stain. Electron microscopy and indirect fluorescent

antibody techniques have also been used successfully on heart transplant or brain tissue obtained by biopsy. Although tissue cysts are selectively stained by periodic acid–Schiff, their presence is not indicative of acute disease. Isolation of the organism can be accomplished by inoculating blood or other body fluids into mice or tissue cultures. Inoculation of other tissues is not usually helpful because a positive result may only reflect the presence of latent tissue cysts.

* Serodiagnosis the primary approach

Serologic procedures are the primary method of diagnosis. To establish the presence of acute infection, it is usual to demonstrate a fourfold rise in the IgG antibody titer between acute and convalescent serum specimens. Peak titers are often reached within 4 to 8 weeks, so the acute serum must be collected early during illness. Of the many tests developed for the detection of IgG antibodies, indirect hemagglutination, indirect fluorescent antibody, or enzyme immunoassay (EIA) tests are the tests most frequently used. Titers may remain high for many years.

Rising titers of IgG or detection of IgM suggest acute infection or reactivation

The detection of IgM antibodies provides a more rapid confirmation of acute infection. These antibodies appear within the first week of infection, peak in 2 to 4 weeks, and may slowly revert to negative. It also appears that immunoglobulin-M (IgM) antibodies are produced after reactivation of latent disease. EIA for IgM antibody is now commonly used. Examination of tissues, urine, and other body fluids for the presence of toxoplasma antigen, or DNA by the PCR, have been shown to be useful adjunctive tests in immunocompromised individuals and in the diagnosis of congenital infections.

TREATMENT AND PREVENTION

* Spiramycin to prevent congenital infection

Usually, patients infected with toxoplasmosis do not require therapy unless symptoms are particularly severe and persistent or unless vital organs, such as the eye, are involved. Immunocompromised and pregnant women, however, should be treated if acute infection (or reactivation) is documented (**Table 51-2**). Routine serial serologic testing of such individuals would allow early detection

of infected persons and enhance the prospects of a successful outcome. It is now clear that early treatment of acutely infected pregnant women significantly reduces the incidence of severe congenital infections and reduces the ratio of benign to subclinical forms in infants. At present, the most commonly used therapeutic regimen in the United States for toxoplasmosis is the combination of pyrimethamine and sulfadiazine plus folinic acid. Unfortunately, the former drug is teratogenic and should not be used in the first trimester of pregnancy; spiramycin, a cytostatic macrolide, is often substituted in this setting.

TABLE 51–2 Indications for Treatment of Toxoplasmosis[a]

SEROLOGIC CRITERIA	CLINICAL CRITERIA
Elevated IgM titers	Recently acquired infection
Fourfold rise in IgG titers	Pregnant woman
Very high IgG titers (>1:1000)	Neonate
	Immunocompromised patient (including AIDS)
	Severe constitutional symptoms
	Vital organ involvement (including active chorioretinitis)

Ig, immunoglobulin.
[a]Must satisfy one serologic plus one clinical criterion.

*** Atovaquone active against tachyzoites and cysts**

Although the pyrimethamine–sulfonamide combination is very effective against trophozoites, it is inactive against the cyst forms. Because both parasitic forms are present in patients with toxoplasmic encephalitis, recrudescence of illness generally follows completion of standard therapy in patients with AIDS. This may be prevented by initiating chronic, low-dose suppressive therapy after completion of the standard regimen. Atovaquone, a recently introduced hydroxynaphthoquinone, possesses activity against both trophozoites and cysts. Its use, therefore, may result in radical cure of toxoplasma encephalitis, eliminating the need for chronic suppression.

Prevention of toxoplasmosis should be directed primarily at pregnant women and immunologically compromised hosts. Hands should be carefully washed after handling uncooked meat. Cysts in meat can be destroyed by proper cooking (56°C for 15 minutes) or by freezing to –20°C. Cat feces should be avoided, particularly the changing of litter boxes.

A transplant recipient develops signs of acute meningitis within 2 weeks of receiving a donor heart. Acute toxoplasmosis is suspected. (1) How would you diagnose this possibility? (2) How might the recipient have acquired this infection and how might you prove your point? (3) What course of action would you take to treat this patient?

KEY CONCLUSIONS

- Cats are the only definitive host for *Toxoplasma*. All other infected animals are intermediate hosts.
- Transmission to humans is via cat feces, meat products, and congenitally.
- Approximately 50% of the world's population is serologically positive for this infection.
- Cell-mediated immunity appears to be most important in controlling this infection.
- Infection immunity or premonition is due to persistence of bradyzoites and prevents reinfection of the same person as long as that person does not become immunocompromised.
- Congenital transmission is most common during the third trimester, but the most severe symptoms are associated with transmission during the first trimester.
- Most individuals are asymptomatic, but severe disease is often seen in the immunocompromised.

CRYPTOSPORIDIUM SPP.

Overview

Cryptosporidia are small parasites that infect the intestinal cells of mammals. Cryptosporidiosis is an intestinal illness acquired from domestic and wild animals and from other humans. The course includes profuse watery diarrhea, vomiting, and weight loss. Spontaneous complete recovery is the usual outcome, except in immunocompromised persons, in whom debilitating illnesses can occur.

Cryptosporidia (“hidden-spore”) are small parasites that can infect the intestinal tract of a wide range of mammals, including humans. Like many other apicomplexan parasites, they are obligate intracellular organisms that exhibit alternating cycles of sexual and asexual reproduction within the gastrointestinal tract of the same host. Long recognized as an important cause of diarrhea in animals, cryptosporidia were not identified as causes of human enteritis until 1976, when first observed in a patient with a congenital IgA immunodeficiency. The advent of the AIDS epidemic sparked an intense interest in this parasite as a problem in humans. There are at least 26 different species of *Cryptosporidium* currently recognized. Of 20 species and genotypes that infect humans, the most common are zoonotic species, *Cryptosporidium parvum*, and a species, *Cryptosporidium hominis*, that only infects humans. The former is more likely to be encountered in rural populations, whereas the latter dominates in urban settings.

PARASITOLOGY

MORPHOLOGY

Small spherical particles associated with microvilli

*** Oocysts acid-fast**

Regardless of animal host, all species of this tiny (2-6 μm) parasite appear morphologically identical. The organisms appear as small spherical structures arranged in rows along the microvilli of the epithelial cells. They are readily stained with Giemsa and hematoxylin–eosin. Although they remain external to the cytoplasm of the intestinal epithelial cell, they are clearly enveloped by a membrane of host cell origin. They are thus said to be intracellular but extracytoplasmic. The parasite replicates at this site giving rise to oocysts. Oocysts shed into the intestinal lumen contain four sporozoites that are not contained within sporocyst structures like their relative, *Toxoplasma*. Their cell wall provides the unusual property of acid-fastness, allowing them to be visualized with stains generally employed for mycobacteria. Oocysts are typically 5 to 6 μm in diameter.

LIFE CYCLE

*** Mature, infective oocysts excreted in stools**

Infective oocysts are excreted in the stool of the parasitized animal. Unlike those of *Toxoplasma*, cryptosporidia oocysts are fully mature and immediately infective to the next host on passage in the feces. After ingestion by another animal, sporozoites are released from the oocyst and attach to the microvilli of the small intestinal epithelial cells, where they are transformed into trophozoites. These divide asexually by multiple fission (schizogony) to form schizonts containing eight daughter cells known as type 1 merozoites. On release from the schizont, each daughter cell attaches itself to another epithelial cell, where it repeats the schizogony cycle, producing another generation of type 1 merozoites. In the absence of effective immunity, this phase may constitute an autoinfective portion of the life cycle allowing perpetuation of the infection.

Cell wall ensures survival of oocysts

A second generation of schizonts follows with the formation of four merozoites. These merozoites are destined to invade intestinal cells and give rise to male (microgametocyte) and female (macrogametocyte) sexual forms. Gamete development ensues and after fertilization, the resulting zygote develops into an oocyst that is shed into the lumen of the bowel. The majority, approximately 80%, possesses a thick protective cell wall that ensures their intact passage in the feces and survival in the external environment.

Think ▸▸ Apply 51-2: (1) Since toxoplasmosis was suspected, a serologic test could be performed to see if IgM anibodies are present. This usually signals acquisition of a recent infection. In addition, PCR testing of cerebrospinal fluid and neuroradiology might be performed. (2) Two likely possibilities: (a) The patient could have received the organisms from the donor's heart. Serology should be performed in both patients and obtained from blood specimen of donor before transplant. If recipient is seronegative and donor is seropositive then you know the parasite was present in the donor's heart. (b) Patient had reactivation of a latent infection due to immunosuppressive therapy to prevent heart rejection. In this case, pre- and postpatient serum is likely IgG-positive with titer rising. (3)

Patient should be put on pyrimethamine and sulfadiazine or another suitable drug if patient allergic to sulfa drugs. In addition, immunosuppressive therapy should probably be dampened. This latter therapy is meant to prevent tissue rejection, but may help exacerbate toxoplasmosis.

Thin-walled oocysts can autoinfect

Approximately 20% fail to develop the thick protective wall. The cell membrane ruptures, releasing infective sporozoites directly into the intestinal lumen and initiating a new “autoinfective” cycle within the original host. In the normal host, the presence of innate or acquired immunity dampens both the cyclic production of type 1 merozoites and the formation of thin-walled oocysts, halting further parasite multiplication and terminating the acute infection. In the immunocompromised, both presumably continue, explaining why such individuals develop severe, persistent infections in the absence of external reinfection.

CRYPTOSPORIDIOSIS

EPIDEMIOLOGY

*** Animal reservoirs, person-to-person transmission important**

Cryptosporidiosis appears to involve most vertebrate groups. In all species, infection rates are highest among the young and immature. Experimental and epidemiologic data suggest that domestic animals constitute an important reservoir of disease in humans. Transmission from young animals at petting zoos to children has been documented. Outbreaks of human disease in day care centers, swimming pools, hospitals, and urban family groups indicate that most human infections result from person-to-person transmission. In Western countries, between 1% and 4% of small children presenting to medical centers with gastroenteritis have been shown to harbor cryptosporidia oocysts. In Third World countries, the rates have varied from 4% to 11%. In some outbreaks of diarrhea in day care centers, most attendees were found to have oocysts in their stool.

Infection rates highest in young children

Infection rates of cryptosporidiosis in adults suffering from gastroenteritis is approximately one-third of that reported in children; it has been highest in family members of infected children, medical personnel caring for patients with cryptosporidiosis, male homosexuals, and travelers to foreign countries. In the United States, the parasite was identified in 15% of patients with AIDS and diarrhea at the onset of the epidemic. Because of the advent of antiretroviral therapies, this has been reduced to 1% to 2%; in Haiti and Africa, high percentages of such individuals who do not have access to antiretroviral therapies may be involved. Asymptomatic carriage is uncommon in these populations. In many developing countries, most children may acquire multiple infections with *Cryptosporidium* before the age of 5 years. After that infections can still be detected, but symptoms may be absent suggesting that constant exposure may help maintain a measure of immunity.

Transmitted via contaminated water

Because oocysts are found almost exclusively in stool, the principal transmission route of cryptosporidiosis is undoubtedly by direct fecal–oral spread. Transmission via contaminated water has been documented. Most noteworthy was the outbreak involving municipal water in the city of Milwaukee in 1993. An estimated 403,000 people were infected via primary and then secondary spread of the organism. The hardy nature of the oocysts, which do not respond to conventional chlorine treatment of water and many other commonly used disinfectants, makes it likely that there is also indirect transmission via contaminated food and fomites. Flies and shellfish have been incriminated as transport hosts for this parasite.

PATHOGENESIS AND IMMUNITY

Minimal intestinal pathology

Prolonged disease in AIDS

Although the jejunum is most heavily involved, cryptosporidia have been found throughout the gastrointestinal, and even in the respiratory, tract, particularly in immunocompromised patients. Cryptosporidial cholecystitis is seen with some frequency in AIDS patients with enteritis. By light microscopy, bowel changes

appear minimal, consisting of mild-to-moderate villous atrophy, crypt enlargement, and a mononuclear infiltrate of the lamina propria. The pathophysiology of the diarrhea is unknown. The vital role played by the host's immune status in the pathogenesis of the disease is indicated by both the enhanced susceptibility of the young to infection and the prolonged severe clinical disease seen in immunocompromised patients. Indirect evidence suggests that antibodies in the intestinal lumen exert a protective effect against initial *C parvum* infection. Experimental animal studies indicate that CD4+ T lymphocytes and interferon play independent roles in the immunologic clearance of the parasite.

CRYPTOSPORIDIOSIS: CLINICAL ASPECTS

MANIFESTATIONS

Self-limiting diarrhea in normal hosts

Immunocompetent patients usually note the onset of explosive, profuse, watery diarrhea 1 to 2 weeks after exposure. Typically, cryptosporidiosis persists for 5 to 11 days and then rapidly abates. Occasionally, purging, accompanied by a mild malabsorption and weight loss, continues for up to 1 month. A few patients complain of nausea, anorexia, vomiting, and low-grade fever. Except for its shorter duration, more prominent abdominal pain, and relative lack of flatulence, the clinical manifestations of cryptosporidiosis closely resemble those produced by *Giardia lamblia*. Radiographic and endoscopic examinations of the gut are either normal or demonstrate mild, nonspecific abnormalities. Recovery is complete.

* Diarrhea more severe in immunocompromised

Cryptosporidiosis has been described in patients with a broad range of immunodeficiencies, including childhood malnutrition in the Third World countries, AIDS, congenital hypogammaglobulinemia, and in those resulting from cancer chemotherapy and immunosuppressive management of organ transplantations. In such patients, cryptosporidiosis is usually indolent at onset, and manifestations are like those seen in normal hosts, but the diarrhea is more severe. Fluid losses of up to 17 L/day have been described. Patients with biliary

cryptosporidiosis present with typical manifestations of cholecystitis and cholangitis. Unless the immunologic defect is reversed, the disease usually persists for the duration of the patient's life. Weight loss is often prominent. The prognosis depends on the nature of the underlying immunologic abnormality; 50% of the patients with AIDS die within 6 months. Although other intercurrent infections are usually the direct cause of death, malnutrition and complications of parenteral nutrition contribute.

DIAGNOSIS

*** Oocysts detected by acid-fast, immunofluorescent stains**

The diagnosis of cryptosporidiosis is established by the recovery and identification of *Cryptosporidium* oocysts in a recently passed or preserved diarrheal stool. Oocyst excretion is most intense during the first week of illness, tapers during the second week, and generally stops with the cessation of diarrhea. Because cryptosporidia oocysts are acid-fast, a presumptive identification can be established with any one of the acid-fast staining procedures developed for mycobacteria (**Figure 51–11**). This is best used in the hands of a competent diagnostician with experience. A direct immunofluorescence antibody stain using a monoclonal antibody to oocyst wall has been introduced, and is superior to acid-fast stains, but more time consuming and expensive. When direct examinations are negative, concentration procedures are used and the concentrate restained. Immunofluorescence and EIAs for the detection of anticryptosporidial antibodies are available as are EIAs and PCR methods for application to stool samples.

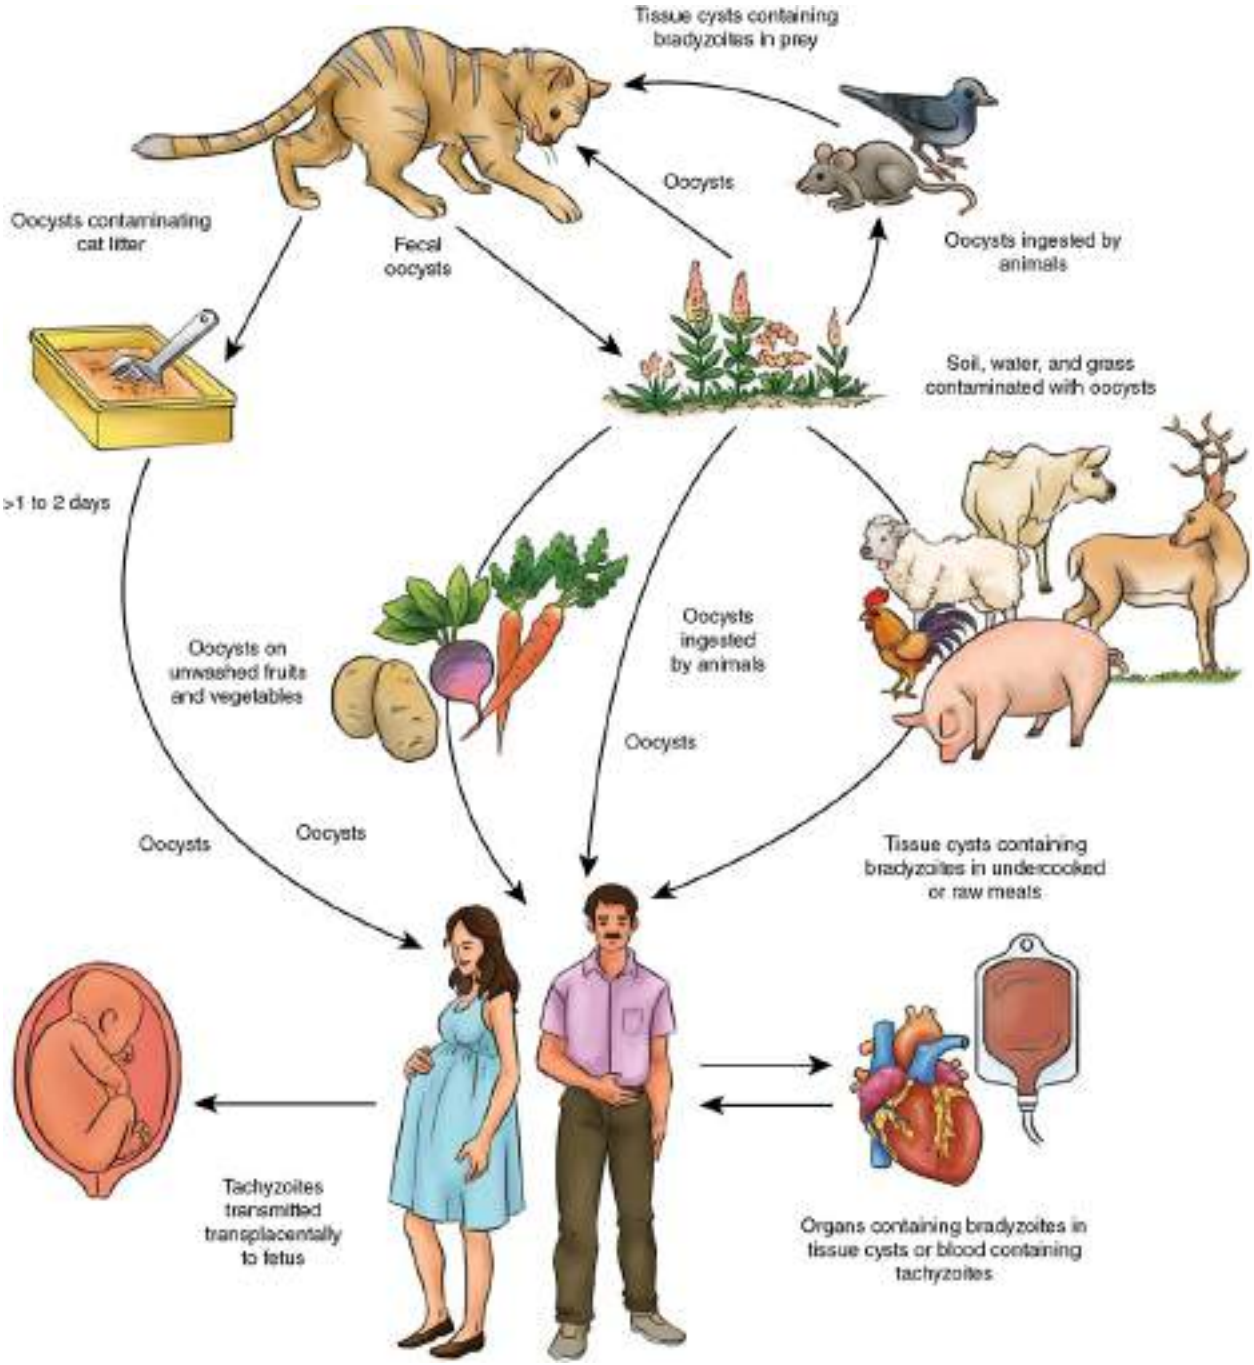

FIGURE 51–10. Toxoplasmosis. Pathways for *Toxoplasma gondii* infection: http://www.aafp.org/afp/2003/0515/p2131.html Fig. 1. *Toxoplasma gondii* life cycle shows oocysts from cat feces or cysts from inadequately cooked meat as infectious to humans and other animals. FIGURE 51–11. ***Cryptosporidium parvum.*** This acid-fast stain demonstrates oocysts in the feces of a diarrheal patient. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

TREATMENT AND PREVENTION

Specific treatment remains problematic

In the immunocompetent patient, the disease is self-limited and attempts at specific antiparasitic therapy are not warranted; rehydration may be required in small children. In the immunocompromised host, the severity and chronicity of the diarrhea warrant therapeutic intervention. Unfortunately, there is no uniformly effective anticryptosporidial agent available now. Paromomycin, a luminal antimicrobial, has been shown to reduce the intensity of diarrhea in some patients, and parenteral octreotide acetate, a somatostatin analog, has been useful in decreasing stool volumes. Macrolide antimicrobials have also been suggested in difficult cases. Nitrazoxanide, a synthetic drug, has been approved for use in all patients over 1 year of age in the United States and is reported to have a cure rate of 72% to 88% by the CDC. Parasitologic cure with this drug approaches 80%. The only uniformly successful approach has been the reversal of underlying immunologic abnormalities. When appropriate, withdrawal of cancer chemotherapy agents or immunosuppressive drugs may result in a cure.

Strict stool precautions for symptomatic patients

The stools of patients with cryptosporidiosis are infectious. Stool precautions should be instituted at the time the diagnosis is first suspected; for the immunosuppressed patient, this should be whenever diarrhea, regardless of the presumed cause, is first noted. This is particularly important in cancer chemotherapy and transplantation units, where spread of the disease from a symptomatic patient to other immunosuppressed patients can have life-threatening consequences. Oocysts can survive for many months in the external environment and have been found in most water sources across the United States. The infectious dose for this parasite is acknowledged to be very low.

KEY CONCLUSIONS

- Humans are infected by many zoonotic spp. of *Cryptosporidium* and *Cryptosporidium hominis*, which only infect humans.
- Infection is predominately fecal–oral, either directly or indirectly.
- Oocysts are immediately infective when released in feces and very few oocysts are required to initiate infection of another host.
- Oocysts are highly resistant to most commonly used disinfectants, accounting for numerous waterborne outbreaks.
- Infections are usually resolved in the immunocompetent, but can be life-threatening to the immunocompromised.

• OTHER INTESTINAL PROTOZOA

CYCLOSPORA AND ISOSPORA

Cyclospora was first recognized in the 1980s, but it was not until 1993 that it was shown to be closely related to both *Cryptosporidium* and *Toxoplasma*. The species that infects humans is *Cyclospora cayetanensis*. The species name was derived from the University in Lima, Peru, where much initial work was done on this parasite. This parasite gained notoriety because of foodborne outbreaks of illness that were ultimately linked to raspberries imported into the United States. Similar outbreaks have now been documented in many countries. Humans appear to be the only host for this parasite and its normal endemicity is usually linked to underdeveloped countries.

The parasite has an oocyst that measures 8 to 10 µm in diameter and stains acid-fast variable. It is remarkably like *Cryptosporidium* in its appearance but is larger **(Figure 51–12).** A big difference between the two is that it takes a week or longer for the oocyst to complete sporulation outside the host. Because of this, direct person-to-person transmission is unlikely. Complete sporulation results in an oocyst with two sporocysts each containing two sporozoites. Where both parasites are present in populations, *Cryptosporidium* has both a greater incidence and prevalence.

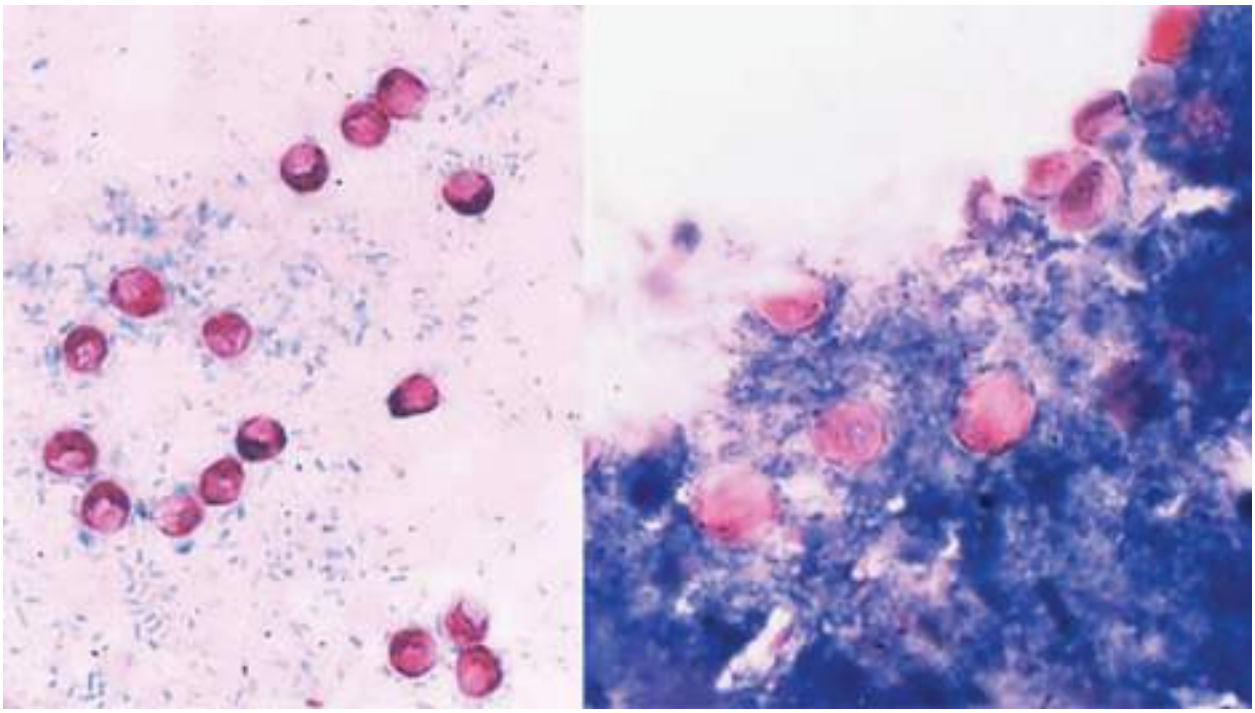

FIGURE 51–12. Side-by-side comparison of staining and size differences between *Cryptosporidium* and *Cyclospora*. *Cyclospora* is on the right.

Symptoms of cyclosporiasis mimic those of *Cryptosporidium. Cyclospora* is treatable with trimethoprim–sulfamethoxazole and for this reason it is important to correctly identify this parasite in stool sample since *Cryptosporidium* does not respond to this drug.

Isospora belli, now named *Cystoisospora belli*, is another protozoan closely related to *Toxoplasma*. Like *Toxoplasma*, oocysts contain two sporocysts, each with four sporozoites. Oocysts, however, are much larger in size (25-30 µm) and almost football shaped (Figure 51–14). They can be stained with modified acid-fast and trichrome procedures. Clinical disease resembles that of cryptosporidiosis and this parasite responds to treatment with trimethoprim–sulfamethoxazole. This parasite has a worldwide distribution in subtropical

areas, but is not that prevalent. It is recognized as a problem in the immunocompromised.

KEY CONCLUSIONS

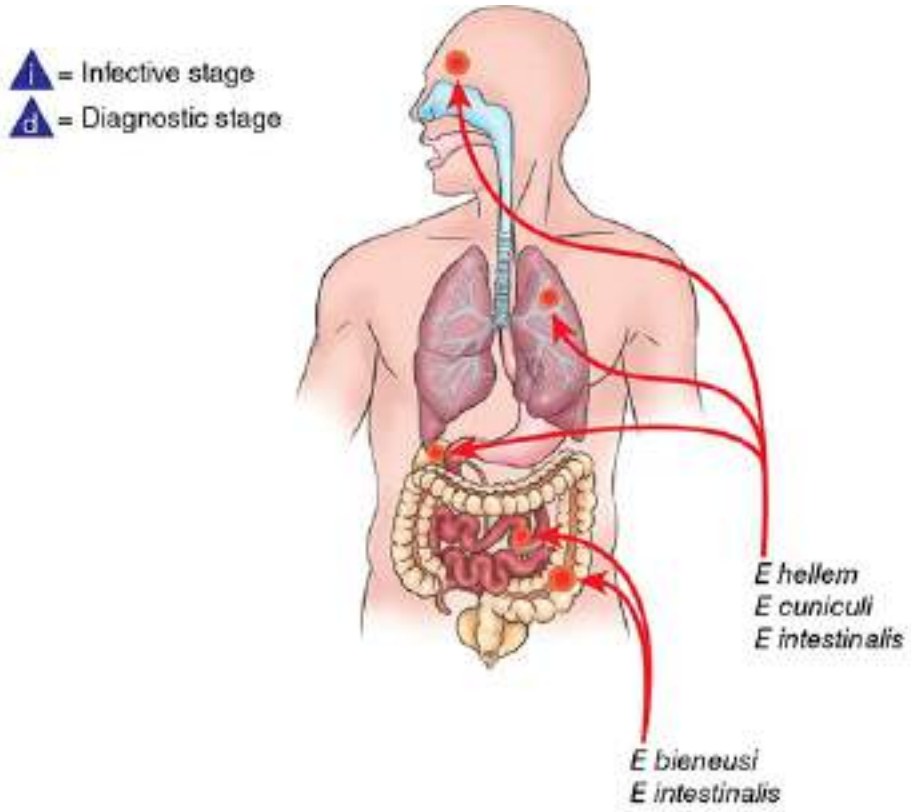
- Cyclospora cayetanensis occurs only in humans and has been linked to foodborne consumption in outbreak situations.
- Symptoms are like those for cryptosporidiosis.
- This parasite should be carefully distinguished from *Cryptosporidium* because it is easily treatable whereas *Cryptosporidium* is not.
- *Isopora* infection is mostly recognized as a problem in the immunocompetent where it can produce profuse diarrheal disease.

MICROSPORIDIA

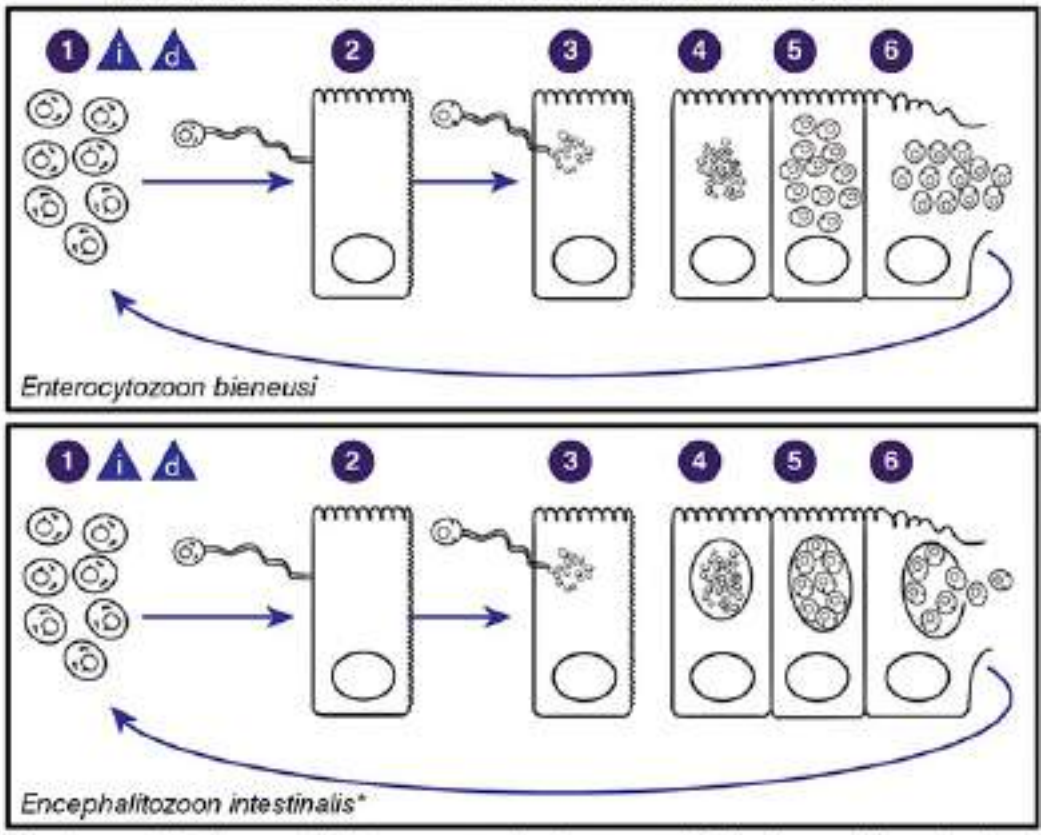
The inclusion of this parasite group in this chapter is because at one time they were placed in the same taxonomic grouping (Sporozoa) as were the other organisms discussed in this chapter. Once classified among the Protozoa they are now known to be fungi and are placed in their own phylum, the Microspora. As the name implies, this group of organisms is characterized by producing small spores. There are over 1200 known species parasitizing a very wide variety of eukaryotic hosts.

These parasites came to our attention because of the advent of the HIV/AIDS pandemic and they are still recognized largely as parasites of the immunocompromised. There have, however, been reports of infections caused by these organisms in children of certain African countries.

At least 14 different species have been recorded from humans. The principal ones of concern are *Enterocytozoon bieneusi* and three different species of *Encephalitozoon. Enterocytozoon bieneusi* inhabits the intestinal tract and causes diarrhea. *Encephalitozoon* spp. can disseminate to a wide variety of organ sites within the body. Infections begin by the ingestion of spores that discharge a polar filament in the environment of the small intestine. Sporoplasm containing a nucleus travels through this polar filament into host cells that have been punctured. Because of this rapid discharge process, the microsporidia have been referred to as nature’s perfect syringe. The sporoplasm and nuclei divide within infected cells ultimately resulting in the formation of more spores which can continue the life cycle (**Figure 51–13**).



Intracellular development of *E bieneusi* and *E intestinalis* spores.



*Development inside parasitophorous vacuole also occurs in *E hellem* and *E cuniculi*.

FIGURE 51–13. Life-cycle diagram of a representative Microsporidian.

The easiest way to diagnose these infections is from stained clinical smears, especially of fecal samples. A quick hot chromotrope technique or acid-fast trichrome is often used to stain the spores (**Figure 51–14**). Chemofluorescent stains such as calcofluor white are also useful.

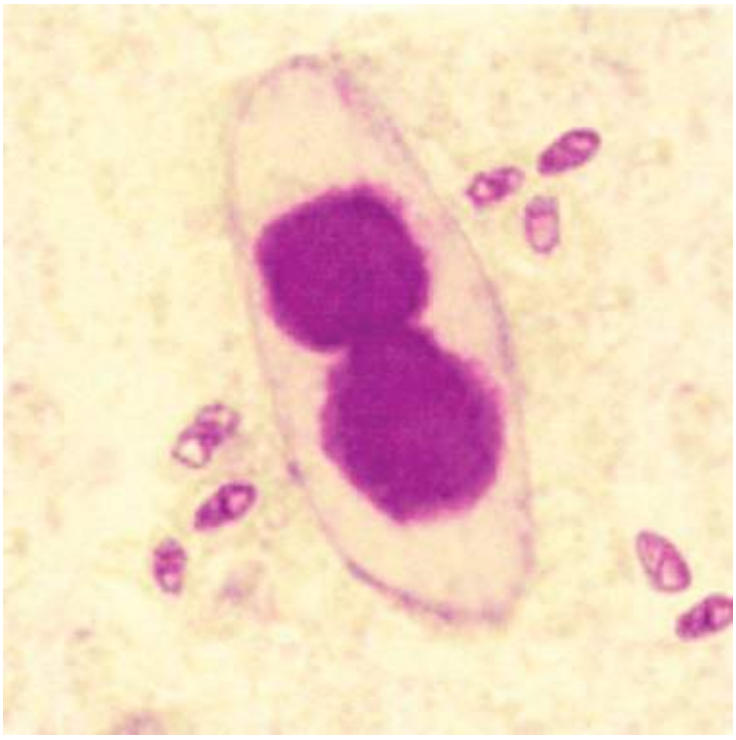


FIGURE 51–14. Fecal smear stained both with modified acid-fast and trichrome stains and showing and Isospora oocyst (large) and microsporidian spores (small). (Reproduced with permission from Garcia LS. Laboratory identification of the microsporidia, *J Clin Microbiol* 2002 Jun;40(6):1892–1901.)

Immune resolution using antiretrovirals resolves enteric microsporidiosis. Fumagillin has proven efficacious against *E bieneusi*. Albendazole has proven useful against disseminated microsporidiosis and a combination of fumagillin drops and albendazole is recommended for ocular infections.

KEY CONCLUSIONS

- Microsporidian infections in humans primarily occur in the immunocompromised.
- *Enterocytozoon bieneusi* infects the gastrointestinal tract while many other microsporidian infections have the ability to disseminate to other organs.

CASE STUDY

Fever After an Excursion

A 30-year-old man returned to the United States 3 weeks ago from a guided tour of Thailand. On advice of his physician, he took oral chloroquine prophylaxis beginning 1 week before departure and ending 1 week after his return. Over the last 4 days, he has developed repeated episodes of fever to 40°C, preceded by chills and associated with a severe headache. The duration of these symptoms has been about 8 hours, ending with profuse sweating, only to recur again within 48 hours.

Physical examination is unremarkable, except for fever.

Laboratory studies reveal only a mild anemia, with a platelet count of 100,000/mm^3 (normal 200,000-400,000).

QUESTIONS

1. Which is the most likely diagnosis for this patient?

A. Vivax malaria
B. Falciparum malaria
C. Toxoplasmosis
D. Ovale malaria
E. Malariae malaria

2. The diagnostic test of choice is:

A. Peripheral blood smears
B. PCR of red blood cells
C. IgM ELISA serology
D. Paired sera for IgG antibody quantitation

3. In some malarial infections, treatment to prevent relapse (by destroying persistent hepatic schizonts) is necessary in which two of the following?

A. *Plasmodium malariae*
B. *Plasmodium ovale*
C. *Plasmodium falciparum*
D. *Plasmodium knowlesi*

4. After primary infection, *T gondii* may persist as cyst forms in all of the following tissues *except* which of the following:

A. Brain
B. Heart
C. Skin
D. Skeletal muscle
E. Retina

ANSWERS

1. **(B)**
2. **(A)**
3. **(B) and (D)**
4. **(C)**

chapter 52

Sarcomastigophora—The Amebas

Entamoeba histolytica • *Entamoeba dispar* • *Naegleria fowleri* • *Acanthamoeba* spp. • *Balamuthia* spp.

Amoebas at the start
Were not complex;
They tore themselves apart
And started sex.
—Arthur Guiterman: *The Light Guitar*

SARCOMASTIGOPHORA—THE AMEBAS—GROUP CHARACTERISTICS

The Sarcomastigophora include both the amebas and flagellate groups. Because of their divergent organization and medical importance, they are considered in separate chapters. The amebas are characterized by movement involving cytoplasmic streaming dependent upon **pseudopodia** formation. These projections of the relatively solid ectoplasm are formed by streaming of the inner, more liquid endoplasm. They move the ameba forward and, incidentally, engulf and internalize food sources found in its path. Amebas multiply by simple binary fission. Most amebas, when faced with a hostile environment, can produce an external cyst wall that surrounds and protects them. These cysts may survive for prolonged periods under conditions that would rapidly destroy the motile trophozoite. Most amebas belong to free-living genera. They are widely distributed in nature, being found in literally all bodies of standing fresh water. Few free-living amebas produce human disease, although two genera, *Naegleria* and *Acanthamoeba*, have been implicated occasionally as causes of meningoencephalitis and keratitis.

Several genera of amebas, including *Entamoeba*, *Endolimax*, and

Iodamoeba, are obligate commensalistic parasites of the human alimentary tract and are passed as cysts from host to host by the fecal–oral route. Most amebas are amitochondriate, presumably because of the anaerobic conditions under which they exist in the colon. Only one, *Entamoeba histolytica*, regularly produces disease; it has been recently subdivided into two morphologically identical but genetically distinct species, an invasive pathogen that retains the species appellation "*histolytica*" and a commensal organism, now designated *Entamoeba dispar*. The two species can be differentiated by isoenzyme analysis, antibodies to surface antigens, and DNA markers.

ENTAMOEBA HISTOLYTICA

Overview

Entamoeba histolytica is an intestinal ameba transmitted between humans. Amebiasis is found worldwide and is caused by the potentially pathogenic *E histolytica*. Approximately 10% of patients with this parasite will have gastrointestinal symptoms and 1% will experience extraintestinal disease which can be life-threatening. Gastrointestinal symptoms may include intermittent diarrhea with abdominal pain. Occasionally, severe dysentery with abdominal cramping and a high fever can occur. Extraintestinal extension depends on the presence of a galactose-specific lectin (Gal/GalNAc) capable of mediating attachment of the organism to colonic mucosa followed by contact dependent cytotoxicity and blood passage of trophozoites to various organs. *Entamoeba dispar*, which is morphologically identical to *E histolytica*, accounts for the vast majority of *E histolytica*-like infections. Treatment is not required for *E dispar*.

PARASITOLOGY

E histolytica is found throughout the world and is the causative agent of diarrhea and amebic dysentery. Infections may spread to extraintestinal sites and become life-threatening. Close to 500 million people are thought to be infected at any one time, but most of these are likely due to the morphologically identical *E dispar*. Because methods are now available to distinguish *E histolytica* from *E dispar*, the figure of 500 million infected with *E histolytica* may actually be closer to 50 million. Transmission is fecal–oral, either directly or indirectly through contaminated water.

LIFE CYCLE, MORPHOLOGY, AND PHYSIOLOGY

* Humans hosts and reservoir; fecal–oral transmission

Humans are the principal hosts and reservoirs of *E histolytica*. Transmission from person to person occurs when a cyst passed in the stool of one host is ingested directly or indirectly, such as through food or water, by another. Human hosts may pass up to 45 million cysts daily. Although the average infective dose exceeds 1000 organisms, ingestion of a single cyst has been known to produce infection. After passage through the stomach, the cyst eventually reaches the distal small bowel. Here, the cyst wall disintegrates, releasing the quadrinucleate parasite, which divides to form eight small trophozoites that are carried to the colon. Colonization is most intense in areas of fecal stasis such as the cecum and rectosigmoid, but may be found throughout the large bowel.

Trophozoites multiply rapidly in the gut

E histolytica possesses both trophozoite and cyst forms (**Figure 52–1**). The trophozoites are microaerophilic, dwell in the lumen or wall of the colon, feed on bacteria and tissue cells, and multiply rapidly in the anaerobic environment of the gut. Even though they are called amitochondriate, they do possess nuclear-encoded mitochondrial genes and a remnant organelle. They do have unusual features including polyploid chromosomes, repetitive DNA, multiple origins of DNA replication, genes lacking introns, and unique endocytic pathways. Trophozoites are passed unchanged in the liquid diarrheic stool. Here they can be recognized by their size (12-20 μm in diameter); directional motility; granular, vacuolated endoplasm; and sharply demarcated, clear ectoplasm with finger-like pseudopods. Invasive strains tend to be larger and may contain ingested erythrocytes within their cytoplasm (**Figure 52–2**). Appropriate stains reveal a 3 to 5 μm nucleus with a small central karyosome or nucleolus and fine regular granules evenly distributed around the nuclear membrane (peripheral chromatin). Electron microscopic studies demonstrate microfilaments, an external glycocalyx, and cytoplasmic projections thought to be important for attachment.

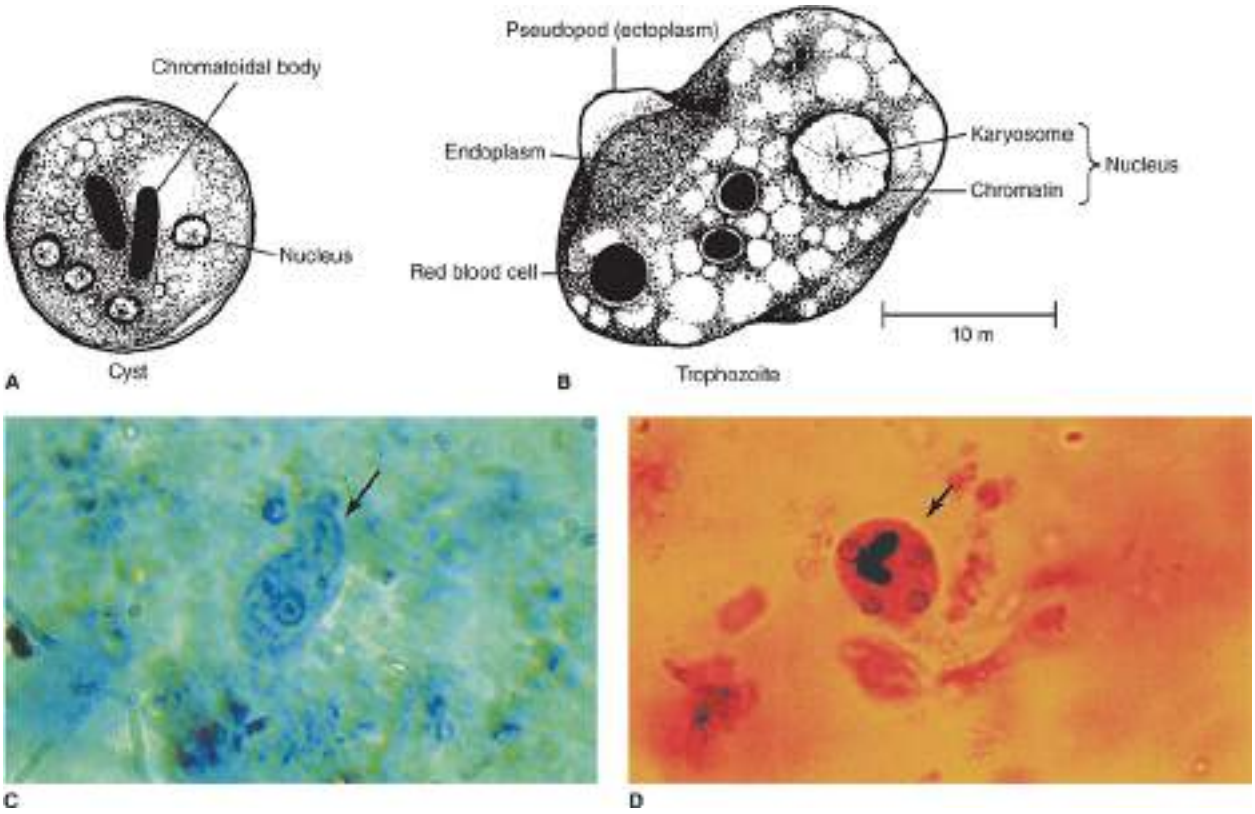

FIGURE 52–1. ***Entamoeba histolytica.*** **A.** Cyst structures. **B.** Trophozoite structures. **C.** Trophozoite in stool (*arrow*). **D.** Cyst (*arrow*) in stool iodine preparation and cysts in stool iodine preparation.

Facultative anaerobes

Trophozoites are facultative anaerobes that require complex media for growth. Sterile culture techniques (axenic) have been developed and are essential for the preparation of the purified antigens required for serologic testing, zymodeme typing, and characterization of virulence factors. Such techniques are generally available only in research laboratories.

* Hardy cysts survive in chlorinated water

With normal stool transit time, trophozoites usually encyst before leaving the gut. Initially, a cyst contains a single nucleus, a glycogen vacuole, and one or more large, cigar-shaped ribosomal clusters known as chromatoid bodies. With maturation, the cyst becomes quadrinucleate, and the cytoplasmic inclusions are

absorbed. In contrast to the fragile trophozoite, mature cysts can survive environmental temperatures up to 55°C, chlorine concentrations normally found in municipal water supplies, and normal levels of gastric acid. *E histolytica* can be differentiated from the other amebas of the gut by its size, nuclear detail, and cytoplasmic inclusions (**Table 52-1**).

TABLE 52–1 Some Differential Characteristics of *Entamoeba* Species

CHARACTERISTICS	*E HISTOLYTICA*	*E HARTMANNI*	*E COLI*
TROPHOZOITES			
Cytoplasm	Differentiated[a]	Differentiated	Undifferentiated
Nucleus			
Peripheral chromatin	Fine	Fine	Coarse, irregular

AMEBIASIS

EPIDEMIOLOGY

Worldwide infection; highest rates in warmer climates

E histolytica infection rates are higher in warm climates, particularly in areas where the level of sanitation is low. Worldwide, this organism is thought to produce more deaths than any other parasite, except those that cause malaria and schistosomiasis. Reports of amebic liver abscess, for instance, emanate primarily

from Mexico, western South America, South Asia, and West and South Africa. For reasons apparently unrelated to exposure, symptomatic illness is much less common in women and children than in men.

Invasive disease rare in the United States

Although stool surveys in the United States indicate that 1% to 5% of the population harbors *Entamoeba*, most of these are now known to be colonized with the nonpathogenic *E dispar*. The incidence of invasive amebiasis in the United States decreased sharply over several decades, reaching a nadir in 1974. Since then, the numbers have increased, but remain relatively low. It is now seen particularly in institutionalized individuals, Indian reservations, migrant labor camps, victims of acquired immunodeficiency syndrome (AIDS), and travelers to endemic areas.

*** Fecal–oral spread via poor hygiene**

Food and water transmission

Symptomatic amebiasis is usually sporadic, the result of direct person-to-person fecal–oral spread under conditions of poor personal hygiene. Venereal transmission is seen in male homosexuals, presumably the result of oral–anal sexual contact. Food- and waterborne spread occurs, occasionally in epidemic form. Such outbreaks, however, are seldom as explosive as those produced by pathogenic intestinal bacteria. One outbreak of intestinal amebiasis was due to colonic irrigation at a chiropractic clinic.

PATHOGENESIS

*** Lectin-mediated adherence to mucosa and capacity to lyse host cells**

Several virulence factors have been identified in *E histolytica*. In an experimental setting, invasiveness correlates well with endocytic capacity, the production of extracellular proteinases capable of activating complement and degrading collagen, the presence of a galactose-specific lectin (Gal/GalNAc) capable of mediating attachment of the organism to colonic mucosa, and—perhaps most important—the capacity to lyse host cells on contact. This has been termed parasite-mediated or **contact-dependent cytotoxicity.** The latter

phenomenon is initiated by the galactose-specific, lectin-mediated adherence of the trophozoite to a target cell. After adherence, the ameba releases a pore-forming protein that polymerizes in the target cell membrane, forming large tubular lesions. Cytolysis rapidly follows. Cysteine proteinases, secreted by the amebas, have also been identified as a major virulence factor. They can degrade portions of the extracellular matrix, including fibronectin, laminin, and type I collagen, and they can interfere with the complement pathway and humoral IgA and IgG responses. Ultimately, this may lead to extraintestinal spread of the trophozoites which may occur in approximately 1% of established infections (**Figure 52–3**). Cyst formation does not take place at extraintestinal sites.

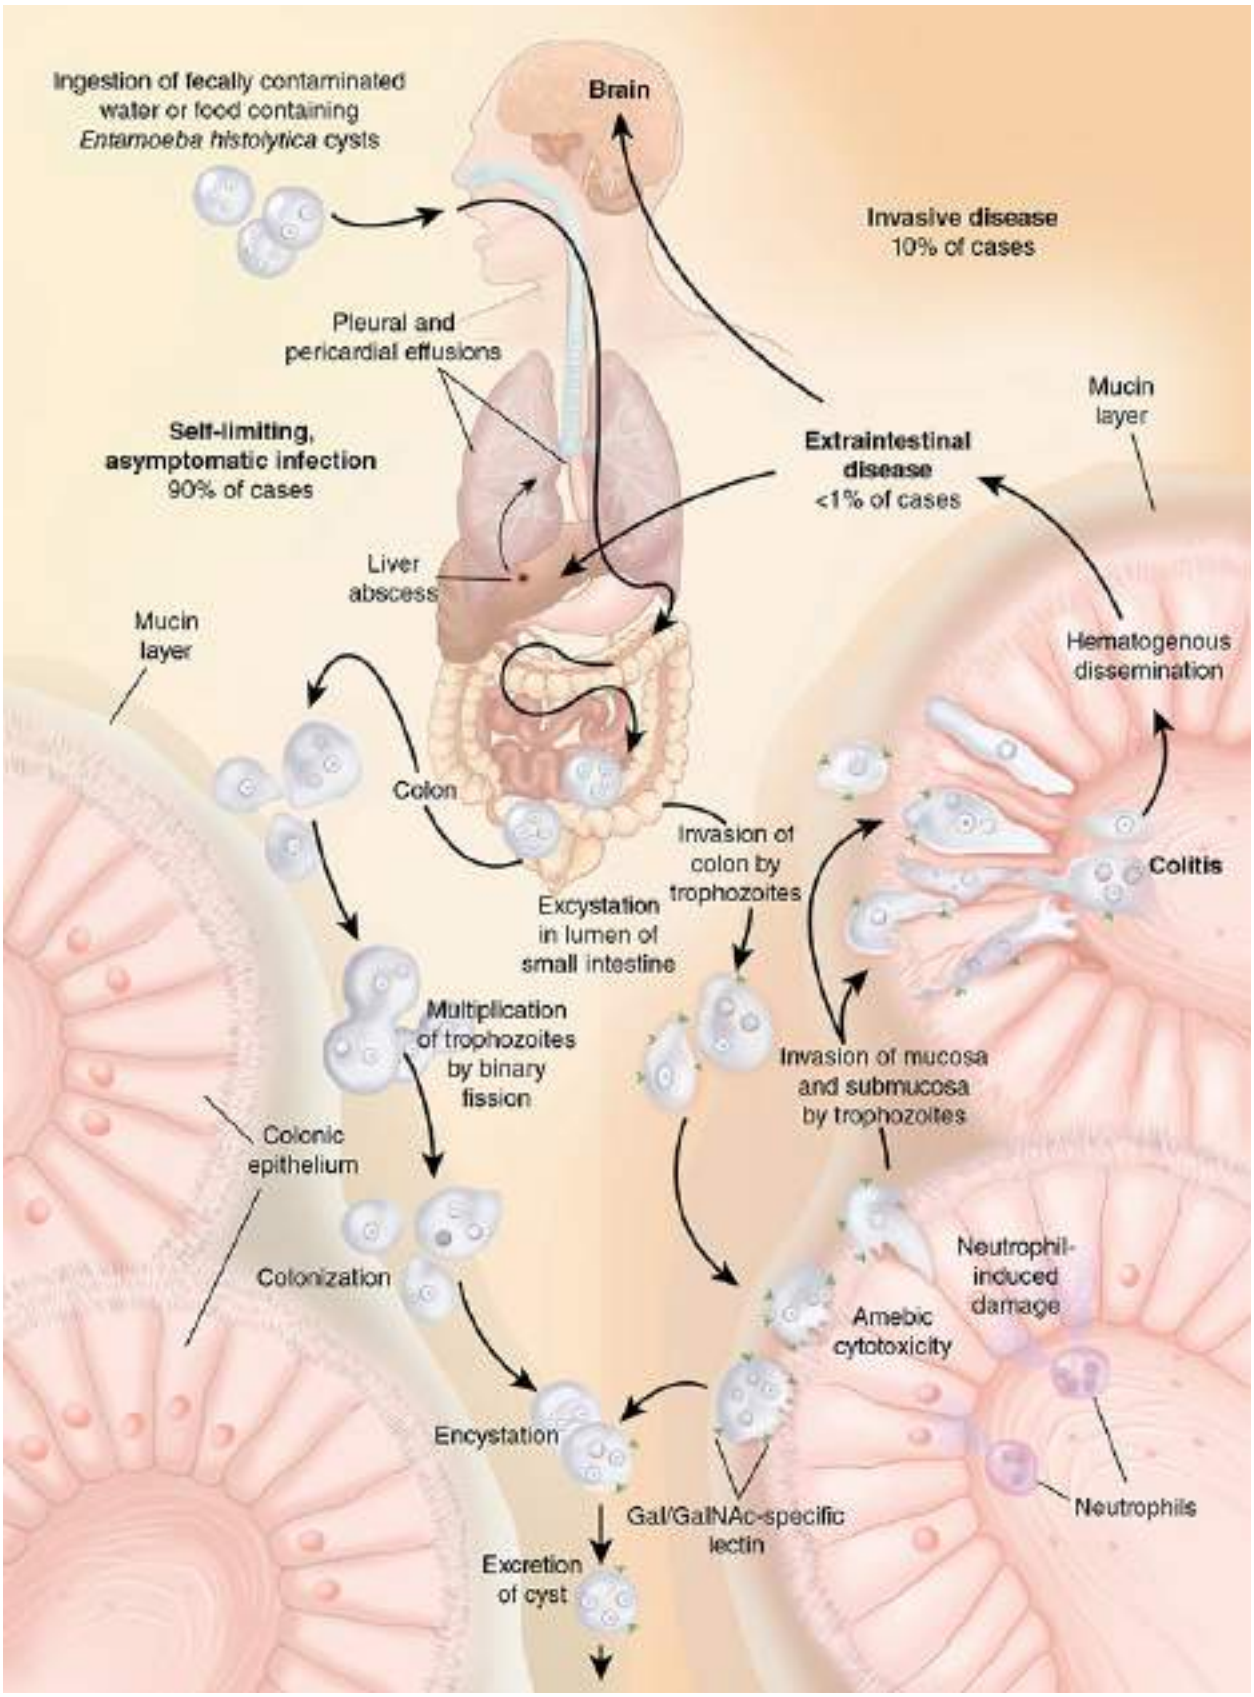

FIGURE 52–3. Pathways of *E histolytica* colonization within the gastrointestinal tract. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Most symptom free

Colonic flora influences invasiveness

In most cases of *E histolytica* infections, however, tissue damage is minimal, and the host remains symptom-free, suggesting that host factors may modulate the invasiveness of virulent strains. These factors are still poorly understood, but changes in host resistance, the colonic milieu, or the parasite itself may amplify tissue damage and clinical manifestations. Protein malnutrition, high-carbohydrate diets, corticosteroid administration, childhood, and pregnancy all appear to render the host more susceptible to invasion. Certain colonic bacteria appear to enhance invasiveness, possibly by providing a more favorable redox potential for survival and multiplication or by facilitating the adherence of the parasite to colonic mucosa. Finally, it is known that the pathogenic strains in the tropics are more invasive than those isolated in temperate areas, possibly because poor sanitation results in more frequent passage through humans.

PATHOLOGY

Mucosal ulceration, little inflammation

*** Flask-like ulcers in submucosa**

Amebomas, amebic abscesses in a few

The interaction of amebas with the intestinal epithelial barrier results in an inflammatory response marked by the secretion of cytokines. This, in turn, results in neutrophil activation which can be protective or result in enhanced tissue destruction. This type of response is characteristic of early invasive amebiasis and contrasts with what is seen in well-established infections manifest by colonic ulcers. In the latter instance, there is little inflammatory response other than edema and hyperemia, and the mucosa between ulcers appears normal. Trophozoites are present in large numbers at the junction between necrotic and viable tissue. Once the lesion penetrates below the superficial epithelium, it meets the resistance of the colonic musculature and spreads laterally in the submucosa, producing a flask-like lesion with a narrow mucosal

neck and a large submucosal body. It eventually compromises the blood supply of the overlying mucosa, resulting in sloughing and a large necrotic ulcer. Extensive ulceration leads to secondary bacterial infection, formation of granulation tissue, and fibrotic thickening of the colon. In approximately 1% of patients, the granulation tissue is organized into large, tumor-like masses known as **amebomas.** The major sites of involvement, in order of frequency, are the cecum, ascending colon, rectum, sigmoid, appendix, and terminal ileum. Amebas may also enter the portal circulation and be carried to the liver or, more rarely, to the lung, brain, or spleen. In these organs, liquefaction necrosis leads to the formation of abscess cavities in which only trophozoites are encountered.

IMMUNITY

Although *E histolytica* elicits both humoral and cellular immune responses in humans, it is still not clear which and to what degree, these responses are capable of modulating initial infection or thwarting reinfection. In endemic areas, the prevalence of gastrointestinal colonization increases with age, suggesting that the host is incapable of clearing *E histolytica* from the gut. However, the relative infrequency with which populations living in these areas suffer repeated bouts of severe amebic colitis or liver abscess indicates that those who experience such infections have protection against recurrent disease.

Innate defense against *E histolytica* begins with the mucous lining of the intestinal epithelium. Ironically, although this may restrict amebic contact with epithelial cells, it also provides a milieu for colonization because of the mucins present. What is clear is that infected hosts produce a rather strong mucosal IgA response and much of this is directed against the carbohydrate domain of the Gal/GalNAc lectin present on the ameba’s surface. Children with this type of response in Bangladesh had 86% fewer new infections than children without it.

As stated previously, interaction of amebas with the intestinal epithelium results in an inflammatory response causing activation of cytokines. Neutrophils become involved, which may help promote further damage because of their destruction by cysteine proteases released by the amebas and resulting in release of superoxide radicals, or they may help mediate protection following activation via TNF-α.

Immunity incomplete, not correlated with antibody

Trophozoites shed antibody, resist complement lysis

Patients with invasive disease are known to produce high levels of circulating antibodies. Nevertheless, no correlation exists between the presence or concentration of such antibodies and protective immunity, possibly because pathogenic *E histolytica* trophozoites have the capacity to aggregate and shed attached antibodies and are resistant to the lytic action of complement. Cell-mediated responses have been described in patients with amebic liver abscess and are associated with lymphocyte proliferation and cytokine secretion. Activated macrophages also have the capacity to kill amebas, presumably through nitric oxide or peroxidase production. The susceptibility to invasive amebiasis of malnourished populations, pregnant women, and steroid-treated individuals or patients indicates that cell-mediated immune mechanisms may be directly involved in the control of tissue invasion. The picture is less clear in patients with AIDS and requires further study.

Pathogenic *E histolytica* strains produce a lectin-like substance that is mitogenic for lymphocytes. It has been suggested that this substance could stimulate viral replication of human immunodeficiency virus-infected lymphocytes as does another mitogen, phytohemagglutinin.

AMEBIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Relationship usually commensal

Individuals who harbor *E histolytica* are usually clinically well. In most cases, particularly in the temperate zones, the organism is avirulent, living in the bowel as a normal commensal inhabitant. Spontaneous disappearance of amebas, over a period of weeks to months, among such patients is common. Serologic data, however, suggest that some asymptomatic carriers possess virulent strains and incur minimal tissue invasion. In this population, the infection may eventually progress to produce overt disease.

* Diarrhea, flatulence, abdominal pain, ulcerations

Diarrhea, flatulence, and cramping abdominal pain are the most common complaints of symptomatic patients. The diarrhea is intermittent, alternating with episodes of normality or constipation over a period of months to years.

Typically, the stool consists of one to four loose to watery, foul-smelling passages that contain mucus and blood. Physical findings are limited to abdominal tenderness localized to the hepatic, ascending colonic, and cecal areas. Sigmoidoscopy reveals the typical ulcerations with normal intertwining mucosa.

*** Hepatic abscess acute or insidious**

Fulminating amebic dysentery is less common. It may occur spontaneously in debilitated or pregnant individuals or may be precipitated by corticosteroid therapy. Its onset is often abrupt, with high fever, severe abdominal cramps, and profuse diarrhea. Most commonly, abscesses occur singly and are localized to the upper outer quadrant of the right lobe of the liver. This localization results in the development of point tenderness overlying the cavity and elevation of the right diaphragm. Liver function is usually well preserved. Isotopic or ultrasound scanning confirms the presence of the lesion. Needle aspiration results in the withdrawal of reddish-brown, odorless fluid free of bacteria and polymorphonuclear leukocytes; trophozoites may be demonstrated in the terminal portion of the aspirate since they are likely colonizing the intact tissue at the periphery of the abscess.

Hepatic abscess may extend

Approximately 5% of all patients with symptomatic amebiasis present with a liver abscess. Ironically, fewer than one-half can recall significant diarrheal illness. Although *E histolytica* can be demonstrated in the stools of 72% of patients with amebic liver abscess when a combination of serial microscopic examinations and culture is used, routine microscopic examination of the stool detects less than half of these. Complications relate to the extension of the abscess into surrounding tissue, producing pneumonia, empyema, or peritonitis. Extension of an abscess from the left lobe of the liver to the pericardium is the single most dangerous complication. It may produce rapid cardiac compression (tamponade) and death or, more commonly, a chronic pericardial disease that may be confused with congestive cardiomyopathy or tuberculous pericarditis.

DIAGNOSIS

*** Stools trophozoites, cysts in stained or wet preparations**

* *E histolytica* ingests erythrocytes

The microscopic diagnosis of intestinal amebiasis depends on the identification of the organism in stool or sigmoidoscopic aspirates. Because trophozoites appear predominantly in liquid stools or aspirates, a portion of such specimens should be fixed immediately to ensure preservation of these fragile organisms for stained preparations. The specimen may then be examined in wet mount for typical motility, concentrated to detect cysts, and stained for definitive identification. If trophozoites or cysts are seen, they must be carefully differentiated from those of the commensal parasites, particularly *E hartmanni* and *Escherichia coli* (Table 52-1). *E histolytica* trophozoites can be differentiated from those of *E dispar* only by the presence of ingested erythrocytes in the former and by molecular methods; the cysts appear identical.

Antigen detected in stool

Recently, sensitive and specific stool antigen tests for *E histolytica* have become commercially available; their value in the clinical diagnosis of amebiasis, when compared with microscopic examination, is not clear. Although cultural and polymerase chain reaction techniques are somewhat more sensitive and are used by reference laboratories, they are not widely available in many clinical laboratories in developing countries where amebiasis is endemic.

* Extraintestinal amebiasis demonstrates high antibody levels

The diagnosis of extraintestinal amebiasis is more difficult because the parasite usually cannot be recovered from stool or tissue. Serologic tests are therefore of paramount importance. Typically, results are negative in asymptomatic patients, suggesting that tissue invasion is required for antibody production. Most patients with symptomatic intestinal disease and more than 90% with hepatic abscess have high levels of antiamebic antibodies. Unfortunately, these titers may persist for months to years after an acute infection, making the interpretation of a positive test difficult in endemic areas. At present, the indirect hemagglutination test and enzyme immunoassays using antigens derived from axenically grown organisms appear to be the most sensitive. Several rapid tests, including latex agglutination, agar diffusion, and counterimmunoelectrophoresis, are available to smaller laboratories.

TREATMENT

* Metronidazole combined with other agents

Treatment for noninvasive infection differs from treatment for invasive infection. Paromomycin is useful for noninvasive infection and should probably be used if it is certain that it is truly *E histolytica* and not *E dispar*. Treatment is directed toward relief of symptoms, blood and fluid replacement, and eradication of the organism. The drug of choice for eradication in the case of invasive amebiasis is metronidazole or tinidazole followed by treatment with iodoquinol or paromomycin. Metronidazole and its derivatives are effective against many forms of amebiasis, but should be combined with a second agent, such as iodoquinol or paromomycin, to improve cure rates in intestinal disease and diminish the chance of recrudescent disease in hepatic amebiasis. It may be prudent to also administer a broad-spectrum antibiotic in severe cases of intestinal amebiasis to treat intestinal bacteria that have the potential to spill into the peritoneum. In severe extraintestinal infections, parenteral dehydroemetine treatment may be considered.

Should all patients diagnosed with an *E histolytica*-like infection be treated?

PREVENTION

Because the disease is transmitted by the fecal–oral route, efforts should be directed toward sanitary disposal of human feces, improvement in personal hygienic practices, and the provision of safe drinking water. In the United States, this applies particularly to institutionalized patients and to camps for migrant farm workers. Male homosexuals should be made aware that certain sexual practices substantially increase their risk of amebiasis and other infections.

KEY CONCLUSIONS

- Transmission of *E histolytica* is fecal–oral, both direct and indirect.
- The majority of *E histolytica* infections are asymptomatic.
- Intestinal symptoms develop in about 10% of infected individuals and extension in 1% of infected individuals.
- Extraintestinal extension depends on the presence of a Gal/GalNAc lectin

present on the ameba's surface. Contact-dependent cytotoxicity mediated by many factors allows tissue invasion.
- Immunity involves both antibody and cell-mediated responses, but is poorly understood. IgA antibody, various cytokines, and neutrophils are involved.
- Cysts and trophozoites may be passed in infected individuals, but only trophozoites are found in extraintestinal lesions.
- *Entamoeba dispar* is morphologically identical to *E histolytica* and accounts for approximately 90% of all *E histolytica*-like infections.

Think ▸▸ Apply 52-1: Keep in mind that the majority of infections caused by *E histolytica*-like infections are caused by the nonpathogenic *E dispar.* With this in mind, and if a reference laboratory can perform PCR on stool specimens, confirmed *E histolytica* should be treated, but not *E dispar*. The question to treat or not in endemic areas where reference laboratories are not as common becomes more difficult. Does the patient exhibit symptoms of intestinal or extraintestinal amebiasis?—then definitely treat. Is the patient from an area where amebiasis is common?—likely treat. Seek differentiation of pathogenic versus nonpathogenic spp. when possible.

PATHOGENIC AND OPPORTUNISTIC FREE-LIVING AMEBAS

Overview

Pathogenic and opportunistic free-living amebas belong to the genera *Acanthamoeba, Balamuthia, Naegleria,* and *Sappinia*. These organisms are widespread in nature and have been found in soil, drinking water, swimming pools, sewage, draining ditches, thermal pools, eyewash solutions, and even dialysis units. *Naegleria fowleri* is the causative agent of primary amebic meningoencephalitis which results in death within 5 to 6 days following full-body contact with contaminated water sources. *Acanthamoeba* and *Balamuthia* are considered opportunistic because they occur primarily in immunocompromised patients and are the causative agents of chronic granulomatous encephalitis, keratitis, and skin lesions. *Naegleria* and *Sappinia* infections, on the other hand, have been described from healthy

patients, and are therefore considered nonopportunistic.

PRIMARY AMEBIC MENINGOENCEPHALITIS

*** Meningoencephalitis due to free-living amebas**

*** Warm weather, brackish water favor *Naegleria***

Primary amebic meningoencephalitis is caused by the free-living ameba *Naegleria fowleri.* This parasite largely affects children and young adults through full-body contact with warm fresh water, and is almost always fatal. *Naegleria* species are found in large numbers in shallow fresh water, particularly during warm weather. The organism exists in trophozoite, flagellate, and cyst forms. The trophozoite is an active feeding form that feeds on bacteria and organic matter. It transforms into a bi-flagellate form when deprived of nutrients, but may revert to a trophozoite if conditions become favorable. Under adverse environmental conditions it will encyst **(Figure 52–4)**.

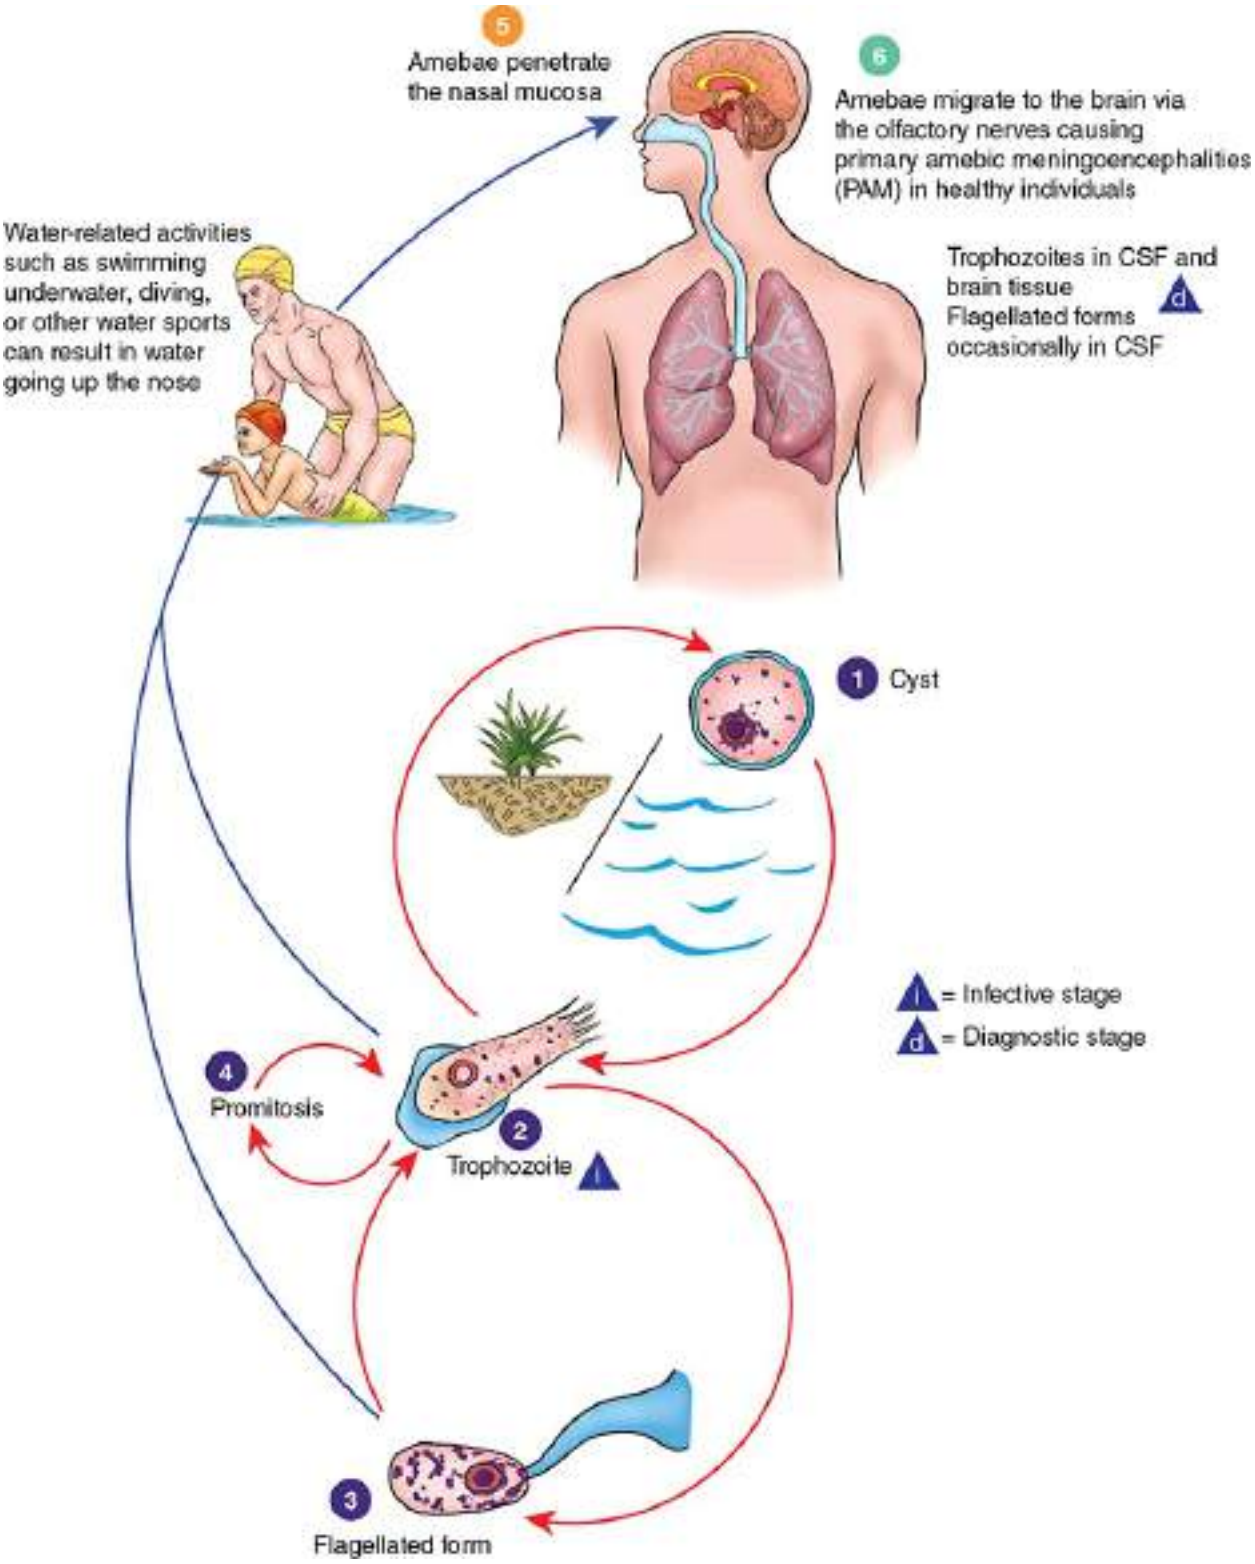

FIGURE 52–4. **Life cycle *of Naegleria fowleri.***

Naegleria associated with freshwater swimming

More than 300 cases of *Naegleria* meningoencephalitis have been reported, mostly in the United States, Australia, and Europe. Serologic studies suggest that inapparent infections are much more common. Most cases in the United States have occurred in the southern states. Characteristically, patients have fallen ill during the summer after swimming or in small, shallow, warm freshwater lakes. A Czechoslovakian case followed swimming in a chlorinated indoor pool, and several cases worldwide have occurred after bathing in hot mineral water.

*** Passage to CNS across cribriform plate**

Infection results from full-body contact with water containing the bi-flagellate parasite form. The parasite enters the body through the nasal passages and traverses the nasal mucosa and the cribriform plate as an ameboid form to the olfactory nerves of the central nervous system (CNS). Here, the amebas, which are the only form found in tissue, produce a severe purulent, hemorrhagic inflammatory reaction, which extends perivascularly from the olfactory bulbs to other regions of the brain. The infection is characterized by the rapid onset of severe bifrontal headache, seizures, and at times abnormalities in taste or smell. The disease runs an inexorably downhill course to coma, ending fatally within a few days.

*** Purulent bloody CSF contains *Naegleria* trophozoites**

A striking feature of this infection is the rapid onset of symptoms following exposure. Because there are no distinctive clinical features to differentiate this infection from acute pyogenic bacterial meningoencephalitis or viral meningoencephalitis, it is imperative for the physician to obtain information regarding the patient's contact with water within the past few days. A careful examination of the cerebrospinal fluid (CSF) may often provide a presumptive diagnosis of *Naegleria* infection. The fluid is usually bloody and demonstrates an intense neutrophilic response. The protein level is elevated, and the glucose level decreased. No bacteria can be demonstrated on stain or culture. Early examination of a wet mount preparation of unspun spinal fluid reveals typical trophozoites. Staining with specific fluorescent antibody confirms the identification. The organism can usually be isolated on agar plates seeded with a Gram-negative bacillus (to feed the amebas) or grown axenically in tissue culture. Unfortunately, most diagnosis of amebic meningoencephalitis is made postmortem **(Figure 52–5)**. To date, there are reports of only six patients who have survived a *Naegleria* infection. All were diagnosed early and treated with

high-dose amphotericin B along with rifampin. An investigational drug, miltefosine, is now available for emergency treatment of naegleria infection.

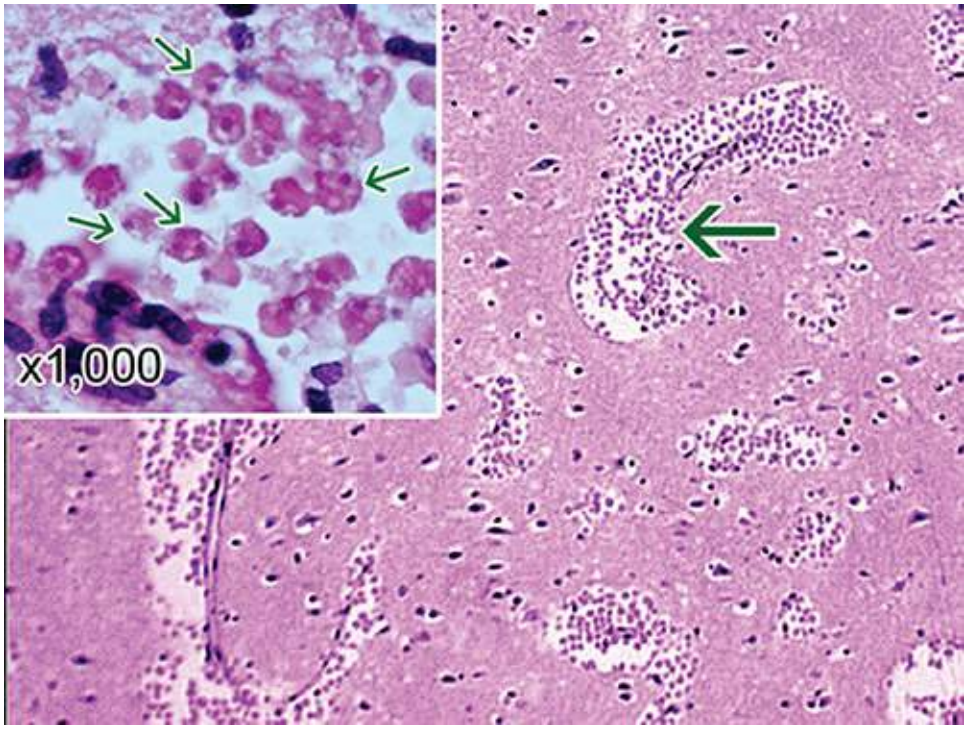

FIGURE 52–5. Primary amebic meningoencephalitis—*Naegleri fowleri*. Large clusters of *Naegleria fowleri* trophozoites and the destruction of the normal brain tissue architecture. Cysts are not seen. (Reproduced with permission from Centers for Disease Control and Prevention. Naegleria fowleri—Primary Amebic Meningoencephalitis (PAM)—Amebic Encephalitis. November, 2013.)

What is one of the most important questions for a physician to ask when presented with symptoms of meningoencephalitis?

Think ▸▸ Apply 52-2: Where have you been and who or what have you been in contact with. With respect to the contact the issue of contact with warm water should be considered. Full body contact is required because the flagellated stage must make contact via the nasal mucosa. Also, symptoms develop very rapidly. *Naegleria* is usually not transmitted via hot tubes because of the high chlorine content. One case was linked to consumption of water from a municipal water source, but this is highly unusual

or unlikely.

KEY CONCLUSIONS

- *Naegleria fowleri* infections are acquired by full-body contact with warm (greater than 40°C) water sources.
- Infections are caused by flagellated trophozoites contacting the nasal mucosa and migrating to the brain.
- Death due to meningoencephalitis usually follows in 5 to 6 days.
- Presumptive diagnosis is usually bacterial or viral meningoencephalitis.

GRANULOMATOUS AMEBIC ENCEPHALITIS

Granulomatous amebic encephalitis (GAE) is caused by one of seven species of free-living amebas belonging to the genus *Acanthamoeba*. These amebas are ubiquitous worldwide and have been described from soil, fresh and brackish waters, cooling towers of electric and nuclear power plants, heating, ventilating and air conditioning units, humidifiers, Jacuzzis, hydrotherapy pools, dental irrigation units, dialysis machines, dust, cell cultures, and various clinical samples. They have also received attention because they may serve as hosts for a wide variety of bacterial pathogens.

Acanthamoeba spp. exist in two forms, trophozoite and cyst. The trophozoite feeds on bacteria and detritus in the environment and divides by binary fission. If environmental conditions become unfavorable, the trophozoite encysts. Cysts have been known to survive for up to 20 years *in vitro*.

***Acanthamoeba* affects older immunocompromised**

*** Granulomatous encephalitis with cysts and trophozoites**

The epidemiology of *Acanthamoeba* encephalitis has not been clearly defined. Infections usually involve older, immunocompromised persons, and a history of freshwater swimming is generally absent. The ameba probably reaches the brain by hematogenous dissemination from an unknown primary site, possibly the respiratory tract, skin, or eye. Metastatic lesions have been reported. Histologically, *Acanthamoeba* infections produce a diffuse, necrotizing, granulomatous encephalitis (**Figure 52–6**), with frequent involvement of the

mid-brain. Both cysts and trophozoites can be found in the lesions. Cutaneous ulcers and hard nodules containing amebas have been detected in patients with AIDS.

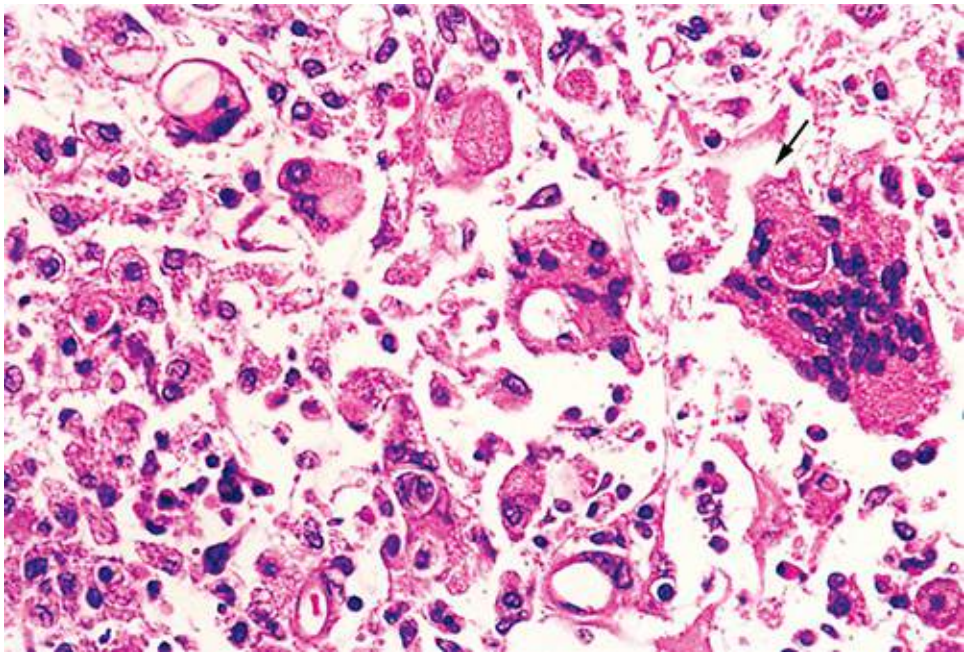

FIGURE 52–6. Acanthamoebic granulomatous encephalitis. A trophozoite (*arrow*) entering an epithelioid cell is seen at the right. The empty ovals in other cells are collapsed cysts. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Prolonged disease, occasional spontaneous recovery

The clinical course of *Acanthamoeba* disease is more prolonged than that of *Naegleria* infection and occasionally ends in spontaneous recovery; the disease in immunocompromised hosts is invariably fatal. The spinal fluid usually demonstrates a mononuclear response. Amebas can occasionally be visualized in or cultured from the CSF or biopsy specimens. Fluorescein-labeled antiserum is available from the Centers for Disease Control and Prevention. Definitive diagnosis is usually made histologically after death. Treatment of GAE using a wide variety of therapeutic agents has been attempted, but only rarely has that led to a successful prognosis. Recently, miltefosine has been shown to have amebicidal activity and was used successfully to treat a patient with disseminated acanthamoebiasis.

OTHER *ACANTHAMOEBA* INFECTIONS

Corneal ulcerations associated with use of contact lens

Skin lesions, uveitis, and corneal ulcerations have also been reported with *Acanthamoeba* disease. The latter are serious, producing a chronic progressive ulcerative lesion that may result in blindness. In recent years, there has been a rise in such infections correlated with the increased number of contact lens wearers. Infection commonly follows mild corneal trauma; most recently reported cases have been in users of soft contact lenses. Clinically, severe ocular pain, a paracentral ring infiltrate of the cornea, and recurrent epithelial breakdown are helpful in distinguishing this entity from the more common herpes simplex keratitis. Trophozoites must be present to bind to the corneal epithelium. The diagnosis can be confirmed by microscopic examination of corneal scraping or corneal biopsy and/or fluorescent antibody techniques. Culture of corneal tissue and contact lenses is frequently successful when the laboratory is given time to prepare satisfactory media. Nucleic acid amplification methods have recently been found more sensitive than culture. Chemotherapy has generally been ineffective unless given very early in the course of infection. Although a combination of corneal transplantation and chemotherapy may be successful later in the course of the disease, enucleation of the eye may be necessary to cure advanced infections. The drugs of choice are propamidine and neomycin eye drops administered alternately for a period of several months. Successful use of clotrimazole has been recently reported. Topical application of steroid is common to relieve pain and lessen inflammation.

KEY CONCLUSIONS

- The primary routes of exposure to *Acantamoeba* and *Balamuthia* infections are not well defined by may be oral or through the skin and rarely involve water contact.
- Infections with these parasites are more prolonged than those involving *Naegleria*.
- Granulomatous encephalitis, keratitis, and skin lesions are most commonly reported.
- The investigational drug, miltefosine, has been used successfully to treat patients.

CASE STUDY

Weight Loss, Abdominal Discomfort, and a Tender Liver

A 21-year-old college student volunteered for a 2-year assignment as a missionary in a rural area of Central Mexico. Within 4 months of arrival, he developed a mild diarrheal illness with flatulence and abdominal discomfort that subsided spontaneously within a few weeks. Six months later, he noted progressive weight loss over several weeks, a low-grade fever, and right upper abdominal tenderness.

He returned to the United States for medical consultation. The primary physical finding was an enlarged right lobe of the liver, which was tender on palpation. An ultrasound study confirmed the presence of an abscess at that site.

The diagnosis of an amebic hepatic abscess was seriously considered.

QUESTIONS

1. Which of the following laboratory findings would be most likely to be helpful in supporting this patient's diagnosis?

A. Demonstration of cyst forms in the stool
B. Demonstration of trophozoites containing erythrocytes in the stool
C. Isolation of the organism from the abscess
D. Demonstration of high-serum antibody titers to *E histolytica*

2. Your choice of treatment would usually be:

A. Tetracycline
B. Amphotericin B
C. Clotrimazole
D. Metronidazole

3. A diagnosis of amebic meningoencephalitis is suggested by a recent history of the following, *except*:

A. Exposure to a household contact with a similar illness
B. Swimming in a freshwater lake
C. Bathing in hot springs
D. Swimming in a chlorinated pool

ANSWERS

1. **(D)**
2. **(D)**
3. **(A)**

Sarcomastigophora—The Flagellates

Trichomonas vaginalis • *Giardia duodenalis (syn. lamblia)* • *Leishmania* spp. • *Trypanosoma brucei gambiense* and *rhodesiense* • *Trypanosoma cruzi*

SARCOMASTIGOPHORA—THE FLAGELLATES—GROUP CHARACTERISTICS

The flagellated protozoa are widespread in nature, multiply by binary fission, and move about by means of a primary organelle of locomotion, the flagellum. This organelle arises from an intracellular focus known as a kinetosome (basal body), extends to the cell wall as a filamentous axoneme composed of microtubules arranged in the typical 9 pairs + 2 central microtubular pattern, and continues extracellularly as the free flagellum. A pair of dynein arms extends from each outer microtubule of a pair to an adjacent microtubular pair and is responsible for flagellar beating through ATP hydrolysis. The long, whip-like free flagella may be single or multiple. The number is distinctive for individual species. When more than one flagellum is present, each has its own associated basal body and axoneme. The entire flagellar unit and any associated organelles are referred to as a mastigont system.

In some flagellates, such as the trypanosomes, the flagellum becomes part of the cell surface and creates a structure called an undulating membrane. Movement occurs in helical waves and seems to be suited for organisms living within a viscous fluid environment such as that found in the bloodstream.

In other flagellates, the mastigont system includes a rod-like costa, which may serve as a supporting structure for the undulating membrane, or a tube-like axostyle, which arises from the base of a flagella and probably functions in rotational motility and support. Trichomonads possess both these structures.

Although several flagellate genera parasitize humans, only four, *Trichomonas*, *Giardia*, *Leishmania*, and *Trypanosoma*, commonly induce disease. *Trichomonas* and *Giardia* are noninvasive organisms that inhabit the lumina of the genitourinary or gastrointestinal tract and spread without the

benefit of an intermediate host. Disease is of low morbidity and cosmopolitan distribution. *Leishmania* and *Trypanosoma*, on the other hand, are invasive tissue and blood parasites that produce highly morbid, frequently lethal diseases. These hemoflagellates require an intermediate insect host for their transmission. Thus, their associated disease states are limited to the semitropical and tropical niches of these intermediate hosts.

• NONINVASIVE LUMINAL FLAGELLATES

* Found in flora of vertebrates

Luminal flagellates can be found in the mouth, vagina, or intestine of almost all vertebrates, and it is common for an animal host to harbor more than one species. Humans may serve as host and reservoir to eight species (**Table 53-1**), but only two cause disease. Of these, *Giardia duodenalis* (=*lamblia*) inhabits the intestinal tract, and *Trichomonas vaginalis* inhabits the vagina and genital tract.

TABLE 53–1 Luminal Flagellates Infecting Humans

FLAGELLATE	PATHOGENICITY TO HUMANS	SITE
Giardia lamblia	+	Intestine
Dientamoeba fragilis	?	Intestine
Chilomastix mesnili	–	Intestine
Enteromonas hominis	–	Intestine
Retortamonas intestinalis	–	Intestine
Trichomonas hominis	–	Intestine
Trichomonas tenax	–	Mouth
Trichomonas vaginalis	+	Vagina

* Morphology and rapid motility are distinctive

These organisms are elongated or oval and typically measure 10 to 20 μm in length. They often possess a rudimentary cytostome (mouth aperture) and organelles, such as ventral discs or axostyles, which help maintain their intraluminal position. They are readily recognized in body fluid or excreta by their rapid motility and some can be specifically identified in unstained preparations. All can be cultivated on artificial media.

*** May or may not have the cyst stage**

Some luminal flagellates, most notably *T vaginalis*, possess only a trophozoite stage and are sexually transmitted. Most, including *G duodenalis*, possess both trophozoite and cyst forms. The latter, which is the infective form, is transmitted via the direct or indirect fecal–oral route. Human-to-human infection is thus found in populations where inadequate sanitation or poor personal hygiene favors spread.

TRICHOMONAS VAGINALIS

Overview

Trichomonas vaginalis is an oval flagellate which exists only in the trophozoite stage. Trichomoniasis, caused by *T vaginalis*, is a sexually transmitted disease that has a worldwide distribution. Infection may be asymptomatic, particularly in men, but often produces vaginitis with pain, discharge, and dysuria in women. The infection fluctuates over weeks to months. Men may have urethritis or prostatitis. It is recommended that both sexual partners in a relationship be treated.

PARASITOLOGY

Three *Trichomonas* species have similar morphology

Three members of the genus *Trichomonas* parasitize humans (Table 53-1), but only *T vaginalis* is an established pathogen. The three species closely resemble one another morphologically, but confusion in identification is rare because of the specificity of their habitats.

*** Protruding axostyle may mediate attachment**

The *T vaginalis* trophozoite (**Figure 53–1**) is oval and typically measures 7 by 15 μm. Organisms up to twice this size are occasionally recovered from asymptomatic patients and from cultures. In stained preparations, a single, elongated nucleus and a small cytostome are observed anteriorly. Five flagella arise nearby. Four immediately exit the cell. The fifth bends back and runs posteriorly along the outer edge of an abbreviated undulating membrane. Lying

along the base of this membrane is a cross-striated structure known as the costa. A conspicuous microtubule containing a supporting rod or axostyle bisects the trophozoite longitudinally and protrudes through its posterior end. It is thought that the pointed tip of this structure is useful for attachment. In unstained wet mounts, *T vaginalis* is identified by its axostyle and jerky, nondirectional movements.

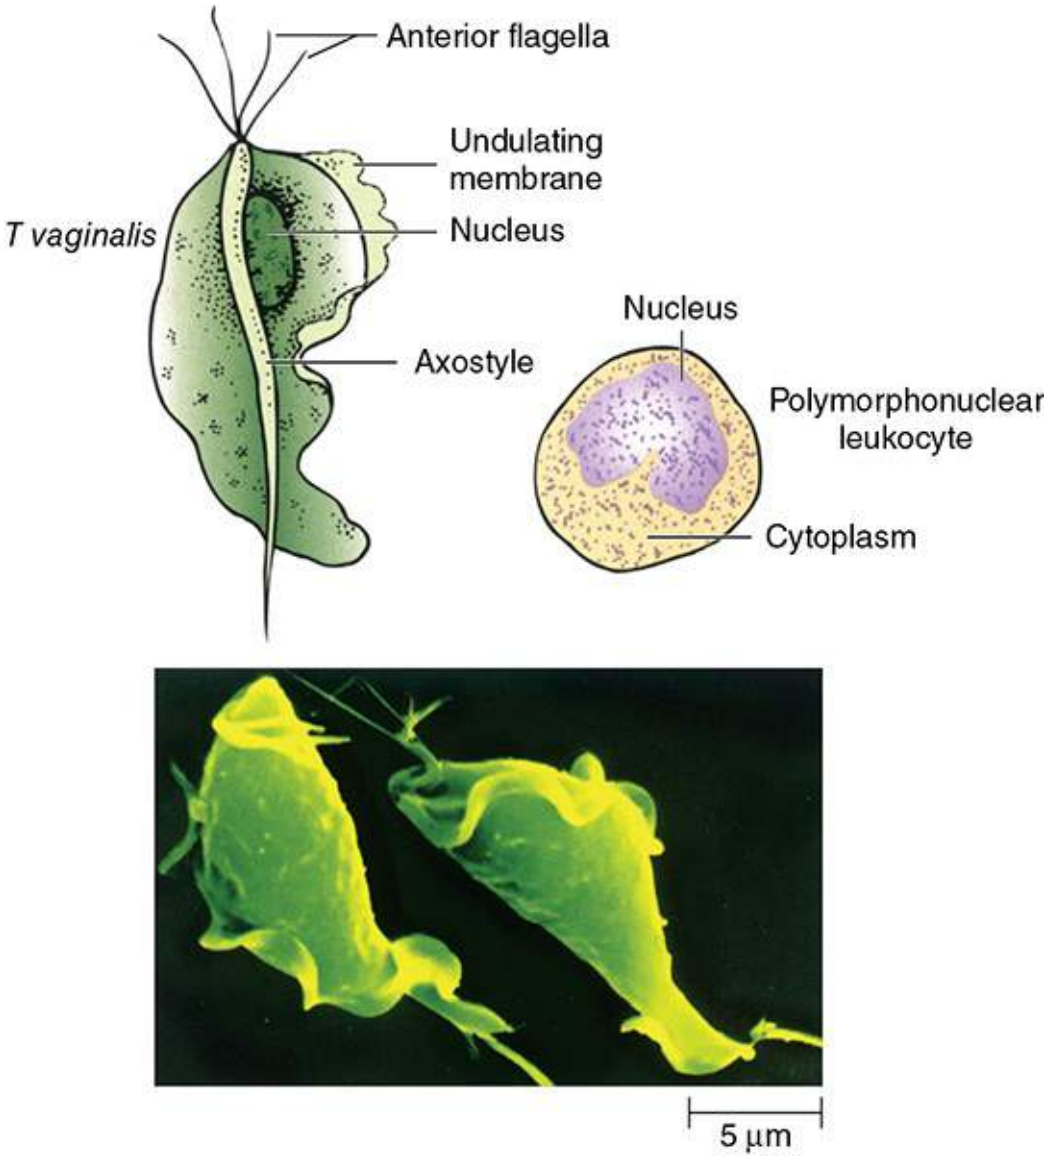

FIGURE 53–1. ***Trichomonas vaginalis.*** The parasite and its structures are shown in relation to the size of a polymorphonuclear leukocyte (*top*). The micrograph below illustrates their use for motility. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

Cultivable *in vitro*

*** Lacks cyst form, may survive hours outside host**

The organism can be grown on artificial media under anaerobic conditions at pH 5.5 to 6.0. Soluble nutrients are absorbed across the cell membrane. A variety of carbohydrates are degraded to short-chained organic acids. Pyruvate is produced via glycolysis and reduced to lactate, part of which enters structures called hydrogenosomes. Molecular hydrogen and ATP are produced in the hydrogenosomes. These structures are analogous to mitochondria, which *T vaginalis* lacks. Although *T vaginalis* lacks a cyst form, the trophozoite can survive outside of the human host for 1 to 2 hours on moist surfaces. In urine, semen, and water, it may be viable for up to 24 hours, making it one of the most resistant of protozoan trophozoites. Attempts to infect laboratory animals have met with limited success.

TRICHOMONIASIS

EPIDEMIOLOGY

*** Transmission usually sexual**

Prevalence linked to sexual activity

Trichomoniasis is a cosmopolitan disease usually transmitted by sexual intercourse. An estimated 8 million infections occur in the United States annually. Worldwide this figure reaches >200 million cases. Twenty-five percent of sexually active women become infected at some time during their lives and 30% to 70% of their male sexual partners are also parasitized, at least transiently. As would be expected, the likelihood of acquiring the disease correlates directly with the number of sexual contacts. Infection is rare in adult virgins, whereas rates as high as 70% are seen among prostitutes, sexual partners of infected patients, and individuals with other venereal diseases. In women, the peak incidence of trichomoniasis is between 16 and 35 years of age, but there is still a relatively high prevalence in the 30- to 50-year age group.

Nonvenereal transmission uncommon

Nonvenereal transmission is uncommon. Transfer of organisms on shared

washcloths may explain, in part, the high frequency of infection seen among institutionalized women. Female neonates are occasionally noted to harbor *T vaginalis*, presumably acquiring it during passage through the birth canal. High levels of maternal estrogen produce a transient decrease in the vaginal pH of the child, rendering it more susceptible to colonization. Within a few weeks, estrogen levels drop, the vagina assumes its premenarcheal state, and the parasite is eliminated.

PATHOGENESIS AND IMMUNITY

Direct contact of *T vaginalis* with the squamous epithelium of the genitourinary tract results in destruction of the involved epithelial cells and the development of a neutrophilic inflammatory reaction and petechial hemorrhages. Attachment appears to be mediated by adhesins, laminin-binding proteins, and lectin-binding carbohydrates. Trophozoites can secret a variety of proteinases that undoubtedly help initiate contact-dependent cytolytic events. These proteinases are also capable of degrading immunoglobulin-G (IgG) and IgA. A contact-independent mechanism of cell damage has also been shown to correlate with the presence of a 200 kDa glycoprotein that is heat and acid labile. Changes in the microbial, hormonal, and pH environment of the vagina as well as factors inherent to the infecting parasite are thought to modulate the severity of the pathologic changes.

Damages epithelial cells on contact

Infection of the vaginal epithelium triggers innate responses by stimulating Toll-like receptors that trigger secretion of proinflammatory cytokines. This brings about a neutrophil and CD4+ response. Humoral and cellular immune responses follow, although they do not appear to result in clinically significant immunity. Because of the proinflammatory response produced, women with this infection are at greater risk of human immunodeficiency virus (HIV) infection. *Trichomonas vaginalis* is also capable of phenotypically varying surface antigenic determinants to help it escape immune detection.

TRICHOMONIASIS: CLINICAL ASPECTS

MANIFESTATIONS

* Chronic vaginitis lasting weeks to months

In women, *T vaginalis* produces a persistent vaginitis. Although up to 50% are asymptomatic at the time of diagnosis, most develop clinical manifestations within 6 months. Approximately 75% develop a discharge, which is typically accompanied by vulvar itching or burning (50%), dyspareunia (50%), dysuria (50%), and a disagreeable odor (10%). Although fluctuating in intensity, symptoms usually persist for weeks or months. Commonly, manifestations worsen during menses and pregnancy. Eventually, the discharge subsides, even though the patient may continue to harbor the parasite. In symptomatic patients, physical examination reveals reddened vaginal and endocervical mucosa. In severe cases, petechial hemorrhages and extensive erosions are present. A red, granular, friable endocervix (strawberry cervix) is a characteristic but uncommon finding. An abundant discharge is generally seen pooled in the posterior vaginal fornix. Although classically described as thin, yellow, and frothy in character, the discharge more frequently lacks these characteristics. Trichomoniasis may increase the risk of preterm birth and enhance susceptibility to HIV infections.

* Urethral, prostatic infection in men asymptomatic

The urethra and prostate are the usual sites of trichomoniasis in men; the seminal vesicles and epididymis may be involved on occasion. Infections are usually asymptomatic, possibly because of the efficiency with which the organisms are removed from the urogenital tract by voided urine. Symptomatic men complain of recurrent dysuria and scant, nonpurulent discharge. Acute purulent urethritis has been reported rarely. Trichomoniasis should be suspected in men presenting with nongonococcal urethritis, or a history of either prior trichomonal infection or recent exposure to trichomoniasis.

DIAGNOSIS

* Wet mount trophozoite examination sufficient in most

The diagnosis of trichomoniasis rests on the detection and morphologic identification of the organism in the genital tract. Identification is accomplished most easily by examining a wet mount preparation for the presence of motile organisms. In women, a drop of vaginal discharge is the most appropriate specimen; in men, urethral exudate or urine sediment after prostate massage may

be used. Although highly specific when positive, wet mounts have a sensitivity of only 50% to 60%. They are most likely to be negative in asymptomatic or mildly symptomatic patients and in women who have douched in the previous 24 hours. Giemsa- and Papanicolaou-stained smears provide little additional help. The recent introduction of a commercial system that allows direct, rapid microscopic examination without the need for daily sampling may ameliorate this situation. Direct immunofluorescent antibody staining has a sensitivity of 70% to 90%. Parasitic culture, though more sensitive, requires several days to complete and is frequently unavailable. Nucleic acid amplification (NAA) methods have been shown to be the most sensitive for diagnosis.

TREATMENT

*** Metronidazole cures 95%**

Oral metronidazole or tinidazole is extremely effective in recommended dosage, curing more than 95% of all *Trichomonas* infections. It may be given as a single dose or over 7 days. Simultaneous treatment of sexual partners may minimize recurrent infections, particularly when single-dose therapy is used for the index case. Because of the disulfiram-like activity of the nitroimidazoles, alcohol consumption should be suspended during treatment. The drug should never be used during the first trimester of pregnancy because of its potential teratogenic activity. Use in the last two trimesters is unlikely to be hazardous but should be reserved for patients whose symptoms cannot be adequately controlled with local therapies. High-dose, long-term metronidazole treatment has been shown to be carcinogenic in rodents. No association with human malignancy has been described to date. NAA-based studies have shown that this infection is underdiagnosed, and therefore infections are undertreated contributing to the continued high incidence of this parasite.

KEY CONCLUSIONS

- *Trichomonas vaginalis* is a common sexually transmitted disease.
- Infected women may experience vaginitis, discharge, and dysuria.
- In females, parasites induce contact-dependent cytotoxicity that leads to inflammation.
- Infection with *T vaginalis* may predispose to HIV infection.
- Infected men are mostly asymptomatic.

- All sexual partners should be treated.

GIARDIA DUODENALIS, SYN. LAMBLIA

Overview

Giardia duodenalis is a sting-ray shaped flagellate which also has a cyst stage. Giardiasis, caused by *G duodenalis*, is an intestinal infection that is fecally-oral transmitted, either directly or indirectly via untreated water sources. It is a common infection worldwide and is most frequent in children. Infection is most often symptomatic, especially in adults. When disease occurs, it is in the form of a diarrhea lasting up to 4 weeks with foul-smelling, greasy stools. Abdominal pain, nausea, and vomiting are also present.

PARASITOLOGY

G duodenalis was first described by Anton von Leeuwenhoek 300 years ago when he examined his own diarrheal stool with one of the first primitive microscopes. It was not until the last several decades, however, that this cosmopolitan flagellate became widely regarded in the United States as a pathogen. Of the six other flagellated protozoans known to parasitize the alimentary tract of humans, only one, *Dientamoeba fragilis*, has been credibly associated with disease. Definitive confirmation or refutation of its pathogenicity will, it is hoped, not require the passage of another three centuries.

*** Trophozoite and cyst stages**

*** Moves about duodenum, jejunum with tumbling motility**

Unlike *T vaginalis*, *Giardia* possesses both a trophozoite and a cyst form (**Figure 53–2**). It is a stingray-shaped trophozoite 9 to 21 µm in length, 5 to 15 µm in width, and 2 to 4 µm in thickness. When viewed from the top, the organism's two nuclei and central parabasal bodies give it the appearance of a face with two bespectacled eyes and a crooked mouth. It is uncertain why this organism has two nuclei, but both are transcriptionally active. Four pairs of flagella—anterior, lateral, ventral, and posterior—reinforce this image by suggesting the presence of hair and chin whiskers. These distinctive parasites reside in the duodenum and jejunum, where they thrive in the alkaline

environment and absorb nutrients from the intestinal tract. They move about the unstirred mucous layer at the base of the microvilli (**Figure 53–3**) with a peculiar tumbling or "falling leaf" motility or, with the aid of a large ventral disk, attach themselves to the brush border of the intestinal epithelium. The exact molecular mechanism by which the ventral disk mediates attachment has not been resolved but is thought, in part, to involve flagellar motility. Unattached organisms may be carried by the fecal stream to the large intestine.

*** Cystic forms in colon**

*** Resistant cysts transmitted host to host**

In the descending colon, if transit time allows, the flagella are retracted into cytoplasmic sheaths and a smooth, clear cyst wall is secreted. These forms are oval and somewhat smaller than the trophozoites. With maturation, the internal structures divide, producing a quadrinucleate organism harboring two ventral discs, four kinetosomes, and eight axonemes. When fixed and stained, the cytoplasm pulls away from the cyst wall in a characteristic fashion. The mature

cysts, which are the infective form of the parasite, may survive in cold water for more than 2 months and are resistant to concentrations of chlorine generally used in municipal water systems. They are transmitted from host to host by direct and indirect fecal–oral routes. In the duodenum of a new host, the cytoplasm divides to produce two binucleate trophozoites.

Giardia is amitocondriate like *Trichomonas*. Instead, *Giardia* possesses mitosomes, which like the hydrogenosomes of *Trichomonas* are thought to represent mitochondrial adaptations in these aerotolerant anaerobe parasites. *Giardia* can respire aerobically or anaerobically with glucose as the main substrate for respiration. Axenic cultivation of this organism has been achieved *in vitro*. Bile salts enhance the parasite's growth. Although *Giardia* has largely been thought to be an asexual parasite, evidence for genetic recombination, hinting at a form of sexual recombination, has recently been reported.

Organisms of the genus *Giardia* are among the most widely distributed of intestinal Protozoa; they are found in fish, amphibians, reptiles, birds, and mammals. At first, it was assumed that *Giardia* strains found in different animals were host-specific; on this basis, some 40 different species were described. Since it is now recognized that some strains can infect multiple animal hosts, the practice of assigning species status by the host from which the parasite was recovered is considered invalid. At present, only five species are considered valid and of these, only *G duodenalis* infects humans. This parasite is also commonly referred to as *G lamblia* or *G intestinalis* in much of the current literature.

GIARDIASIS

EPIDEMIOLOGY

*** Transmission facilitated by poor hygiene, IgA deficiency**

High rates in day care centers

Common among male homosexuals

Giardiasis has a cosmopolitan distribution; its prevalence is highest in areas with poor sanitation and among populations unable to maintain adequate personal

hygiene. In developing countries, infection rates may reach 25% to 30%; in the United States, *G duodenalis* is found in 4% of stools submitted for parasitologic examination, making it, along with *Cryptosporidium*, this country's most frequently identified intestinal parasite. All ages and economic groups are represented, but young children and young adults are preferentially involved. Children with immunoglobulin deficiencies are more likely to acquire the flagellate, possibly because of a deficiency in intestinal IgA. Giardiasis is also common among attendees of day care centers. Attack rates of over 90% have been seen in the ambulatory non–toilet-trained population (age 1-2 years) of these institutions, suggesting direct person-to-person transmission of the parasite. The frequency with which secondary cases are seen among family contacts reinforces this probability. Undoubtedly, direct fecal spread is also responsible for the high infection rate among male homosexuals. In several recent studies, the prevalence of giardiasis and/or amebiasis in that population has ranged from 11% to 40% and is correlated closely with the number of oral–anal sexual contacts.

*** Water- or foodborne traveler's diarrhea lasts for weeks**

*** Beavers, other mammals possible sources**

Waterborne and, less frequently, foodborne transmission of *G duodenalis* has also been documented, and probably accounts for the frequency with which American travelers to Third World nations acquire infection. Unlike the typical bacterial diarrhea syndrome seen in travelers, the diarrhea begins late during travel and may persist for several weeks. More than 20 waterborne outbreaks of giardiasis have also been reported in the United States. The sources have included swimming pools, untreated pond or stream water, sewage-contaminated municipal water supplies, and chlorinated but inadequately filtered water. In a few of these outbreaks, epidemiologic data have suggested that wild mammals, particularly beavers, served as the reservoir hosts. Despite the evidence for zoonotic transmission, this remains a controversial topic. In some areas of the world, where different animals, including man's closest friend, the dog, and many have been shown to be infected with *Giardia*, the infecting genotypes differed. In others, the same genotypes were demonstrated in man and animals. In most cases, humans sampled were shown to predominantly harbor human genotypes. Extensive infectivity studies using human genotypes have not been conducted.

PATHOGENESIS

Malabsorption, jejunal pathology mechanisms uncertain

Disease manifestations appear related to intestinal malabsorption, particularly of fat and carbohydrates. Disaccharidase deficiency with lactose intolerance, altered levels of intestinal peptidases, and decreased vitamin B12 absorption have been demonstrated. The precise pathogenetic mechanisms responsible for these changes remain poorly understood. Mechanical blockade of the intestinal mucosa by large numbers of *Giardia*, damage to the brush border of the microvilli by the parasite's ventral disc, organism-induced deconjugation of bile salts, altered intestinal motility, accelerated turnover of mucosal epithelium, and mucosal invasion have all been suggested. None of these correlates well with clinical manifestations. Patients with severe malabsorption have jejunal colonization with enteric bacteria or yeasts, suggesting that these organisms may act synergistically with *Giardia.* Eradication of the associated microorganism, however, has not uniformly resulted in clinical improvement. Jejunal biopsies sometimes reveal a flattening of the microvilli and an inflammatory infiltrate, the severity of which correlates roughly with that of the clinical disease. Generally, both malabsorption and the jejunal lesions have been reversed with specific treatment. The demonstration of occasional trophozoites in the submucosa raises the possibility that these changes reflect T-lymphocyte–mediated damage.

IMMUNITY

Predisposing factors include hypochlorhydria, immunocompromise

Susceptibility to giardiasis has been related to several factors, including strain virulence, inoculum size, achlorhydria or hypochlorhydria, and immunologic abnormalities. In one experimental study, humans were challenged with varying doses from as few as 10 cysts. They were uniformly parasitized when 100 or more were ingested. Several workers have noted the frequency with which giardiasis occurs in achlorhydric and hypochlorhydric individuals. *Giardia* infection produces little or no host inflammation suggesting that local responses may help control the infection. Both innate responses involving nitric oxide, defensins, phagocytic, mast and dendritic cells, and adaptive responses involving IgA and T cells have been identified in mouse models of infections and are thought to operate in human infections as well. Animal studies have

demonstrated that *Giardia*-specific, secretory IgA (sIgA) antibodies inhibit attachment of trophozoites to intestinal epithelium, perhaps by blocking parasite surface lectins. Moreover, antitrophozoite IgM or IgG antibodies, plus complement, are known to be capable of killing *Giardia* trophozoites. Another indication that antibodies play a role in controlling infections is that humans with immunodeficiencies involving antibody production are more likely to suffer from chronic giardiasis. *Giardia* trophozoites are also capable of changing their surface coat variant surface proteins (VSPs). VSP switching appears to be transcriptionally controlled. Over 200 VSP genes have been identified for this organism. This process occurs once every 6 to 16 generations. The process of VSP switching undoubtedly helps the organism evade host responses.

GIARDIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Subclinical infections common

*** Diarrhea, cramping, flatus, greasy stools**

In endemic situations, over two-thirds of persons infected with giardiasis are asymptomatic. In acute outbreaks, this ratio of asymptomatic to symptomatic patients is usually reversed. When they do occur, symptoms begin 1 to 3 weeks after exposure and typically include diarrhea, which is sudden in onset and explosive in character. The stool is foul-smelling, greasy in appearance, and floats. It is devoid of blood or mucus. Upper abdominal cramping is common. Large quantities of intestinal gas produce abdominal distention, sulfuric eructations, and abundant flatus. Nausea, vomiting, and low-grade fever may be present. The acute illness generally resolves in 1 to 4 weeks; in children, however, it may persist for months, leading to significant malabsorption, weight loss, and malnutrition.

Subacute and chronic with weight loss

Lactose intolerance

In many adults, the acute phase of giardiasis is often followed by a subacute

or chronic phase characterized by intermittent bouts of mushy stools, flatulence, “heartburn,” and weight loss that persist for weeks or months. At times, patients presenting in this fashion deny having experienced the acute syndrome described previously. In the majority, symptoms and organisms eventually disappear spontaneously. It is not uncommon for lactose intolerance to persist after eradication of the organisms. This condition may be confused with an ongoing infection, and the patient may be subjected to unnecessary treatment.

DIAGNOSIS

*** Trophozoites and cysts in stool, duodenal aspirates**

*** EIAs detect *Giardia* antigen in stool**

The diagnosis of giardiasis is made by finding the cyst in formed stool or the trophozoite in diarrheal stools, duodenal secretions, or jejunal biopsy specimens. In acutely symptomatic patients, the parasite can usually be demonstrated by examining one to three stool specimens after appropriate concentration and staining. In chronic cases, excretion of the organism is often intermittent, making parasitologic confirmation more difficult. Many of these patients can be diagnosed by examining specimens taken at weekly intervals over 4 to 5 weeks. Another approach is to perform an enterotest, in which a bead encapsulated in a gelatinous capsule and attached to a thread is swallowed and then retrieved. The recovered bead is washed onto a slide and examined for active trophozoites. Alternatively, duodenal secretions can be collected and examined for trophozoites in trichrome or Giemsa-stained preparations. There are now several reliable, commercially available, enzyme immunoassays (EIAs) for the direct detection of parasite antigen in stool. They appear to be as sensitive and specific as microscopic examinations. Immunofluorescent assays for the detection of cysts are also available. The organism can be grown in culture, but the methods are not currently adaptable to routine diagnostic work. NAA assays are highly sensitive and can distinguish infecting genotypes.

TREATMENT

Several drugs available

Close contacts should be examined

Five drugs are currently available for the treatment of giardiasis in the United States: quinacrine hydrochloride, metronidazole, tinidazole, furazolidone, and paromomycin. Quinacrine and metronidazole are effective (70-95%) and are preferred for patients capable of ingesting tablets. Furazolidone is used by pediatricians because of its availability as a liquid suspension, but it has the lowest cure rate. These three agents require 5 to 7 days of therapy. Tinidazole, an oral agent that has been widely used in many countries for more than 25 years outside the United States, is safe and effective as a single-dose treatment. This drug has been shown to be the most effective. It has been available in the United States since 2004. Because of the potential for person-to-person spread, it is important to examine and, if necessary, treat close physical contacts of the infected patient, including playmates at nursery school, household members, and sexual contacts. None of the aforementioned agents should be used in pregnant women because of their potential teratogenicity. Paromomycin, a nonabsorbed but somewhat less effective agent, may be used in this circumstance.

Should all patients diagnosed with *G duodenalis* be treated?

PREVENTION

Avoid drinking untreated surface water

Hikers should avoid ingestion of untreated surface water, even in remote areas, because of the possibility of contamination by feces of other people and potentially by feces of infected animals. Adequate disinfection can be accomplished with halogen tablets yielding concentrations higher than that generally achieved in municipal water systems. The safety of the latter results from additional flocculation and filtration procedures. Use of portable filtration units having a nominal pore size of 1 μm is even more effective. Boiling of water, if possible, is even better.

Think ▸▸ Apply 53-1: Since this infection is easily spread, especially in children, many schools mandate that children with a diagnosis of giardiasis stay at home and not return until

symptoms have abated. Hopefully they receive treatment as well. Family members of sick children should monitor themselves for signs of disease and receive treatment if they come down with giardiasis. Since this is such a common disease in developing countries, it may not be possible to treat all who are infected. However, drugs are usually available over the counter and relatively cheap.

KEY CONCLUSIONS

- *Giardia* infections occur worldwide but are most common in underdeveloped countries lacking good sanitation practices.
- Infection is fecal–oral, either directly or indirectly, and can be caused by ingesting as few as 10 cysts.
- Children are more likely to be symptomatic compared to adults.
- Malabsorption is often linked to symptoms which may include persistent diarrhea, foul-smelling stools, abdominal pain, nausea, and vomiting.
- Cyst shedding may be intermittent, making microscopic detection difficult based on a single stool sample.

▪ Blood and Tissue Flagellates

*** Life cycle includes insect host**

*** Promastigote, epimastigote in insects**

*** Trypomastigote, amastigote in humans**

Two of the many genera of hemoflagellates, *Leishmania* and *Trypanosoma*, are pathogenic to humans. They reside and reproduce within the gut of specific insect hosts. When these vectors feed on a susceptible mammal, the parasite penetrates the feeding site, invades the blood and/or tissue of the new host, and multiplies to produce disease. American trypanosomes differ somewhat in that the infective parasite is passed in the feces of the specific vector during the act of feeding on its host and later rubbed into the feeding site wound. The life cycle is completed when a second insect ingests the infected mammalian blood or tissue fluid. During their passage through insect and vertebrate hosts, flagellates

undergo developmental change. Within the gut of the insect (and in culture media), the organism assumes the promastigote (*Leishmania*) or epimastigote (*Trypanosoma*) form (**Figure 53–4**). These protozoa are motile and fusiform and have a blunt posterior end and a pointed anterior end from which a single flagellum projects. They measure 15 to 30 μm in length and 1.5 to 4.0 μm in width. In the promastigote form, the kinetoplast complex is located in the anterior extremity, and the flagellum exits from the cell immediately. The kinetoplast complex of the epimastigote form, in contrast, is located centrally, just in front of the vesicular nucleus. The flagellum runs anteriorly in the free edge of an undulating membrane before passing out of the cell. In the mammalian host, hemoflagellates appear as trypomastigotes (*Trypanosoma*) or amastigotes (*Leishmania, T cruzi*). The former circulate in the bloodstream and closely resemble the epimastigote form, except that the kinetoplast complex is in the posterior end of the parasite. The amastigote stage is found intracellularly. It is round or oval, measures 1.5 to 5.0 μm in diameter, and contains a clear nucleus with a central karyosome. Although it has a kinetoplast complex and an axoneme, there is no free flagellum.

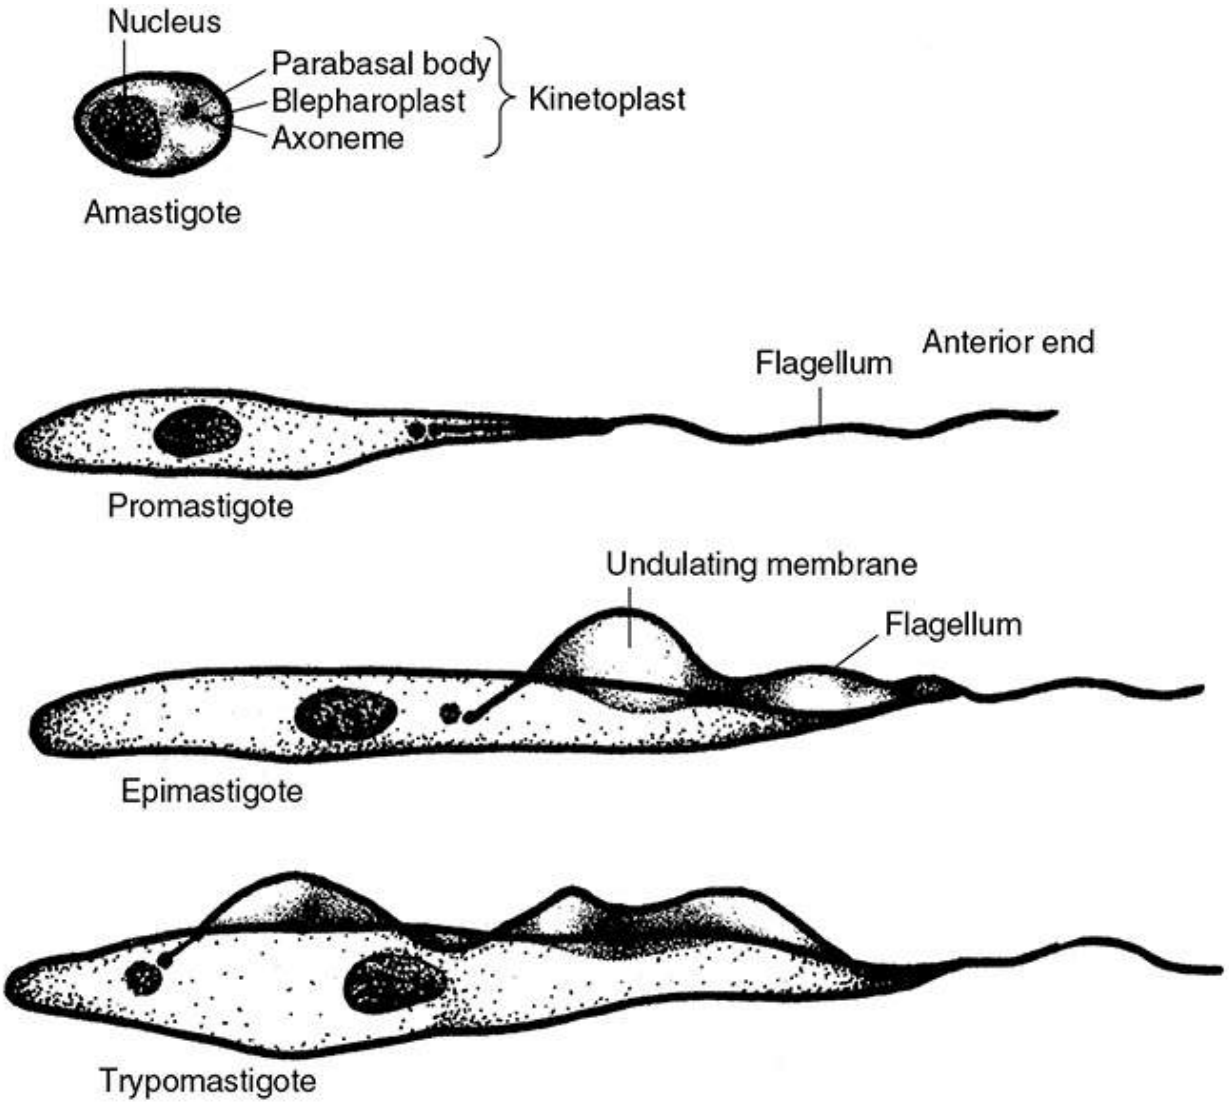

FIGURE 53–4. Stages in the life cycle of the hemoflagellates (Trypanosomidae).

The flagellated forms move in a spiral fashion, and all reproduce by longitudinal binary fission. The flagellum itself does not divide; rather, a second one is generated by one of the two daughter cells. The organisms use carbohydrate obtained from the body fluids of the host in aerobic respiration. Glycolysis is carried out in structures called glycosomes. In addition, these organisms possess a kinetoplast/mitochondrion complex. Up to 15% of total cellular DNA is found within the kinetoplast. Profound changes occur in this complex as the parasite transits from its vertebrate to invertebrate host since the parasite needs to respire more efficiently under conditions encountered in the latter host.

LEISHMANIA SPP.

Overview

Leishmania are obligate intracellular parasites distinguished by a slender body and polar flagellum. Leishmaniasis is caused by different species of *Leishmania* and results in a variety of clinical presentations dependent upon the infecting species. The most common forms of the disease are classified as cutaneal or visceral with accompanying disease manifestations. Cutaneal lesions may or may not heal depending on the infecting species and immune status of the host. Visceral leishmaniasis is often acute and highly lethal.

PARASITOLOGY

Species morphologically similar; differ in molecular features

Leishmania species are obligate intracellular parasites of mammals. Several strains can infect humans; they are all morphologically similar, resulting in some confusion over their proper speciation. Definitive identification of these strains requires isoenzyme analysis, monoclonal antibodies, kinetoplast DNA buoyant densities, DNA hybridization, and DNA restriction endonuclease fragment analysis or chromosomal karyotyping using pulse-field electrophoresis. The many strains can be more simply placed in four major groups based on their serologic, biochemical, cultural, nosologic, and behavioral characteristics. For the sake of clarity, these groups are discussed as individual species. Each, however, contains a variety of strains that have been accorded separate species or subspecies status by some authorities. The organisms can be propagated in hamsters and in a variety of commercially available liquid media.

DISEASE TRANSMISSION

Cutaneous ulcer or visceral infection (kala azar)

It is estimated that over 20 million people worldwide suffer from leishmaniasis, and 1 to 2 million additional individuals acquire the infection annually. *Leishmania tropica* in the Old World and *Leishmania mexicana* in the New World produce a localized cutaneous lesion or ulcer, known popularly as oriental sore or chiclero ulcer; *Leishmania braziliensis* is the cause of American

mucocutaneous leishmaniasis (espundia); and *Leishmania donovani* and *Leishmania infantum* are the etiologic agents of kala azar, a disseminated visceral disease.

*** Transmitted by nocturnally feeding sandflies**

*** Complement mediates macrophages attachment**

*** Inhibit macrophage killing**

Amastigotes infect sandfly

All five groups are transmitted by phlebotomine sandflies. These small, delicate, short-lived insects are found in animal burrows and crevices throughout the tropics and subtropics. At night, they feed on a wide range of mammalian hosts. Amastigotes ingested during a meal assume the flagellated promastigote form, multiply within the gut, and eventually migrate to the proboscis. When the fly next feeds on a human or animal host, the promastigotes are injected into the skin of the new host together with salivary peptides capable of inactivating host macrophages. Here, they activate complement by the classic (*L donovani*) or alternative pathway and are opsonized with C3, which mediates attachment to the CR1 and CR3 complement receptors of macrophages. After phagocytosis, the promastigotes lose their flagella and multiply as the rounded amastigote form within the phagolysosome. In stained smears, the parasites take on a distinctive appearance and have been termed Leishman–Donovan bodies. Intracellular survival is mediated by a surface lipophosphoglycan and an abundance of membrane-bound acid phosphatase, which inhibits the macrophage's oxidative burst and/or inactivates lysosomal enzymes. Continued multiplication leads to the rupture of the phagocyte and release of the daughter cells. Some may be taken up by a feeding sandfly; most invade neighboring mononuclear cells.

Cellular immune responses produce cure

Mucocutaneous metastases in *L braziliensis*

Continuation of this cycle results in extensive histiocytic proliferation. The course of the disease at this point is determined by the species of parasite and the response of the host's T cells. CD4+ T cells of the T_H1 type secrete interferon (IFN)-γ in response to leishmanial antigens. This, in turn, activates macrophages to kill intracellular amastigotes by the production of toxic nitric oxide. In the

localized cutaneous forms of leishmaniasis, this immune response results in the development of a positive delayed skin (leishmanin) reaction, lymphocytic infiltration, reduction in the number of parasites, and, eventually, spontaneous disappearance of the primary skin lesion. In infections with *L braziliensis*, this sequence may be followed weeks to months later by mucocutaneous metastases. These secondary lesions are highly destructive, presumably because of the host's hypersensitivity to parasitic antigens. Scrapings from these lesions show a noticeable absence of lymphocytes indicating that the cell-mediated immune response has been impaired.

* Lack of cellular immune response in disseminated, chronic infections

Some strains of *L tropica* and *L mexicana* fail to elicit an effective intracellular immune response in certain hosts. Such patients appear to have a selective suppressor T-lymphocyte–mediated anergy to leishmanial antigens. Consequently, there is no infiltration of lymphocytes or decrease in the number of parasites. The skin test remains negative, and the skin lesions disseminate and become chronic (diffuse cutaneous leishmaniasis). In infections with *L donovani*, there is a more dramatic inhibition of the T_H1 response. The leishmanial organisms can disseminate through the bloodstream to the visceral organs, possibly because of a relative resistance of *L donovani* to the natural microbicidal properties of normal serum, and/or their ability to better survive at 37°C than strains of *Leishmania*, causing cutaneous lesions. Although dissemination is associated with the development of circulating antibodies, they do not appear to serve a protective function and may, via the production of immune complexes, be responsible for the development of glomerulonephritis. A simplified outline of the immune responses in different forms of leishmaniasis is presented in **Table 53-2.**

TABLE 53–2 Immune Response to Leishmaniasis

HUMAN DISEASE	PARASITE	LEISHMANIN SKIN TEST	NUMBER OF LYMPHOCYTES	NUMBER OF PARASITES	PROGNOSIS	HUMORAL ANTIBODY TITER
Localized skin ulcer (oriental sore, chiclero ulcer, uta)	*L tropica* *L mexicana*	Positive	Many	Few	Good	Low
Mucocutaneous lesions (espundia)	*L braziliensis*	Positive	Many	Few	Poor	Low
Disseminated cutaneous						
Ethiopian	*L tropica*[a]	Negative	Few	Many	Poor	High
American	*L mexicana*[a]					
Disseminated visceral (kala azar)	*L donovani*	Negative	Few	Many	Poor	High

[a]Different subspecies from those causing localized skin ulcers.

LOCALIZED CUTANEOUS LEISHMANIASIS

EPIDEMIOLOGY

Distribution related to human, rodent reservoirs

Urban reservoir is canine

Cutaneous leishmaniasis is a zoonotic infection of tropical and subtropical rodents. It is particularly common in areas of Central Asia, the Indian subcontinent, Middle East, Africa, the Mediterranean littoral, and Central and South America. In the latter area, *L mexicana* infects several species of arboreal rodents. Humans become involved when they enter forested areas to harvest chicle for chewing gum and are bitten by infected sandflies. In the Eastern Hemisphere, the desert gerbil and other burrowing rodents serve as the reservoir hosts of *L tropica.* Human infection occurs when rural inhabitants come in close contact with the burrows of these animals. In the Mediterranean area, southern Russia, and India, human disease involves urban dwellers, primarily children. In this setting, the domestic dog serves as the reservoir, although sandflies may also transmit *L tropica* directly from human to human.

LOCALIZED CUTANEOUS LEISHMANIASIS

MANIFESTATIONS

*** Chronic, self-limiting skin ulceration**

Strain-specific immunity

Lesions usually appear on the extremities or face (the ear in cases of chiclero ulcer) weeks to months after the bite of the sandfly (**Figure 53–5**). They first appear as pruritic papules, often accompanied by regional lymphadenopathy. In a few months, the papules ulcerate, producing painless craters with raised erythematous edges, sharp walls, and a granulating base. Satellite lesions may form around the edge of the primary sore and fuse with it. Multiple primary lesions are seen in some patients. Spontaneous healing occurs in 3 to 12 months, leaving a flat, depigmented scar. Occasionally, the lesions fail to heal, particularly on the ears, leading to progressive destruction of the pinna. A permanent strain-specific immunity usually follows healing. Multiple, disseminated nonhealing lesions may be seen in patients with acquired immunodeficiency syndrome (AIDS).

FIGURE 53–5. Cutaneous leishmaniasis. A well-developed lesion on the forehead of a 7-year-old girl. This more closely resembles a lesion that is progressing toward healing. See comments associated with this figure in the text. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

DIAGNOSIS AND TREATMENT

*** Demonstrate Leishman–Donovan bodies or culture from tissue**

In endemic areas, the diagnosis of localized cutaneous leishmaniasis is made on clinical grounds and confirmed by the demonstration of the organism in the advancing edge of the ulcer. Material collected by biopsy, curettage, or aspiration is smeared and/or sectioned, stained, and examined microscopically for the pathognomonic Leishman–Donovan bodies. Material should also be cultured in liquid media. The leishmanin skin test becomes positive early during the disease and remains so for life. Recently, it has been demonstrated that small numbers of *Leishmania* may be detected in tissue by NAA methods, and strains distinguished with probes to kinetoplast DNA. These techniques, though not widely available, permit direct, rapid, and specific diagnosis of all leishmanial infections.

Patients with small, cosmetically minor lesions that do not involve the mucous membrane may be carefully followed without treatment. Pentavalent antimonial agents and liposomal amphotericin B have proved to be effective chemotherapeutic agents for individuals with more consequential lesions. Recently, ketoconazole and itraconazole, alone or in combination with the previously mentioned agents, have been found to be effective in some forms of cutaneous leishmaniasis. Paromomycin has also proved to be useful. What has become clear is that what works for one form of cutaneal leishmaniasis may not work for another. Combinations of thermotherapy and drugs have also been tried. Bacterial superinfections are treated with appropriate antibiotics. Prophylactic measures include the control of the sandfly vector by use of insect repellents and fine mesh screening on dwellings.

MUCOCUTANEOUS LEISHMANIASIS

EPIDEMIOLOGY

*** Rodent reservoir of *L braziliensis***

Leishmania braziliensis causes a natural infection in the large forest rodents of tropical Latin America. Sandflies transmit the infection to humans engaged in military activities, road builders, opening jungle areas for new settlements, and others.

MUCOCUTANEOUS LEISHMANIASIS

MANIFESTATIONS

*** Primary metastasizes to oral, nasal areas**

A primary skin lesion similar to oriental sore develops 1 to 4 weeks after sandfly exposure. Occasionally, it undergoes spontaneous healing. More commonly, it progressively enlarges, often producing large vegetating lesions. After a period of weeks to years, painful, destructive, metastatic mucosal lesions of the mouth, nose, and occasionally the perineum, appear in 2% to 50% of the patients. Sometimes, decades pass and the primary lesion totally resolves before the metastases manifest themselves. Destruction of the nasal septum produces the characteristic tapir nose. Erosion of the hard palate and larynx may render the patient aphonic. In blacks, the lesions are often large, hypertrophic, polypoid masses that deform the lips and cheeks. Fever, anemia, weight loss, and secondary bacterial infections are common. Mucosal lesions caused by other *Leishmania* species may be seen after visceral dissemination in AIDS patients.

Detection of organisms as with cutaneous leishmaniasis

The diagnosis of mucocutaneous leishmaniasis is made by finding the organisms in the lesions as described for localized cutaneous leishmaniasis. Because the propensity to metastasize to mucocutaneous sites is specific to certain species and subspecies, precise identification of the responsible organism as described in the introduction is of clinical importance. The leishmanin skin test yields positive results, and most patients have detectable antibodies. As described for cutaneous leishmaniasis, it is now possible to provide a rapid, direct, species-specific diagnosis using NAA methods and probes to kinetoplast DNA.

TREATMENT

Treatment is accomplished with the agents described later in the chapter for kala azar. Advanced lesions are often refractory and relapse is common. Cured patients are immune to reinfection. Control measures, other than insect repellents and screening of dwellings, are impractical because of the sylvatic nature of the

disease.

DISSEMINATED VISCERAL LEISHMANIASIS (KALA AZAR)

EPIDEMIOLOGY

Geographic differences in reservoirs and disease severity

Kala azar is caused by *L donovani* and *L infantum. L donovani* is found in East Africa and the Indian subcontinent, whereas *L infantum* is found in Europe, North Africa, and Latin America. Its epidemiologic and clinical patterns vary from area to area. In Africa, rodents serve as the primary reservoir. Human cases occur sporadically, and the disease is often acute and highly lethal. In Eurasia and Latin America, the domestic dog is the most common reservoir. Human disease is endemic, primarily involves children, and runs a subacute to chronic course. In India, the human is the only known reservoir, and transmission is carried out by anthropophilic species of sandflies. The disease recurs in epidemic form at 20-year intervals, when a new cadre of nonimmune children and young adults appears in the community. There appears to be a high incidence of visceral leishmaniasis in patients with HIV infection. Presumably, HIV-induced immunosuppression either facilitates acquisition of the disease and/or allows reactivation of latent infection.

PATHOGENESIS

* Invade macrophages of reticuloendothelial system

After the host is bitten by an infected sandfly, the parasites disseminate in the bloodstream and are taken up by the macrophages of the spleen, liver, bone marrow, lymph nodes, skin, and small intestine. Histiocytic proliferation in these organs produces enlargement with atrophy or replacement of the normal tissue.

KALA AZAR: CLINICAL ASPECTS

MANIFESTATIONS

*** Delayed onset, recurrent fever, chronic disease, diarrhea**

Immune complex glomerulonephritis

Most kala azar infections are asymptomatic; these become symptomatic years later during periods of host immunocompromise. Symptomatic disease most commonly manifests itself 3 to 12 months after acquisition of the parasite. It is often mild and self-limited. A minority of infected individuals develop the classic manifestations of kala azar. Fever, which is usually present, may be abrupt or gradual at the onset. It persists for 2 to 8 weeks and then disappears, only to reappear at irregular intervals during the disease. A double-quotidian pattern (two fever spikes in a single day) is a characteristic but uncommon finding. Diarrhea and malabsorption are common in Indian cases, resulting in progressive weight loss and weakness. Physical findings include enlarged lymph nodes and liver, massively enlarged spleen, and edema. In light-skinned persons, a grayish pigmentation of the face and hands is commonly seen, which gives the disease its name (kala azar, black disease). Anemia with resulting pallor and tachycardia are typical in advanced cases. Thrombocytopenia induces petechial formation and mucosal bleeding. The peripheral leukocyte count is usually less than 4000/mm^3; agranulocytosis with secondary bacterial infections contributes to lethality. Serum IgG levels are enormously elevated but play no protective role. Circulating antigen–antibody complexes are present and are probably responsible for the glomerulonephritis seen so often in this disease.

DIAGNOSIS AND TREATMENT

*** Demonstrate Leishman–Donovan bodies or culture**

The diagnosis of kala azar is made by demonstrating the presence of the organism in aspirates taken from the bone marrow, liver, spleen, or lymph nodes. In the Indian form of kala azar, *L donovani* is also found in circulating monocytes. The specimens may be smeared, stained, and examined for the typical Leishman–Donovan bodies (amastigotes in mononuclear phagocytes) or

cultured in artificial media and/or experimental animals. As described for cutaneous leishmaniasis, a limited number of reference laboratories can provide a rapid, direct, species-specific diagnosis using NAA and probes to kinetoplast DNA. Results of the leishmanin skin test are negative during active disease but become positive after successful therapy.

Up to 90% mortality without treatment

The mortality rate in untreated cases of kala azar is 75% to 90%. Treatment with pentavalent antimonial drugs lowers this rate dramatically. Initial therapy, however, fails in up to 30% of African cases, and 15% of those that do respond eventually relapse. Resistant cases are treated with the more toxic pentamidine, amphotericin B, or liposomal amphotericin B. Allopurinol and IFN-γ have proved to be useful adjunctive therapies in resistant cases. A new oral drug, miltefosine, has been shown to be very efficient and safe for both cutaneal and visceral leishmaniasis. Post-Kala azar dermal leishmaniasis, a condition marked by hypopigmented macules, papules, nodules, or facial erythema may appear many years after partial or even successful treatment of visceral leishmaniasis, particularly caused by *L donovani.* The lesions can be confused with those caused by leprosy. The lesions coincide with IFN-γ–producing cells causing skin inflammation as a reaction to persisting parasites in the skin. Patients need to be treated as those for visceral leishmaniasis. Control measures are directed at the *Phlebotomus* vector, with the use of residual insecticides, and at the elimination of mammalian reservoirs by treating human cases and destroying infective dogs.

KEY CONCLUSIONS

- All *Leishmania* spp. are transmitted by sandflies.
- Rodents and/or dogs are principal reservoir hosts.
- Parasites initially take up residence in macrophages and can survive with phagolysosomes.
- Cutaneal and visceral forms of the disease exist depending on the infecting species.
- Immunity is largely cell-mediated.
- HIV infection may enhance leishmaniasis and infection with *Leishmania* may predispose to HIV infection.

AFRICAN *TRYPANOSOMA*

Overview

Three species of *Trypanosoma* are morphologically the same. African trypanosomiasis is a highly lethal meningoencephalitis transmitted to humans by bloodsucking flies of the genus *Glossina*. It occurs in two distinct clinical and epidemiologic forms: West African or Gambian (chronic) sleeping sickness caused by *Trypanosoma brucei gambiense*, and East African or Rhodesian (acute) sleeping sickness caused by *T brucei rhodesiense*. Both of these organisms use antigenic variation to escape immune elimination. This, in turn, causes overall immune depression, leading to disease exacerbation. Nagana, a disease of cattle caused by a closely related trypanosome, renders over 10 million square kilometers of Central Africa unsuitable for animal husbandry.

PARASITOLOGY

*** Epimastigote and trypomastigote forms in tsetse fly**

*** Trypomastigote form injected into blood from fly's saliva**

*** Antigenic variation of glycoprotein coat due to shifting expression of preexisting genes**

The trypanosomes that comprise this group are all related to an ancestral *T brucei*. They are morphologically identical, but vary in their disease-producing capabilities in animals and humans. The three subspecies, known as *T brucei brucei*, *T brucei gambiense*, and *T brucei rhodesiense*, can be distinguished by their biologic characteristics, host preferences, zymodeme types, and DNA hybridization patterns. *Trypanosoma brucei* only infects animals due to the presence of a lytic factor in human serum, while *T brucei gambiense* and *T brucei rhodesiense* give rise to West African and East African Sleeping Sickness in humans, respectively. All of them undergo similar developmental changes during their passage between their insect (tsetse fly) and mammalian host. On ingestion by the tsetse fly (*Glossina* spp.) and after a period of multiplication in the midgut, the parasites migrate to the insect's salivary glands and assume the

epimastigote form. After a period of time they are transformed into metacyclic trypomastigotes, rendering them infectious to mammals. When the fly again takes a meal, the parasites are inoculated with the fly's saliva. Newly emerged and young flies are more efficient transmitters of the disease than older flies. A highly variable surface glycoprotein (VSG) coat, which is acquired in the tsetse fly, accounts for this organism's ability to undergo a process of antigenic variation in its mammalian host. The parasite enters the bloodstream and trypomastigote stage parasites referred to as slender forms divide by longitudinal fission every 5 to 10 hours. For reasons independent of the host's immune response, multiplication eventually slows and some parasites of a dominant population of organisms assume a short, stumpy appearance. These forms have a more developed kinetoplast–mitochondrial complex and constitute the parasites that are infective to the tsetse fly. Near the end of the episode of parasitemia, both slender and stumpy types may be seen in a single blood specimen. Metacyclic trypomastigotes inoculated by a tsetse fly usually contain a population of organisms dominated by a distinctive antigenic type. After a period of time in the vertebrate host, usually a week or so, the antigenic variant type changes. This change is under the control of up to 1000 genes that have been identified in some strains of these organisms that can account for a change in the variant surface glycoprotein antigenic type. Each dominant population usually contains a few organisms that have already undergone antigenic change so that when the host responds immunologically to the dominant population there will be survivors that give rise to the next dominant population. Expression of individual genes largely appears to be controlled by the sequential duplication and subsequent transfer of each gene (expression-linked copy) to one or more areas of the genome responsible for gene expression. Genes located near expression loading sites and referred to as nonduplication activated genes also can give rise to new, and sometimes repeat, antigenic types.

AFRICAN TRYPANOSOMIASIS (SLEEPING SICKNESS)

EPIDEMIOLOGY

Tsetse fly confined to Central Africa

The tsetse fly, and consequently sleeping sickness, is confined to the central area of Africa between the continent's two great deserts, the Sahara in the north and the Kalahari in the south. The disease is also separated into West and East African forms and is loosely divided by the Rift Valley. Approximately 50 million people live in this area, and presently about 1000 acquire sleeping sickness annually. At the height of its resurgence, this number was near 40,000 in 1998. Because of the activity of many species of tsetse flies that transmit sleeping sickness and other trypanosome infections of animals, it has been estimated that an additional 100,000,000 cattle cannot be raised in this tsetse-infested area. Major outbreaks of human infection have been reported in several locations within the endemic area over the past two decades, partly because of the internecine wars in this area that have interrupted control programs. Although an estimated 20,000 Americans travel to endemic areas each year, less than two dozen cases of African trypanosomiasis have been diagnosed in Americans since 1967.

Humans reservoir of West African sleeping sickness

Riverine tsetse flies found in the forest galleries that border the streams of West and Central Africa serve as the vectors of the Gambian disease. Although these flies are not exclusively anthropophilic, humans are thought to be the major reservoirs of the parasite. The infection rate in humans is affected by proximity to water but seldom exceeds 2% to 3% in nonepidemic situations. Nevertheless, the extreme chronicity of the human disease ensures its continued transmission.

Antelopes reservoir of East African trypanosomiasis; humans infected incidentally

Rhodesian sleeping sickness, in contrast, is transmitted by flies indigenous to the great savannas of East Africa that feed on the blood of the small antelope and other ruminants inhabiting these areas. The antelope serves as a principal parasite reservoir, although human-to-human and cattle-to-human spread has been documented. Humans typically become infected when they enter the savanna to hunt or to graze their domestic animals. The Sudan is one country where both the Gambian and Rhodesian forms of sleeping sickness are still found. Continued civil strife and deforestation in other countries could change that picture. At present, there is little evidence of coinfections with African trypanosomes and HIV, possibly because the former is primarily rural in

distribution and the latter is concentrated in cities and because major immune responses to trypanosomes are largely antibody-mediated and bypass T cells.

PATHOGENESIS AND IMMUNE RESPONSIVENESS

*** Local chancre, lymphadenitis at inoculation site**

*** Intermittent parasitemia with antigenic shifts**

*** Localize in blood vessels of heart and CNS with vasculitis**

Multiplication of the trypomastigotes at the inoculation site produces a localized inflammatory lesion. After the development of this chancre, organisms spread through lymphatic channels to the bloodstream, inducing a proliferative enlargement of the lymph nodes. The subsequent parasitemia is typically low grade and recurrent. Replicating organisms of the dominant antigenic type continuously produce surface glycoproteins. Much of this is shed from the parasite's surface and serves as a T-cell–independent antigen to directly stimulate B cells to produce antibody. The antibody produced in this fashion is IgM which can bind to the organism, leading to its destruction by lysis and opsonization. The trypomastigotes disappear from the blood, reappearing 3 to 8 days later as a new dominant antigenic variant arises. The recurrences gradually become less regular and frequent, but may persist for weeks to years before finally disappearing. During parasitemia, trypanosomes localize in the small blood vessels of the heart and central nervous system (CNS). This localization results in endothelial proliferation and a perivascular infiltration of plasma cells and lymphocytes. In the brain, hemorrhage and a demyelinating panencephalitis may follow.

IgM levels specific and nonspecific

*** Immune complexes cause anemia, vasculitis**

The mechanism by which the trypanosomes elicit vasculitis is uncertain. The infection stimulates a massive, nonspecific polyclonal activation of B cells, the production of large quantities of IgM (typically 8-16 times the normal limit), and the suppression of other immune responses. Most of this reaction represents specific protective antibodies that are ultimately responsible for the control of the parasitemia. Some, however, consist of nonspecific heterophile antibodies,

antibodies to DNA, and rheumatoid factor. Antibody-induced destruction of trypanosomes releases invariant nuclear and cytoplasmic antigens with the production of circulating immune complexes. Many authorities believe that these complexes are largely responsible for anemia and vasculitis seen in this disease.

Is vaccine development likely to provide a rationale approach to controlling African trypanosomiasis?

AFRICAN TRYPANOSOMIASIS (SLEEPING SICKNESS): CLINICAL ASPECTS

MANIFESTATIONS

* **Raised red papule on exposed surface**
* **Parasitemic manifestations 2 to 3 weeks later**
* **Late CNS involvement**

The trypanosomal chancre appears 2 to 3 days after the bite of the tsetse fly as a raised, reddened nodule on one of the exposed surfaces of the body. With the onset of parasitemia 2 to 3 weeks later, the patient develops recurrent bouts of fever, tender lymphadenopathy, skin rash, headache, and impaired mentation. In the Rhodesian form of disease, myocarditis and CNS involvement begin within 3 to 6 weeks. Heart failure, convulsions, coma, and death follow in 6 to 9 months. Gambian sleeping sickness usually progresses more slowly, but in some areas of Africa clinical manifestations of disease may overlap with the Rhodesian form of the disease. Bouts of fever often persist for years before CNS manifestations gradually appear. Spontaneous activity progressively diminishes, attention wavers, and the patient must be prodded to eat or talk. Speech grows indistinct, tremors develop, sphincter control is lost, and seizures with transient bouts of paralysis occur. In the terminal stage, the patient develops a lethal intercurrent infection or lapses into a final coma. Recent studies have shown great variability in the progression of both the Rhodesian and Gambian forms of the disease.

DIAGNOSIS

* Trypomastigotes in lymph nodes, blood, and CSF

Animal inoculation in Rhodesian disease

A definitive diagnosis is made by microscopically examining lymph node aspirates, blood, or cerebrospinal fluid for the presence of trypomastigotes (**Figure 53–6**). Early in the disease, actively motile organisms can often be seen in a simple wet mount preparation smear; identification requires examination of an appropriately stained smear. If these tests prove negative, the blood can be centrifuged and the stained buffy coat examined. Inoculation of rats or mice can also prove helpful in diagnosing the Rhodesian disease. The patient may also be screened for elevated levels of IgM in the blood and spinal fluid or specific trypanosomal antibodies by a variety of techniques. A card agglutination test for trypanosomiasis (CATT), which can be performed on fingerstick blood, can provide serologic confirmation within minutes. Subspecies-specific DNA probes may eventually prove useful for the identification of organisms in clinical specimens.

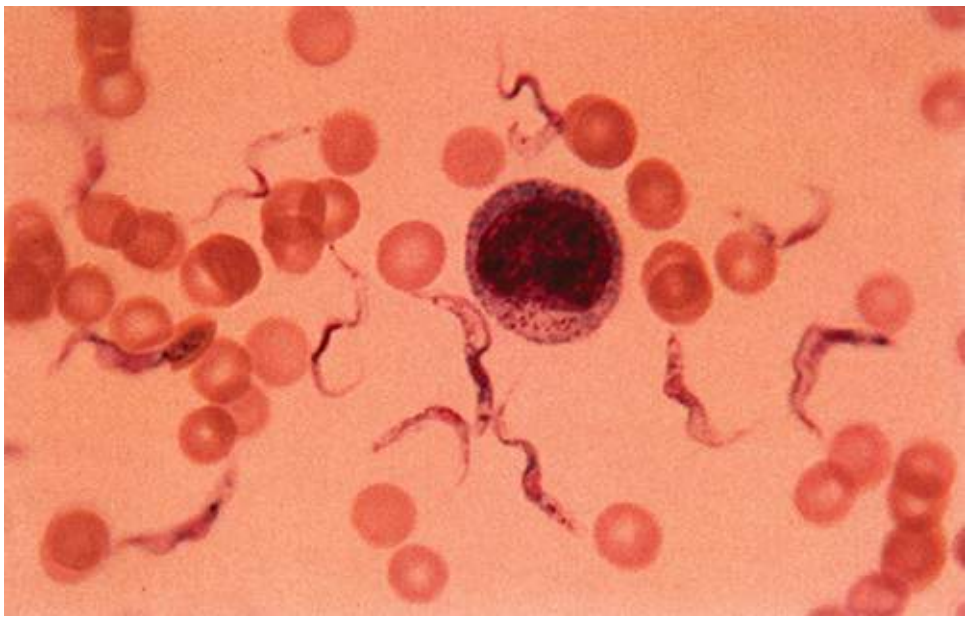

FIGURE 53–6. African sleeping sickness. *Trypanosoma brucei* in a routine blood smear. (Reproduced with permission from Nester EW, Anderson DG, Roberts CE Jr, et al: *Microbiology: A Human Perspective*, 6th ed. New York, NY: McGraw Hill; 2008.)

Think ▸▸ Apply 53-2: Presently, the answer is no. Antibodies can destroy dominant populations of trypanosomes in the bloodstream, but antigenic variation helps the parasite escape total destruction and gives rise to new dominant populations. It would be impossible to raise a vaccine against the complete genetic variant types possible—more than 1000. In addition, such an approach will result in stimulation of IgM antibodies, which are short lived. Experimental vaccination studies in animal models have also shown that the host's capacity to mount an efficient immune response and to maintain its immunological memory may be undermined. Despite all of this, the fact that some animal species become trypanotolerant suggests that a vaccine strategy can eventually be developed.

TREATMENT

Drugs depend on CNS involvement

Without CNS recovery often complete

Lumbar puncture must always be performed before initiation of therapy for sleeping sickness. If the specimen reveals evidence of CNS involvement, agents that penetrate the blood–brain barrier must be included. Unfortunately, the most effective agent of this type is a highly toxic arsenical, melarsoprol (Mel B). Although this agent occasionally produces a lethal hemorrhagic encephalopathy, the invariably fatal outcome of untreated CNS disease warrants its use. The ornithine decarboxylase inhibitor, eflornithine (DFMO) appears capable, when used alone, or in combination with suramin, of curing CNS disease caused by *T brucei gambiense* without the serious side effects associated with melarsoprol. Unfortunately, it is very expensive and is only variably effective in *T brucei rhodesiense* infections. If the CNS is not yet involved, less toxic agents, such as suramin, pentamidine, or eflornithine, can be used. In such cases, the cure rate is high and recovery complete.

PREVENTION

Neither vector or reservoir control has been successful

Although a variety of tsetse fly control measures, including the use of insecticides, deforestation, and the introduction of sterile males into the fly population, have been attempted, none has proved totally practicable. The tsetse fly is larviparous and carries a larva within its body until mature and ready to pupate. This means flies have a better chance of survival. In addition, adults are strong fliers. Similarly, eradication of disease reservoirs by the early detection and treatment of human cases and the destruction of wild game has had limited success. Attempts to develop effective vaccines are currently underway but are complicated by the antigenic variability of the trypanosomes. A degree of personal protection can be achieved with insect repellents and protective clothing. Although prophylactic use of pentamidine was once advocated, enthusiasm for this treatment has waned.

KEY CONCLUSIONS

- The tsetse flies of several species are the vectors of all species of African trypanosomes.
- The unique life cycle of this fly makes fly control very difficult.
- Humans are the predominant reservoirs of *T brucei gambiense*, while wild ungulates are the predominant reservoirs of *T brucei rhodesiense*.
- Antigenic variation in trypanosome is a genetically controlled process.
- Immune responses are largely driven by T-independent antigens resulting in IgM antibody production which eliminates dominant homotype populations, but not the heterotypes which give rise to the next dominant homotype population.
- Immune depression often accompanies disease because of B-cell depletion.
- Invasion of the central nervous system by parasites gives rise to the “sleeping sickness” phase of the disease.

AMERICAN *TRYPANOSOMA*

Overview

Trypanosoma cruzi is a small curved trypanosome. American trypanosomiasis is a disease produced by *T cruzi* and transmitted by true bugs of the family Reduviidae, also known as kissing bugs. About 7 to 10 million people,

predominantly in Central and South America are infected. Clinically, the infection may present as an acute phase with febrile illness such as seen in children, an indeterminant phase in which symptoms may largely be absent, and a chronic phase in which heart or gastrointestinal maladies are manifest, largely in adults.

PARASITOLOGY

* Mammalian cycle with nondividing extracellular trypomastigotes, dividing intracellular amastigotes and epimastigotes

Invertebrate cycle produces trypomastigotes in bug

The trypomastigotes of *T cruzi* are smaller than those of *T brucei* and typically assume a C shape when seen in the peripheral circulation. Their developmental cycle differs in several respects from that of *T brucei*. Most significant, *T cruzi* does not multiply in the bloodstream. The circulating trypomastigotes must invade tissue cells, lose their flagella, and assume the amastigote form before binary fission can occur. Continued multiplication as amastigotes and epimastigotes in intracellular nests leads to distention and eventual rupture of the tissue cell. Released trypomastigotes regain the bloodstream. This new generation of trypomastigotes may invade other host cells, thus continuing the mammalian cycle. Alternatively, they may be ingested by a feeding reduviid and develop into epimastigotes within its midgut. On completion of the invertebrate cycle, the parasites migrate to the hindgut and are discharged as infectious metacyclic trypomastigotes when the reduviid defecates in the process of taking another blood meal. This process can recur at each feeding for as long as 2 years. Infection in the new host is initiated when the trypomastigotes contaminate either the feeding site or the mucous membranes.

Trypanosoma cruzi comprises several strains, each with its own distinct geographic distribution, tissue preference, and virulence. These strains may be distinguished from one another with specific antisera and by differences in their isoenzyme and DNA restriction patterns. All are somewhat morphologically similar. In blood specimens, the trypomastigotes can be distinguished from those of *T brucei* by their characteristic C or U shape, narrow undulating membrane, and large posterior kinetoplast. *T cruzi* does not undergo antigenic variation.

AMERICAN TRYPANOSOMIASIS (CHAGAS DISEASE)

EPIDEMIOLOGY

*** Chagas disease in South and Central America**

*** "Kissing bug" feeds at night**

*** Infected Immigrants from Central and South America**

Chagas disease affects 7 to 10 million people in a geographic area extending from Mexico to southern Argentina, producing death in 50,000 annually. Within these areas, it is the leading cause of chronic heart disease, accounting for 25% of all deaths in the 25- to 44-year age group. Transmission occurs primarily in rural settings, where the reduviid can find harborage in animal burrows and in the cracked walls and thatch of poorly constructed buildings. This large (3 cm) insect leaves its hiding place at night to feed on its sleeping hosts. Its predilection to bite near the eyes or lips has earned this pest the nicknames of "kissing bug" and "assassin bug." Most new infections in these areas occur in children. Infections can also be acquired transplacentally and through blood transfusions or organ transplantations. As many as 300,000 individuals who have immigrated from Central and South America to the United States are infected with *T cruzi* and likely do not know it!

Wild and domestic animal reservoirs amplify transmission

In addition to humans, several wild and domestic animals, including rats, cats, dogs, opossums, racoons, and armadillos, serve as reservoirs for Chagas disease. The close association of many of these hosts with human dwellings tends to amplify the incidence of disease in humans and the difficulty involved in its control.

Organ transplantation and transfusion-related infections are rapidly increasing problems in urban settings within endemic areas. Recrudescence of the latent infection is increasingly seen in immunosuppressed individuals, including patients with HIV infections. More effective blood bank screening provides hope that transmission of this disease will be substantially curtailed in

the near future.

Recently, oral/foodborne transmission of Chagas disease has gained attention. For this to occur, the parasite must survive in the feces of its natural vector on foods that are consumed. Outbreaks in Brazil have been linked to the consumption of açai juice prepared from a reddish/purple fruit from the açai palm tree. In total, more than 1000 cases of infection with *T cruzi* has been linked with oral infection in different regions of Brazil, Columbia, Bolivia, Guyana Francesa, Argentina, and Ecuador.

An estimated 300,000 infected Latin American immigrants are currently living in the United States. Because *T cruzi* has been found in both vertebrate and invertebrate hosts in the southern United States, there is a possibility of sustained transmission of this organism within this country. Although serologic evidence suggests that the acquisition of human infection in this area is not uncommon, clinically apparent autochthonous cases have been rare. Most of these acquired the infection through blood–blood transfusions.

PATHOGENESIS

*** Local chancre at inoculation site**

*** Entry to mesenchymal cells facilitated by fibronectin-binding protein**

*** Pore-forming protein aids escape from phagosome**

Pseudocysts from cytoplasmic multiplication

Multiplication of the parasite at the portal of entry stimulates the accumulation of neutrophils, lymphocytes, and tissue fluid, resulting in the formation of a local chancre or chagoma. The subsequent dissemination of the organism with invasion of tissue cells produces a febrile illness that may persist for 1 to 3 months and result in widespread organ damage. Any nucleated host cell may be involved, but those of mesenchymal origin, especially the heart, skeletal muscle, smooth muscle, and ganglion neural cells, are particularly susceptible. Cell entry is facilitated by binding to host cell fibronectin; a 60-kDa *T cruzi* surface protein (penetrin) appears to promote adhesion. After penetration, the trypomastigote escapes the phagosome via the production of a pore-forming protein, transforms to the amastigote form, and multiplies freely within the cytoplasm to produce a

pseudocyst, a greatly enlarged and distorted host cell containing masses of organisms (**Figure 53–7**). With the rupture of the pseudocyst, many of the released parasites disintegrate, eliciting an intense inflammatory reaction with destruction of surrounding tissue. The development of an antibody-dependent, cell-mediated immune response leads to the eventual destruction of the *T cruzi* parasites and the termination of the acute phase of illness.

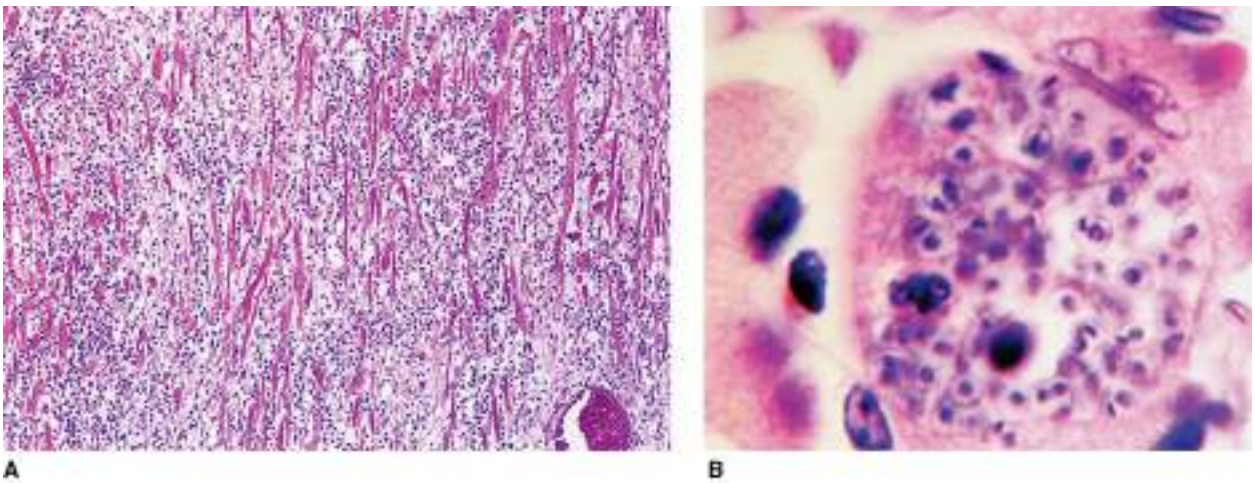

FIGURE 53–7. Chagas disease. A. Acute myocarditis with atrophic myofibers separated by inflammatory cells. **B.** *Trypanosoma cruzi* amastigotes clustered in myofiber from the same case. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Heart damage may be autoimmune

Ganglionic, smooth muscle loss in GI tract

Parasitic antigens released during this acute phase may bind to the surface of tissue cells, rendering them susceptible to destruction by the host's immune response. It has been suggested by some that this results in the production of antibodies that cross-react with host tissue, initiating a sustained autoimmune inflammatory reaction in the absence of systemic manifestation of illness. In the heart, this reaction leads to changes in coronary microvasculature, loss of muscle tissue, interstitial fibrosis, degenerative changes in the myocardial conduction system, and loss of intracardiac ganglia. In the digestive tract, loss of both ganglionic nerve cells and smooth muscle results in dilatation and loss of peristaltic movement, particularly of the esophagus and colon.

AMERICAN TRYPANOSOMIASIS (CHAGAS DISEASE): CLINICAL ASPECTS

MANIFESTATIONS

Most asymptomatic; acute disease in children

Myocardial injury indicated by tachycardia and ECG

Serologic studies suggest that only one-third of the persons newly infected with Chagas disease develop clinical illness. Acute manifestations, when they occur, are seen primarily in children. They begin with the appearance of the nodular, erythematous chagoma 1 to 3 weeks after the bite of the reduviid. If the eye served as a portal of entry, the patient presents with Romaña sign: reddened eye, swollen lid, and enlarged preauricular lymph node. The onset of parasitemia is signaled by the development of a sustained fever; enlargement of the liver, spleen, and lymph nodes; signs of meningeal irritation; and the appearance of peripheral edema or a transient skin rash. In a small percentage of symptomatic patients, heart involvement results in tachycardia, electrocardiographic (ECG) changes, and occasionally arrhythmia, enlargement, and congestive heart failure. Newborns may experience acute meningoencephalitis. Clinical manifestations persist for weeks to months. In 5% to 10% of untreated patients, severe myocardial involvement or meningoencephalitis leads to death.

*** Chronic cardiomyopathy leads to heart block, failure**

Dilatation of esophagus and colon seen in southern latitudes

Chronic disease, the result of end-stage organ damage, is usually seen only in adulthood. Ironically, most patients with late manifestations have no history of acute illness. The most serious of the late manifestations is heart disease. Studies of asymptomatic, seropositive patients in endemic areas have shown that a significant proportion have cardiac abnormalities demonstrated by electrocardiographic, echocardiographic, or cineangiographic techniques, suggesting that Chagas cardiomyopathy is a progressive, focal disease of the myocardium and conduction system, leading eventually to clinical disease. This may present as arrhythmia, thromboembolic events, heart block, enlargement

with congestive heart failure, and cardiac arrest. In some areas of rural Latin America, up to 10% of the adult population may show cardiac manifestations. In the United States, chagasic heart disease in immigrants is usually initially misdiagnosed as coronary artery disease or idiopathic dilated cardiomyopathy. Megaesophagus and megacolon, which are less devastating than the heart disease, are typically seen in more southern latitudes. This geographic variation in clinical manifestations is thought to be attributable to a difference in tissue tropism between individual strains of *T cruzi.* Megaesophagus leads to difficulty in swallowing and regurgitation, particularly at night. Megacolon produces severe constipation with irregular passage of voluminous stools. *T cruzi* brain abscess has been described in a small number of AIDS patients.

DIAGNOSIS

*** Trypomastigotes in peripheral blood**

Xenodiagnosis involves allowing bugs to feed

Organisms difficult to recover in chronic disease

The diagnosis of acute Chagas disease rests on finding the trypomastigotes in the peripheral blood or buffy coat, and their morphologic identification as *T cruzi.* The methods are like those described for diagnosis of African trypanosomiasis. If the results are negative, a laboratory-raised reduviid can be fed on the patient, then dissected and examined for the presence of parasites, a procedure known as **xenodiagnosis.** Alternatively, the blood may be cultured in a variety of artificial media or experimental animals. In the diagnosis of chronic disease, recovery of the organisms is the exception rather than the rule, and diagnosis depends on the clinical, epidemiologic, and immunodiagnostic findings. A variety of serologic tests are available; small numbers of false-positive results limit their usefulness, particularly when used as screening procedures in nonendemic areas. The recent production of specific recombinant proteins and synthetic peptides for use as antibody targets may improve the reliability of these procedures. Polymerase chain reaction techniques for the amplification of trypomastigote DNA are available.

TREATMENT

Treatment may reduce acute disease

The role of treatment in Chagas disease remains unsettled. Two agents, nifurtimox and benznidazole, effectively reduce the severity of acute disease but appear to be ineffective in chronic infections. Both drugs must be taken for prolonged periods of time, may cause serious side effects, and do not always result in parasitologic cure. Allopurinol, a hypoxanthine oxidase inhibitor devoid of serious side effects, has recently been shown to be capable of suppressing parasitemia and reversing the serostatus of patients with acute disease. Additional studies to confirm these encouraging results are necessary.

PREVENTION

* Control of reduviid bugs in homes most important

The reduviid vector can be controlled by applying residual insecticides to rural buildings at 2- or 3-month intervals. The addition of latex to the insecticide creates a colorless paint that prolongs activity. This approach has proven effective because larval instar stages of the kissing bug lack wings and, therefore, stay close to their source of blood. A strong initiative using this approach has been undertaken in the southern portion of South America. Fumigants can be used to prevent reinfection. Patching wall cracks, cementing floors, and moving debris and woodpiles away from human dwellings reduces the number of reduviids within the home. Transfusion-induced disease, a major problem in endemic areas, has been partially controlled by the addition of gentian violet to all blood packs before use or by screening potential donors serologically for Chagas disease. The large number of infected immigrants now entering nonendemic countries presents an increasing risk of transfusion-mediated parasite transmission in these areas as well. Cases of acute Chagas disease have been reported in the United States in immunosuppressed patients who received blood from donors unaware of their infection status; the resulting diseases were particularly fulminant. Immunodiagnostic tests for Chagas disease are neither readily available nor sufficiently specific for use in nonendemic areas; prevention will probably require deferral of blood donations from persons who have recently emigrated from endemic areas. Immunoprophylaxis is not available at present.

KEY CONCLUSIONS

- *Trypanosoma cruzi* infections are transmitted primarily through the feces of infected kissing bugs.
- Infection is manifest by acute, indeterminant, and chronic phases.
- Chronic disease is manifest as cardiomyopathies and/or gastrointestinal maladies in about 25% of infected individuals.
- Chagas disease can be transmitted congenitally and via blood transfusion and organ transplantation.
- At present, therapies are only available during acute phase infection.

CASE STUDY

A Child With Recurrent Fever and Diarrhea

This 3-year-old girl who resides in Central Africa has had recurrent fevers for the last 6 weeks, accompanied by persistent diarrhea and weight loss. A physical examination reveals her to be alert but with significant generalized weakness, widespread lymphadenopathy, hepatomegaly, and massive splenomegaly.

Laboratory findings include anemia, leukopenia, thrombocytopenia, and hematuria.

QUESTIONS

1. Which is the most likely cause of this child's illness?

A. *Leishmania donovani*
B. *Leishmania tropica*
C. *Trypanosoma cruzi*
D. *Trypanosoma brucei*

2. Which is the insect vector involved?

A. Mosquito
B. Tsetse fly
C. Sandfly
D. Reduviid bug

3. *Trypanosoma cruzi* can significantly affect all of the following tissues, *except*:

A. Heart
B. Smooth muscle
C. Skin
D. Skeletal muscle
E. Neural tissue

ANSWERS

1. (A)

2. (C)

3. (C)

Intestinal Nematodes

Enterobius vermicularis • *Trichuris trichiura* • *Ascaris lumbricoides* • *Necator americanus* • *Ancylostoma duodenale* • *Strongyloides stercoralis*

Life is dear to every living thing; the worm that crawls upon the ground will struggle for it.

— Solomon Northup

OVERVIEW

Nematodes are worms with bodies that are round in cross-section. They come in two broad categories: Intestinal nematodes (covered here) and tissue nematodes (covered in Chapter 55). The distinction between these groups may seem arbitrary because some intestinal nematodes migrate through tissue on their way to the gut, and some tissue nematodes spend part of their lives in the intestines! However, the difference between the groups will be clear if you focus on whether the *adult* form spends its time chiefly in the intestines or in other body tissues.

Impact

Six intestinal nematodes commonly infect humans: *Enterobius vermicularis* (pinworm), *Trichuris trichiura* (whipworm), *Ascaris lumbricoides* (large roundworm), *Necator americanus* and *Ancylostoma duodenale* (human hookworms), and *Strongyloides stercoralis*. Together, they infect more than 25% of all humans. Most people who carry a small number of any of these intestinal roundworms have no symptoms whatsoever. However, people with large numbers of adult worms may suffer from abdominal discomfort, malnutrition, anemia, and occasionally death. Other closely related nematodes of animals that occasionally infect humans are also listed in **Table 54-1,** but are not discussed here.

TABLE 54–1 Intestinal Nematodes

HUMAN PARASITE	ANIMAL PARASITE	HUMAN DISEASE
Enterobius vermicularis (pinworm)		Enterobiasis
Trichuris trichiura (whipworm)		Trichuriasis
	Capillaria philippinensis	Intestinal capillariasis
Ascaris lumbricoides (large roundworm)		Ascariasis
	Ascaris suum	Ascariasis
	Anisakis spp.	Anisakiasis
Necator americanus (hookworm) *Ancylostoma duodenale* (hookworm)		Hookworm disease
	Ancylostoma braziliense	Cutaneous larva migrans
Strongyloides stercoralis		Strongyloidiasis

▪ Morphology

All intestinal nematodes have cylindrical, tapered bodies covered with a tough, acellular cuticle. Sandwiched between this tegument and the body cavity are layers of muscle, longitudinal nerve trunks, and an excretory system. A tubular alimentary tract consisting of a mouth, esophagus, midgut, and anus runs from the anterior to the posterior extremity. Highly developed reproductive organs fill the remainder of the body cavity. The sexes are separate; the male worm is generally smaller than its mate, and may be distinguished by a more curled posterior end than the tapered end in females.

▪ Life Cycles

Helminth life cycles have confused and frustrated generations of students. They may seem arcane, but they reveal how the pathogen will be transmitted to a new host. Therefore, physicians and public health experts who aim to develop strategies for prevention and control must understand life cycle fundamentals. The life cycles of the six main human intestinal nematodes are summarized in **Table 54-2.**

TABLE 54–2 Life Cycles of Intestinal Nematodes

PARASITE	ROUTE OF INFECTION	MIGRATION IN BODY	DIAGNOSTIC FORM	SITE OF EMBRYONATION	INFECTIVE FORM	FREE-LIVING CYCLE
Enterobius vermicularis (pinworm)	Mouth	Intestinal	Egg	Perineum	Egg	No
Trichuris trichiura (whipworm)	Mouth	Intestinal	Egg	Soil	Egg	No
Ascaris lumbricoides (giantworm)	Mouth	Pulmonary	Egg	Soil	Egg	No
Necator americanus[a] (hookworm)	Skin	Pulmonary	Egg	Soil	Filariform larvae	No
Strongyloides stercoralis	Skin	Pulmonary	Rhabditiform larvae	Soil; Intestine[b]	Filariform larvae	Yes

Life is difficult for worm offspring, most of which will die before reaching adulthood. Thus, female worms are extremely prolific, and may produce thousands of offspring every day, generally in the form of eggs. In most cases, eggs are fertilized and then carried from the adult to the environment in human feces. Typically, the eggs must incubate or "embryonate" outside of the human host before they become infectious to another person; during this time, the embryo repeatedly segments, eventually developing into an adolescent form known as a **larva.** The egg may then be ingested with contaminated food. In some species, the egg hatches outside of the host, releasing a larva capable of penetrating the skin of a person who comes in direct physical contact with it. Obviously, intestinal nematodes are principally found in areas where human feces are deposited indiscriminately or used for fertilizer.

▪ Pathogenesis

Long survival in gut lumen

* Worm load, repeated infection important to severity

The adults of each of the six nematodes listed previously can survive for months or years within the lumen of the human gut. The severity of illness produced by each depends on the level of adaptation to the host it has achieved. Some species have a simple life cycle that can be completed without serious consequences to the host. Less well-adapted parasites, on the other hand, have more complex cycles, often requiring tissue invasion and/or production of enormous numbers of offspring to ensure their continued survival and dissemination. Within a given species, disease severity is related directly to the number of adult worms harbored by the host. The greater the worm load or worm burden, the more serious the consequences. Because most nematodes do not multiply within the human, small worm loads may remain asymptomatic and undetected throughout the lifespan of the parasite. Repeated infections, however, progressively increase

the worm burden and at some point may cause symptomatic disease. Although humans can mount an immune response that may eventually contribute to the expulsion of worms, it is slow to develop and incomplete. It is therefore the frequency and intensity of reinfection more than the host's immune response that determine the worm burden. This burden is seldom uniform within affected populations, but rather "aggregated" within subgroups of "wormy persons," presumably related to their exposure or perhaps undefined immunologic factors.

• PARASITES AND DISEASES

ENTEROBIUS

ENTEROBIUS VERMICULARIS (PINWORM): PARASITOLOGY

*** Common name pinworm or threadworm**

The adult female pinworm is 10 mm long, cream colored, with a sharply pointed tail; such characteristics have given rise to the common name pinworm, or threadworm. Running longitudinally down both sides of the body are small ridges that widen anteriorly to fin-like alae. The seldom-seen male is smaller (3 mm) and possesses a ventrally curved tail and copulatory spicule. The clear, thin-shelled, ovoid eggs are flattened on one side and measure 25 by 50 µm (**Figure 54–1**).

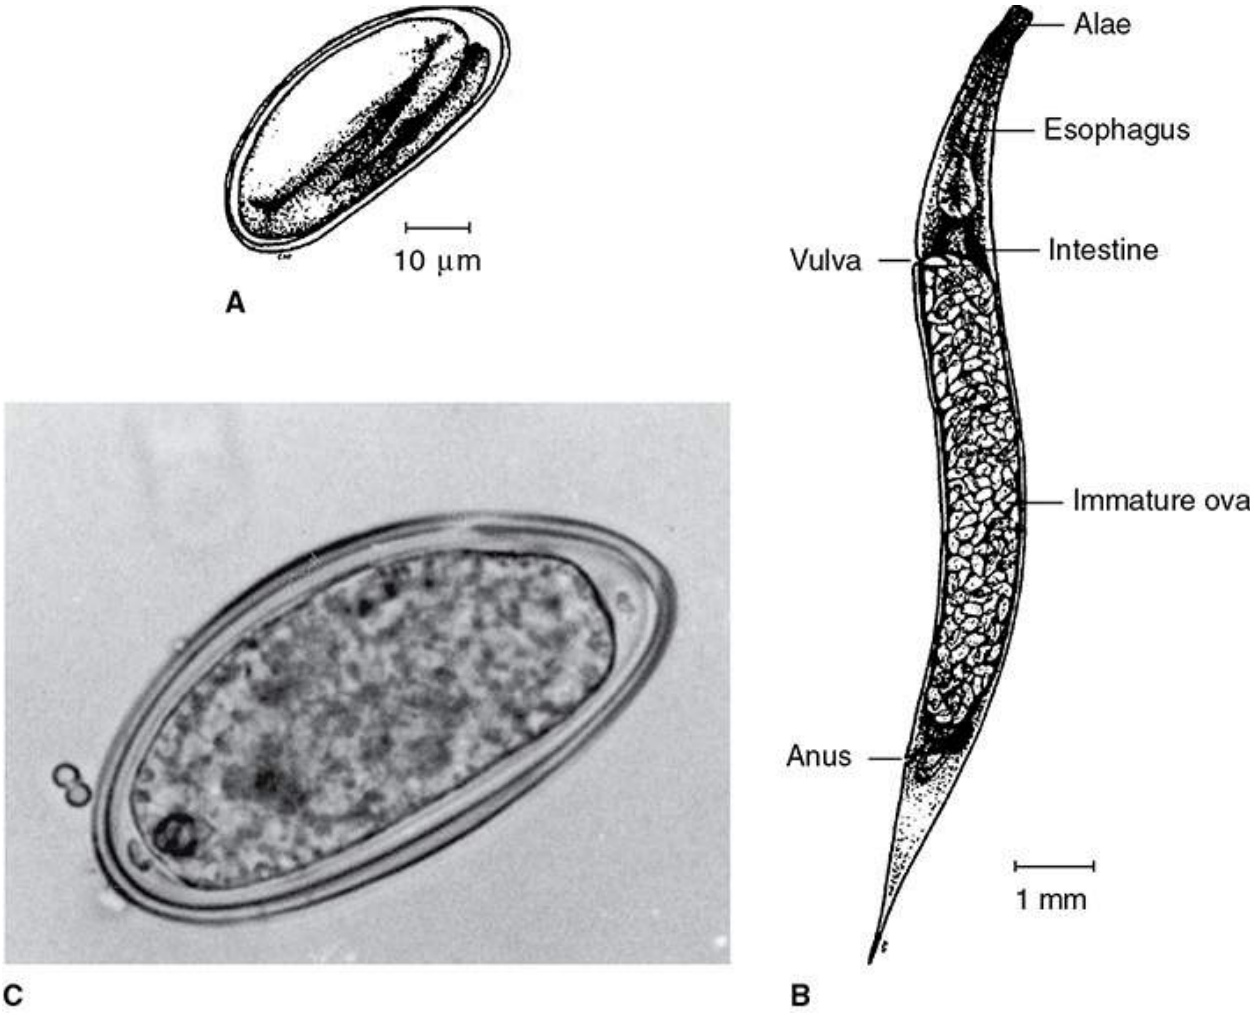

FIGURE 54–1. ***Enterobius vermicularis*. A.** Egg structure. **B.** Structure of adult female pinworm. **C.** Embryonated egg recovered from stool. (C, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

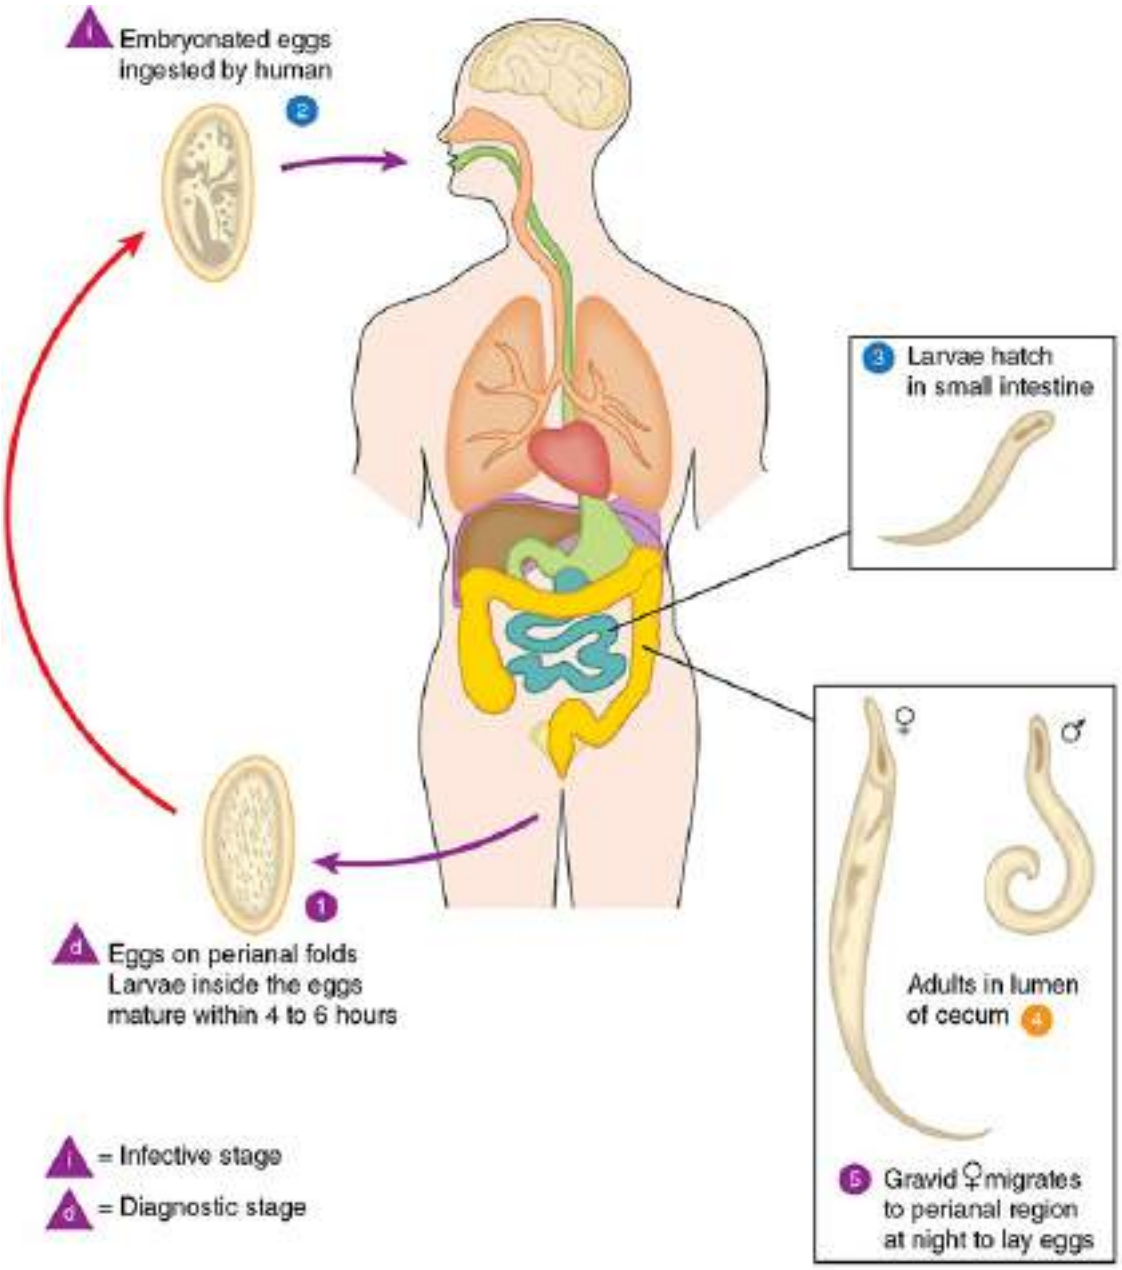
LIFE CYCLE (FIGURE 54–2)



Eggs are deposited on perianal folds 1. Self-infection occurs by transferring infective eggs to the mouth with hands that have scratched the perianal area 2. Person-to-person transmission can also occur through handling of contaminated clothes or bed linens. Enterobiasis may also be acquired through surfaces in the environment that are contaminated with pinworm eggs (eg, curtains, carpeting). Some small number of eggs may become airborne and inhaled. These would be swallowed and follow the same development as ingested eggs. Following ingestion of infective eggs, the larvae hatch in the small intestine 3 and the adults establish themselves in the colon 4. The time interval from ingestion of infective eggs to oviposition by the adult females is about 1 month. The life span of the adults is about 2 months. Gravid females migrate nocturnally outside the anus and oviposit while crawling on the skin of the perianal area 5. The larvae contained inside the eggs develop (the eggs become infective) in 4 to 6 hours under optimal conditions 1. Retroinfection, or the migration of newly hatched larvae from the anal skin back into the rectum, may occur but the frequency with which this happens is unknown.

FIGURE 54–2. ***Enterobius vermicularis*** **life cycle.**

Adults inhabit cecum

*** Female transits anus at night to deposit eggs on perineum**

Eggs infectious shortly after deposition

Larvae mature in intestine

Enterobius has the simplest life cycle of the intestinal nematodes. The adult worms lie attached to the mucosa of the cecum, where the male inseminates the female. As her period of gravidity draws to a close, the female migrates down the colon, slips unobserved through the anal canal in the dark of the night, and deposits as many as 20,000 sticky eggs on the host's perianal skin, bedclothes, and linens. The eggs are near maturity at the time of deposition and become infectious shortly thereafter. Handling of bedclothes or scratching of the perianal area results in adhesion of the eggs to the fingers and fingernails; subsequently the eggs are ingested during eating or thumb sucking. Alternatively, the eggs may be shaken into the air (eg, during making of the bed), inhaled, and swallowed. The eggs subsequently hatch in the upper intestine, and the larvae migrate to the cecum, where they mature to adults and mate. The entire adult-to-adult cycle is completed in 2 weeks.

ENTEROBIASIS

EPIDEMIOLOGY

The pinworm is well adapted to the human host. Eggs have been found in a 10,-000-year-old coprolith, making this nematode the oldest demonstrated infectious agent of humans. It has been estimated to infect at least 200 million people worldwide, particularly children, including millions in the United States alone. Despite evidence that its prevalence is now decreasing in the United States, it remains the single most common cause of human helminthiasis in industrialized nations. Infection is more common among children.

Infects 30 to 40 million in the United States

Hardy infective eggs

The eggs are relatively resistant to desiccation and may remain viable in linens, bedclothes, or house dust for several days. Once infection is introduced into a household, other family members are often rapidly infected.

PATHOGENESIS AND IMMUNITY

The adult worms produce no significant intestinal pathology and do not appear to induce protective immunity.

ENTEROBIASIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Nocturnal pruritus ani**

Occasional infection of female GU tract

E vermicularis seldom produces serious disease. Many carriers have no complaints at all, but when symptoms do develop, the most common presentation is pruritus ani (anal itching). This symptom is most severe at night and has been attributed to the migration of the gravid female. It may lead to irritability in children. In severe infections, the intense itching may lead to excoriation and secondary bacterial infection. In female patients, the worm may enter the genital tract, producing vaginitis, granulomatous endometritis, or even salpingitis. Adult worms may be found in the appendix of patients with acute appendicitis, although it is unclear whether they have triggered the attack or are merely bystanders. It has also been suggested that errant worms might carry enteric bacteria into the urinary bladder in young women, triggering acute bacterial cystitis.

DIAGNOSIS

*** Perianal cellophane tape test detects ova**

Eosinophilia is usually absent. The diagnosis is suggested by the clinical

manifestations and confirmed by the recovery of the characteristic eggs from the perianal skin. This is accomplished by applying the sticky side of cellophane tape to the mucocutaneous junction, then transferring the tape to a glass slide and examining the slide for eggs (Figure 54–1C) under the low-power lens of a microscope. Occasionally, adult females are seen by the parent of an infected child or recovered with the cellophane tape procedure.

TREATMENT AND PREVENTION

Family members may need treatment

*** Reinfection common**

Several highly satisfactory agents, including pyrantel pamoate, mebendazole, and albendazole are available for treatment of enterobiasis. Many experts believe that all members of a family or other cohabiting group should be treated simultaneously. Although cure rates are high, reinfection is extremely common. In severe infections, retreatment after 2 weeks is recommended. Enhanced hygiene, including scrubbing under children's fingernails, may help to break the chain of transmission.

TRICHURIS

TRICHURIS TRICHIURA (WHIPWORM): PARASITOLOGY

Produces up to 10,000 eggs a day

The adult whipworm is 30 to 50 mm in length. The anterior two-thirds is thin and thread-like, whereas the posterior end is bulbous, giving the worm the appearance of a tiny whip. The tail of the male is coiled; that of the female is straight. The female produces 3000 to 10,000 oval eggs each day. They are of the same size as pinworm eggs, but have a distinctive thick brown shell with translucent knobs on both ends (**Figure 54–3**).

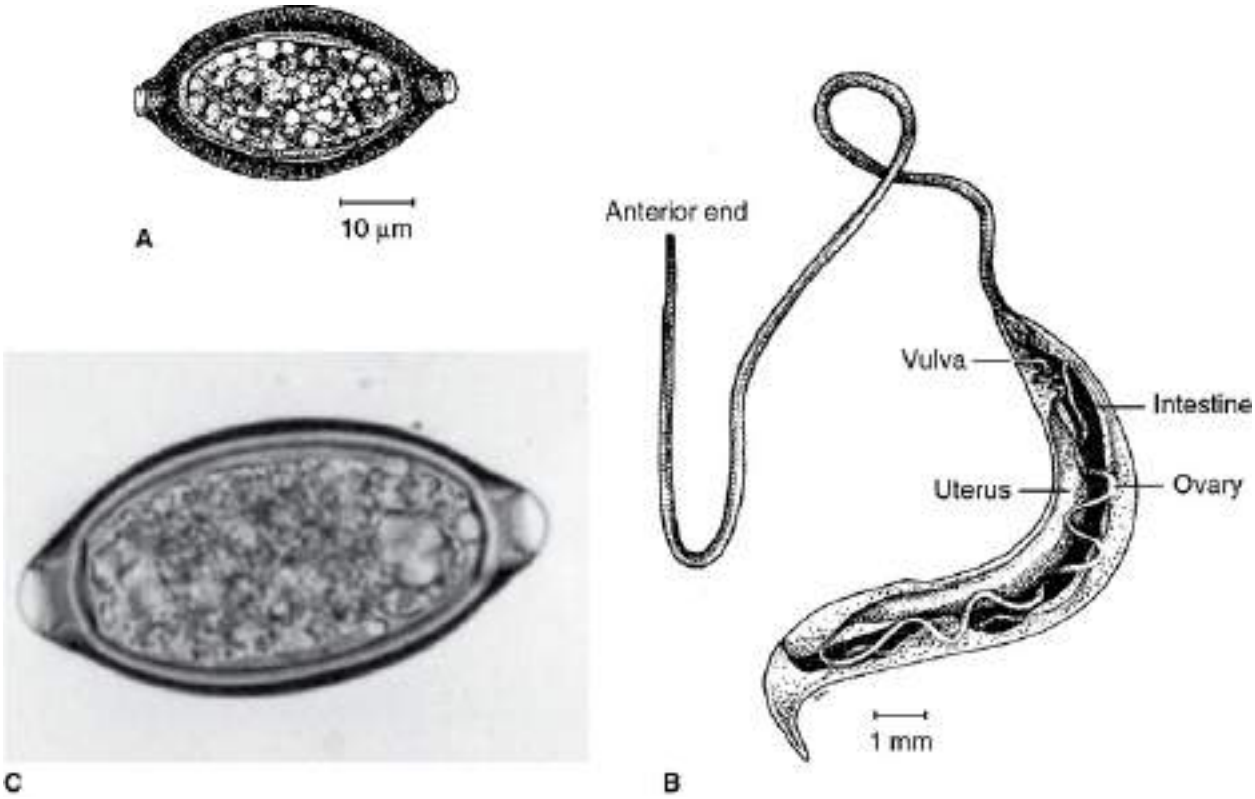


FIGURE 54–3. Trichuris trichiura. A. Egg structure. **B.** Structure of female adult whipworm. **C.** Embryonated egg with bipolar plugs from stool. (**C**, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

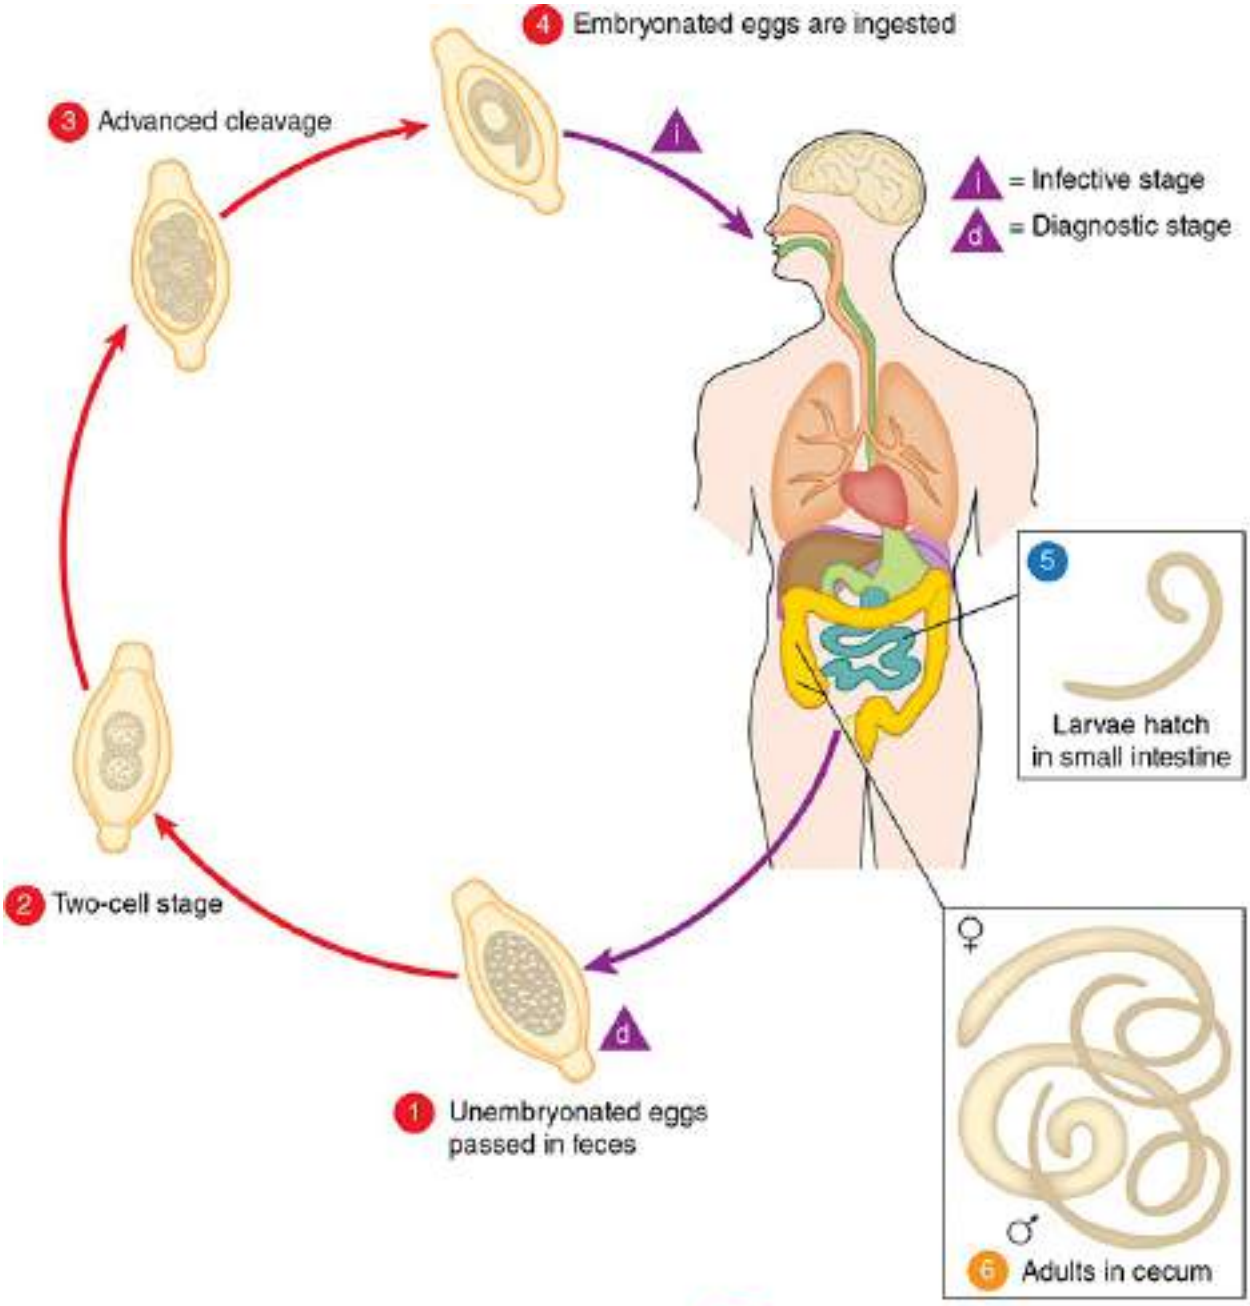
LIFE CYCLE (FIGURE 54–4)



The unembryonated eggs are passed with the stool 1. In the soil, the eggs develop into a two-cell stage 2, an advanced cleavage stage 3, and then they embryonate 4; eggs become infective in 15 to 30 days. After ingestion (soil-contaminated hands or food), the eggs hatch in the small intestine, and release larvae 5 that mature and establish themselves as adults in the colon 6. The adult worms (approximately 4 cm in length) live in the cecum and ascending colon. The adult worms are fixed in that location, with the anterior portions threaded into the mucosa. The females begin to oviposit 60 to 70 days after infection. Female worms in the cecum shed between 3000 and 20,000 eggs per day. The lifespan of the adults is about 1 year.

FIGURE 54–4. ***Trichuris trichiura*** **life cycle.**

Adults inhabit cecum, release eggs to lumen

*** Complexity: eggs must mature in soil 10 days**

Trichuris trichiura has a life cycle slightly more complex than that of the pinworm. The adults live attached to the colonic mucosa by their thin anterior end, using the larger ends for copulation. While retaining its position in the cecum, the gravid female releases its eggs into the lumen of the gut. These pass out of the body with the feces and, in poorly sanitized areas of the world, are deposited on soil. The eggs are immature at the time of passage and must incubate for at least 10 days (longer if soil conditions, temperature, and moisture are suboptimal) before they become fully embryonated and infectious. Once in this state, they are ingested unknowingly by the next human host—picked up on the hands of children at play, or by agricultural workers, or diners in areas where human feces are used as fertilizer. After ingestion, the eggs hatch in the duodenum, and the released larvae mature for approximately 1 month in the small bowel before migrating to their adult habitat in the cecum.

TRICHURIASIS

EPIDEMIOLOGY

Soil defecation in warm, humid climate

Adult worms live for years

Although it is less widespread than the pinworm, the whipworm is a cosmopolitan parasite, infecting approximately 800 million people globally. It is concentrated in areas where indiscriminate defecation and a warm, humid environment produce extensive seeding of soil with infectious eggs. In some communities in tropical climates, infection rates may be as high as 80%. Although the incidence is much lower in temperate climates, trichuriasis affects individuals throughout the rural areas of the southeastern United States. Although the intensity of infection is generally low, adult worms may live 4 to 8 years.

PATHOGENESIS AND IMMUNITY

Colonic ulceration provides bacterial bloodstream entry

Attachment of adult worms to the colonic mucosa and their subsequent feeding activities produce localized ulceration and hemorrhage (0.005 mL blood per worm per day). The ulcers provide enteric bacteria with a portal of entry to the bloodstream, and occasionally a sustained bacteremia results. Decreased prevalence of trichuriasis in the postadolescent period and the demonstration of acquired immunity in experimental animal infections suggest that immunity may develop in human infections. An IgE-mediated immune mucosal response is demonstrable in humans, but is insufficient to cause appreciable parasite expulsion.

TRICHURIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Colonic damage, abdominal pain, diarrhea

* Worm load causes dysentery, rectal prolapse

Light infections of trichuriasis are asymptomatic. With moderate worm loads, damage to the intestinal mucosa may induce nausea, abdominal pain, diarrhea, and stunting of growth. Occasionally, a child may harbor 800 adult worms or more. In these situations, the entire colonic lumen is parasitized, with significant mucosal damage, blood loss, and anemia (**Figure 54–5**). This may cause a "dysentery syndrome" with bloody diarrhea that mimics infection with bacterial pathogens such as *Shigella*. Heavy worm burdens may cause tenesmus, the sensation that one needs to defecate, which may trigger prolapse of the rectum through the anus, particularly when the host strains during a bowel movement.

FIGURE 54–5. Whipworm infestation. Terminal ileum covered with adult *Trichuris trichiura*. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

DIAGNOSIS

Stools examined for characteristic eggs

In light infections, stool concentration methods may be required to recover the eggs. Such procedures are almost never necessary in symptomatic infections, because they produce more than enough eggs per gram of feces to be readily detected by examining 1 to 2 mg of emulsified stool with the low-power lens of a microscope (Figure 54–3C). Unlike enterobiasis, a moderate eosinophilia is common in heavy *Trichuris* infections, presumably because the adults have anchored themselves within the colonic mucosa, thus presenting antigens to the gut-associated lymphatic tissue (GALT) and triggering an eosinophilic response.

TREATMENT AND PREVENTION

*** Treatment effective**

*** Prevention via sanitation**

Albendazole or mebendazole may be used; albendazole may have slightly superior efficacy, perhaps because it is absorbed into the bloodstream and thus reaches the worm's head where it is buried in the gut wall. Although the full microbiologic cure rate is less than perfect, more than 90% of adult worms are usually expelled with treatment, rendering the patient asymptomatic. Prevention requires the improvement of sanitary facilities, both for waste disposal and hand hygiene, and improved washing or cooking of contaminated fruits and vegetables.

ASCARIS

ASCARIS LUMBRICOIDES: PARASITOLOGY

Earthworm-sized roundworm produces elliptical eggs

Viable in soil 6 years

A lumbricoides, a short-lived worm (6-18 months), is the largest and most common of the intestinal helminths. Measuring 15 to 30 cm in length, it dwarfs its fellow gut roundworms. Its firm, creamy cuticle and more pointed extremities differentiate it from the common earthworm, which it otherwise resembles in both size and external morphology. The male is slightly smaller than the female and possesses a curved tail with copulatory spicules. The female passes 200,000 eggs daily, whether or not she is fertilized. Eggs are elliptical, measure 35 by 55 µm, and have a rough, mammillated, albuminous coat over their chitinous shells (**Figure 54–6**). These eggs are highly resistant to environmental conditions and may remain viable for up to 6 years in mild climates.

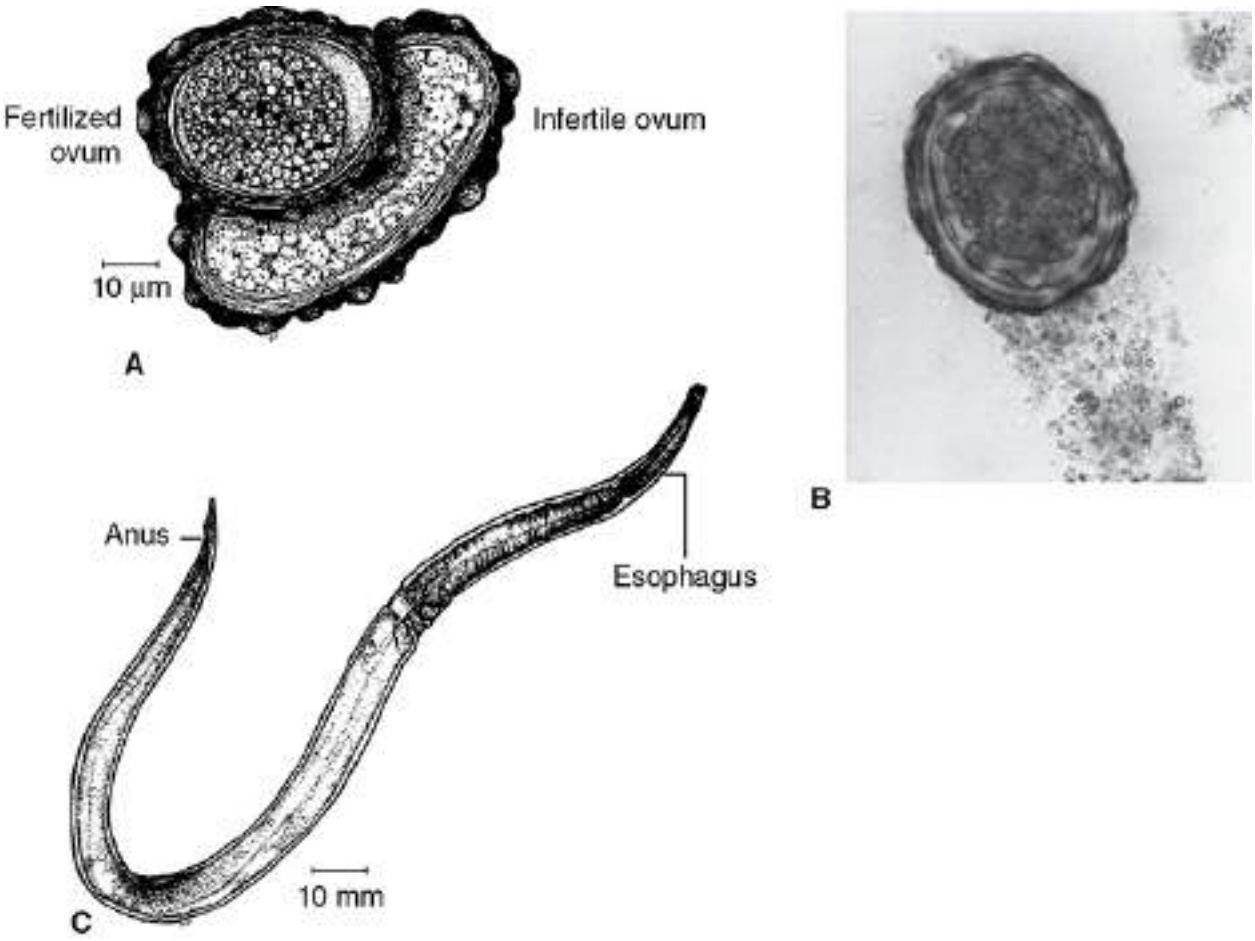


FIGURE 54–6. ***Ascaris lumbricoides.*** **A.** Structure of fertile and infertile egg. **B.** Fertilized egg in stool. **C.** Adult female worm. (B, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

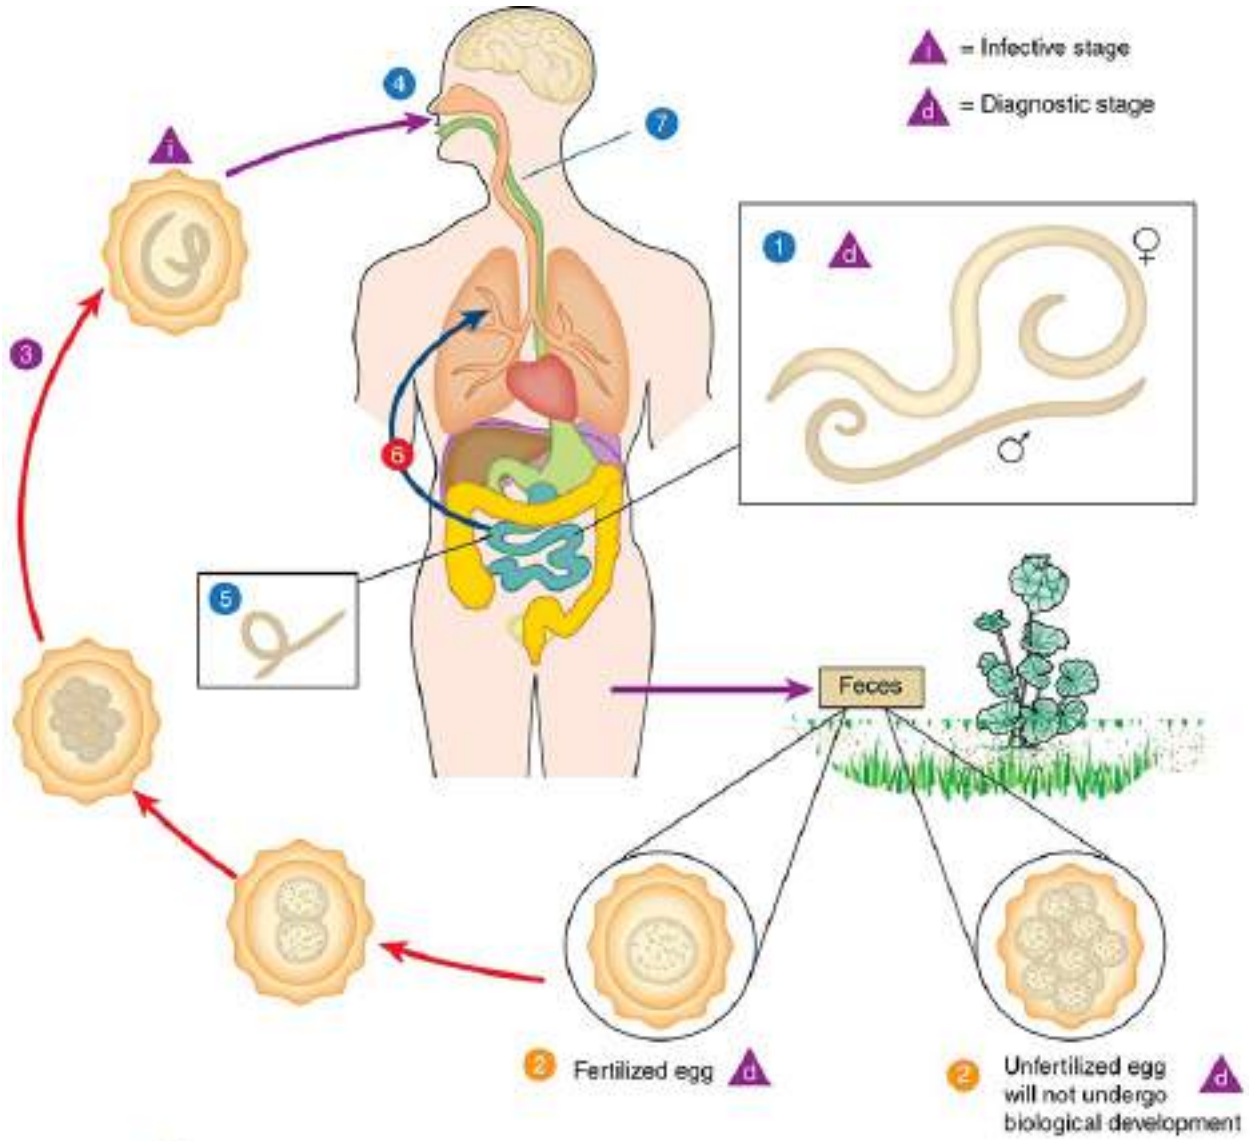
LIFE CYCLE (FIGURE 54–7)



Adult worms (1) live in the lumen of the small intestine. A female may produce approximately 200,000 eggs per day, which are passed with the feces (2). Unfertilized eggs may be ingested but are not infective. Fertile eggs embryonate and become infective after 18 days to several weeks (3), depending on the environmental conditions (optimum: moist, warm, shaded soil). After infective eggs are swallowed (4), the larvae hatch (5), invade the intestinal mucosa, and are carried via the portal, then systemic circulation to the lungs (6). The larvae mature further in the lungs (10-14 days), penetrate the alveolar walls, ascend the bronchial tree to the throat, and are swallowed (7). Upon reaching the small intestine, they develop into adult worms (1). Between 2 and 3 months are required from ingestion of the infective eggs to oviposition by the adult female. Adult worms can live for 1 to 2 years.

FIGURE 54–7. ***Ascaris lumbricoides*** **life cycle.**

Adults inhabit small intestine

Eggs mature 3 weeks in soil

*** Complexity: larvae enter blood, pass through alveoli, respiratory tract, esophagus to intestines**

The adult ascarids live high in the small intestine, where they actively maintain their position not by burrowing into the mucosa, but rather by sheer strength of muscular activity, swimming against the stream of stool to avoid being expelled. The eggs are deposited into the intestinal lumen and passed in the feces. Like those of *Trichuris*, the eggs must embryonate in soil, usually for a minimum of 3 weeks, before becoming infectious. And, like *Trichuris*, the eggs of *Ascaris* must be ingested, but the similarity to *Trichuris* ends after ingestion. Once they hatch in the intestines, *Ascaris* larvae penetrate the intestinal mucosa and invade the portal venules. They are carried to the liver, where they are still small enough to squeeze through that organ's capillaries and exit in the hepatic vein. They are then carried to the right side of the heart and pumped out to the lung. By the time they reach the pulmonary capillaries, they are too large to pass through to the left side of the heart. Finding their route blocked, they rupture into the alveolar spaces, are coughed up, and subsequently swallowed. After regaining access to the upper intestine, they complete their maturation and mate. Their reasons for making this circuitous journey are unknown, although the high oxygen tension in the alveoli may provide a growth advantage.

ASCARIASIS

EPIDEMIOLOGY

Epidemiology similar to *Trichuris*

More than 1 billion of the world's population, including millions of Americans, are infected with *A lumbricoides*. Together they have been estimated to pass tons of *Ascaris* eggs into the environment annually. Like trichuriasis, with which it often coexists, ascariasis is a disease of warm climates and poor sanitation. It may be maintained by small children who defecate in the immediate vicinity of the home and pick up infectious eggs on their hands during play, and by adults who consume contaminated uncooked vegetables. In dry, windy climates, eggs may become airborne and then inhaled and swallowed. In tropical areas, the entire population may be involved; most worms, however, appear to be

aggregated in a minority of the population, suggesting that some “wormy persons” are predisposed to heavy infections for reasons unknown. Isolated infected family clusters are more common in temperate climates.

PATHOGENESIS AND IMMUNITY

*** Hypersensitivity to larval migration**

There is evidence that ascariasis induces a partially protective immune response in the host. Moreover, the severity of pulmonary damage induced by the migration of larvae through the lung appears to be related in part to an immediate hypersensitivity reaction to larval antigens.

ASCARIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Clinical manifestations of ascariasis may result from larvae when they migrate through the lung or from adults in the intestinal lumen. During migration through the lungs, larvae may induce fever, cough, wheezing, and shortness of breath. Laboratory studies may reveal eosinophilia, oxygen desaturation, and migratory pulmonary infiltrates. This syndrome is sometimes called Loeffler’s syndrome. The severity of these symptoms related to the degree of hypersensitivity induced by previous infections and the intensity of the current exposure. Death from respiratory failure has been noted occasionally, but this is a rare exception to the rule of spontaneous improvement in most patients.

Asymptomatic with small worm loads

*** Larval migration through lungs mimics pneumonia**

*** Malabsorption, occasional obstruction with heavy adult worm loads**

If the worm load is small, intestinal infections with adult worms may be completely asymptomatic. They often come to clinical attention when the parasite is vomited up or passed in the stool. This situation is most likely during

episodes of fever due to other causes, which appear to stimulate the worms to increase motility. Many physicians who have worked in highly endemic regions have had the disconcerting experience of observing an ascarid crawl out of a patient's mouth or nose during an otherwise uneventful evaluation of fever. Occasionally, an adult worm may migrate to the appendix, bile duct, or pancreatic duct, causing obstruction and inflammation of the organ. After intestinal surgery, adults may migrate through the surgical anastomosis and into the peritoneum, causing peritonitis. Heavy worm loads may produce abdominal pain and malabsorption of fat, protein, carbohydrate, and vitamins. The overall growth of marginally nourished children may be restricted. Occasionally, a bolus of worms may form and cause intestinal obstruction, particularly in young children (**Figure 54–8**). Worm loads of 50 are not uncommon, although 2000 worms have been recovered from a single child. WHO estimates 60,000 may die from ascariasis annually worldwide.

FIGURE 54–8. Ascariasis intestinal obstruction. Mass of adult worms recovered from infant at autopsy. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

DIAGNOSIS

Stool reveals characteristic eggs

When it happens, the passage of an adult worm makes the diagnosis easy. Otherwise, ascariasis is generally confirmed by finding its characteristic eggs (Figure 54–7B) in feces. The extreme productivity of the female ascarid generally makes this easy, except when atypical-appearing unfertilized eggs predominate. The pulmonary phase of ascariasis is diagnosed by the finding of larvae and eosinophils in the sputum.

TREATMENT AND PREVENTION

*** Prevention via sanitation**

Albendazole, mebendazole, and pyrantel pamoate are highly effective; albendazole is preferred when *T trichiura* is also present, which happens commonly. Community-wide control of ascariasis can be achieved with mass drug administration every 6 months. Ultimately, durable control requires adequate sanitation facilities.

Why do we not expect eosinophilia in patients with longstanding infection with adult ascaris worms?

HOOKWORMS

ANCYLOSTOMA AND *NECATOR*: PARASITOLOGY

***N americanus, A duodenale* infect humans**

Oral cavity morphology distinctive

Two species, *Necator americanus* and *A duodenale*, infect humans. Adults of both species are pinkish-white and measure about 10 mm in length (**Figure 54–9**). The head is often curved in a direction opposite to that of the body, giving these worms the hooked appearance from which their common name is derived. The males have a unique fan-shaped copulatory bursa, rather than the curved,

pointed tail common to the other intestinal nematodes. The two species can be readily differentiated by the morphology of their oral cavity. *A duodenale* possesses four sharp tooth-like structures, whereas *N americanus* has dorsal and ventral cutting plates. With the aid of these structures, the hookworms attach to the mucosa of the small bowel and suck minute quantities of blood. The fertilized female releases 10,000 to 20,000 eggs daily. They measure 40 by 60 µm, possess a thin shell, and are usually in the two- to eight-cell stage when passed in the feces (Figure 54–9A).

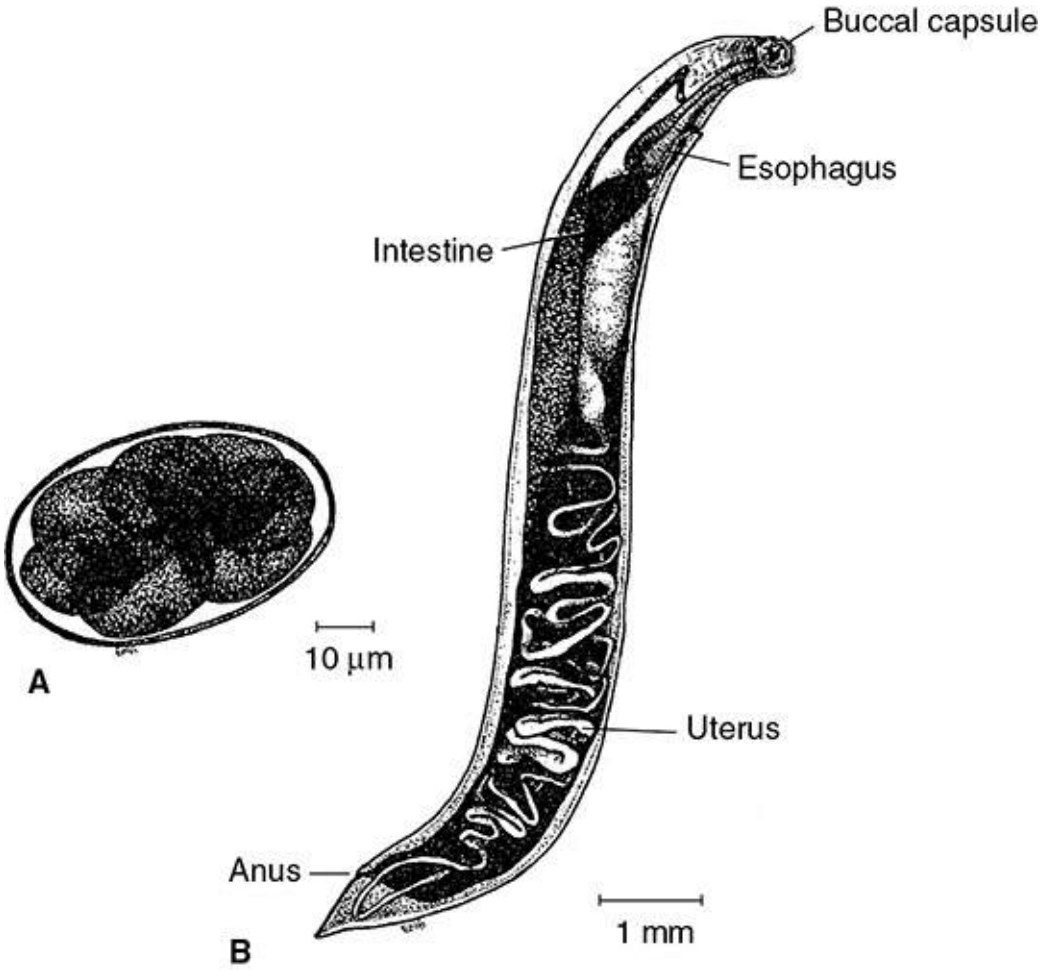


FIGURE 54–9. ***Necator americanus*. A.** Structure of hookworm egg in stool. **B.** Structure of female adult hookworm.

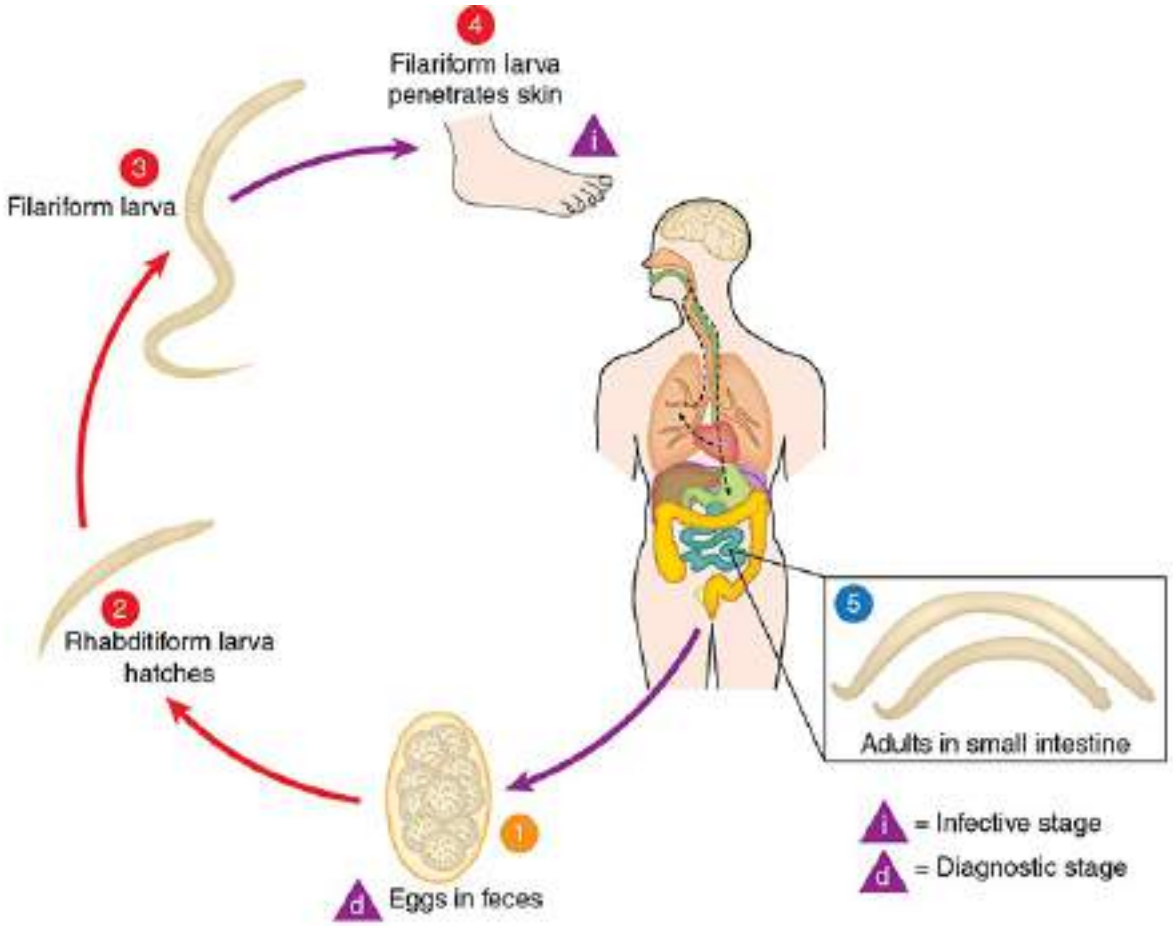
LIFE CYCLE (FIGURE 54–10)



Eggs are passed in the stool (1), and under favorable conditions (moisture, warmth, shade), larvae hatch in 1 to 2 days. The released rhabditiform larvae grow in the feces and/or the soil (2), and after 5 to 10 days (and two molts) they become filariform (third-stage) larvae that are infective (3). These infective larvae can survive 3 to 4 weeks in favorable environmental conditions. On contact with the human host, the larvae penetrate the skin and are carried through the blood vessels to the heart and then to the lungs. They penetrate into the pulmonary alveoli, ascend the bronchial tree to the pharynx, and are swallowed (4). The larvae reach the small intestine, where they reside and mature into adults. Adult worms live in the lumen of the small intestine, where they attach to the intestinal wall with resultant blood loss by the host (5). Most adult worms are eliminated in 1 to 2 years, but the longevity may reach several years. Some *A duodenale* larvae, following penetration of the host skin, can become dormant (in the intestine or muscle). In addition, infection by *A duodenale* may probably also occur by the oral and transmammary route. *Necator americanus*, however, requires a transpulmonary migration phase.

FIGURE 54–10. Hookworm life cycle.

*** Complexity: Filariform larvae penetrate skin and then follow same path as *Ascaris* larvae to gut**

The life cycles of the two hookworms, *N americanus* and *A duodenale*, are

identical. Adults live attached to the small bowel mucosa, where they suck blood, mate, and shed eggs. The eggs are passed in the feces at the four- to eight-cell stage of development. On reaching soil, the eggs hatch within 48 hours, releasing microscopic **rhabditiform larvae.** These move actively through the surface layers of soil, feeding on bacteria and debris. After doubling in size, they molt to become infective **filariform larvae,** which may survive in moist conditions without feeding, for up to 6 weeks. On contact with human skin, these hookworms penetrate the epidermis, reach the lymphohematogenous system, and are passively transported to the right side of the heart and onward to the lungs. Here, like juvenile ascarids, they develop and ultimately rupture into alveolar spaces, are coughed up, swallowed, and pass into the small intestine, where they mature into adults.

Think ▸▸ Apply 54-1: Although the larvae may trigger short-term eosinophilia when they transit the lungs, adult worms live in the patient's gut lumen, where they are relatively shielded from the immune system.

HOOKWORM DISEASE

EPIDEMIOLOGY

Larvae require hot, moist conditions, human skin

Limited to tropical areas, southern United States.

Hookworm transmission requires deposition of egg-containing feces on shady, well-drained soil; development of larvae under conditions of abundant rainfall and high temperatures (23-33°C); and direct contact of unprotected human skin with filariform larvae. Infections become particularly intense in closed, densely populated communities, such as tea and coffee plantations. *Necator americanus* is found in the tropical areas of South Asia, Africa, and America, as well as the southern United States. *A duodenale* is seen in the Mediterranean basin, the Middle East, northern India, China, and Japan. It has been estimated that

together these two worms may cause 50,000 to 60,000 deaths annually, and extract over 1 million liters of blood each day from 700 million people scattered around the globe, including hundreds of thousands in the United States.

PATHOGENESIS AND IMMUNITY

Adults live in gut for years

*** Blood loss in heavy infections**

Peripheral and gut eosinophilia

Each adult *A duodenale* extracts 0.2 mL of blood daily, *N americanus* 0.03 mL of blood. Additional blood loss may be related to the worms' tendency to migrate within the intestine, leaving bleeding points at old sites of attachment. Because the adults may survive 2 to 14 years, the accumulated blood loss in heavy infections may be substantial, especially in patients with other reasons for iron deficiency. Infection elicits both a humoral antibody response and immediate hypersensitivity reaction in the host, but evidence that these influence the infection is lacking. Eosinophils in the blood and gut may play a role in the destruction of worms and/or modulation of the immediate hypersensitivity reaction.

HOOKWORM DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

*** Asymptomatic depending on worm load**

*** Pruritus, rash at skin penetration site**

In most patients infected with hookworms, the adult worm burden is small and the infection asymptomatic. Clinical manifestations, when they do occur, may be related to the penetration of the skin by the filariform larvae, the migration of the larvae through the lung, and/or the presence of adult worms in the gut. Skin penetration may produce a pruritic erythematous rash and swelling, known as "ground itch." This manifestation is more common in infection with *N*

americanus, and happens on any skin that has come into contact with the ground, generally occurs between the toes or on the ankle, and may persist for days before resolving spontaneously.

Iron-deficiency anemia caused by blood loss from intestinal worms

Pulmonary manifestations of hookworm disease may mimic those seen in ascariasis, but are generally less frequent and less severe. In the gut, the adult worm may produce epigastric pain and abnormal peristalsis. The major manifestations, however, are the result of chronic blood loss: anemia and hypoalbuminemia. The severity of the anemia depends on the worm burden, other concurrent causes of blood loss such as menses, and the intake of dietary iron. If iron intake exceeds iron loss resulting from hookworm infection, a normal hemoglobin will be maintained. Commonly, however, dietary iron is ingested in a form that is poorly absorbed. As a result, severe anemia may develop over a period of months or years. In children, this condition may precipitate heart failure or kwashiorkor. Neurocognitive and physical development may be impacted.

DIAGNOSIS

*** Diagnose by eggs in human stool**

Eggs of both look the same

The diagnosis of hookworm disease is made by examining direct or concentrated stool specimens for the distinctive eggs (Figure 54–9A). Because these eggs are nearly identical in the two species and because treatment of both species is the same, precise identification of the causative worm is not important. Quantitative egg counts permit estimation of worm load, information of epidemiological rather than clinical use. If the stool is allowed to stand too long before it is examined, the eggs may hatch, releasing rhabditiform larvae. These larvae closely resemble those of *S stercoralis* and must be differentiated from them (see below).

TREATMENT AND PREVENTION

*** Treatment highly effective**

*** Prevention via improved sanitation**

The anemia must be corrected. When it is mild or moderate, iron replacement is adequate. More severe anemia may require blood transfusions. The three most widely used anthelmintic agents, albendazole, mebendazole, and pyrantel pamoate are all highly effective. As with *Trichuris* and *Ascaris*, prevention of hookworm infection requires improved sanitation. However, an additional prevention benefit may be afforded by wearing shoes, because this provides defense against skin invasion by filariform larvae. Attempts to develop effective vaccines against human hookworm infection have not yet borne fruit.

STRONGYLOIDES

STRONGYLOIDES STERCORALIS:

PARASITOLOGY

S stercoralis has the most complex life cycle of all the intestinal nematodes—and the greatest risk of life-threatening, overwhelming infection. The adults measure only 2 mm in length, making them the smallest of the intestinal nematodes. The male is seldom seen within the human host, suggesting that the female can conceive parthenogenetically in this environment. Strongyloides eggs are not diagnostically important because they usually hatch within the intestinal wall, releasing microscopic rhabditiform larvae. These larvae then develop into larger infectious filariform larvae. These larvae, which measure about 16 by 200 μm, can be distinguished from the similar larval stage of the hookworms by their short buccal cavity and large genital primordium (**Figure 54–11**).

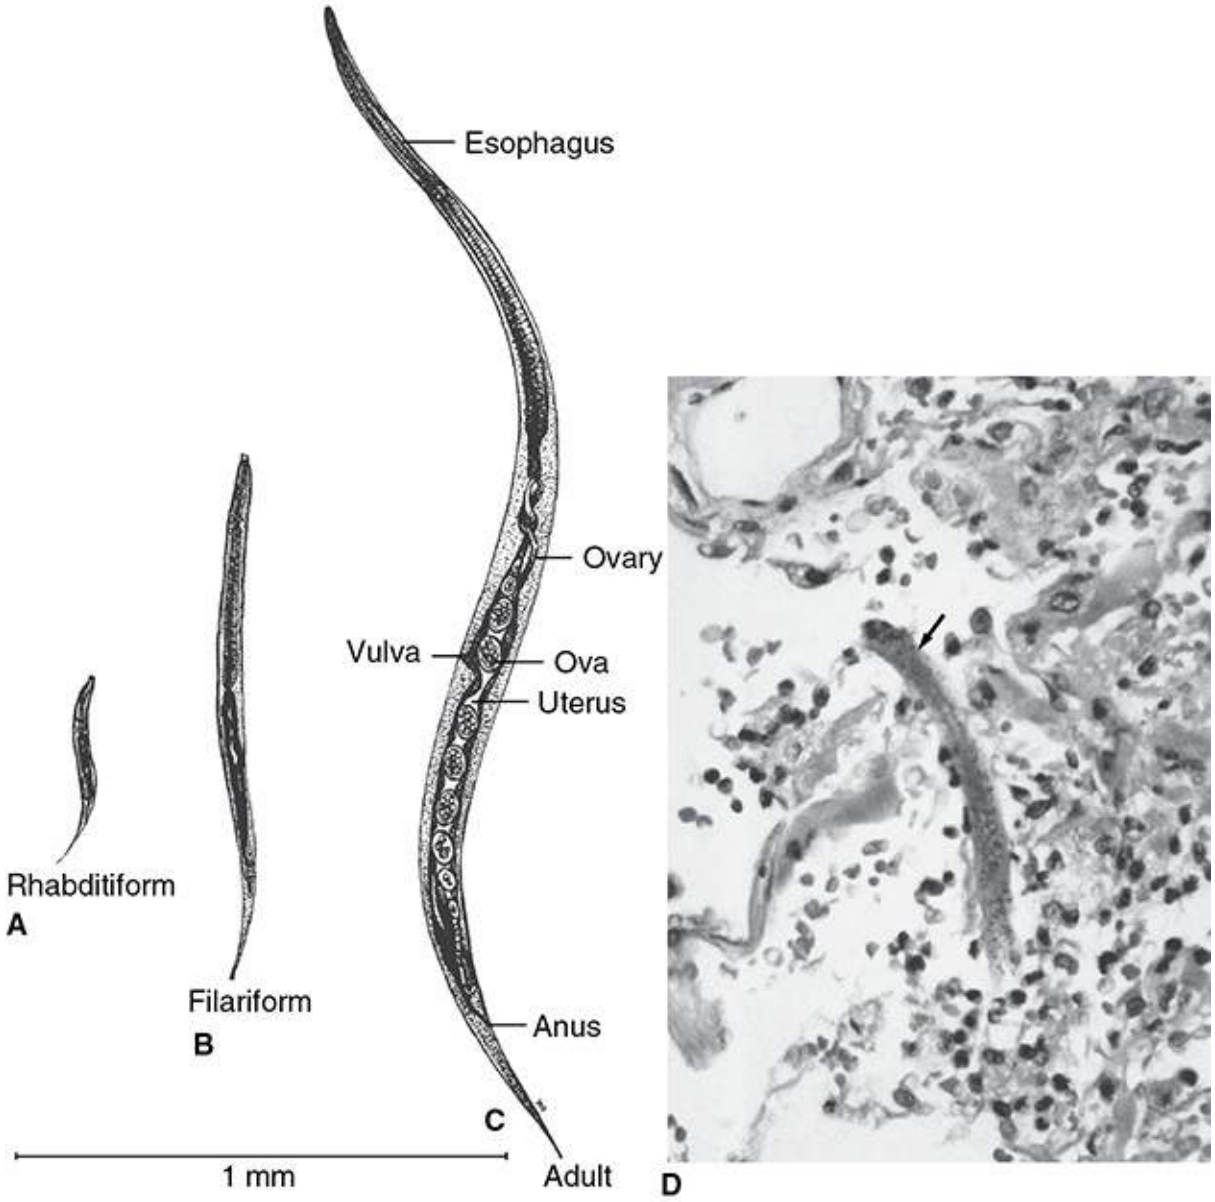


FIGURE 54–11. ***Strongyloides stercoralis.*** **A–C.** Structure of rhabditiform larvae, filariform larvae, and adult worm. **D.** Filariform larvae (arrow) in lung surrounded by fibrin and inflammatory cells. (D, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

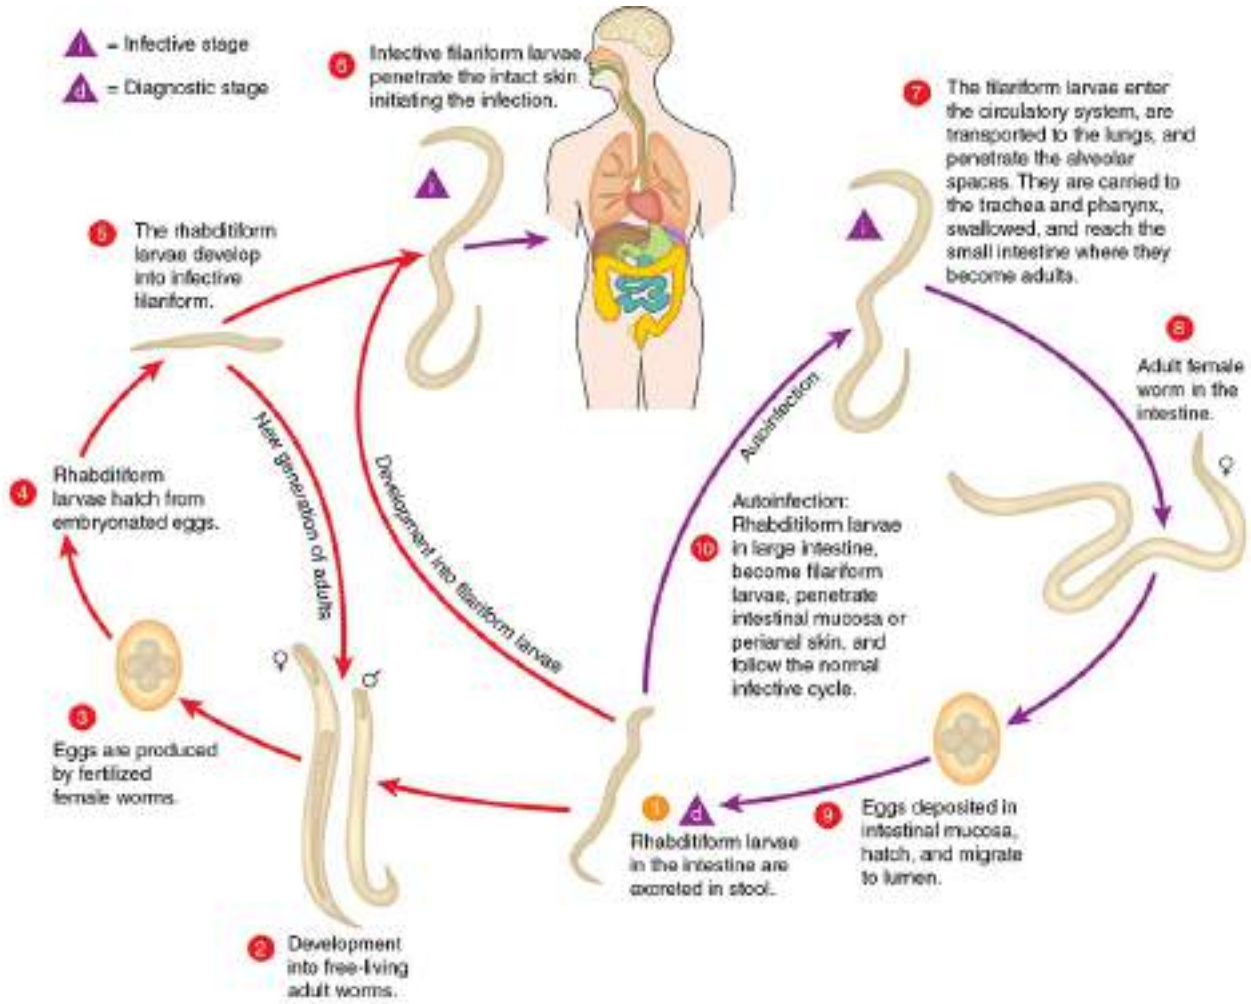
LIFE CYCLE (FIGURE 54–12)



The *Strongyloides* life cycle is more complex than that of most nematodes with its alternation between free-living and parasitic cycles, and its potential for autoinfection and multiplication within the host. Two types of cycles exist:

Free-living cycle: The rhabditiform larvae passed in the stool (1) (see "Parasitic cycle" below) can either molt twice and become infective filariform larvae (direct development) (6) or molt four times and become free-living adult males and females (2) that mate and produce eggs (3) from which rhabditiform larvae hatch (4). The latter in turn can either develop (5) into a new generation of free-living adults (as represented in (2)), or into infective filariform larvae (6). The filariform larvae penetrate the human host skin to initiate the parasitic cycle (see below) (3).

Parasitic cycle: Filariform larvae in contaminated soil penetrate the human skin (3), and are transported to the lungs where they penetrate the alveolar spaces; they are carried through the bronchial tree to the pharynx, are swallowed and then reach the small intestine (7). In the small intestine they molt twice and become adult female worms (8). The females live threaded in the epithelium of the small intestine and by parthenogenesis produce eggs (9), which yield rhabditiform larvae. The rhabditiform larvae can either be passed in the stool (1) (see "Free-living cycle" above), or can cause autoinfection (10). In autoinfection, the rhabditiform larvae become infective filariform larvae, which can penetrate either the intestinal mucosa (internal autoinfection) or the skin of the perianal area (external autoinfection); in either case, the filariform larvae may follow the previously described route, being carried successively to the lungs, the bronchial tree, the pharynx, and the small intestine where they mature into adults; or they may disseminate widely in the body. To date, occurrence of autoinfection in humans with helminthic infections is recognized only in *Strongyloides stercoralis* and *Capillaria philippinensis* infections. In the case of *Strongyloides*, autoinfection may explain the possibility of persistent infections for many years in persons who have not been in an endemic area and of hyperinfections in immunodepressed individuals.

FIGURE 54–12. ***Strongyloides*** **life cycle.**

*** Complexity: direct cycle resembles hookworm, except larvae develop in human gut**

* Further complexity: development of filariform stage in gut produces human autoinfection

Three different life cycles have been described for the *Strongyloides* nematode. The first, or **direct cycle,** is similar to that observed with the hookworms. Adult females live in the small intestinal mucosa, where they lay eggs. These eggs often hatch within the intestinal tissue, releasing rhabditiform larvae that work their way out to the gastrointestinal (GI) lumen. After these larvae are passed in the stool, they molt in the soil to become larger, infectious filariform larvae, which can penetrate human skin just like hookworms—or be ingested on soil-contaminated food. After transport from the skin to the lung (Figure 54–11D) via the vascular system, they are coughed up and swallowed, then mature into adults in the small bowel. In the second, or **autoinfective cycle,** the rhabditiform larva's passage from the colon to the outside world is delayed by constipation or other factors, allowing it to transform into an infective filariform larva while still within the body of its host. This larva may then invade the internal mucosa (internal autoinfection) or perianal skin (external autoinfection) without an intervening soil phase. Thus, *S stercoralis*—unlike any of the other intestinal nematodes—has the capacity to multiply within the human body. The worm burden may increase dramatically, and the infection may persist indefinitely, without the need for reinfection from the environment—and with potentially dire consequences to the host, as described later. In the third, or **free-living cycle,** the rhabditiform larvae are passed in the stool and deposited on the soil, where they develop into free-living adult males and females. These adults feed on bacteria in the earth and may propagate several generations of free-living worms before infective filariform larvae are again produced. This cycle creates a soil reservoir that may persist even without continued deposition of feces.

STRONGYLOIDIASIS

EPIDEMIOLOGY

Like hookworm but may persist for years in travelers and migrants

The distribution of *S stercoralis* parallels that of the hookworms, although it is less prevalent in all but tropical areas. It infects 90 million individuals

worldwide, including hundreds of thousands throughout the rural areas of Puerto Rico and the southeastern sections of the continental United States. Like hookworm infection, *S stercoralis* is generally acquired by direct contact of skin with soil-dwelling larvae, although infection may also follow ingestion of filariform-contaminated food. Transformation of the rhabditiform larvae to the filariform stage within the gut can result in seeding of the perianal area with infectious organisms. These larvae may continue to autoinfect the original host over and over again for years or decades. Thus, individuals who currently reside in low-prevalence areas may still harbor the infection long after leaving highly endemic regions—an epidemiological factor that separates strongyloidiasis from the other intestinal nematode infections we have covered.

PATHOGENESIS AND IMMUNITY

Damage may cause malabsorption

*** Immunosuppression enhances autoinfection by accelerating larval development**

Invasion of the intestinal epithelium may accelerate epithelial cell turnover, alter intestinal motility, and induce acute and chronic inflammatory lesions, ulcerations, and abscess formation, all of which may play a role in the malabsorptive syndrome that frequently characterizes clinical disease. Steroid- or malnutrition-related immunosuppression of the GALT appears to accelerate the metamorphosis of rhabditiform to filariform larvae within the bowel lumen, enhancing the frequency and intensity of autoinfection. T lymphocytes are important for maintaining control of auto-infection, although in many cases the immune system is unable to permanently clear the infection. and so the loss of T-lymphocyte function may trigger catastrophic hyperinfection.

STRONGYLOIDIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Pulmonary, intestinal manifestations like hookworm, *Ascaris*

Patients with strongyloidiasis often have no symptoms at all. They may present with a history of “ground itch,” or with the pulmonary disease seen in both ascariasis and, less often, in hookworm infection. The intestinal infection itself is usually asymptomatic. With heavy worm loads, however, the patient may complain of epigastric pain and tenderness, often aggravated by eating. In fact, peptic ulcer-like pain associated with peripheral eosinophilia strongly suggests strongyloidiasis. In severe infections, the biliary and pancreatic ducts, the entire small bowel, and the colon may be involved. With widespread involvement of the intestinal mucosa, vomiting, diarrhea, paralytic ileus, and malabsorption may be seen.

Autoinfection lesions over buttocks, abdomen, back

*** May persist for decades**

Sometimes, rhabditiform larvae remain on the perianal skin after a bowel movement, and develop into infectious filariform larvae which penetrate the skin and continue the life cycle. This external autoinfection produces transient, raised, red, serpiginous lesions over the buttocks, abdomen, and lower back caused by larval invasion of the perianal area, called **larva currens.** If the patient is not treated, these lesions may recur at irregular intervals over a period of decades; they are particularly common after recovery from a febrile illness. Over 25% of British and American servicemen imprisoned in Southeast Asia during World War II continued to demonstrate such lesions before diagnosis and treatment some 40 years after exposure.

*** Hyperinfection in immunosuppressed, uncommon in AIDS**

*** Rule out strongyloidiasis before immunosuppression**

Massive **hyperinfection** with strongyloidiasis may occur in immunosuppressed patients, especially in those receiving glucocorticoid therapy, which reduces the GALT’s T-lymphocyte–mediated cellular immune response that usually keeps *Strongyloides* under control. Because the original infection may have happened years earlier, and because autoinfection is often asymptomatic, patients and physicians often fail to appreciate the presence of these infections. This can have catastrophic consequences if immunosuppressive medications are initiated before the infection is cured. In these tragic cases of hyperinfection, larvae cause severe enterocolitis and disseminate throughout the

body to organs including the heart, lungs, and central nervous system. The larvae may carry enteric bacteria with them, producing Gram-negative bacteremia and occasionally Gram-negative meningitis that may result in death. Surprisingly, this phenomenon has been unusual in patients with acquired immunodeficiency syndrome (AIDS), even in areas where strongyloidiasis is highly endemic. Immunodeficiency due to another retrovirus, human T-lymphotropic virus-1 (HTLV-1), has a stronger association with *Strongyloides* hyperinfection.

DIAGNOSIS

*** Subclinical autoinfection: serology, eosinophilia, rhabditiform larvae in stool or duodenal aspirates**

*** Symptomatic or hyperinfection: filariform larvae in sputum, no eosinophilia**

The diagnosis of strongyloidiasis is sometimes made by finding rhabditiform larvae in the stool. Preferably, only fresh specimens should be examined to avoid the confusion induced by the hatching of hookworm eggs with the release of their look-alike larvae. The number of larvae passed in the stool varies from day to day, often requiring the examination of several specimens before the diagnosis of strongyloidiasis can be made. When absent from the stool, larvae may sometimes be found in duodenal aspirates or jejunal biopsy specimens. If the pulmonary system is involved, the sputum should be examined for the presence of larvae. Agar plate culture methods may recover organisms that go undetected by microscopic examination. Diagnosing autoinfection is best accomplished with a blood test: serology via enzyme-linked immunosorbent assays for antibodies to excretory–secretory or somatic antigens is the preferred method, because rhabditiform larvae are challenging to detect in stool. Serology carries a strong positive predictive value. Unfortunately, serology's negative predictive value is less reliable. On the other hand, during hyperinfection time is of the essence and a more rapid and reliable technique is essential. Fresh and stained specimens from the sputum or bronchoalveolar fluid should be inspected with a microscope, because these may teem with filariform larvae. Whereas eosinophilia is common in autoinfection, it is usually *absent* in hyperinfection; indeed, it is the lack of these cells that seems to predispose patients to hyperinfection in the first place.

TREATMENT AND PREVENTION

*** Treat autoinfection to prevent hyperinfection**

*** Outcomes poor in hyperinfection**

All infected patients should be treated to prevent the buildup of the worm burden by autoinfection and the serious consequences of hyperinfection. The drug of choice for uncomplicated strongyloidiasis is two doses of oral ivermectin, another contrast with the other intestinal nematodes which respond best to albendazole. In strongyloides hyperinfection syndrome, supportive treatment and antibacterials are essential to address sepsis; ivermectin therapy must be extended for at least 1 week, and potentially as long as 6 months, if the underlying immunosuppression cannot be removed. The cure rate is less than 100%, and stools should be checked after therapy to see whether retreatment is indicated. Patients who have resided in an endemic area at any time in their lives should be assessed for *S stercoralis* both before corticosteroid treatment or immunosuppressive therapy. Medical personnel caring for patients with hyperinfection syndromes should wear gowns and gloves because stool, saliva, vomitus, and body fluids may contain infectious filariform larvae.

Which of the gastrointestinal helminth infections described earlier could be prevented with improved disposal of human waste?

KEY CONCLUSIONS

- Embryonation in the soil is a common theme for most of these worms.
- Gastrointestinal helminths are usually well tolerated by the human host.
- Some have larvae that migrate through tissue, causing temporary side effects.
- Symptoms caused by adults in the gut increase with the number of adult worms: a handful of adults are usually harmless, whereas hundreds may cause true illness.
- Of the common GI helminths discussed here, only strongyloides may persist in the human host indefinitely.
- Infections with all the GI helminths can be treated medically.

CASE STUDY

A Worm in the Throat!

This 4-year-old boy, who resides in the rural Southeastern United States, likes to play barefooted in the summer. He is brought to the physician’s office with a 3-day history of fever, cough, and mild wheezing. On initial examination, the physician is startled to observe two small worm-like objects in the posterior oropharynx.

QUESTIONS

1. Which of the following is the LEAST likely cause?

A. *Ascaris*
B. *Trichuris*
C. *Necator*
D. *Ancylostoma*

2. Stool examination is the usual initial diagnostic approach in all of the following, EXCEPT:

A. *Enterobius*
B. *Trichuris*
C. *Ascaris*
D. *Necator*

3. Which of the following can multiply within the human host (autoinfection)?

A. *Ascaris*
B. *Ancylostoma*
C. *Trichuris*
D. *Strongyloides*

ANSWERS

1. (B)

2. (A)

3. (D)

Think ▸▸ Apply 54-2: All except for enterobiasis, which is usually spread directly from anus to hand to mouth. The others involve transmission via feces deposited on the ground.

Tissue Nematodes

Toxocara canis • *Baylisascaris procyonis* • *Trichinella spiralis* • *Ancylostoma braziliense* • *Wuchereria bancrofti* • *Brugia malayi* • *Onchocerca volvulus* • *Loa Loa* • *Dracunculus medinensis*

The message is not so much that the worms will inherit the Earth, but that all things play a role in nature, even the lowly worm.

—Gary Larson

OVERVIEW

The nematodes discussed in this chapter cause disease through their presence in the tissues and lymphohematogenous system of the human body. Some migrate through the human gastrointestinal tract on their way there, but because this is a temporary part of their life cycle, they are not considered to be "intestinal" nematodes.

Four of them—*Toxocara canis*, *Baylisascaris procyonis*, *Trichinella spiralis*, and *Ancylostoma braziliense*—are **zoonotic,** meaning natural parasites of domestic and wild animals. Although they are capable of infecting humans, they cannot complete their life cycle in the human host. Humans, therefore, serve only as "accidental hosts," injured bystanders rather than major participants in the life cycle of these parasites.

The remaining four major tissue nematodes—*Wuchereria bancrofti*, *Brugia malayi*, *Onchocerca volvulus*, and *Loa loa*—are members of a single superfamily (Filarioidea). All are **anthroponotic,** meaning they use humans as their definitive host. The thin, thread-like adults live for years in the subcutaneous tissues and lymphatic vessels, where they discharge their live-born offspring called "microfilariae." These progeny circulate in the blood or migrate in the subcutaneous tissues until they are ingested by a specific blood-sucking insect. Within this insect, they transform into filariform larvae capable of infecting another human when the vector again takes a blood meal. We will also

touch briefly on *Dracunculus medinensis*, the guinea worm, which is on the verge of eradication.

Table 55-1 summarizes these nematodes, diseases they cause, their definitive host, and usual routes of human infection.

TABLE 55–1 General Characteristics of Tissue Nematodes

PARASITE	DISEASE	NATURAL DEFINITIVE HOST	USUAL SOURCE OF HUMAN INFECTION
Toxocara canis	Toxocariasis (visceral or ocular larva migrans)	Dog	Ingestion of ova from canine stools
Baylisascaris procyonis	Eosinophilic CNS or ocular disease	Raccoon	Ingestion of ova from raccoon stools
Trichinella spiralis	Trichinosis	Pig	Ingestion of improperly cooked pork
Ancylostoma braziliense	Cutaneous larva migrans	Cat	Soil contaminated with dog or cat feces
Wuchereria bancrofti, *Brugia malayi*	Lymphatic filariasis (elephantiasis)	Human	Mosquito
Onchocerca volvulus	Onchocerciasis (river blindness, dermatitis)	Human	*Simulium* fly
Loa loa (eye worm)	Loiasis (Calabar swellings)	Human	*Chrysops* fly
Dracunculus medinensis (guinea worm)	Dracunculiasis	Human	Drinking water contaminated by cyclops

• *TOXOCARA*

TOXOCARA CANIS: PARASITOLOGY AND LIFE CYCLE (FIGURE 55–1)

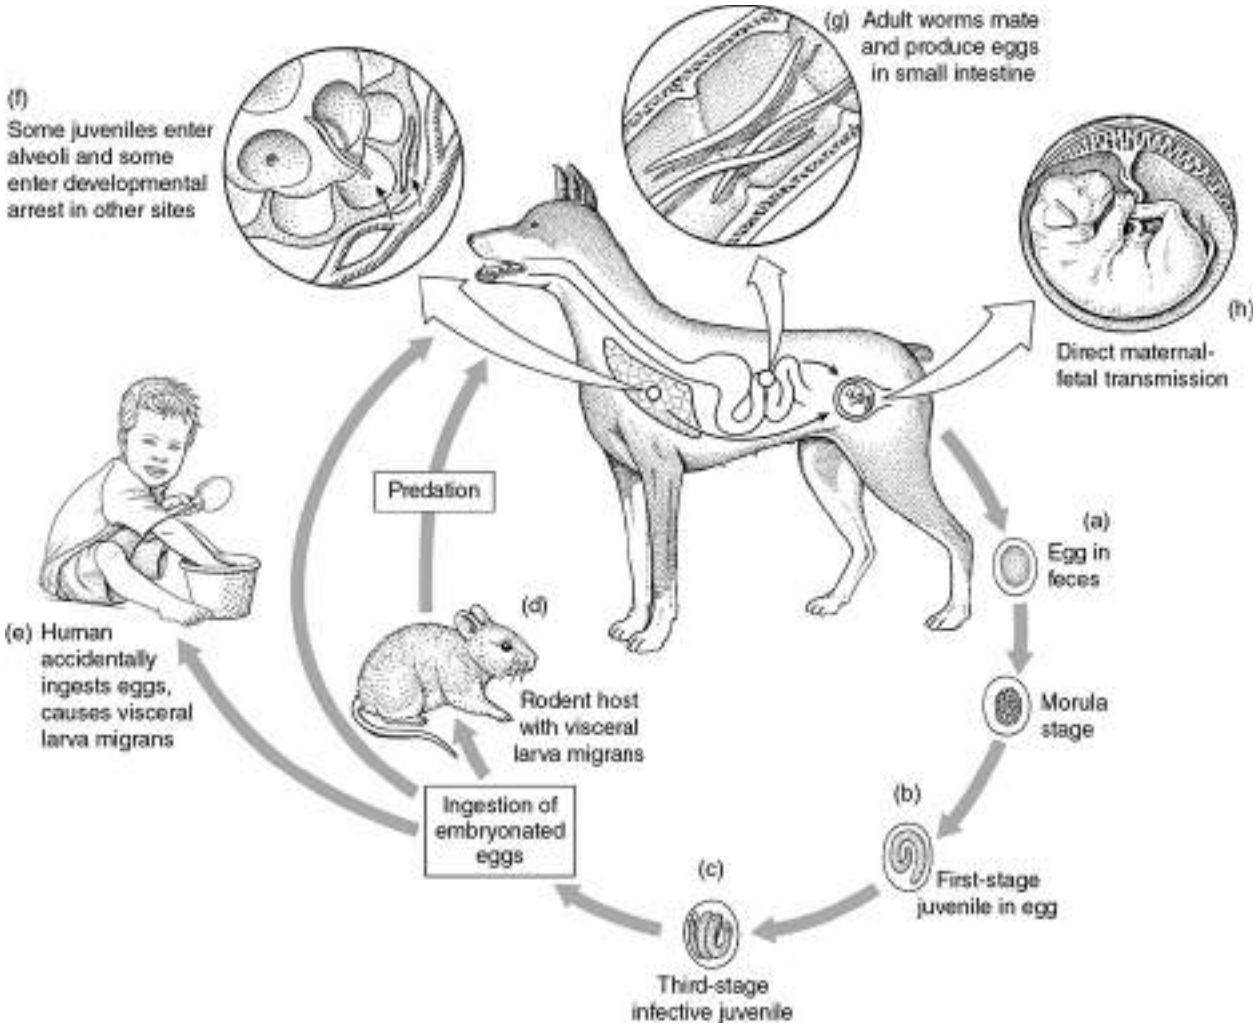

FIGURE 55–1. Life cycle of *Toxocara canis.* (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

Cycle in canines resembles ascariasis in humans, but with tissue cysts

* Infected puppies, lactating mothers excrete numerous ova

Eggs embryonate in soil

T canis is a large intestinal ascarid of canines, including dogs, foxes, and wolves. Occasionally, a related organism found in cats (*Toxocara cati*) can behave in a similar fashion. (Note: Do not confuse this worm with the similar-sounding protozoan *Toxoplasma gondii*. Both derive their name from the Latin root “toxo” meaning “poison” or “harm.”) Each female worm discharges approximately 200,000 thick-shelled eggs daily into the fecal stream. After reaching the soil, these eggs embryonate for a minimum of 2 to 3 weeks. Thereafter, the eggs are

infectious to canines, humans, and other mammals that ingest them. The eggs may remain infectious in the soil for months to years. When eaten by a puppy, the larvae exit from the eggshell, penetrate the intestinal mucosa, and migrate through the liver to the right side of the heart and from there to the lung. Here, like the offspring of *Ascaris lumbricoides*, they burst into the alveolar airspaces and are coughed up and swallowed; thereafter, they mature in the small bowel. However, in fully grown dogs, the life cycle is different: most of the migrating larvae pass through the pulmonary capillaries and reach the systemic circulation. These larvae eventually are filtered out and encyst in the dog's tissues, where they lie dormant for months or longer. Hormonal changes and/or diminished immunity in the pregnant female stimulate the larvae to resume development, migrate across the placenta, and infect the unborn pups. Larvae may also pass to the newborn puppies in their mother's milk. Approximately 4 weeks after birth, both the puppies and the lactating mother begin to pass large numbers of eggs in their stools, shed by the adult worms that inhabit their intestinal tract. These eggs embryonate in the soil for 2 to 3 weeks before becoming infectious. The mother may then be superinfected by ingesting the eggs from the soil or eating visceral cysts in an intermediate host such as a rodent.

*** Transmission to humans by ingestion of eggs in soil**

Like ascaris, but larvae invade tissues and encyst instead of returning to GI tract via lung

Think of the life cycle of human toxocariasis as the same as human ascariasis, but with a key difference: When humans ingest infectious eggs, the liberated larvae are small enough to pass through the pulmonary capillaries and reach the systemic circulation. Only rarely do larvae break into the alveoli, get coughed up, and swallowed to reach the intestine to mature into adults, which is what happens in human ascariasis. Instead, larvae in the systemic circulation continue to grow there. Thus, humans are intermediate rather than definitive hosts of *T canis*. When their size exceeds the diameter of the vessel through which they are passing, they penetrate its wall and enter the tissue. The larvae induce a T_H2-type CD4+ response characterized by eosinophilia and IgE production.

TOXOCARIASIS

EPIDEMIOLOGY

Eggs deposited soil by domestic dogs

Children often infected

Infection more common than disease

T canis is a cosmopolitan parasite. The infection rate in the 50 million dogs inhabiting the United States is very high; over 80% of puppies and 20% of older animals are parasitized. “Man’s best friend” deposits more than 3500 tons of feces daily in the streets, yards, and parks of America, and there is a real health risk. In some areas, between 10% and 30% of soil samples taken from public parks have contained viable *Toxocara* eggs. Moreover, serologic surveys of humans indicate that 4% to 20% of the population has ingested these eggs at some time. The incidence of infection appears to be higher in the Southeastern United States; presumably the warm, humid climate prolongs survival of the eggs, thereby increasing exposure. Indeed, seroprevalence rates of more than 50% have been noted in some developing nations. Puppies in the home increase the risk of infection. Clinical manifestations occur predominantly among children 1 to 6 years of age; many have a history of geophagia, suggesting that disease transmission results from direct ingestion of eggs in the soil. Most infections are subclinical, but the incidence of overt disease is likely underreported.

TOXOCARIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Any tissue invaded by larvae

*** Organ invasion causes hypersensitivity**

*** Ocular invasion produces granulomatous endophthalmitis**

The larvae of *Toxocara* that reach the systemic circulation may invade any tissue of the human body, where they can induce necrosis, bleeding, eosinophilic granulomas, and subsequent fibrosis. The liver, lungs, heart, skeletal muscle, brain, and eye are involved most frequently. The severity of clinical manifestations is related to the number and location of these lesions and the degree to which the host has become sensitized to larval antigens. Children with more intense infection may have fever and an enlarged, tender liver. Those who are seriously ill may develop a skin rash, an enlarged spleen, asthma, recurrent pulmonary infiltrates, abdominal pain, sleep and behavioral changes, focal neurologic defects, and seizures. This illness, called “visceral larva migrans,” often persists for weeks to months. Death may result from respiratory failure, cardiac arrhythmia, or brain damage. In older children and adults, these systemic manifestations are uncommon, although eye invasion by larvae (“ocular larva migrans”) is more common. Typically, unilateral strabismus, loss of red reflex (leukocoria), or decreased visual acuity causes the patient to consult an ophthalmologist. Examination reveals granulomatous endophthalmitis, a reaction to larvae that are often already dead; it is sometimes mistaken for malignant retinoblastoma, and unnecessary enucleations have been performed.

DIAGNOSIS

*** Usually a clinical diagnosis**

Serodiagnosis using EIA

Tissue biopsy provides confirmation

Stool examination for eggs is not helpful because the parasite seldom reaches adulthood in humans. A presumptive diagnosis may be made based on the clinical picture: eosinophilic leukocytosis, elevated serum levels of IgE, and elevated antibody titers to blood group antigens, particularly the group A antigen. An enzyme immunoassay (EIA) using larval antigens has been developed, providing clinicians with a reasonable but imperfect negative and positive predictive value. A western blot procedure is somewhat more sensitive but is not widely available. Unfortunately, many patients with related ocular infections remain seronegative; some demonstrate elevated antibody titers within the ocular fluids. Definitive diagnosis requires demonstration of the larva in a

liver biopsy specimen or at autopsy.

TREATMENT AND PREVENTION

*** Corticosteroids in serious disease**

Disposal of pet feces, deworming

Reduction of the exuberant host immune response is the main goal of treatment. Corticosteroid treatment may be lifesaving if the patient has serious pulmonary, myocardial, or central nervous system (CNS) involvement. Anthelmintic therapy using albendazole is often administered after steroids are started, although the efficacy of this drug remains uncertain. Prevention requires control of indiscriminate defecation by dogs and repeated deworming of household pets. Deworming must begin when the animal is 3 weeks of age and should be repeated every 3 months during the first year of life and twice a year thereafter.

• *BAYLISASCARIS*

*** Raccoon roundworm mimics *Toxocara*, but can be lethal**

Another nematode that shares clinical and epidemiologic similarities with *Toxocara* has been increasingly recognized. *B procyonis* (raccoon roundworm) has predominantly affected children playing in wooded areas that are frequented by raccoons. Raccoons tend to defecate in dedicated areas called “latrines” which may teem with infective eggs. When these eggs area accidentally ingested, they may cause a disease that mimics toxocariasis. Unfortunately, this organism has a predilection for neural and eye tissue, and can lead to devastating eosinophilic meningoencephalitis and retinitis. The diagnostic and therapeutic approaches are like those for *Toxocara*, but the clinical outcome may be fatal, especially when therapy is delayed.

• *TRICHINELLA*

TRICHINELLA SPIRALIS: PARASITOLOGY AND

LIFE CYCLE

Intestinal parasites of many flesh-eating mammals

Adult *Trichinella* live in the duodenal and jejunal mucosa of carnivores throughout the world, particularly swine, rodents, bears, canines, felines, and marine mammals. Originally thought to be members of a single species, it is now clear that arctic, temperate, and tropical strains of *Trichinella* demonstrate significant epidemiologic and biologic differences, and they have been reclassified into eight distinct species. Only two species, *T spiralis* and the arctic species *T nativa*, display a high level of pathogenicity for humans. (Note: Do not confuse the tissue roundworm *T spiralis* with the similar-sounding protozoan *Trichomonas vaginalis*; both derive their name from the Latin root "trich," meaning "hairy," based on their appearance under the microscope.)

Within the host intestinal tissue, the tiny (1.5 mm) male copulates with his larger (3.5 mm) mate and, apparently spent by the effort, dies. Within 1 week, the inseminated female begins to discharge offspring. Unlike those of most nematodes, these progeny undergo intrauterine embryonation and are released as second-stage larvae. The viviparous birthing continues for the next 4 to 16 weeks, resulting in the generation of some 1500 larvae, each measuring 6 by 100 μm.

*** Larvae reach striated muscle, encapsulate but viable**

*** Eating infected flesh spreads disease**

From their submucosal position, the larvae find their way into the vascular system and pass from the right side of the heart through the pulmonary capillary bed to the systemic circulation, where they are distributed throughout the body. Larvae that end up in tissue other than skeletal muscle disintegrate and die. Those finding their way to striated muscle continue to grow, molt, and gradually encapsulate over a period of several weeks. Calcification of the cyst wall begins 6 to 18 months later, but the contained larvae may remain viable for 5 to 10 years (**Figure 55–2**). The muscles invaded most frequently are the extraocular muscles of the eye, the tongue, the deltoid, pectoral, and intercostal muscles, the diaphragm, and the gastrocnemius. If a second animal feeds on the infected flesh of the original host, the encysted larvae are freed by gastric digestion, penetrate the columnar epithelium of the intestine, and mature just above the lamina propria. This cycle is summarized in **Figure 55–3.**

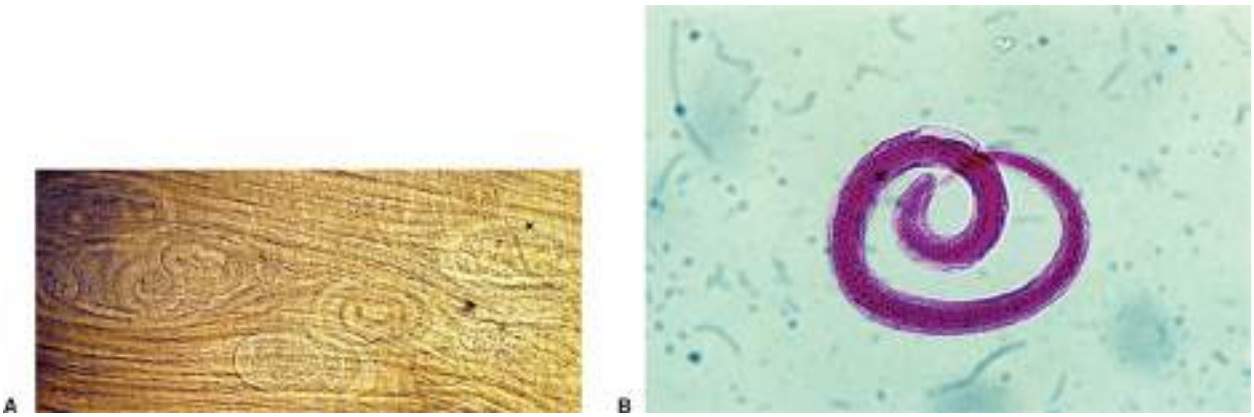

FIGURE 55–2. ***Trichinella spiralis*** **larvae. A.** Coiled larvae in a "squash prep" of deltoid muscle biopsy, in which a small sliver of muscle is squashed under the cover slip and examined without further fixation. **B.** Coiled larva from a muscle digest. (A, Used with permission from Paul Pottinger MD. B. Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

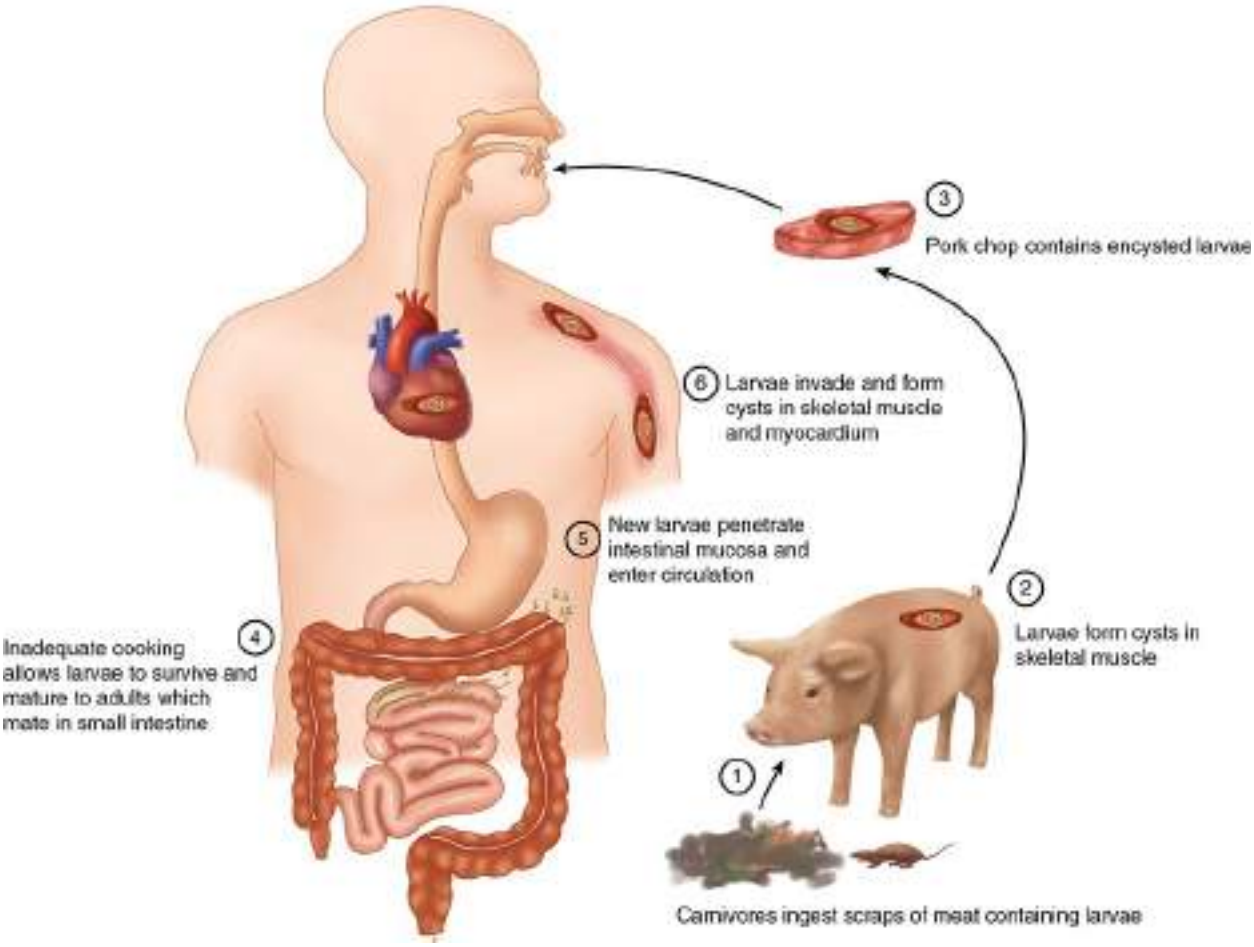

FIGURE 55–3. **Trichinosis.** *Trichinella spiralis* larvae ingested by pig (1) eventually end up as human cysts (6).

TRICHINOSIS

EPIDEMIOLOGY

Swine infected by eating rats or meat in garbage

*** Human infection from undercooked pork, wild animals**

Trichinosis, also called trichinellosis, is widespread in carnivores worldwide. Among domestic animals, swine are most frequently involved. They acquire the infection by eating dead rats or garbage containing cyst-laden scraps of uncooked meat. Human infection, in turn, results largely from the consumption of improperly prepared pork products. In the United States, agricultural regulations have greatly reduced the incidence of trichinosis, and most pig-associated outbreaks have been traced to pork sausage prepared in the home or in small, unlicensed butcheries. Clusters have also followed feasts on wild pig in California and Hawaii. At present, however, the majority of human cases in the United States, particularly those in Alaska and other western states, have been attributed to consumption of wild animal meat, especially bear meat. Outbreaks among Alaskan and Canadian Inuit populations have followed the ingestion of raw *T nativa*-infected walrus meat. Outbreaks in Europe have involved horse meat or wild boar flesh. In other areas of the world, infection is commonly acquired from wild animals (“sylvatic sources”), including wild boar, bush pigs, and warthogs.

Declining due to meat inspection, cooking, freezing pork

Infections usually subclinical

Human infections occur worldwide. In the United States, the prevalence of cysts found in the diaphragms of patients at autopsy has declined substantially. This decline has been attributed to decreased consumption of pork and pork products; federal guidelines for the commercial preparation of such foodstuffs; the widespread practice of freezing pork, which kills all but arctic strains of *T nativa*; and legislation requiring the thorough cooking of any meat scraps to be used as hog feed. Nevertheless, it is estimated that many Americans carry live *Trichinella* in their musculature and that more acquire it annually. Fortunately,

most have a small number of larvae and are asymptomatic. Only a handful of clinically recognized cases are reported annually to federal officials.

PATHOGENESIS AND IMMUNITY

*** Larvae in striated muscle, heart, CNS**

Eosinophil-mediated larvae destruction

The pathologic lesions of trichinosis are related almost exclusively to the presence of larvae in striated muscle, heart, and CNS. Invaded muscle cells enlarge, lose their cross-striations, and undergo basophilic degeneration. Intense inflammation surrounds the involved area, consisting of neutrophils, lymphocytes, and eosinophils. With the development of specific IgG and IgM antibodies, eosinophil-mediated destruction of circulating larvae begins, production of new larvae is slowed, and the expulsion of adult worms is hastened. A vasculitis demonstrated in some patients has been attributed to deposition of circulating immune complexes in the walls of the vessels.

TRICHINOSIS: CLINICAL ASPECTS

MANIFESTATIONS

Abdominal pain, diarrhea as adults penetrate gut wall

*** Symptoms depend on extent of larval muscle invasion**

Complications: hemoptysis, heart failure, coma, death

One or two days after the host ingests tainted meat, the newly matured adults penetrate the intestinal mucosa, producing nausea, abdominal pain, and diarrhea. In mild infections, these symptoms may be overlooked, except in a careful retrospective analysis; in more serious infections, they may persist for several days and render the patient prostrate. Diarrhea persisting for a period of weeks has been characteristic of *T nativa* outbreaks after ingestion of walrus meat by the Inuit population of northern Canada. Larval invasion of striated muscle begins approximately 1 week later and initiates the more characteristic phase of

the disease, which may last for about 6 weeks. Patients in whom 10 or fewer larvae are deposited per gram of tissue are usually asymptomatic; those with 100 or more generally develop significant disease; and those with 1000 to 5000 have a very stormy course that occasionally ends in death. Fever, muscle pain, muscle tenderness, and weakness are the most prominent manifestations of trichinosis. Patients may also display eyelid swelling, a maculopapular skin rash, and small hemorrhages beneath the conjunctiva of the eye and the nails of the digits. Hemoptysis and pulmonary consolidation are common in severe infections. If there is myocardial involvement, electrocardiographic abnormalities, tachycardia, or congestive heart failure may be seen. CNS invasion is marked by encephalitis, meningitis, and polyneuritis. Delirium, psychosis, paresis, and coma can follow.

DIAGNOSIS

*** Eosinophilia up to 50% starting in second week**

Trichinosis presents in a protean fashion, which can delay diagnosis and impact clinical outcomes. The most consistent laboratory abnormality is an eosinophilic leukocytosis during the second week of illness, which persists for the remainder of the clinical course. Eosinophils typically range from 15% to 50% of the white cell count, and in some patients, this may induce extensive damage to the cardiac endothelium. In severe or terminal cases, the eosinophilia may disappear altogether. Serum levels of IgE and muscle enzymes are elevated in most clinically ill patients.

There are a number of valuable serologic tests, including indirect fluorescent antibody and enzyme-linked immunosorbent assay. Significant antibody titers are generally absent before the third week of illness but may then persist indefinitely.

Antibody after 2 weeks

*** Muscle biopsy reveals larvae**

Biopsy of the deltoid or gastrocnemius muscles during the third week of illness often reveals encysted larvae **(Figure 55–2B)**.

TREATMENT

*** Corticosteroids in severe cases**

*** Antihelminthic therapy with caution**

Patients with severe edema, pulmonary manifestations, myocardial involvement, or CNS disease are treated with corticosteroids. The value of specific anthelmintic therapy remains controversial. The mortality rate of symptomatic patients is 1%, rising to 10% if the CNS is involved. Mebendazole and albendazole halt the production of new larvae, but in severe infection, the destruction of tissue larvae may provoke a hazardous hypersensitivity response in the host. This may be moderated by initiating corticosteroids before treating with antihelminthics.

PREVENTION

*** Prevention via thorough cooking**

Control of trichinosis requires adherence to feeding regulations for pigs, and limiting contact between domestic pigs and wild animals, particularly rodents, who might be carrying *Trichinella* larvae in their tissues. Domestically, care should be taken to cook pork to an internal temperature of at least 76.6°C, or freeze it at −15°C for 3 weeks before cooking. *Trichinella nativa* in the flesh of arctic animals may survive freezing for a year or more. All strains may survive apparently adequate cooking in microwave ovens due to the variability in the internal temperatures achieved.

• *ANCYLOSTOMA BRAZILIENSE*

Larvae of dog and cat hookworms

*** Filariform larvae penetrate, migrate in skin**

Cutaneous larva migrans, or “creeping eruption,” is an infection of the skin caused by the larvae of a number of animal and human parasites, most commonly the dog and cat hookworm *A braziliense.* Adult worms live and copulate in the intestines of infected animals. Eggs discharged in animal feces onto warm, moist, sandy soil then develop into filariform larvae capable of penetrating mammalian skin on contact, just as with human hookworm infection.

These parasites are common in tropical areas worldwide; in the United States, parasite transmission is particularly common in the beach areas of the southern Atlantic and Gulf states.

Adult forms do not develop in humans

*** Intensely itchy, linear rash**

However, these species are not well adapted to human hosts, and larvae rarely make it across the lung to reach the human intestines. Rather, they may migrate within the skin for a period of weeks to months. Clinically, the patient notes a pruritic, raised, red, serpiginous, irregularly linear lesion 10 to 20 cm long. Skin excoriation from scratching increases the likelihood of secondary bacterial infection. Some patients develop transient, migratory pulmonary infiltrations associated with peripheral eosinophilia, probably reflecting pulmonary migration of larvae. Larvae are rarely found in either sputum or skin biopsies, and the diagnosis must be established on skin pattern recognition (**Figure 55–4**).

FIGURE 55–4. Creeping eruption caused by infection with *Ancylostoma braziliense* larva. (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

Cutaneous larva migrans respond well to albendazole or ivermectin. Antihistamines and antibiotics may be helpful in controlling pruritus and

secondary bacterial infection, respectively.

In toxocariasis, baylisascariasis, trichinosis, and dog hookworm, which form is responsible for human symptoms: adult worms or larvae?

• LYMPHATIC FILARIA

Lymphatic filariasis encompasses a group of diseases produced by certain members of the superfamily Filarioidea ("thread like") that inhabit the human lymphatic system. Their presence induces an acute inflammatory reaction, chronic lymphatic blockade, and, in some cases, grotesque lymphedematous swelling of the extremities and genitalia. When the skin becomes rough and thickened over time, this is called **elephantiasis.**

WUCHERERIA AND *BRUGIA*: PARASITOLOGY AND LIFE CYCLE

*** Adult worms live in lymphatic vessels for a decade**

Microfilariae develop from ova

*** Microfilariae circulate in peripheral blood each night**

The two agents most commonly responsible for lymphatic filariasis are *W bancrofti* and *B malayi*. Both are thread-like worms whose adults lie coiled in the lymphatic vessels, male and female together, for the duration of their decade-long lifespan. The female *W bancrofti* measures 100 mm in length, and the male 40 mm. *B malayi* adults are approximately half these sizes. The gravid females produce large numbers of embryonated eggs. At oviposition, the embryos uncoil to their full length (200-300 μm) to become microfilariae ("small threads"). The shell of the egg elongates to accommodate the embryo and is retained as a thin, flexible sheath. Although the offspring of the two species resemble each other, they may be differentiated on the basis of length, staining characteristics, and

internal structure (**Table 55-2**). The microfilariae eventually reach the blood (**Figure 55–5**). In most *W bancrofti* and *B malayi* infections, they accumulate in the pulmonary vessels during the day. At night, possibly in response to changes in oxygen tension, they spill out into the peripheral circulation, where they are found in greatest numbers between 9 PM and 2 AM. A Polynesian strain of *W bancrofti* displays a different periodicity, with the peak concentration of organisms occurring in the early evening. Periodicity has an important epidemiologic consequence, because it happens in response to the species of mosquito that serves as vector and intermediate host: to improve their chances of being taken up during the blood meal of a mosquito, the different filarial species enter the bloodstream during the nighttime when that mosquito is most likely to bite. Presumably, they do not spend all their time in the peripheral blood because doing so would increase their odds of being cleared via the spleen and liver.

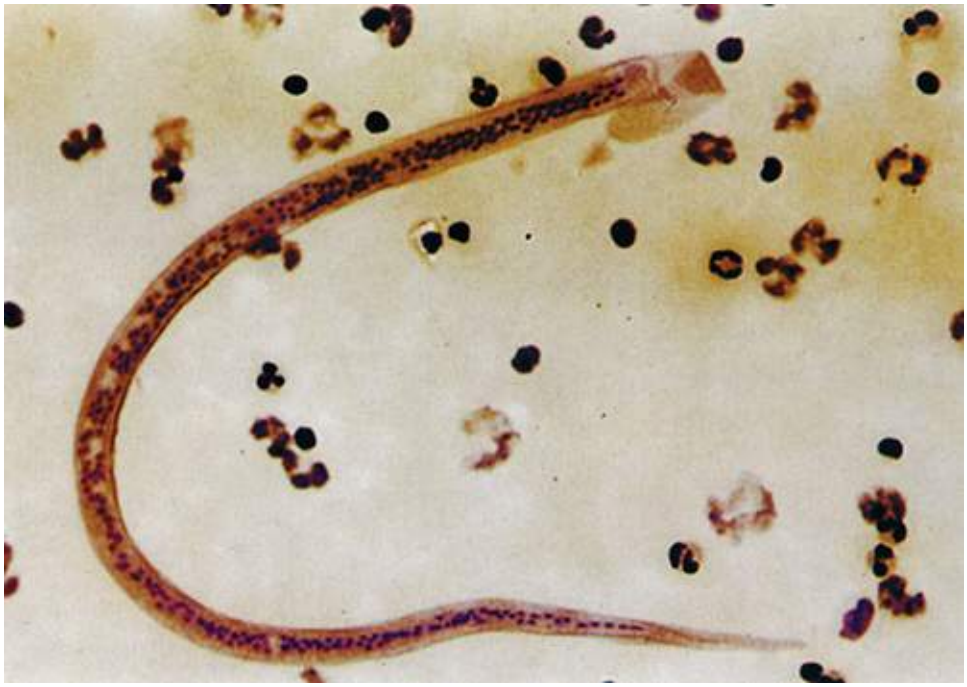

FIGURE 55–5. Microfilaria of *Wuchereria bancrofti* in blood film. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

TABLE 55–2 Differentiation of Microfilariae

PARASITE	LOCATION	SHEATH	SIZE (MM)	NUCLEI OF TAIL	PERIODICITY
Wuchereria bancrofti	Blood	Yes	360	None	Usually nocturnal
Brugia malayi	Blood	Yes	220	Two	Nocturnal
Loa loa	Blood	Yes	275	Continuous	Diurnal
Onchocerca volvulus	Skin	No	300	None	None

Think ▸▸ Apply 55-1: The larvae of these animal parasites cause symptoms in humans, when they migrate through our tissues.

Once ingested by a mosquito during the blood meal, the microfilariae enter its thoracic muscles and transform first into rhabditiform and then into filariform larvae. The latter actively penetrate the human skin at the feeding site when the mosquito takes its next meal. Within the new host, the parasite migrates to the lymphatic vessels, undergoes a series of molts, and reaches adulthood in 6 to 12 months (**Figure 55–6**). Bancroftian filariasis is exclusive to humans, whereas certain strains of brugian filariasis can also infect domestic and wild animals. The life cycle is illustrated in **Figure 55–7.**

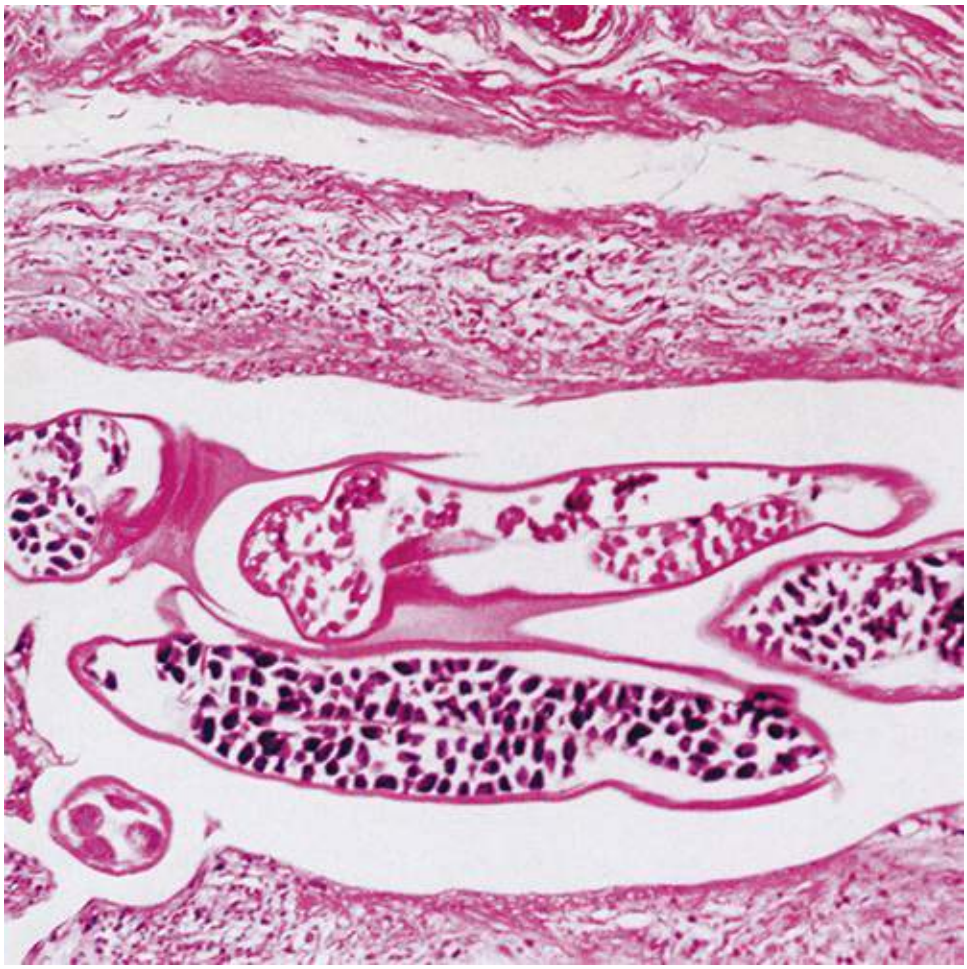

FIGURE 55–6. Lymphatic filariasis. These dilated lymphatics are filled with a gravid adult *W bancrofti* female. Eggs and developing microfilaria are within the paired uterine tubes. Note the surrounding thickened fibrous tissue. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

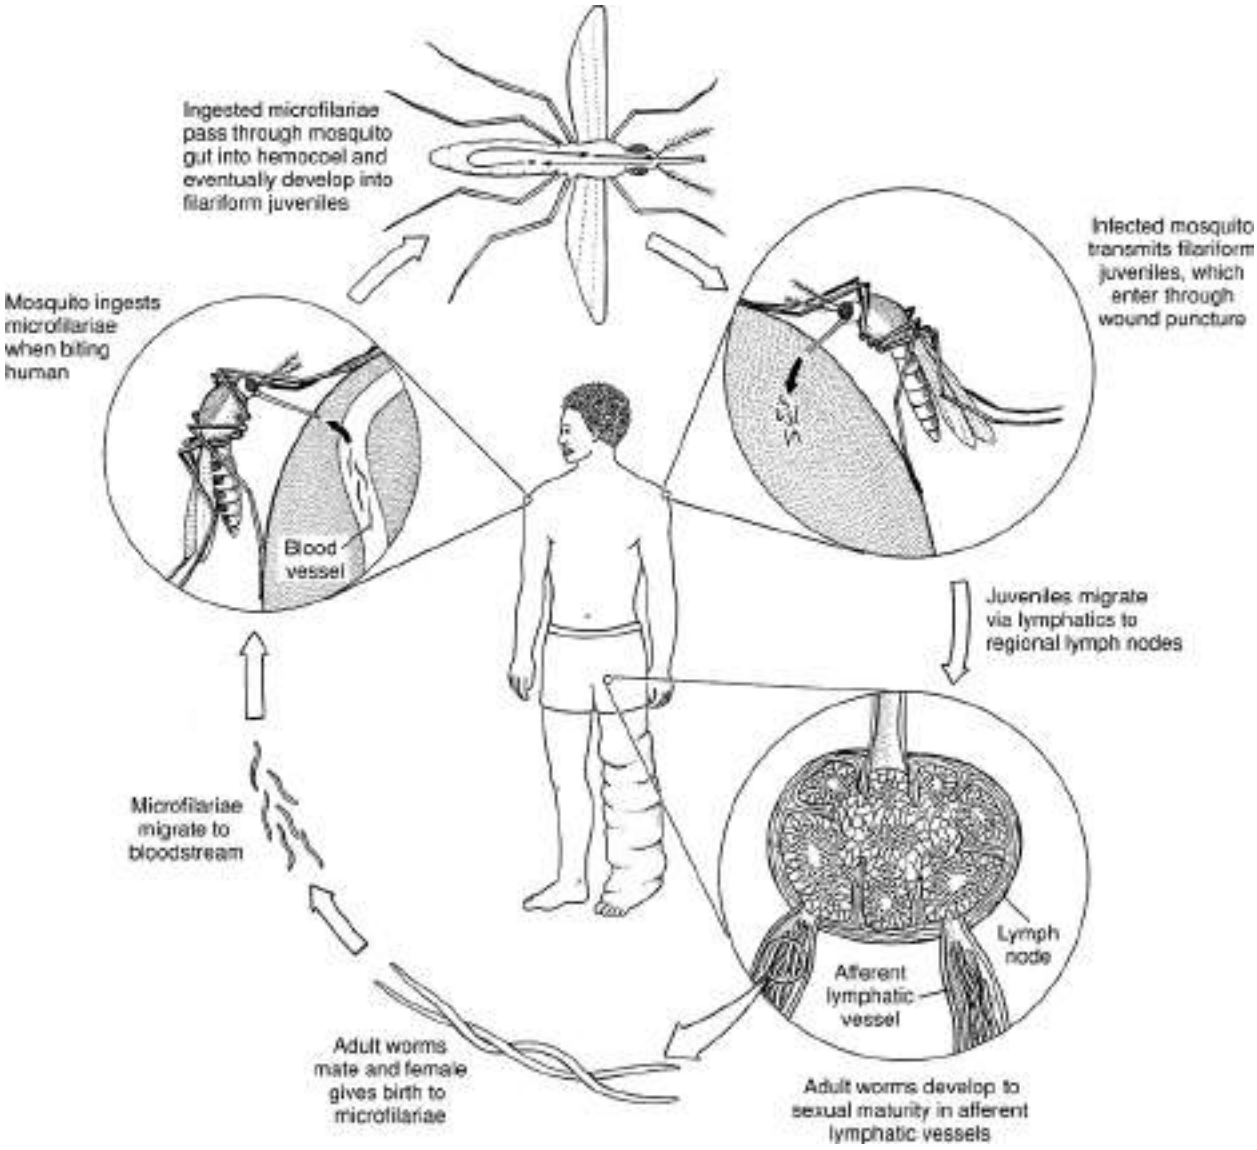

FIGURE 55–7. Life cycle of *Wuchereria bancrofti* and *Brugia malayi.* (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

Wuchereria and Brugia worms contain Wolbachia bacteria.

Adult filarial worms have a fascinating feature: They carry endosymbiotic bacteria of the genus *Wolbachia* in their gut. These bacteria are beneficial to the worm in ways that are not yet fully understood. However, adult worms seem much healthier when their *Wolbachia* are healthy, and when *Wolbachia* are not present they are less able to reproduce. This observation has implications for disease treatment and control, as described below.

LYMPHATIC FILARIASIS

EPIDEMIOLOGY

Primarily in Asia and other tropical areas

Lymphatic filariasis currently infects about 120 million people in Africa, Latin America, the Pacific Islands, and Asia; most of these cases are concentrated in Asia. *W bancrofti*, transmitted primarily by mosquitoes of the genera *Anopheles* or *Culex*, is the more cosmopolitan of the two species; it is found in patchy distribution throughout the poorly sanitized, densely crowded urban areas of all three continents.

B malayi, transmitted by mosquitoes of the genus *Mansonia*, is confined to the rural coastal areas of Asia and the South Pacific. Strains with an unusual periodicity have been found in animals. In the eastern Indonesian archipelago, a closely related species, *B timori*, is transmitted by night-feeding anopheline mosquitoes.

PATHOLOGY AND PATHOGENESIS

*** Lymphatic blockade with repeated infections**

Pathologic changes, which are confined primarily to the lymphatic system, can be divided into acute and chronic lesions. In acute disease, the presence of molting adolescent worms and dead or dying adults stimulates dilatation of the lymphatics, hyperplastic changes in the vessel endothelium, lymphatic infiltration by lymphocytes, plasma cells, and eosinophils, and thrombus formation (ie, acute lymphangitis). These developments are followed by granuloma formation, fibrosis, and permanent lymphatic obstruction. Repeated infections eventually result in massive lymphatic blockade. The skin and subcutaneous tissues become edematous, thickened, and fibrotic. Dilated lymphatics may rupture, spilling lymph into the tissues or body cavities, including the ureters. Bacterial and fungal superinfections of the skin often supervene and contribute to tissue damage.

LYMPHATIC FILARIASIS: CLINICAL ASPECTS

MANIFESTATIONS

Lymphadenitis, urticaria, eosinophilia early findings

Acute manifestations recur

Individuals who enter endemic areas as adults and reside therein for months to years often present with acute lymphadenitis, urticaria, eosinophilia, and elevated serum IgE levels; they seldom go on to develop lymphatic obstruction. A significant proportion of indigenous populations present with asymptomatic microfilaremia. Some of these spontaneously clear their infection, whereas others go on to experience “filarial fevers” and lymphadenitis 8 to 12 months after exposure. The fever is typically low grade; in more serious cases, however, temperatures as high as 40°C, chills, muscle pains, and other systemic manifestations may be seen. Classically, lymphadenitis is first noted in the femoral area as an enlarged, red, tender lump. The inflammation spreads centrifugally down the lymphatic channels of the leg. The lymphatic vessels become enlarged and tender, the overlying skin warm, red, and edematous. In Bancroftian filariasis, the lymphatic vessels of the testicle, epididymis, and spermatic cord are frequently involved, producing a painful orchitis, epididymitis, and funiculitis; inflamed retroperitoneal vessels may simulate an acute abdomen. Epitrochlear, axillary, and other lymphatic vessels are involved less frequently. These acute manifestations last a few days and resolve spontaneously, only to recur periodically over a period of weeks to months.

*** Lymphedema, recurrent inflammation triggered by adult worms in lymphatics**

With repeated infection, permanent lymphatic obstruction develops in the involved areas. Edema, ascites, pleural effusion, hydrocele, and joint effusion may result. The lymphadenopathy persists and the palpably swollen lymphatic channels may rupture, producing an abscess or draining sinus. Rupture of intraabdominal vessels may give rise to chylous ascites or urine. In patients heavily and repeatedly infected over a period of decades, elephantiasis may develop. Such patients may continue to experience acute inflammatory episodes.

Recurrent streptococcal and staphylococcal skin infections are common sequels to this condition, which in turn lead to more lymphatic damage, perpetuating a cycle of pain and suffering.

*** Tropical pulmonary eosinophilia caused by microfilariae in tissues (not found in blood)**

In southern India, Pakistan, Sri Lanka, Indonesia, Southeast Asia, and East Africa, an aberrant form of filariasis is sometimes seen. This form, termed tropical eosinophilia syndrome or tropical pulmonary eosinophilia, is characterized by an intense eosinophilia, elevated levels of IgE, high titers of filarial antibodies, the absence of microfilariae from the circulating blood, and a chronic clinical course marked by massive enlargement of the lymph nodes and spleen in children or chronic cough, nocturnal bronchospasm, and pulmonary infiltrates in adults. Untreated, it may progress to interstitial pulmonary fibrosis. Microfilariae have been found in the tissues of such patients, and the clinical manifestations may be terminated with antifilarial treatment. It is believed that this syndrome is precipitated by the removal of circulating microfilariae by an IgG-dependent, cell-mediated immune reaction. Microfilariae are trapped in various tissue sites, where they incite an eosinophilic inflammatory response, granuloma formation, and fibrosis.

DIAGNOSIS

Eosinophilia during acute episodes

*** Search for microfilariae in blood**

Eosinophilia is usually present during the acute inflammatory episodes, but definitive diagnosis requires the presence of microfilariae in the blood or lymphatic, ascitic, or pleural fluid. They are sought in Giemsa- or Wright-stained thick and thin smears. The major distinguishing features of these and other microfilariae are listed in Table 55-2. Because the appearance of the microfilariae is usually periodic, specimen collection must be properly timed. If the parasitemia is below the threshold of detection, the specimen may be concentrated before it is examined. If this procedure proves fruitless, the patient may be retested after being challenged with the antifilarial agent diethylcarbamazine (DEC). This drug stimulates the migration of the microfilariae from the pulmonary to the systemic circulation and enhances the

possibility of their recovery. Once found, the microfilariae can be differentiated from those produced by other species of filariae. A number of serologic tests have been used for the diagnosis of microfilaremic disease, but until recently they have lacked adequate sensitivity and specificity; IgG4 testing is the most specific for filarial infection, although cross-reactivity to other tissue parasites is well described, and these tests are of little diagnostic significance in individuals indigenous to the endemic area, because many people have experienced a prior filarial infection. Circulating filarial antigens can be found in most microfilaremic patients and also in some seropositive nonmicrofilaremic individuals. Antigen detection may thus prove to be a specific indicator of active disease, although the test is not widely available. Tropical eosinophilia is diagnosed as described previously.

TREATMENT AND PREVENTION

*** Killing microfilariae with DEC may stimulate allergic response**

*** Killing adult worms' endosymbiotic *Wolbachia***

*** Treatment of complications improves quality of life**

DEC eliminates the microfilariae from the blood and may injure or even kill some of the adult worms, resulting in long-term suppression of the infection or parasitologic cure in some cases. Frequently, the dying microfilariae stimulate an allergic reaction in the host. This response is occasionally severe, requiring antihistamines and corticosteroids. This phenomenon is even more common among patients coinfected with onchocerciasis (see later), and thus coinfection with that condition should be ruled out before DEC is dosed in endemic areas. However, DEC use in lymphatic filariasis is generally safe, so much so that it is sometimes added to cooking salt in highly endemic areas or dosed intermittently on a mass scale; the idea is to suppress microfilaremia, which benefits the individual patient and the entire community by reducing transmission pressure. Ivermectin has a similar effect on microfilariae, and it can temporarily clear microfilaremia after the administration of a single dose. Albendazole seems to have beneficial effects on both microfilariae and adult worms. The antibiotic doxycycline has been demonstrated to kill endosymbiotic *Wolbachia* bacteria, and with prolonged administration, alone or in combination with other agents such as albendazole, may ultimately help to kill the adult worms. The tissue changes of elephantiasis are often irreversible, but the enlargement of the

extremities may be ameliorated with pressure bandages or plastic surgery. Treatment and prevention of bacterial superinfection are essential, and can be augmented by access to proper shoe gear plus soap and water. Control programs combine mosquito control with mass treatment of the entire population.

• *ONCHOCERCA*

Onchocerciasis, or "river blindness," is produced by the skin filaria *O volvulus.* The disease is characterized by subcutaneous nodules, thickened pruritic skin, and—in some cases—blindness.

ONCHOCERCA VOLVULUS: PARASITOLOGY AND LIFE CYCLE

*** Adults in subcutaneous tissue, skin, eye**

*** Transmitted by bite of *Simulium* fly**

The 40 to 60 cm long, thread-like female adults lie with their diminutive male partners in coiled masses within fibrous subcutaneous and deep tissue nodules. The female gives birth to more than 2000 microfilariae each day of her 15-year lifespan. These progeny lose their sheaths soon after leaving the uterus, exit from the fibrous capsule, and migrate for up to 2 years in the subcutaneous tissues, skin (**Figure 55–8**), and eye. In contrast to the microfilariae of lymphatic filariasis that travel in the bloodstream, the microfilariae of onchocerciasis migrate through the subcutaneous tissues to the skin, where ultimately they die or are ingested by black flies of the genus *Simulium.* Unlike stealthy blood-sucking mosquitoes, flies feed on humans by taking a bite of skin—if an *O volvulus* larva happens to be in the hunk of skin taken by the fly, the life cycle will continue. After transformation into filariform larvae in the fly, they are transmitted to another human host. There they molt repeatedly over 6 to 12 months before reaching adulthood and becoming encapsulated. Like the worms of lymphatic filariais, adult *O volvulus* parasites appear to harbor endosymbiotic *Wolbachia* bacteria. The name "river blindness" derives from the association of the infection with exposure to turbulent, fast-moving streams, where the vector *Simulium* fly breeds. The *Onchocerca* life cycle is illustrated in **Figure 55–9.**

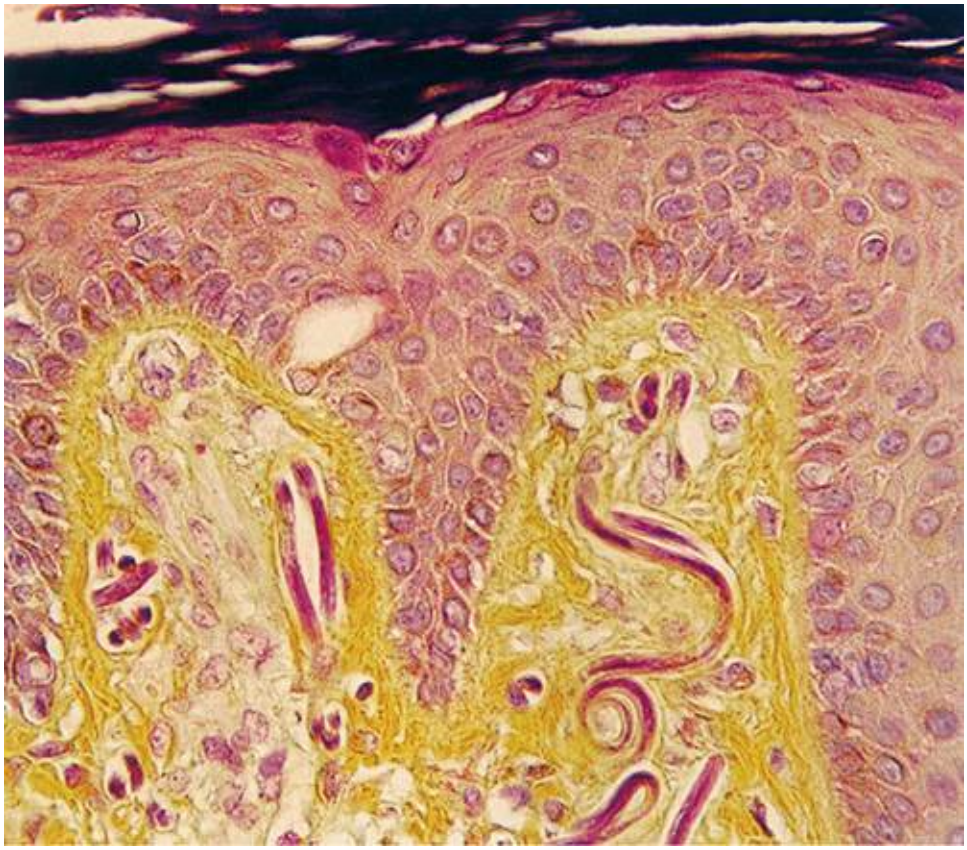

FIGURE 55–8. Onchocercal dermatitis. *Onchocerca volvulus* microfilaria are concentrated in the dermal papillae, which makes them particularly available when the vector *Simulium* flies bite and feed. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

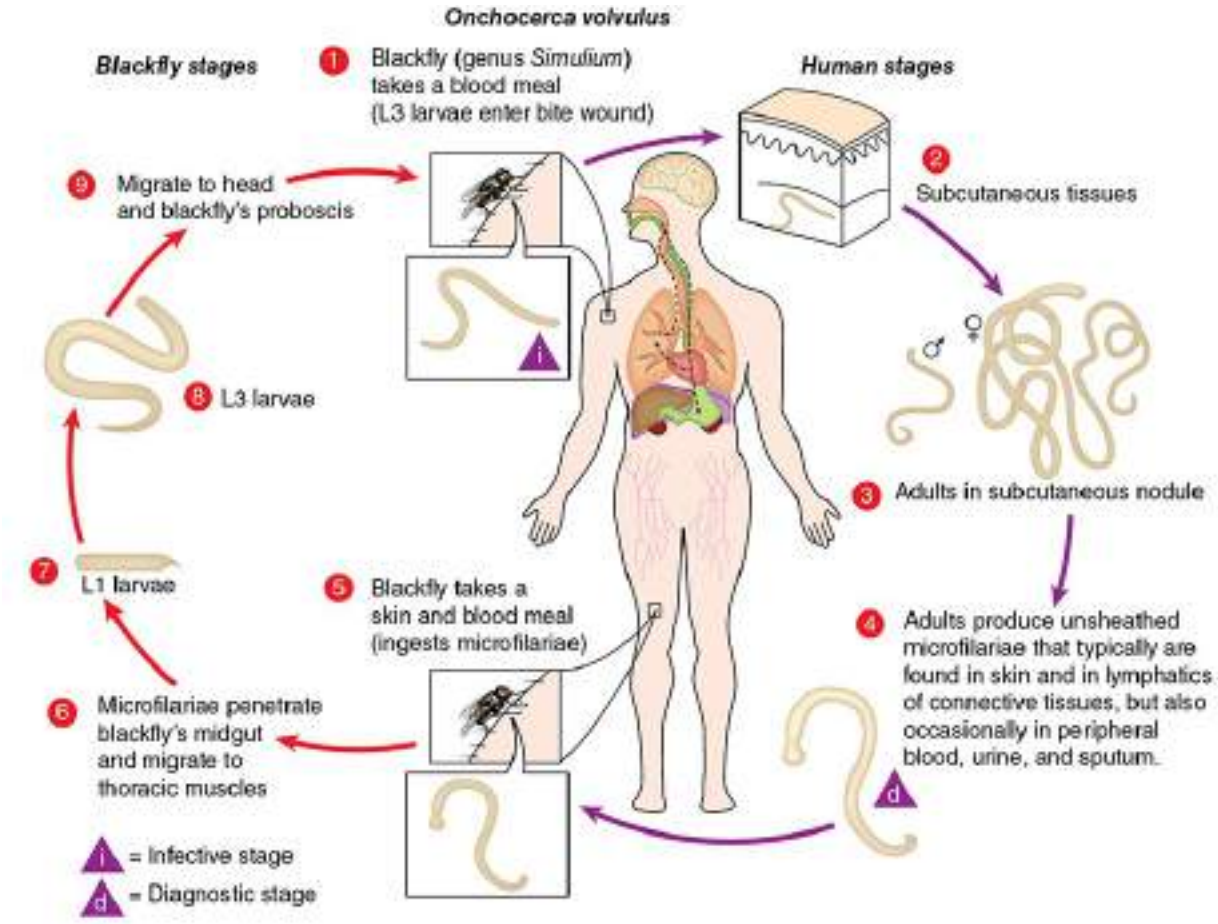

During a blood meal, an infected blackfly (genus *Simulium*) introduces third-stage filarial larvae onto the skin of the human host, where they penetrate into the bite wound 1. In subcutaneous tissues the larvae 2 develop into adult filariae, which commonly reside in nodules in subcutaneous connective tissues 3. Adults can live in the nodules for approximately 15 years. Some nodules may contain numerous male and female worms. Females measure 33 to 50 cm in length and 270 to 400 µm in diameter, whereas males measure 19 to 42 mm by 130 to 210 µm. In the subcutaneous nodules, the female worms are capable of producing microfilariae for approximately 9 years. The microfilariae, measuring 220 to 360 µm by 5 to 9 µm and unsheathed, have a life span that may reach 2 years. They are occasionally found in peripheral blood, urine, and sputum but are typically found in the skin and in the lymphatics of connective tissues 4. A blackfly ingests the microfilariae during a blood meal 5. During a skin and blood meal, the microfilariae migrate from the blackfly's midgut through the hemocoel to the thoracic muscles 6. There the microfilariae develop into first-stage larvae 7 and subsequently into third-stage infective larvae 8. The third-stage infective larvae migrate to the blackfly's proboscis. 9 and can infect another human when the fly takes a blood meal 1.

FIGURE 55–9. Life cycle of *Onchocerca volvulus*.

ONCHOCERCIASIS

EPIDEMIOLOGY

Most cases in tropical Africa

Onchocerciasis infects approximately 37 million persons, rendering approximately 500,000 of them blind. Most of the afflicted live in sub-Saharan Africa, over half of these in Nigeria and the Congo. Foci of infection are also found in Yemen, Saudi Arabia, and Latin America from southern Mexico through the northern half of South America. It has been suggested that the disease was introduced into South America by West Africans enslaved and transported there for the purpose of mining gold in the mountain streams of Venezuela and Colombia. The Central American foci probably date from Napoleon III's use of Sudanese troops to support his invasion of Mexico in 1862. Onchocerciasis persists on the high slopes of the Sierra, where coffee plantations lie along the rapidly flowing streams that serve as breeding places for *Simulium* species.

ONCHOCERCIASIS: CLINICAL ASPECTS

MANIFESTATIONS

The subcutaneous nodules that harbor the adult worms can be located anywhere on the body, generally over bony prominences. In Mexico and Guatemala, where flies typically bite the upper part of the body, they are concentrated on the head; in South America and Africa, they are found primarily on the trunk and legs. Although nodules may number in the hundreds, most infected persons have fewer than 10. The nodules are firm, movable, and measure 1 to 3 cm in diameter. Unless the nodule is located over a joint, pain and tenderness are unusual.

Adult worms cause multiple subcutaneous nodules

*** Microfilariae cause hypersensitivity reactions: pruritus, eye damage**

*** Important cause of blindness**

Of greater consequence to the patient are the effects of the presence of

microfilariae in the tissues. An immediate hypersensitivity reaction to antigens released by dead or dying parasites results in acute and chronic inflammatory reactions. In the skin, this manifests as a papular or erysipelas-like rash with severe itching. In time, due to the trauma of repeated scratching, the skin thickens and lichenifies. As subepidermal elastic tissue is lost, wrinkles and large skinfolds or “hanging groins” may form. In parts of Africa, fibrosing, obstructive lymphadenitis may result in elephantiasis. The most devastating lesions, however, are caused by invasion of the eye. Iritis and chorioretinitis can lead to decreased visual acuity and, in time, total blindness. Even if the anterior eye alone is infected, scarring and opacification of the cornea may cause irreversible blindness when the optic disk atrophies due to lack of light perception. In Central America, eye lesions may be seen in up to 30% of infected patients. In certain communities in West Africa, 85% of the population has ocular lesions, and 50% of the adult male population is blind. *O volvulus* microfilariae may trigger autoimmunity that is responsible for an unusual form of epilepsy called “nodding syndrome,” although this is not proven.

DIAGNOSIS

* Microfilariae seen in skin samples

Patients from endemic areas who present with subcutaneous nodules, unexplained pruritus, or ocular changes should be ruled out for onchocerciasis. The diagnosis is confirmed by demonstrating the microfilariae in thin skin snips taken from an involved area (**Figure 55–10**). When the eye is involved, the organism may sometimes be seen in the anterior chamber with the help of a slit lamp. Topical DEC can be applied safely to a patch of skin, which will yield a local wheal and flare when microfilariae die and release antigens. Previously, a technique called the “Mazzotti test” was performed, in which DEC was administered in a low dose to patients, who were then observed for a flare of their pruritus due to rapid microfilariae death and resultant inflammatory reactions. However, this practice is generally discouraged for safety concerns, especially when skin snips can be obtained.

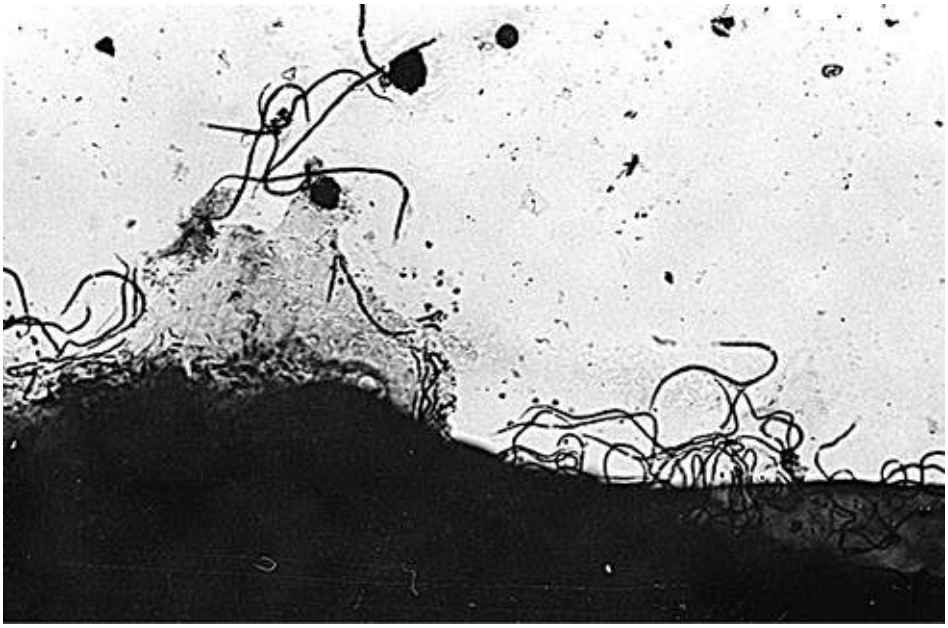

FIGURE 55–10. Skin snip from a patient with onchocerciasis, dropped into a vial of saline. Note microfilariae emerging from the specimen into surrounding solution. (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.

TREATMENT AND PREVENTION

* DEC treatment may cause hypersensitivity

Traditionally, DEC has been used to kill the microfilariae. Treatment was begun with very small doses to prevent rapid parasite destruction and the attendant allergic consequences. This consideration was particularly important when the eye was involved, because a treatment-induced inflammatory reaction can damage the eye further. This hypersensitivity reaction, sometimes called a "Mazzotti reaction," can have grave consequences for the patient.

* Ivermectin clears microfilariae, but retreatment necessary

Risky if *Loa loa* coinfection

Ivermectin is a safer and more effective microfilaricide than DEC and does not appear to induce the severe allergic manifestations seen with the latter agent. However, because it does not kill the adult worm, periodic retreatment is necessary. Mass treatment or chemoprophylaxis with ivermectin has been a major achievement. The manufacturer of this drug has pledged a virtually unlimited, cost-free supply of ivermectin to governments that administer it on a

mass scale to endemic populations. This improves symptoms and may reduce parasitism in biting *Simulium* flies, helping to interrupt the transmission cycle. Mass ivermectin administration has allowed communities to reclaim large areas of arable land in Africa previously abandoned because of disease burden. However, because ivermectin does not fully cure the individual patient, retreatment is required. Furthermore, ivermectin carries a risk of perversely facilitating the entry of *L loa* worms (see later) into the CNS of patients coinfected with that parasite, thus posing challenges for mass drug administration in areas endemic for both infections.

*** Targeting *Wolbachia* may kill or sterilize adults**

The finding that doxycycline is toxic to endosymbiotic *Wolbachia* has led to interest in an approach similar to that being adopted in lymphatic filariasis, in which doxycycline is combined with ivermectin or albendazole. The goal is to simultaneously kill microfilariae with the antihelminthic while gradually killing —or at least rendering sterile—the adult worms with the antibiotic. Unfortunately, prolonged courses of doxycycline are not practical to administer on a mass scale, and thus this approach is generally reserved for individual patients.

Progress has been substantial, although no fully satisfactory methods of control have yet been developed. There is no effective vaccine. Application of insecticides to the vector's breeding waters must be sustained for decades to disrupt transmission permanently, because the parasite is so long-lived within humans. A World Health Organization-funded *Simulium* larva control program using aerial insecticides has succeeded in interrupting transmission of onchocerciasis in parts of the savanna regions of West Africa.

How does the approach to onchocerciasis differ between treating individual patients and controlling the infection in an entire community?

• *LOA LOA*

*** Adults migrate through subcutaneous tissues producing Calabar**

swellings

Microfilariae generally harmless

Loiasis is a filarial disease of West Africa produced by the eye worm, *L loa*. Biting deer flies of the genus *Chrysops* serve as vectors. The female produces sheathed microfilariae, which are found in the bloodstream during daytime hours —because that is the time when the flies bite their victims (**Figure 55–11**). Unlike onchocerciasis, and more similar to lymphatic filariasis, it is the adult worm rather than the microfilariae that cause clinical illness. The long-lived adults migrate continuously through the subcutaneous tissues of humans at a maximum rate of about 1 cm/hour. During migration, they may produce localized areas of allergic inflammation termed “Calabar swellings.” These may appear as egg-sized lesions or swollen extremities which persist for 2 to 3 days and may be accompanied by fever, itching, urticaria, and pain, before they resolve fully and spontaneously. Occasionally, the adult worms may cross under the conjunctiva of the eye, producing tearing, pain, and alarm (**Figure 55–12**). However, in contrast to onchocerciasis, this phenomenon is harmless and does not threaten the patient’s sight.

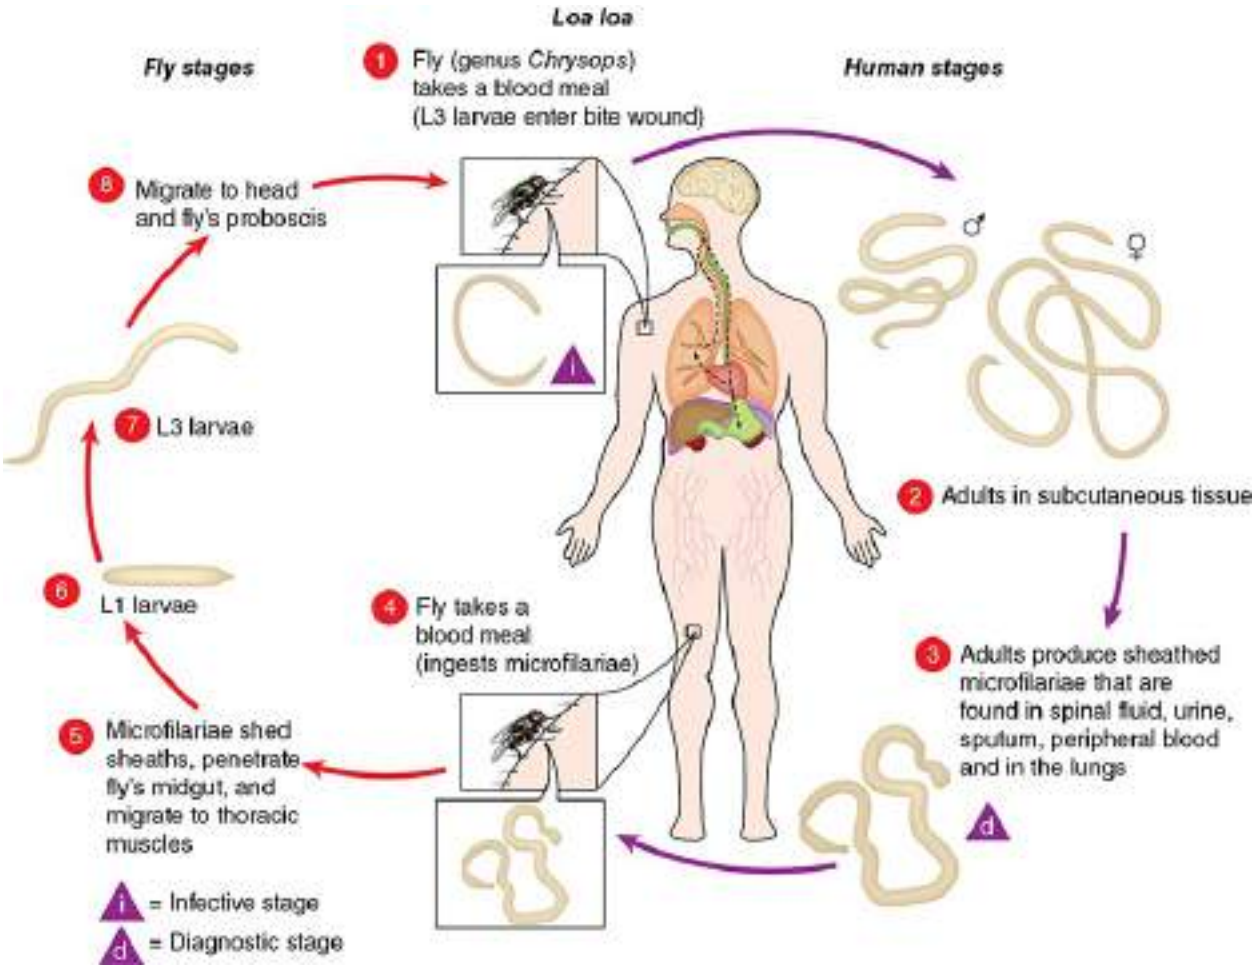

FIGURE 55–11. **Life cycle of *Loa loa*.**

FIGURE 55–12. Adult female *L loa* coiled under the conjunctival epithelium (*arrow*) of the eye of a patient from the Congo. (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

Adult worm in eye, microfilaria in blood or tissue

Treatment options limited

*** Natural history usually benign**

The diagnosis is usually made by asking patients whether they have noticed a worm wriggling across their eye—a memorable experience. If in doubt, the diagnosis is confirmed by recovering the adult worm from the eye or by isolating the characteristic microfilariae from the blood or Calabar swellings. Eosinophilia is common. DEC destroys microfilariae, but is less effective in killing the adults, and must be administered cautiously to avoid marked allergic reactions. Albendazole slowly decreases microfilarial levels without producing allergic reactions, possibly by preferential action on the adult worms. In some cases, symptoms persist for years, in spite of treatment, until the adults are removed while they cross the eye, or until they die of old age. As described above, ivermectin is contraindicated in patients with loiasis: for unknown reasons, ivermectin may ironically make things worse by facilitating adult *L loa* entry

into the CNS, thus causing dangerous meningoencephalopathy. Thus, perhaps the most important medical reason to diagnose Loiasis is to avoid giving ivermectin to patients who are coinfected with *O volvulus*. Unfortunately, *L loa* adults do not harbor endosymbiotic *Wolbachia* bacteria, making doxycycline ineffective.

Think ▸▸ Apply 55-2: For individual patients, the goal is cure via killing the adult worms with prolonged courses of doxycycline. Because this is not practical on a massive scale, control strategies for entire communities involve periodic mass drug administration of ivermectin to kill the microfilariae—thus easing symptoms and interrupting the transmission cycle.

• OTHER FILARIAL WORMS

Other microfilariae of unclear significance

Other microfilarial parasites have been detected in humans, including species of *Mansonella*. These are transmitted to people during the bite of the *Culicoides* midge. For generations, these worms were felt to be harmless to patients, and their importance in parasitology was limited to distinguishing them from "pathogenic" microfilariae found in the blood. However, this opinion may be changing. It is now believed that *M perstans* may cause a wide variety of problems, including fever, fatigue, headache, arthralgias, CNS disturbances, and occasionally migration across the eye, as seen in loiasis. Like most other microfilarial infections, their adults contain endosymbiotic *Wolbachia*, and treatment with doxycycline may accelerate clearance of the adult parasites; whether this will lead to widespread clinical benefit is unclear.

• *DRACUNCULUS*

Near eradication of guinea worm by filtering water supply

The guinea worm, *Dracunculus medinensis*, deserves inclusion here as an example of successful control of a parasitic infection. Guinea worms are

transmitted when humans drink water contaminated with infected, tiny copepods of the *Cyclops* family. Larval *Dracunculus* worms exit *Cyclops* in the human gut, then migrate to the loose connective tissues and mate. The female may grow to more than 60 cm in length. Eventually she migrates to the skin, where her uterus protrudes into the environment, releasing young into the water when the patient bathes. These exit sites are exquisitely painful, often become secondarily infected, and may cause orthopedic injury if an ankle or knee joint is involved. Pulling on the uterus too quickly leads to worm injury and death, making the situation worse; only painstaking, gradual removal over time may succeed. Prevention of this painful and disfiguring condition has been achieved to a tremendous degree by simply filtering the water before it is consumed, as well as by applying larvicides to the water supply. Currently, only a few nations including Chad are still believed to have ongoing transmission. However, the discovery that dogs are also parasitized poses a barrier to full global eradication of this parasite.

KEY CONCLUSIONS

- Tissue nematode infections may be acquired via ingestion, skin penetration, or the bite of arthropod vectors. Know their route of transmission summarized in Table 55-1.
- In lymphatic filariasis and loiasis, the *adult* worms cause symptoms, whereas in the other worms covered here the *larval* forms are harmful to the patient.
- Care must be exercised when treating some of these infections, because killing their larvae may elicit a brisk allergic reaction.
- The adult worms of lymphatic filariasis, onchocerciasis, and loiasis are relatively resistant to antihelminthic treatment; because they harbor endosymbiotic Wolbachia bacteria, the first two (but not *L loa*) may respond to prolonged courses of antibacterials such as doxycycline.
- For the vector-borne tissue invasive nematodes, strategies may differ when treating individual patients (goal of killing the adult worms) versus interrupting transmission in communities (goal of killing the microfilariae).

CASE STUDY

A Toddler Who Loves Dogs

This 2-year-old boy loves to go to the public park and play with other people’s pets. He also has a history of pica (eating dirt). Over the last week, he has developed fever and wheezing, along with some vague complaints of abdominal discomfort. Physical findings include wheezes and a moderately enlarged, tender liver.

Laboratory findings: white blood cell count of 29,000/mm^3 with 40% eosinophils and a mild anemia. Imaging findings: scattered interstitial pulmonary infiltrates;

QUESTIONS

1. What worm is the most likely cause of this child's illness?

A. *Trichinella*
B. *Toxocara*
C. *Baylisascaris*
D. *Ancylostoma*

2. *Ancylostoma* infections are acquired by:

A. Mosquito transmission
B. Black fly bites
C. Deer fly bites
D. Direct larval penetration of skin

3. Skin snips are used to diagnose:

A. *Loa*
B. *Wuchereria*
C. *Brugia*
D. *Onchocerca*

ANSWERS

1. (B)

Cestodes

Taenia saginata • *Taenia solium* • *Dibothriocephalus latus* • *Echinococcus granulosus* • *Echinococcus multilocularis Hymenolepis nana*

Only kings, presidents, editors, and people with tapeworms have the right to use the editorial "we."

—Mark Twain

OVERVIEW

Cestodes are long, ribbon-like helminths that have gained the common appellation of "tapeworm" from their superficial resemblance to sewing tape. Although improvements in sanitation have dramatically reduced their prevalence in the United States, they continue to inhabit the bowels of many of its citizens. In some parts of the world, people take purgatives regularly to rid themselves of these large, repulsive intestinal parasites. Ironically, when a human serves as the definitive host for tapeworms (when they harbor adult worms), it is usually of little medical consequence to that person; the intestinal form of these creatures rarely causes serious harm. In contrast, clinical disease is a greater concern when people serve as *intermediate* hosts (harbor larvae), because it is the presence of cysts in tissue that is most dangerous. Life cycles and characteristics of the six most important tapeworms infecting humans are summarized in **Table 56-1.**

TABLE 56–1 Intestinal and Tissue Tapeworms

PARASITOLOGY

MORPHOLOGY

Nutrients absorbed from host

*** Divided into scolex, neck, segmented strobila**

Proglottids hermaphroditic units releasing eggs

Like all helminths, tapeworms lack vascular and respiratory systems. In addition, they are devoid of both gut and body cavities. Nutrients are absorbed across their surface cuticle, and the internal organs are embedded in solid parenchyma. The adult is divided into three distinct parts: The “head” or scolex; a generative “neck”; and a long, segmented body called the strobila. The scolex typically measures less than 2 mm in diameter and is equipped with muscular sucking disks used to attach the worm to the intestinal mucosa of its host. (In one genus, *Dibothriocephalus*, the disks are replaced by two grooves called bothria.) As a further aid in attachment, the scolex of some species possesses a retractable protuberance, or rostellum, armed with a crown of chitinous hooks. Immediately

posterior to the scolex is the neck from which individual segments, or proglottids, are generated one at a time to form the chain-like strobila. Each proglottid is a self-contained hermaphroditic reproductive unit joined to the remainder of the colony by a common cuticle, nerve trunks, and excretory canals. Its male and female gonads mature and self-fertilize as the segment is pushed farther and farther from the neck by the formation of new proglottids. When the segment reaches gravidity, it releases its eggs by rupturing, disintegrating, or passing them through its uterine pore.

• BEEF TAPEWORM

TAENIA SAGINATA: PARASITOLOGY AND LIFE CYCLE

*** *T saginata* inhabits human jejunum**

Gravid proglottids passed in stool

Eggs ingested by herbivore intermediates

Transform into larvae forming cysts in cow

*** Humans infected by eating inadequately cooked meat**

Taenia saginata inhabits the human jejunum, where it may live for up to 25 years and grow to a maximum length of 10 m. Its 1 mm scolex lacks hooklets but possesses the four sucking disks typical of most cestodes (**Figure 56–1A**). The creamy white strobila consists of 1000 to 2000 individual proglottids. The terminal segments are longer (20 mm) than they are wide (5 mm), and contain testes and a large uterus with 15 to 20 lateral branches; these characteristics are useful in differentiating them from those of the closely related pork tapeworm, *Taenia solium* (see later). When fully gravid, strings of six to nine terminal proglottids, each containing approximately 100,000 eggs, break free from the remainder of the strobila. These muscular segments may crawl unassisted through the anal canal or be passed intact with the stool. Proglottids reaching the soil may remain motile for a time, perhaps in order to move away from human

feces and into fresh grass that will entice a cow during grazing. Eventually, the proglottids disintegrate, releasing their distinctive ova. These eggs are 30 to 40 μm in diameter, spherical, and possess a thick, radially striated shell which appear very similar to those of *T solium* (**Figure 56–1B**). In appropriate environments, the embryo may survive in the egg for months. If ingested by cattle or certain other herbivores, the embryo is released, penetrates the intestinal wall, and is carried by the vascular system to the striated muscles of the tongue, diaphragm, and hindquarters. Here it transforms into a white, ovoid (5 by 10 mm) cysticercus (*Cysticercus bovis*). When present in large numbers, cysticerci impart a spotted or "measly" appearance to the flesh. Humans are infected when they ingest inadequately cooked meat containing these larval forms, which evaginate into scolices, attach to the jejunal epithelium, and begin to grow into a full-sized adult tapeworm, thus completing the life cycle.

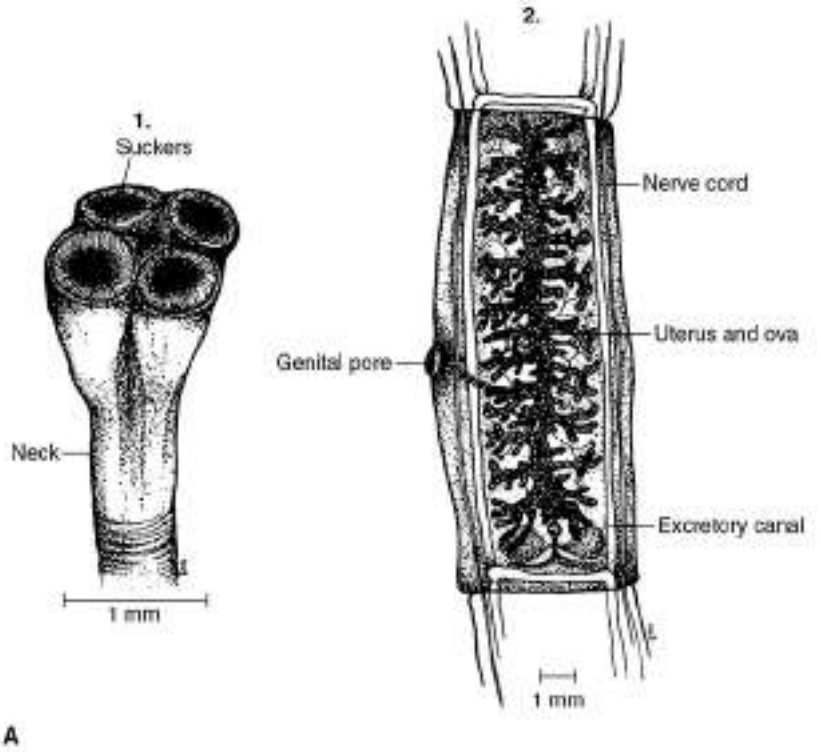

FIGURE 56–1. Tapeworm structures. A. *Taenia saginata.* **B.** *Taenia solium.* (1, 3) scolices; (2, 4) gravid proglottids; (5) ova (indistinguishable between species).

BEEF TAPEWORM DISEASE

EPIDEMIOLOGY

Disease rare in the United States

In the United States, sanitary disposal of human feces and federal inspection of meat have nearly interrupted transmission of *T saginata.* At present, fewer than 1% of examined carcasses are infected. In countries where sanitary facilities are less comprehensive and undercooked or raw beef is eaten, *T saginata* is highly prevalent. Examples include Kenya, Ethiopia, the Middle East, the former Yugoslavia, and parts of the former Soviet Union and South America.

BEEF TAPEWORM DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

*** Symptoms usually mild**

Most persons infected with beef tapeworm are asymptomatic and become aware of the infection only through the spontaneous passage of proglottids. The proglottids may be observed on the surface of the stool or appear in the underclothing or bedsheets of the alarmed host. Passage may occur irregularly and can be precipitated by excessive alcohol consumption. Some patients report epigastric discomfort, nausea, abdominal irritability, diarrhea, and weight loss. Occasionally, the proglottids may obstruct the appendix, biliary duct, or pancreatic duct.

DIAGNOSIS

*** Cellophane tape technique, stool examination detect eggs,**

proglottids

The diagnosis of beef tapeworm disease is made by finding eggs or proglottids in the stool. Eggs may also be distributed on the perianal area secondary to rupture of proglottids during passage. The adhesive cellophane tape technique described for pinworm can be used to recover the worms from this area. With this procedure, 85% to 95% of infections are detected, in contrast to only 50% to 75% by stool examination. Because the eggs of *T solium* and *T saginata* are morphologically identical, it is necessary to examine a proglottid to identify the species correctly—*T saginata* proglottids are motile and have more uterine branches than the immotile *T solium* proglottids. As discussed below, the implications and management of these two infections may be substantially different.

TREATMENT AND PREVENTION

*** Sewage waste disposal, meat inspection, adequate cooking**

The drug of choice is praziquantel, which acts directly on the worm and is highly effective in single-dose oral preparations. To ensure cure, fecal specimens should be examined again approximately 3 months following treatment. Ultimately, control is best achieved through the sanitary disposal of human feces. Meat inspection is helpful; the cysticerci are readily visible. In areas where the infection is common, thorough cooking is the most practical method of control. Internal temperatures of 56°C or more for 5 minutes or longer destroy the cysticerci. Salting or freezing for 1 week at −15°C or below is also effective.

• PORK TAPEWORM

TAENIA SOLIUM: PARASITOLOGY AND LIFE CYCLE

T solium* strobila shorter than *T saginata

*** Humans worms by eating undercooked pork cysts**

* Complexity: cysts just like swine when eggs consumed from human stool

Like the beef tapeworm, which it closely resembles, *T solium* inhabits the human jejunum, where it may survive for decades. It can be distinguished from its close relative only by careful scrutiny of the scolex and proglottids; *T solium* possesses a rostellum armed with a double row of hooklets (**Figure 56–1B3**). The strobila is generally smaller than that of *T saginata*, seldom exceeding 5 m in length or containing more than 1000 proglottids. Gravid segments measure 6 by 12 mm and thus appear less elongated than those of the bovine parasite (**Figure 56–1B4**). Typically, the uterus has only 8 to 12 lateral branches. Although the eggs appear morphologically identical to those of *T saginata*, they are infective only to swine and—perhaps reflecting a genetic proximity we might prefer to overlook—humans. Unlike *T saginata*, both pigs and people may become intermediate hosts when they ingest food contaminated with viable eggs (**Figure 56–2**). Humans with tapeworms may be autoinfected when gravid proglottids are carried backward into the stomach during the act of vomiting, initiating the release of the contained eggs. Autoinfection probably also results when eggs are transported from the perianal area to the mouth on contaminated fingers. The pork tapeworm life cycle is illustrated in Figure 56–2.

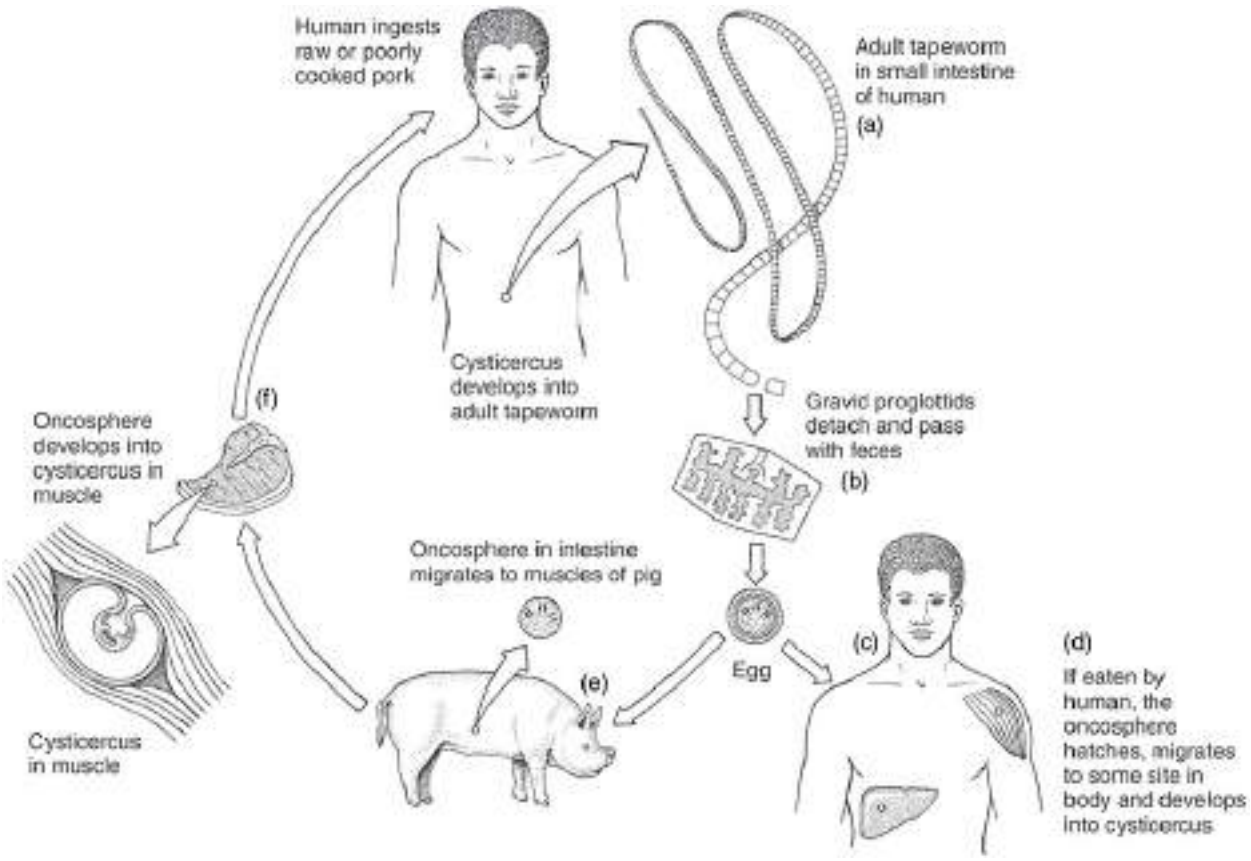

FIGURE 56–2. Pork tapeworm life cycle. (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

*** Difference from beef tapeworm: tissue cysticerci develop in swine and humans**

*** Mantra of *T solium*: "Eat a cyst in pork, get a worm … Eat an egg in human stool, get a cyst"**

Regardless of the route of entry, an egg reaching the stomach of an appropriate intermediate host hatches, releasing an embryo called a "hexacanth," because it has six hooklets. The embryo penetrates the intestinal wall and may be carried by the lymphohematogenous system to any tissue in the body. There it develops into a 1 cm, white, opalescent cysticercus over 3 to 4 months (**Figure 56–3**). The cysticercus may remain viable in pigs for up to 5 years, eventually infecting humans when they ingest undercooked "measly" flesh. In the human gut, the scolex everts, attaches to the mucosa, and develops into a new adult worm, thereby completing the cycle. When humans eat eggs, we serve as accidental, dead-end hosts, because the cysts will never be eaten by another person. However, these cysts may cause seizures if they form in the brain.

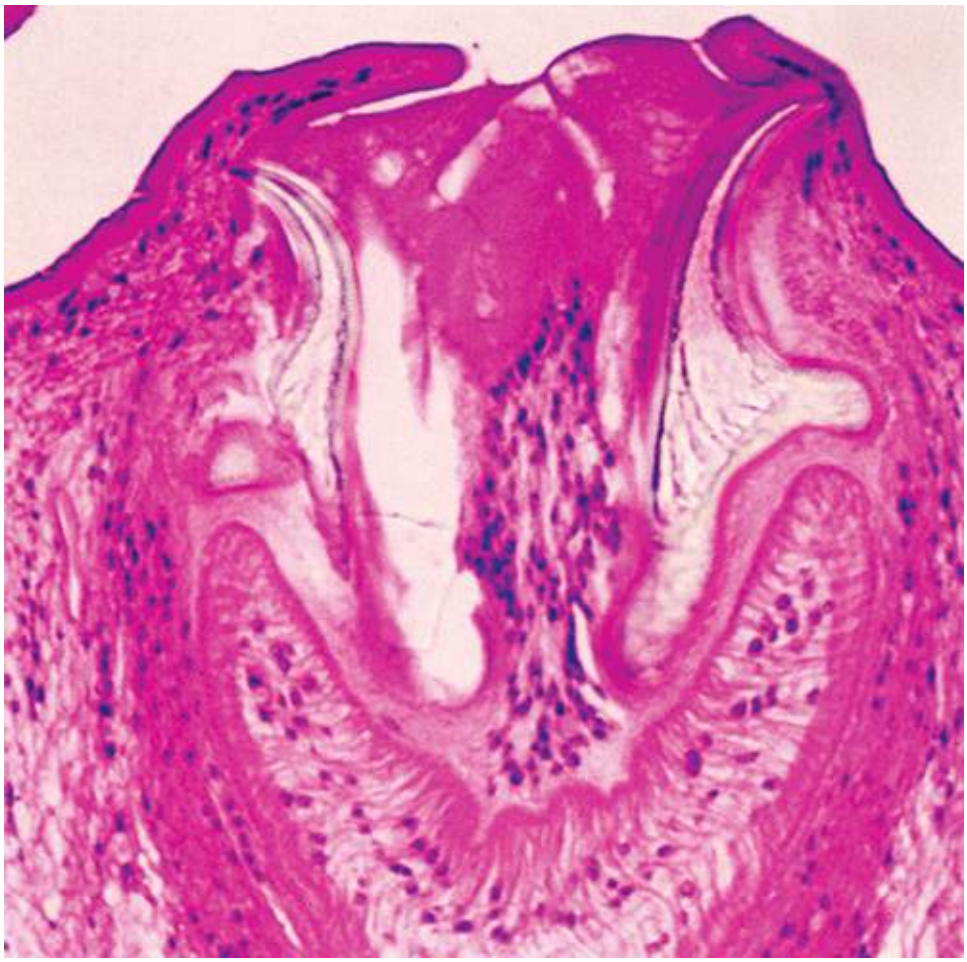

FIGURE 56–3. Cysticercosis of muscle. This section shows a cysticercus with the hooklets of a worm scolex. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

In summary, humans will acquire pork tapeworms if they consume undercooked pork; they will acquire cysticercosis if they consume tapeworm eggs from human feces.

PORK TAPEWORM DISEASE

EPIDEMIOLOGY

T solium rarely found in the U.S. swine

Although infected swine are still occasionally found in the United States, most

human disease is diagnosed in immigrants from endemic areas. Although pork tapeworm disease is widely distributed throughout the world, it is particularly common in South and Southeast Asia, Africa, Latin America, and Eastern Europe.

PORK TAPEWORM DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

Gut tapeworms well tolerated

*** Manifestations reaction to cysts in tissue**

The signs and symptoms of infection with the *adult* worm are mild and similar to those of *T saginata* taeniasis. However, clinical manifestations are totally different when humans serve as *intermediate* hosts. Cysticerci develop in the subcutaneous tissues, muscles, heart, lungs, liver, eye, and brain (**Figure 56–4**). As long as their number is small and the cysticerci remain viable, tissue reaction is moderate and the patient is typically asymptomatic. The death of the larvae, however, may lead to a marked inflammatory reaction, fever, muscle pains, and eosinophilia.

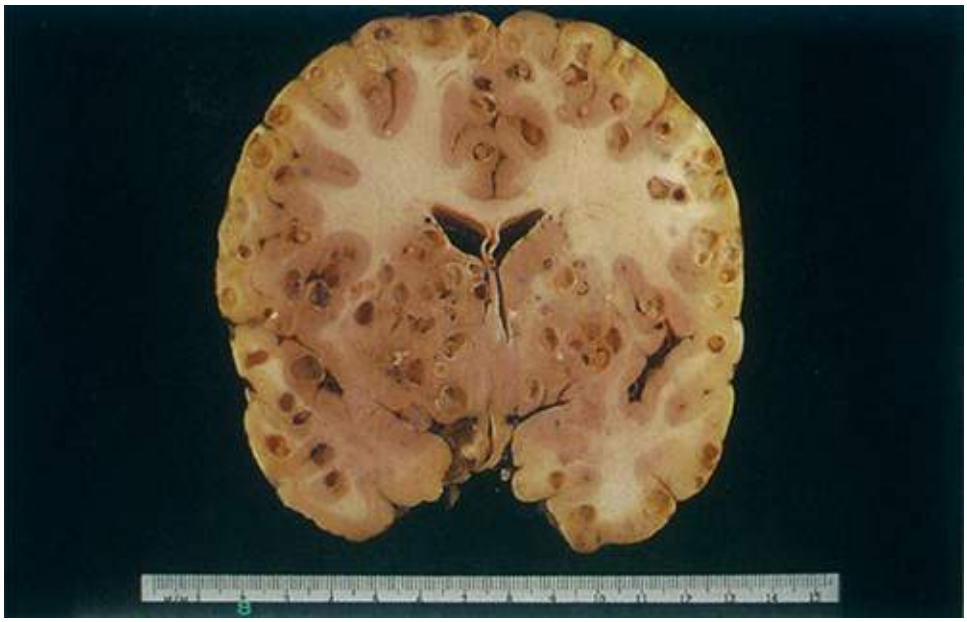

FIGURE 56–4. Cysticercosis of brain. This brain from a 16-year-old girl shows multiple cysticercal cysts

primarily at the junction of white and gray matter. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

*** CNS invasion called neurocysticercosis**

Multiple small cysts form

*** Meningoencephalitis, eosinophilia, focal neurologic signs, epilepsy**

The most important and dramatic clinical presentation of lesions in the central nervous system (CNS) is called neurocysticercosis. During the acute invasive stage, patients may experience fever, headache, and eosinophilia. In heavy infections, a meningoencephalitic syndrome with cerebrospinal fluid (CSF) eosinophilic pleocytosis may be present. Established cysts can be found in the cerebrum, ventricles, subarachnoid space, spinal cord, and eye. Cerebral cysts are usually small, often measuring 2 cm or less in diameter; racemose (clustered) lesions may be threefold larger. Parenchymal infections can induce focal neurologic abnormalities, personality changes, intellectual impairment, and/or seizures; in many endemic areas, cysticercosis is the leading cause of epilepsy. Subarachnoid lesions and cysticerci located within the fourth ventricle may obstruct the flow of CSF, producing increased intracranial pressure with associated headache, vomiting, visual disturbances, or psychiatric abnormalities. Multiple lesions have a predilection for the basal cisterns. Spinal involvement produces cord compression or meningeal inflammation. Eye lesions incite pain and visual disturbances.

DIAGNOSIS

*** Adult worm diagnosed from proglottids, eggs in stool**

Cysticercosis diagnosed by imaging, biopsy, serology

Infection with the adult worm is diagnosed as described for *T saginata.* Cysticercosis is suspected when an individual who has been in an endemic area presents with neurologic manifestations or subcutaneous nodules. Radiographs of the soft tissues may reveal dead, calcified cysticerci. Viable lesions may be detected as low-density masses by computed tomography (CT) or magnetic resonance imaging (MRI). Brain cysticerci typically are 5 to 10 mm in diameter (Figure 56–4). Subarachnoid lesions are often larger, may be lobulated, and are

often “isodense,” making them difficult to identify radiographically. The lesions may resemble brain malignancy, which is managed differently, and thus it is important to confirm the diagnosis. This can be done by demonstrating the larva in a biopsy sample of a subcutaneous nodule or by detecting specific antibodies in the circulating blood. Serum and CSF enzyme immunoassays and western blot testing for specific anticysticercal antibodies have a sensitivity of 80% to 95%. The presence of IgG antibodies alone may reflect the presence of past or inactive disease.

TREATMENT AND PREVENTION

*** Antiepileptic medications with or without antiparasitics, corticosteroids**

Surgery occasionally needed

Infection with the adult worm is treated with praziquantel, as described for *T saginata.* Symptomatic neurocysticercosis requires a different approach. For patients who present with seizures, antiepileptic medications are the most important priority; treatment of brain parenchymal lesions can then be attempted with albendazole and corticosteroids (to help minimize the inflammatory response to dying cysticerci). However, seizure control—not antiparasitic medication—is the first priority. Mechanical blockage of the brain’s ventricles is another feared complication. Intraventricular, subarachnoid, and eye lesions appear relatively refractory to chemotherapy; surgery, CSF shunts, and corticosteroids may help ameliorate symptoms. Tapeworm acquisition can be prevented by adequately cooking pork before ingestion. Egg ingestion can be prevented by proper hand hygiene among food service workers after using the toilet.

Is it possible for someone who consumes no pork to develop neurocysticercosis?

• FISH TAPEWORM

DIBOTHRIOCEPHALUS LATUS: PARASITOLOGY AND LIFE CYCLE

Dibothriocephalus latus has broad proglottids

This parasite was formerly called *Diphyllobothrium latum*. The adult *D latus* attaches to the human ileal mucosa with the aid of two sucking grooves (bothria) located in an elongated fusiform scolex (**Figure 56–5**). In lifespan and overall length, it resembles the *Taenia* species discussed previously. The 3000 to 4000 proglottids, however, are uniformly wider than they are long, accounting for this cestode's species designation as well as one of its common names, the "broad tapeworm." The gravid segments contain a centrally positioned, rosette-shaped uterus unique among the tapeworms of humans. Over 1 million oval (55 by 75 μm) operculated eggs are released daily into the stool (Figure 56–5).

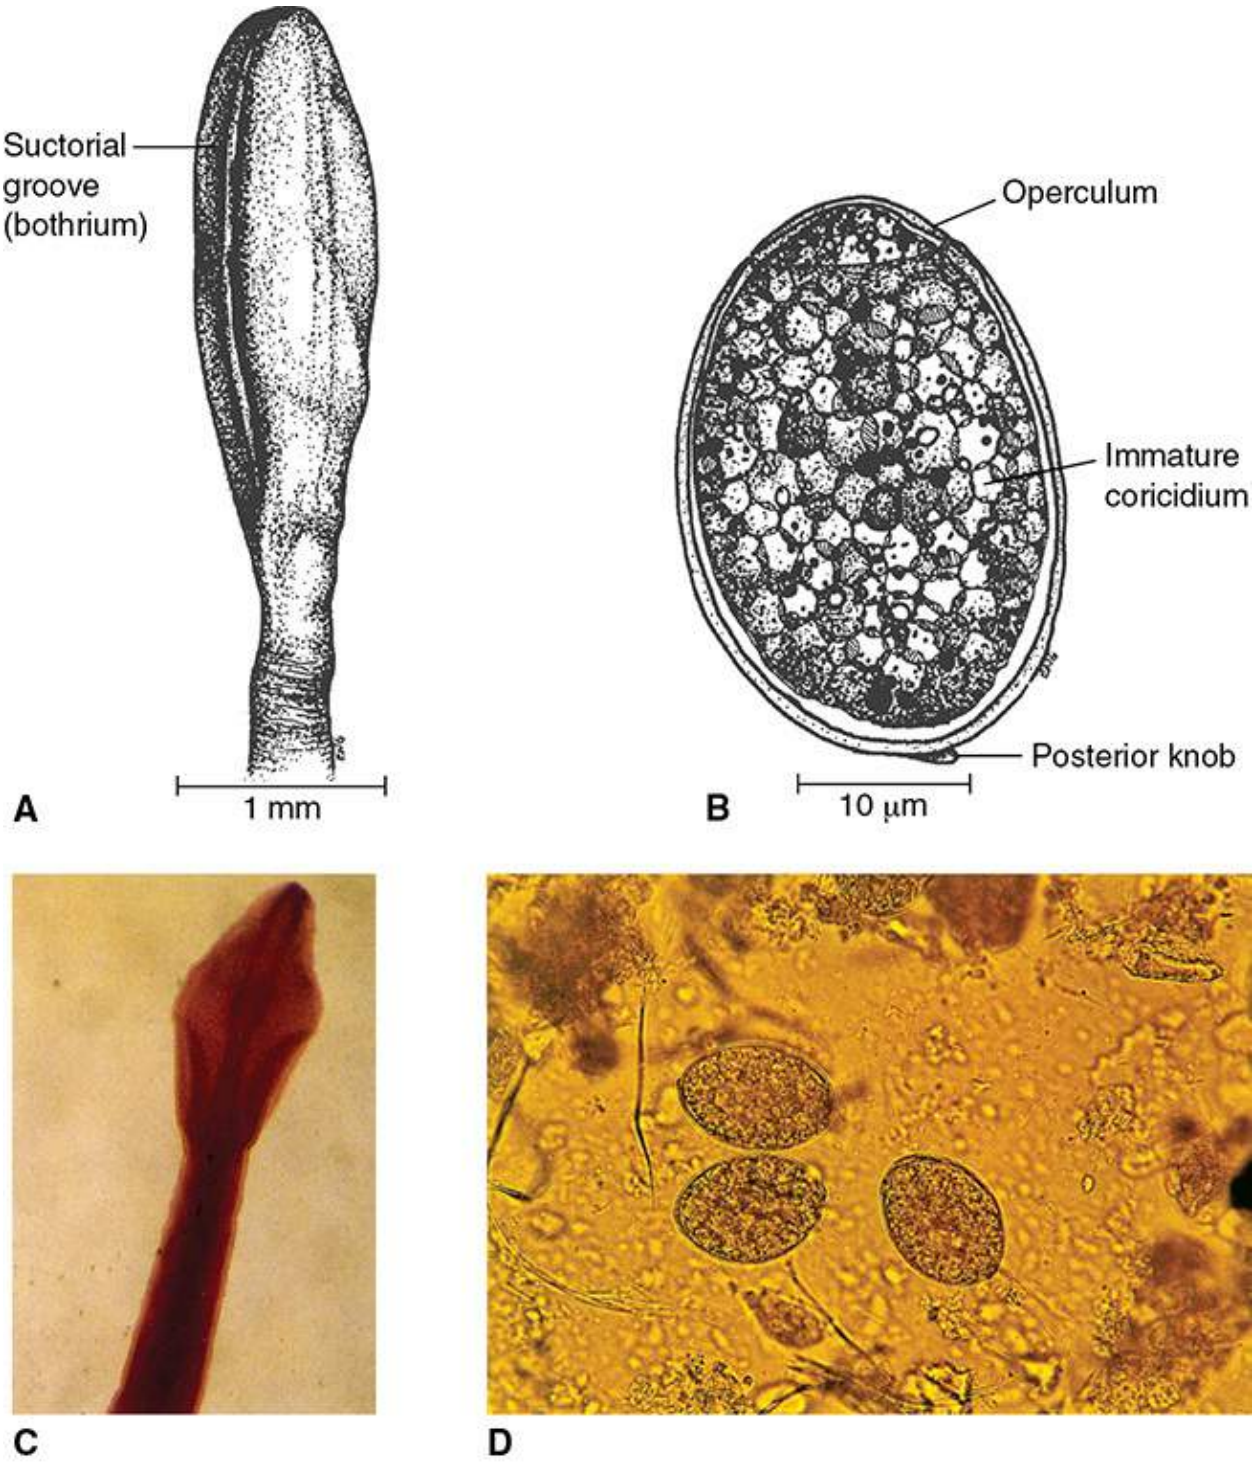

FIGURE 56–5. ***Dibothriocephalus latus*****. A.** Structure of scolex. **B.** Structure of egg. **C.** Scolex from a human case. **D.** Ova in stool stained with iodine. (C and D, Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

Think ▸▸ Apply 56-1: Yes. Neurocysticercosis happens when humans ingest eggs from the feces of other humans, who in turn harbor an adult worm (taeniasis) they acquired by eating undercooked pork. "Eat a cyst, get a worm … eat an egg, get a cyst."

Eggs release motile coracidia into water

*** Humans infected eating undercooked fish**

On reaching fresh water the eggs hatch, releasing ciliated, free-swimming larvae called coracidia. If ingested within a few days by small freshwater crustaceans of the genera *Cyclops* or *Diaptomus*, they develop into procercoid larvae. When the parasitized crustacean is then ingested by a freshwater or anadromous marine fish (eg, salmon), the larvae migrate into the musculature of the fish and develop into infectious plerocercoid larvae. Humans are infected when they eat improperly prepared freshwater fish containing such forms. The life cycle is illustrated in **Figure 56–6.**

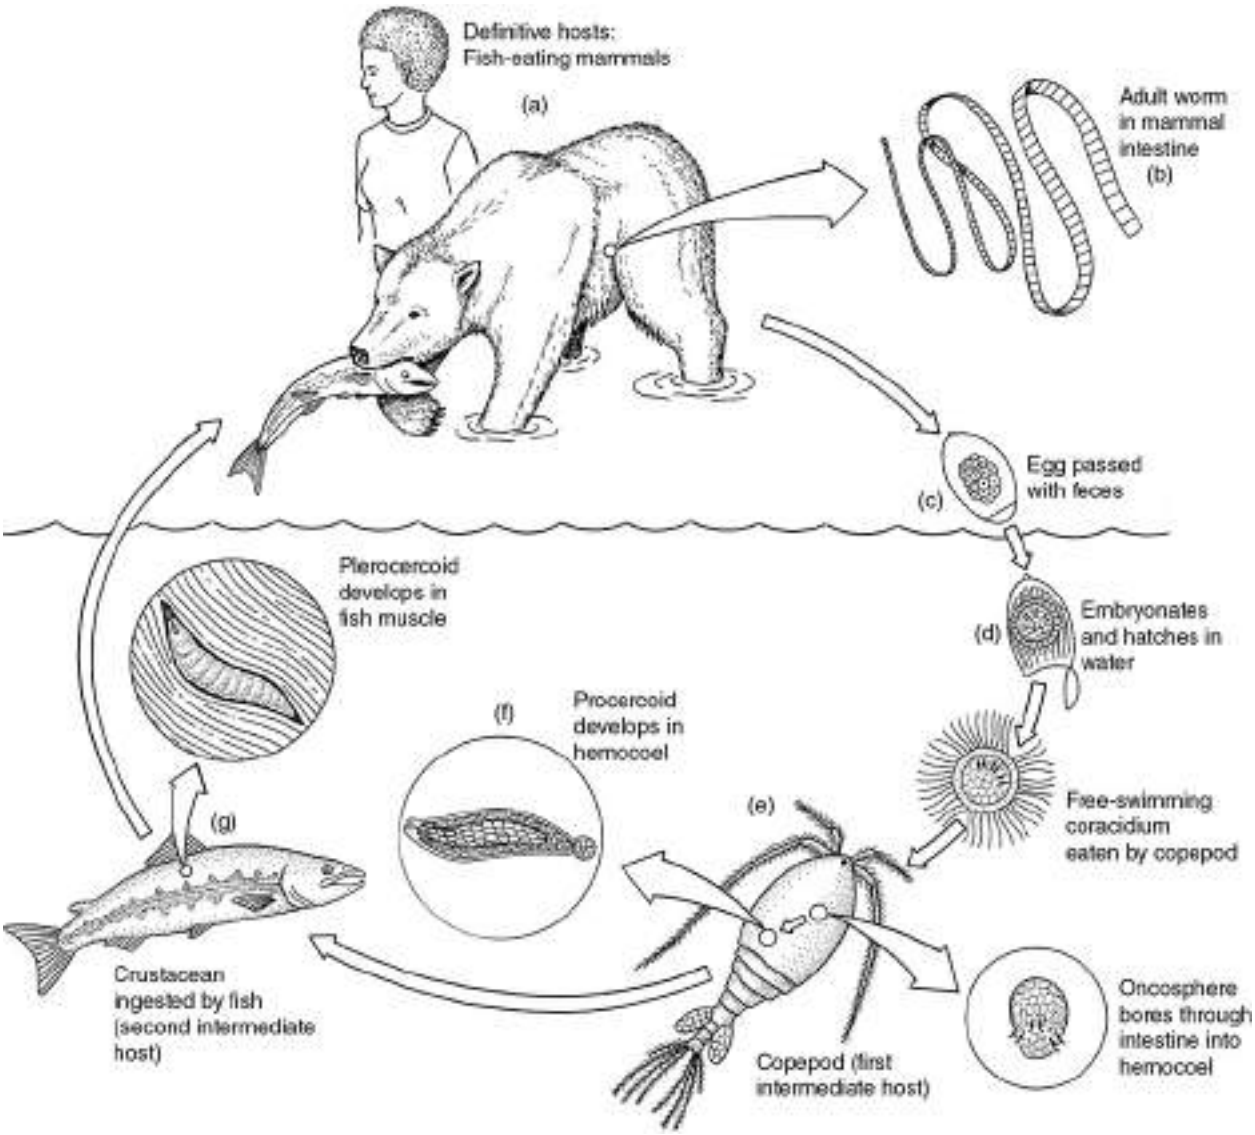

FIGURE 56–6. Life cycle of *Dibothriocephalus latus.* (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

FISH TAPEWORM DISEASE

EPIDEMIOLOGY

Worldwide distribution

Worm in Alaska, Canada, Midwest, California, Florida

*** Eating raw fish increases risk**

Fish tapeworms are found wherever raw, pickled, or undercooked freshwater fish from fecally contaminated lakes and streams are eaten by humans. Other fish-eating mammals like cats, dogs, and bears may serve as reservoir hosts. Human infections have been described in the Baltic and Scandinavian countries, Russia, Switzerland, Italy, Japan, China, the South Pacific, Chile, and Argentina. The worm, possibly brought to North America by Scandinavian immigrants, is now found in Alaska, Canada, the midwestern states, California, and Florida. In the Pacific Northwest and Pacific Rim, a closely related species *Dibothriocephalus nihonkaiense* seems comparatively hardy in cold conditions and is able to form infectious plerocercoid larvae in anadromous salmon. Human cases have been traced to the ingestion of fish freshly taken from Alaskan waters. The increasing popularity of raw fish dishes, such as Japanese sushi and sashimi, may lead to increased prevalence of this disease in the United States—although freezing the fish before consumption is usually fatal to the cysts. Among native Americans, infection has been acquired by eating salted fish. Even when fish is appropriately cooked, individuals may become infected by sampling the flesh during the process of preparation.

FISH TAPEWORM DISEASE: CLINICAL ASPECTS

MANIFESTATIONS

Occasional intestinal obstruction

*** Vitamin B_{12} deficiency due to consumption by worm**

Most infected patients are asymptomatic. On occasion, however, they may complain of epigastric pain, abdominal cramping, vomiting, and weight loss. Moreover, the presence of several adult worms within the gut has been known to precipitate intestinal or biliary obstruction. Forty percent of fish tapeworm carriers demonstrate low serum levels of vitamin B_{12}, apparently because of the competition between the host and the worm for this ingested nutrient. Studies have shown that a worm located high in the jejunum may take up 80% to 100% of vitamin B_{12} given by mouth. Approximately 0.1% to 2% of patients develop

macrocytic anemia. They tend to be elderly, to have impaired production of intrinsic factor, and to have worms located high in the jejunum. In many, folate absorption is also diminished. Lysolecithin, a tapeworm product, may also contribute to anemia. Neurologic manifestations of vitamin B_{12} deficiency may occur, sometimes in the absence of anemia. They include numbness, paresthesias, loss of vibration sense, and, rarely, optic atrophy with central scotoma.

DIAGNOSIS

*** Eggs demonstrated in stool**

The diagnosis should be suspected among patients with a compatible dietary history, ill-defined GI symptoms, or B_{12} deficiency. It is confirmed by finding eggs in the stool. Because *D latus* produces large numbers of ova, identification is usually accomplished without the need for concentration techniques.

TREATMENT AND PREVENTION

*** Fish noninfectious if cooked or frozen**

Treatment is the same as described for *T saginata* tapeworm infections, using praziquantel. When anemia or neurologic manifestations are present, parenteral administration of vitamin B_{12} is also indicated. Personal protection can be accomplished by thorough cooking of all salmon and freshwater fish. Devotees of raw fish may choose to freeze their favorite dish at −10°C for 48 hours before serving, as this is also effective in killing the plerocercoids. Ultimately, control of *Dibothriocephalus* infection is accomplished by prohibiting the discharge of untreated sewage into lakes and streams, although animal reservoir hosts are not addressed via this technique.

• ECHINOCOCCUS

Echinococcosis, or “hydatid disease,” is a tissue infection of humans caused by larvae of *Echinococcus granulosus* and *E multilocularis.* The former is a more common cause of human disease.

ECHINOCOCCUS GRANULOSUS

PARASITOLOGY AND LIFE CYCLE

Adult in canines

*** Herbivores, humans intermediate hosts**

Larvae reach portal or systemic circulation

*** Cysts in tissues**

Cycle completed in canines

The adult *E granulosus* tapeworm inhabits the small bowel of dogs, wolves, and other canines, where it survives for a scant 12 months. The scolex possesses four sucking disks and a double row of hooklets. The entire strobila, however, measures only 5 mm in length, and contains just three proglottids: one immature, one mature, and one gravid. The latter segment splits open either before or after passage in the stool, releasing eggs that appear identical to those of *T saginata* and *T solium.* A number of mammals may serve as intermediates, including sheep, goats, camels, deer, caribou, moose, and—most importantly—humans. When one of these hosts ingests eggs, they hatch, releasing embryos that penetrate the intestinal mucosa and are then carried via the portal blood to the liver. There, many are trapped in the hepatic sinusoids. The rest traverse the liver and are carried to the lung, where they may lodge. A few pass through the pulmonary capillaries, enter the systemic circulation, and are carried to the brain, heart, bones, kidneys, and other organs. Many of the larvae are phagocytosed and destroyed by host immune cells. The survivors form a cyst wall composed of an external laminated cuticle and an internal germinal membrane. The cyst fills with fluid and slowly expands, reaching a diameter of 1 cm over the next 5 to 6 months (**Figure 56–7**). However, they may grow substantially larger in subsequent months and years, in some cases reaching diameters greater than 10 cm. In time, secondary “brood capsules” arise from the germinal layer and form within the original hydatid, or break through the cyst surface to form new “daughter cysts.” Within these brood capsules and daughter cysts, new protoscolices develop from the germinal lining. Degenerated protoscolices and

germinal membranes fall to the bottom of the cyst to form hydatid “sand.” When hydatid-containing tissues of the intermediate host are ingested by a canine, scolices are released in the intestine where they develop into adult worms. The life cycle is illustrated in **Figure 56–8.**

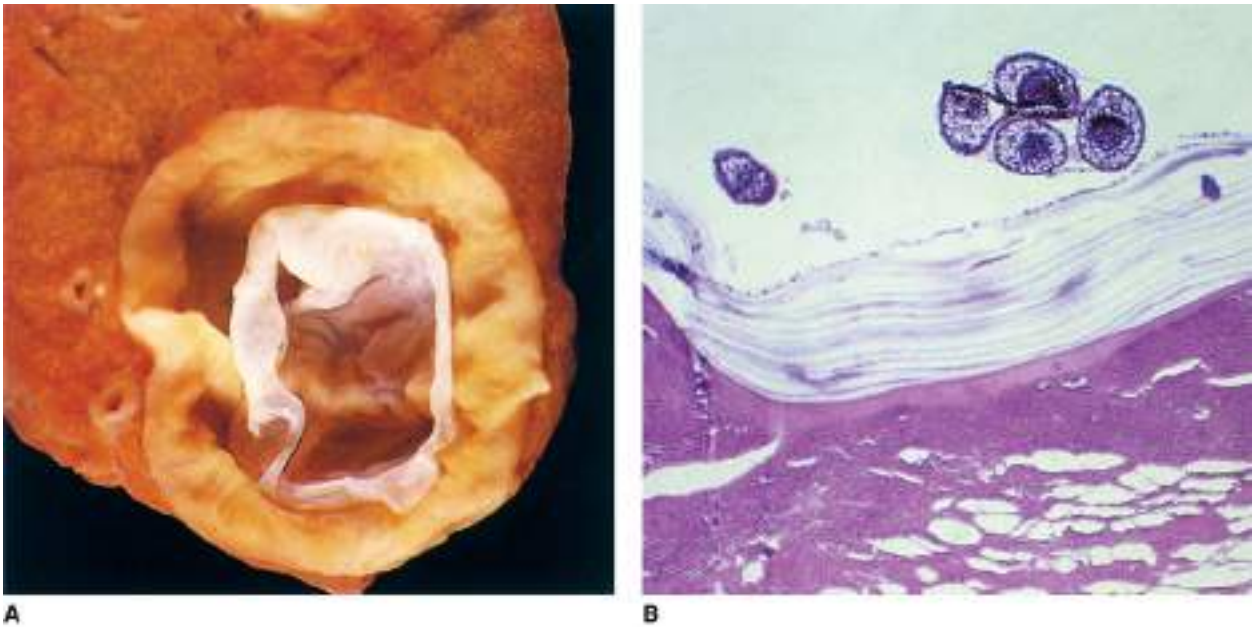

FIGURE 56–7. Echinococcosis. A. Echinococcal cyst in lung with white lining membrane. **B.** Echinococcal cyst wall with lung parenchyma below and five scolices above. (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

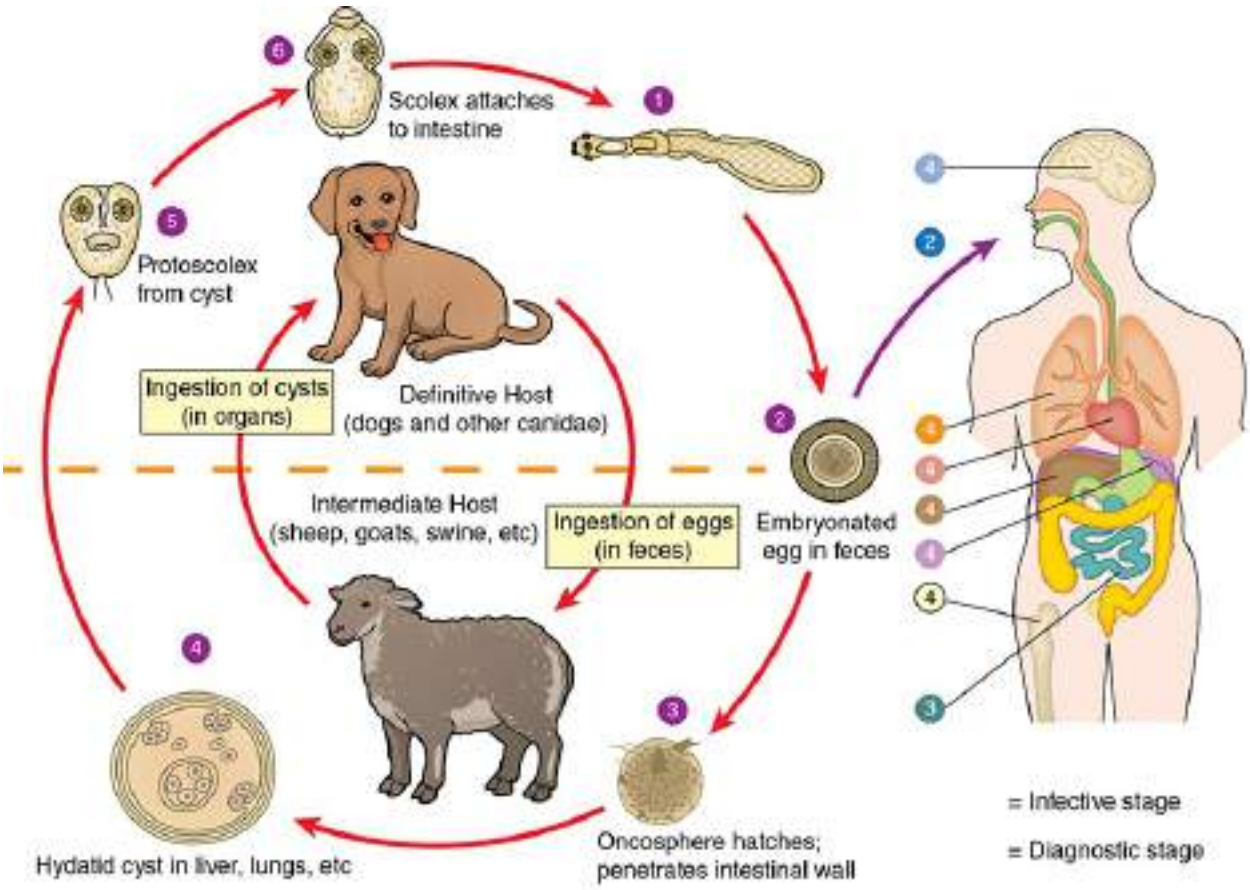

The adult *Echinococcus granulosus* (3-6 mm long) (1) resides in the small bowel of the definitive hosts, dogs, or other canids. Gravid proglottids release eggs (2) that are passed in the feces. After ingestion by a suitable intermediate host (under natural conditions: sheep, goat, swine, cattle, horses, and camel), the egg hatches in the small bowel and releases an oncosphere (3) that penetrates the intestinal wall and migrates through the circulatory system into various organs, especially the liver and lungs. In these organs, the oncosphere develops into a cyst (4) that enlarges gradually, producing protoscolices and daughter cysts that fill the cyst interior. The definitive host becomes infected by ingesting the cyst-containing organs of the infected intermediate host. After ingestion, the protoscolices (5) evaginate, attach to the intestinal mucosa (6), and develop into adult stages (1) in 32 to 80 days. The same life cycle occurs with *E multilocularis* (1.2-3.7 mm), with the following differences: The definitive hosts are foxes, and to a lesser extent dogs, cats, coyotes, and wolves; the intermediate host are small rodents; and larval growth (in the liver) remains indefinitely in the proliferative stage, resulting in invasion of the surrounding tissues. With *E vogeli* (up to 5.6 mm long), the definitive hosts are bush dogs and dogs; the intermediate hosts are rodents; and the larval stage (liver, lungs, and other organs) develops both externally and internally, resulting in multiple vesicles. *E oligarthrus* (up to 2.9 mm long) has a life cycle that involves wild felids as definitive hosts and rodents as intermediate hosts. Humans become infected by ingesting eggs (2), with resulting release of oncospheres (3) in the intestine and the development of cysts (4), (4), (4), (4), (4), (4) in various organs.

FIGURE 56–8. Life cycle of *Echinococcus* species.

ECHINOCOCCOSIS

EPIDEMIOLOGY

*** Hand-to-mouth infection of humans after dog contact**

Maintained by dogs feeding on sheep viscera

Sylvatic cycle in Alaska and western Canada

There are two major epidemiologic forms of *E granulosus*-induced echinococcosis: Pastoral and sylvatic. The more common pastoral form has its highest incidence in Australia, New Zealand, South and East Africa, the Middle East, Central Europe, and South America, where domestic herbivores such as sheep, cattle, and camels are raised by people in close contact with domestic dogs. Although approximately 200 human cases are reported each year in the United States, most were acquired internationally. Indigenous cases have been reported, however, particularly among Basque sheep farmers in western states and Native Americans in the southwest. Animal husbandry practices that permit dogs to feed on the raw viscera of slaughtered sheep perpetuate cycle. Transmission also depends on suboptimal hand hygiene, in that shepherds become infected while handling their dogs: microscopic eggs are transferred from dog feces to their fur, where they are transferred onto their masters' hands and later ingested. Sylvatic echinococcosis, in contrast, is found principally in Alaska and western Canada, where wolves act as the definitive hosts and moose or caribou are the intermediates. In two counties in California, a second sylvatic cycle involving deer and coyotes has been described. When hunters kill these wild deer and feed their offal to accompanying dogs, a pastoral cycle may be established.

ECHINOCOCCOSIS: CLINICAL ASPECTS

MANIFESTATIONS

*** Disease caused by mechanical effects of cysts**

The enlarging *E granulosus* cysts produce tissue damage by mechanical means. The clinical presentation depends on their number, location, and rate of growth. Typically, a latent period of 5 to 20 years occurs between acquisition of infection

and subsequent diagnosis. Intervals as long as 75 years have been reported.

*** Many asymptomatic**

Cysts may attain large size

*** Rupture leads to hypersensitivity, dissemination**

The majority of cysts are found in the liver and/or in the lung. One-fifth of all patients show involvement of multiple sites. Many patients are asymptomatic when the lesion is discovered on routine imaging or physical examination. Occasionally, the patient may present with hemoptysis, pain in the right upper quadrant of the abdomen, or a tender hepatic mass. Significant morbidity is uncommon, and death rare. However, hydatid cysts may reach enormous size. They may eventually rupture, inducing fever, pruritus, urticaria, and—at times—anaphylactic shock. Germinal tissue or brood capsules may also spread to other areas, leading to dissemination of the infection. Rupture of pulmonary lesions also induces cough, chest pain, and hemoptysis. Liver cysts may break through the diaphragm or rupture into the bile duct or peritoneal cavity. Most patients who develop symptoms, however, present with a tender, palpable hepatic mass. Intrabiliary extrusion of calcified cysts may mimic the signs of acute cholecystitis; complete obstruction results in jaundice. Bone cysts may produce pathologic fractures. Lesions in the CNS may manifest with blindness or seizures. Cardiac lesions have been associated with conduction disturbances, ventricular rupture, and embolic metastases. It has been suggested that circulating antigen–antibody complexes may deposit in the kidney, initiating membranous glomerulonephritis.

DIAGNOSIS

*** Radiologic, scanning appearance characteristic**

*** Cyst puncture perilous**

In *E granulosus*-infected patients, chest X-rays may demonstrate pulmonary lesions as slightly irregular, round masses of uniform density, often devoid of calcification. In contrast, more than one-half of hepatic lesions display a smooth, calcific rim. CT, ultrasonography, and MRI may reveal either a simple fluid-filled cyst or daughter cysts with hydatid sand. Endoscopic retrograde

cholangiography has been valuable for determining cyst location and possible communication with the biliary tree. Because of the potential for an allergic reaction or spread of infection, diagnostic aspiration may be contraindicated. Nevertheless, in select cases, ultrasonically guided percutaneous drainage, followed by the introduction of hypertonic saline to kill protoscolices and germinal layer, has proved safe and useful both diagnostically and therapeutically (see PAIR later). In patients with ruptured pulmonary cysts, scolices may be demonstrated in the sputum.

Serology needs improved sensitivity

In some cases, confirmation of the diagnosis before drainage requires serologic testing. Unfortunately, current options are not totally satisfactory. Indirect hemagglutination and latex agglutination tests are positive in 90% of patients with hepatic lesions and 60% of those with pulmonary hydatid cysts. Polymerase chain reaction assay has been shown to be capable of detecting picogram quantities of *Echinococcus* genomic DNA in fine-needle biopsy material from patients with suspected echinococcosis.

TREATMENT AND PREVENTION

*** Treatment may include PAIR with concomitant albendazole**

For years, the only definitive therapy available was surgical extirpation. Patients with pulmonary hydatid cysts of the sylvatic type and small calcified hepatic lesions underwent surgery only when they became symptomatic or the cysts increased dramatically in size over time. However, for uncomplicated lesions, **P**uncture, **A**spiration, **I**njection of scolicide, and **R**easpiration (PAIR) can be used in lieu of surgery. The scolicide of choice is probably hypertonic saline, although other chemicals have been used. If performed properly, this technique is safer and better tolerated than open surgery. Presently, it is recommended that high-dose albendazole be administered before and for several weeks (or years in the case of *E multilocularis* infection) after surgery and/or aspiration. Infected dogs should be dewormed, and infected carcasses and offal burned or buried. Hands should be carefully washed after contact with potentially infected dogs.

A shepherd is shocked to learn that he has hydatid disease,

because he is a lifelong vegetarian who has never consumed undercooked animal organ meat. How do you explain this?

ECHINOCOCCUS MULTILOCULARIS

Foxes definitive hosts

Larvae bud externally; produce multilocular cysts

Echinococcus multilocularis is found primarily in subarctic and arctic regions in North America, Europe, and Asia. The adult worms are found in the gut of foxes and, to a lesser extent, coyotes. Their larvae grow in the tissues of mice and voles, the rodent prey of canines. Domestic dogs may acquire adult tapeworms by killing and ingesting these larva-infected sylvatic rodents. Humans are infected with larval forms through the ingestion of eggs passed in the feces of their domestic dogs or ingestion of egg-contaminated vegetation, for instance when eating berries sprayed with an invisible layer of fox stool. Unlike the larval forms of *E granulosus*, those of *E multilocularis* bud *externally*, producing proliferative, multilocular cysts that slowly but progressively invade and destroy the affected organs and adjacent tissues.

The clinical course in humans is characterized by epigastric pain, obstructive jaundice, and, less frequently, metastasis to the lung and brain, closely mimicking liver cancer. As with *E granulosus*, medical treatment of *E multilocularis* often fails to achieve cure. Patients with multilocular infection may require surgical management. The prognosis is grim if not diagnosed early.

• *HYMENOLEPIS*

Can be transmitted directly from human to human

Like *Echinococcus* species, and in contrast to the cow, pig, and fish tapeworms, the adult *Hymenolepis nana* worm is very small, perhaps 4 cm in length. Rodents are the most common definitive hosts, but humans may become infected. In fact, the so-called “dwarf tapeworm” is the only tapeworm that can be transmitted directly from human to human. Eggs are ingested via the fecal–oral route. They then release embryos that penetrate the intestinal wall. The resulting cysts mature in the intestinal wall, then reenter the gut lumen to

develop into adult worms again. Endemic areas include parts of Asia, Europe, Central and South America, and Africa. Occasionally, it is found in institutionalized persons in North America. Most persons are asymptomatic, but heavy worm burdens may be associated with diarrhea, abdominal cramping, and anorexia. Finding characteristic eggs in the stool makes the diagnosis. Treatment is similar to that for other tapeworms, but may need to be prolonged to fully eradicate cysts in the intestinal wall.

Think ▸▸ Apply 56-2: Presumably, he acquired hydatid disease from accidental ingestion of the feces of his sheepdog, which in turn was infected while eating livestock offal filled with cysts. Dogs get worms by eating cysts; humans get cysts by consuming eggs in dog stool.

KEY CONCLUSIONS

- The clinical manifestations of tapeworm infections depend on whether humans are definitive hosts (harboring intestinal tapeworms) or intermediate hosts (harboring tissue-invasive cysts).
- Generally, intestinal worms are well tolerated, whereas tissue cysts are more dangerous.
- Treatment of taeniasis is straightforward and effective using praziquantel.
- Treatment of cystic disease is more complex and hazardous.
- Breaking the cycle of cestode infection requires knowledge of their transmission modes.

CASE STUDY

Seizures on the Tennis Court

A 26-year-old professional tennis player from Mexico suddenly developed a left-sided epileptic seizure, lasting for 5 minutes, while competing in an international tournament. He had no history of such occurrences and had been well before this episode.

Physical examination was normal, but brain MRI imaging revealed a

round, calcified 3 cm lesion in the right parietal lobe.

QUESTIONS

1. Which of the following is most likely responsible for this patient's condition?

A. *Taenia saginata*
B. *Taenia solium*
C. *Echinococcus granulosus*
D. *Dibothriocephalus latus*

2. Vitamin B_{12} deficiency, with macrocytic anemia is associated with which of the following parasites?

A. *Echinococcus multilocularis*
B. *Dibothriocephalus latus*
C. *Taenia saginata*
D. *Taenia solium*

3. Which is the most common definitive host for transmission of echinococcosis?

A. Pig
B. Cow
C. Fish
D. Dog

Trematodes

Paragonimus westermani • *Clonorchis sinensis* • *Schistosoma haematobium* • *Schistosoma japonicum* • *Schistosoma mansoni*

Sometimes the patient with schistosomiasis experiences no trouble whatever; in other instances the suffering is very great.

—Sir Patrick Manson, 1898

OVERVIEW

Trematodes are flatworms, also called "platyhelminths" or "flukes." They are divided into two major categories: the *hermaphrodites* and the *schistosomes* (**Table 57-1**). Of the many relationships that have developed between humans and helminths over millennia, perhaps the most destructive to our health and productivity is that forged by the trematodes. Typically, the adults live for decades within human tissues (for the hermaphrodites) and vasculature (for the schistosomes), where they resist immunologic attack and damage vital organs. Physicians and public health officers must understand trematode life cycles in order to make a meaningful difference in the lives of people impacted by these parasites.

TABLE 57–1 General Characteristics of Trematodes

CHARACTERISTIC	SCHISTOSOMES	HERMAPHRODITES

Biology		
Sexes	Separate	Hermaphroditic
Intermediates	One	Two
Lifespan	Long	Long

GENERAL FEATURES OF TREMATODES

Flukes move through tissue and vasculature with inchworm locomotion

Morphologically, trematodes are bilaterally symmetric, vary in length from a few millimeters to several centimeters, and possess two deep suckers from which they derive their name ("body with holes"). One surrounds the oral cavity, and the other is located on the ventral surface of the worm. These organs are used for both attachment and locomotion; movement is accomplished in a characteristic inchworm fashion.

The digestive tract begins at the oral sucker and continues as a muscular pharynx and esophagus before bifurcating to form bilateral ceca that end blindly near the posterior extremity of the worm. Undigested food is vomited through the oral cavity. The excretory system consists of a number of hollow, ciliated "flame" cells that excrete waste products into interconnecting ducts terminating in a posterior pore.

* Hermaphrodites and Schistosomes

Snails release motile cercariae in water

*** Cercariae infect human skin**

*** Hermaphroditic cercariae encyst on aquatic plant or animal, transform into metacercariae**

Trematodes are divided into two major categories, based on their reproductive systems: the *hermaphrodites* and the *schistosomes* (Table 57-1). The adult hermaphrodites contain both male and female gonads and produce operculated eggs (defined as having a lid). In contrast, the schistosomes have separate sexes, and the fertilized female deposits nonoperculated eggs. However, the two groups have similar life cycles. In both cases, eggs are excreted from the human host and—if they reach fresh water—hatch to release ciliated larvae called **miracidia.** These larvae find and penetrate a snail host specific for the trematode species. In this intermediate snail host, they are transformed by a process of asexual reproduction into thousands of tail-bearing larvae called **cercariae,** which are released from the snail over a period of weeks. The cercariae swim in fresh water, searching vigorously for their next host. In the case of schistosomal cercariae, this host is the human: When they contact the skin surface, they attach, discard their tails, and invade, thereby completing their life cycle. The cercariae of the hermaphroditic flukes, in contrast, encyst in or on an aquatic plant or animal, where they undergo a second transformation to become infective **metacercariae.** Their cycle is completed when this second intermediate host is ingested by a human.

Of the many trematodes that infect humans, only the five of greatest medical importance are discussed here: the hermaphroditic lung (*Paragonimus* spp.) and liver (*Clonorchis sinensis*) flukes; and the blood flukes, all of which are members of the genus *Schistosoma* (*S mansoni*, *S haematobium*, and *S japonicum*). Basic features of these and other hermaphroditic tissue and intestinal flukes are listed in **Table 57-2.**

• *PARAGONIMUS*

PARAGONIMUS SPECIES: PARASITOLOGY AND LIFE CYCLE

*** Adults encapsulate in lung**

Capsule erodes into bronchiole, eggs coughed up; continue if eggs reach water with snail

*** Crayfish, freshwater crabs second intermediate hosts**

Other carnivores also definitive hosts

Several *Paragonimus* species may infect humans. *Paragonimus westermani*, which is widely distributed in East Asia, is the species most frequently involved. The short, plump (10 by 5 mm), reddish-brown adults are characteristically

found encapsulated in the pulmonary parenchyma of their definitive host. The adults are often, but not always, found in pairs in these capsules, where they usually cross-fertilize each other. Here they deposit operculated, golden-brown eggs, which are distinguished by their size (50 by 90 μm) and prominent periopercular shoulder (**Figure 57–1**). Eggs may be released into a bronchiole before the capsule of human fibrous tissue is complete, or when a capsule erodes into a bronchiole. The eggs are then coughed up and spat out or swallowed and passed in the stool. In either case, if they reach fresh water, they embryonate for several weeks before the ciliated miracidia emerge through the open opercula. After invasion of an appropriate snail host, 3 to 5 months pass before cercariae are released. These larval forms invade the gills, musculature, and viscera of certain crayfish or freshwater crabs; over 6 to 8 weeks, the cercariae transform into metacercariae. When the raw or undercooked flesh of the second intermediate host is ingested by humans, the metacercariae encyst in the duodenum and burrow through the gut wall into the peritoneal cavity. Most then continue their migration through the diaphragm and reach maturity in the lungs 5 to 6 weeks later (**Figure 57–2**). However, some are retained in the intestinal wall and mesentery or wander to other foci such as the liver, pancreas, kidney, skeletal muscle, or subcutaneous tissue. Young worms migrating through the neck and jugular foramen may encyst in the brain, a common ectopic site. Paragonimiasis is a zoonosis: in addition to humans, other carnivores may serve as definitive hosts, including the rat, cat, dog, and pig. Immature ectopic adults in the striated muscles of the pig may infect humans after ingestion of undercooked pork.

PARAGONIMIASIS (LUNG FLUKE INFECTION)

EPIDEMIOLOGY

Infected snails found in mountain streams

*** Humans infected by ingesting undercooked infected crustaceans**

There are thought to be millions of human infections worldwide. Although most are concentrated in the Far East (eg, Korea, Japan, China, Taiwan, the Philippines, and Indonesia), paragonimiasis has been described in India, Africa (*Paragonimus africanus*), and Latin America (*Paragonimus mexicanus*). *Paragonimus kellicotti*, a parasite of mink, is widely distributed in eastern Canada and the United States but rarely produces human infection. Approximately 1% of recent Vietnamese immigrants to the United States were once found to be infected with *P westermani.* Infection of the snail host, which is typically found in small mountain streams located away from human habitation, is probably maintained by animal hosts other than humans. Human disease occurs when food shortages or local customs expose individuals to infected crabs. When these crustaceans are prepared for cooking, juice containing metacercariae may be left behind on the working surface and contaminate other foods subsequently prepared in the same area. Fresh crab juice, which has been used to treat infertility in Cameroon and measles in Korea, may also transmit the disease. In Southeast Asia, crabs are eaten after they have been lightly salted, pickled, or immersed briefly in wine (“drunken crab”), practices seldom lethal to the metacercariae. This has occurred in the United States as well. Children living in endemic areas may be infected while handling or ingesting crabs during the course of play.

PARAGONIMIASIS (LUNG FLUKE INFECTION):

CLINICAL ASPECTS

MANIFESTATIONS

Multiple lung cysts may form

During their migration from the gut to the lungs, larvae may cause tender, raised subcutaneous nodules, which migrate slowly along the abdominal wall. Adult worms in the lung elicit an eosinophilic inflammatory reaction and, eventually, the formation of a 1 to 2 cm fibrous capsule that surrounds and encloses one or more parasites. An infected patient may harbor more than 20 such lesions. With the onset of oviposition, the capsule swells and erodes into a bronchiole, resulting in expectoration of the brownish eggs, blood, and an inflammatory exudate. Secondary bacterial infection of the evacuated cysts is common, producing a clinical picture of chronic bronchitis or bronchiectasis. When cysts rupture into the pleural cavity, chest pain and effusion can result.

*** Chronic pulmonary abscess resembles TB**

Early in infection, chest X-rays demonstrate small segmental infiltrates; these are gradually replaced by round nodules that may cavitate. Eventually, cystic rings, fibrosis, and calcification occur, producing a picture closely resembling that of pulmonary tuberculosis (TB). This confusion is compounded by the frequent coexistence of the two diseases.

Adult flukes in the intestine and mesentery produce pain, bloody diarrhea, and occasionally palpable abdominal or cutaneous masses; the latter is more characteristic of a related Chinese fluke, *P skrjabini*. In approximately 1% of the cases of paragonimiasis in Southeast Asia, more commonly in children, parasites lodge in the brain and produce a variety of neurologic manifestations, including epilepsy, paralysis, homonymous hemianopsia, optic atrophy, and papilledema.

DIAGNOSIS

*** Eggs in sputum, pleural fluid, feces**

*** Serology for diagnosis, monitor treatment**

Eggs are usually absent from the sputum during the first 3 months of overt infection; however, repeated examinations eventually demonstrate them in more than 75% of infected patients. When a pleural effusion is present, it should be checked for eggs. Stool examination is frequently helpful, particularly in

children who swallow their expectorated sputum. Approximately 50% of patients with brain lesions demonstrate calcification on X-ray films of the skull. The cerebrospinal fluid in such cases shows elevated protein levels and eosinophilic leukocytosis. A diagnosis in these cases, however, often depends on the detection of circulating antibodies via immunoblot technique. Their presence usually correlates well with acute disease and eventually disappears with successful therapy.

TREATMENT AND PREVENTION

Lung fluke infection responds well to praziquantel therapy. Brain lesions may require anti-seizure medications, and a short course of corticosteroids before praziquantel is initiated. Control requires adequate cooking of shellfish before ingestion.

• *CLONORCHIS*

CLONORCHIS SINENSIS: PARASITOLOGY AND LIFE CYCLE

*** Adults survive decades in biliary tract**

Eggs discharged in bile ducts appear in feces

*** Snails first intermediate host; fish the second**

Metacercariae migrate to biliary system

Flukes of the genera *Fasciola, Opisthorchis,* and *Clonorchis* all may infect the human biliary tract and at times produce manifestations of ductal obstruction (Table 57-2). *Clonorchis sinensis*, the "Chinese liver fluke," is discussed here. The small, slender (5 by 15 mm) adult survives up to 50 years in the biliary tract of its host by feasting on its rich mucosal secretions. A cone-shaped anterior pole, a large oral sucker, and a pair of deeply lobular testes arranged one behind the other in the posterior third of the worm distinguish it from other hepatic parasites (Figure 57–4H). Approximately 2000 tiny (15 by 30 μm) fertilized

ovoid eggs are discharged daily and travel down the bile duct and into the fecal stream. The urn-shaped eggshells have a discernible shoulder at their opercular rim and a tiny knob on the broader posterior pole (Figure 57–4A). On reaching fresh water, they are ingested by their intermediate snail host, where they transform into cercariae (**Figure 57–3A**). These cercariae are released into the water, where they swim until they penetrate the tissues of freshwater fish, in which they encyst to form metacercariae. If the latter host is ingested by a fish-eating mammal, the larvae are released in the duodenum, ascend the common bile duct, migrate to the second-order bile ducts, and mature to adulthood over 30 days (**Figure 57–4**).

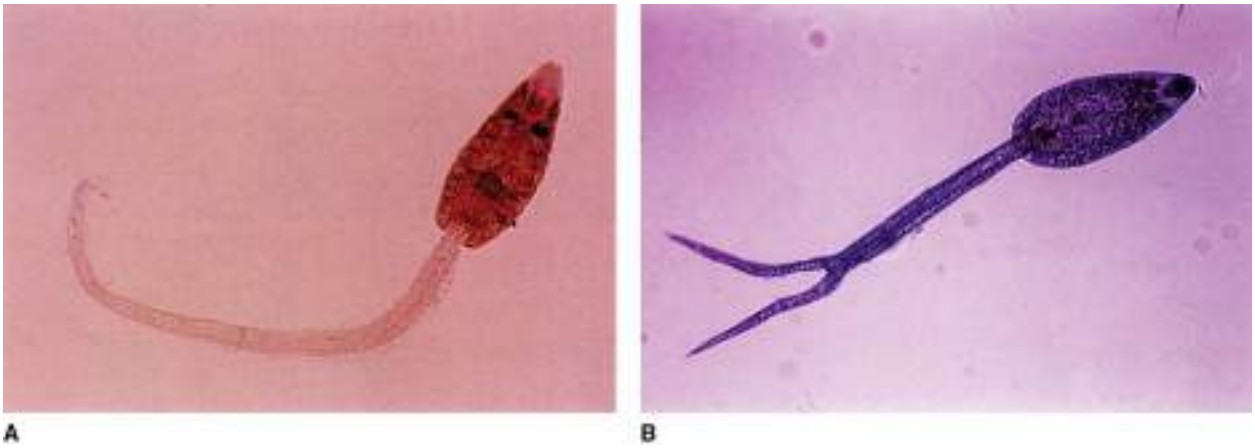

FIGURE 57–3. Trematode cercarial larvae. A. *Clonorchis sinensis.* **B.** *Schistosoma mansoni.* (Reproduced with permission from Connor DH, Chandler FW, Schwartz DQ, et al: *Pathology of Infectious Diseases*. Stamford CT: Appleton & Lange; 1997.)

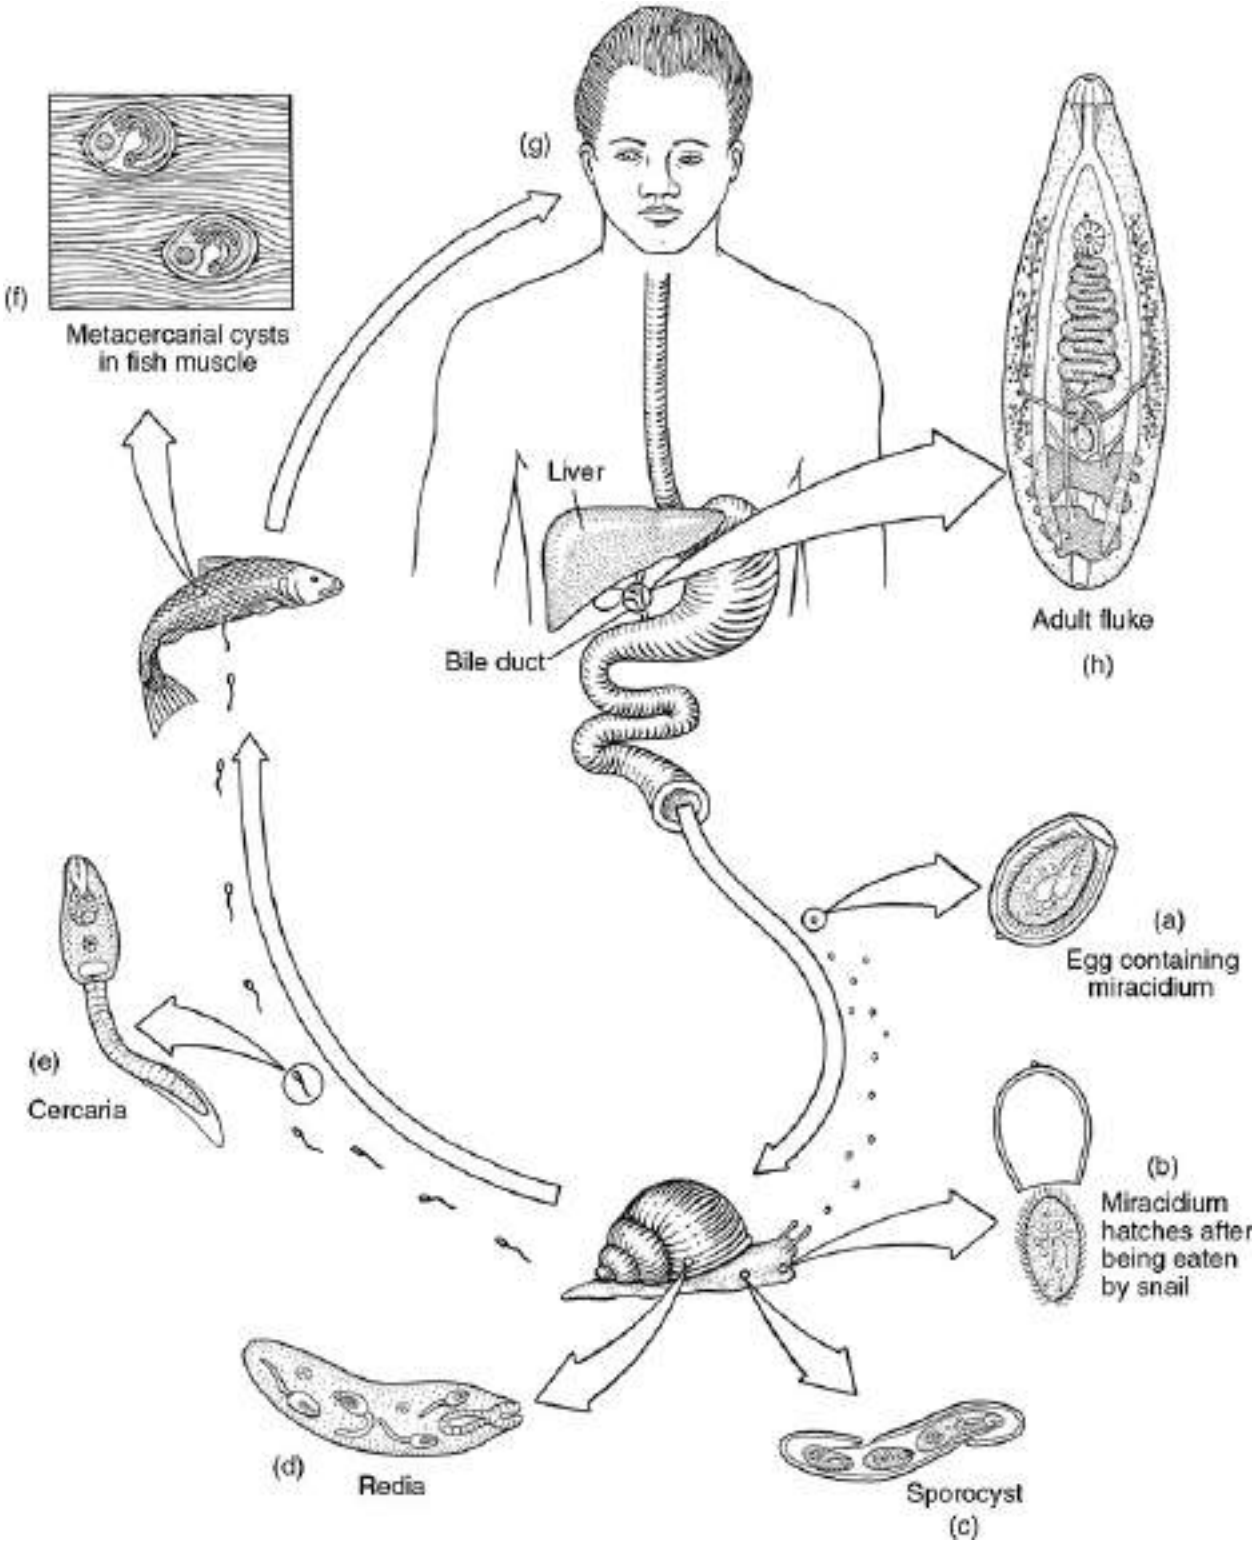

FIGURE 57–4. Life cycle of *Clonorchis.* (Reproduced with permission from Roberts RL, Janovy J, Nadler S: *Foundations of Parasitology*, 9th ed. New York, NY: McGraw Hill; 2013.)

In addition to humans, rats, cats, dogs, and pigs may serve as definitive

hosts.

CLONORCHIASIS (LIVER FLUKE INFECTION)

EPIDEMIOLOGY

*** Endemic in Southeast Asia**

*** Human transmission related to waste disposal**

*** Eating uncooked fish infects humans**

Clonorchiasis is endemic in Southeast Asia, particularly in Korea, Japan, Taiwan, the Red River Valley of Vietnam, the Southern Chinese province of Guangdong, and Hong Kong. In previous years, parasite transmission was perpetuated by the practice of fertilizing commercial fish ponds with human feces. Improvements in the disposal of human waste have diminished acquisition of the disease in many areas. However, the extremely long lifespan of these worms is reflected in a much slower decrease in the overall infection prevalence. In some villages in southern China, virtually the entire adult population may be infected. A survey of stool specimens from immigrants from Hong Kong to Canada showed an infection rate of more than 15% overall and 23% in adults between 30 and 50 years of age. Clonorchiasis is acquired by eating raw, frozen, dried, salted, smoked, or pickled fish. Commercial shipment of such products outside of the endemic area may result in the acquisition of worms far from their original source.

CLONORCHIASIS (LIVER FLUKE INFECTION):

CLINICAL ASPECTS

MANIFESTATIONS

Light infection usually asymptomatic

*** Hepatic, biliary manifestations from worm loads, including cholangiocarcinoma**

Migration of the larvae from the duodenum to the bile duct may produce fever, chills, mild jaundice, eosinophilia, and liver enlargement. The adult worm induces epithelial hyperplasia, adenoma formation, and periductal inflammation. In light infection, clinical disease seldom results. However, numerous reinfections may produce worm loads of 500 to 1000, resulting in the formation of bile stones and sometimes bile duct carcinoma (cholangiocarcinoma) in patients with severe, long-standing infections. Calculus formation may be accompanied by asymptomatic biliary carriage of *Salmonella enterica* serovar Typhi. Dead worms may obstruct the common bile duct and induce secondary bacterial cholangitis, which may, in turn, be accompanied by bacteremia and endotoxic shock. Occasionally, adult worms are found in the pancreatic ducts, where they can produce ductal obstruction and acute pancreatitis.

DIAGNOSIS

Eggs in feces, duodenal aspirates

*** Eosinophilia common in acute disease**

Definitive diagnosis of clonorchiasis requires the recovery and identification of the distinctive egg from the stool or duodenal aspirates. In mild infections, repeated examinations may be required. Because most patients are asymptomatic, any individual with clinical manifestations of disease in whom *Clonorchis* eggs are found should be evaluated for the presence of other causes of illness. In acute symptomatic clonorchiasis, there is usually leukocytosis, eosinophilia, elevation of alkaline phosphatase levels, and abnormal computed tomography and ultrasonographic liver scans. Cholangiograms may reveal dilatation of the intrahepatic ducts, small filling defects compatible with the presence of adult worms, and occasionally cholangiocarcinoma.

TREATMENT AND PREVENTION

*** Praziquantel or albendazole**

Manage complications

Praziquantel is the treatment of choice, although albendazole has also been found to be effective. Patients with acute obstructive cholangitis due to a worm or stone in the large collecting ducts should be managed as for any other cause of obstruction, including consideration of antibiotics for secondary infection and correction of the obstruction (eg, via endoscopic retrograde pancreatography cholangiopancreatography [ERCP]). Prevention requires thorough cooking of freshwater fish and appropriate sanitary disposal of human feces.

• *SCHISTOSOMA*

SCHISTOSOMA SPECIES: PARASITOLOGY AND LIFE CYCLE

The schistosomes are a group of closely related flukes that inhabit the vascular system of a number of animals. Of the five species known to infect humans, *S mansoni*, *S haematobium*, and *S japonicum* are of primary importance. The remaining two species are found in limited areas of West Africa (*S intercalatum*) and Southeast Asia (*S mekongi*), and are not discussed here in detail.

*** Separate sexes, different morphology**

*** *S japonicum*—small intestines veins**

*** *S mansoni*—portal colon veins, rectum**

*** *S haematobium*—bladder veins, pelvic organs**

The adult worms can be distinguished from the hermaphroditic trematodes by the anterior location of their ventral sucker, by their cylindric bodies, and by their reproductive systems (ie, separate sexes). Adult specimens of different species are differentiated from one another only with difficulty. The 1 to 2 cm male possesses a deep ventral groove, or "schist." Within this canal it carries the longer, more slender female in lifelong copulatory embrace. The schistosome life cycle (**Figure 57–5**) begins after mating in the hepato-portal circulation when the conjoined couple uses their suckers to ascend the mesenteric vessels against the flow of blood. Guided by unknown stimuli, *S japonicum* enters the superior mesenteric vein, eventually reaching the venous radicals of the small

intestine and ascending colon; *S mansoni* and *S haematobium* are directed to the inferior mesenteric system. The destination of the former is the descending colon and rectum; the latter, however, passes through the hemorrhoidal plexus to the systemic venous system, ultimately coming to rest in the venous plexus of the bladder and other pelvic organs.

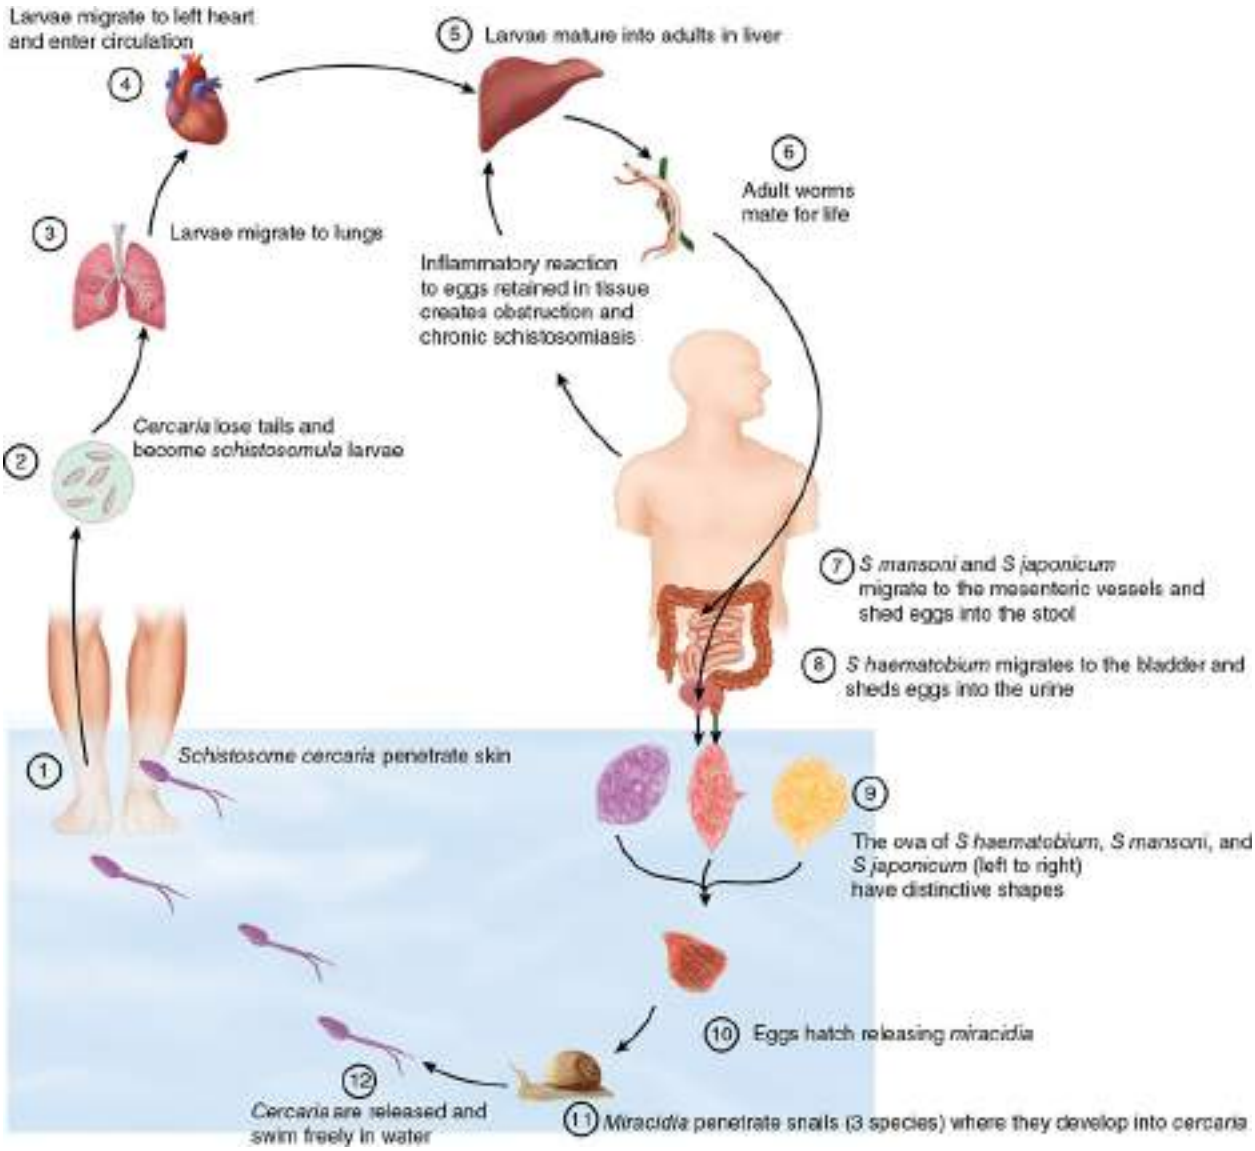

FIGURE 57–5. Life cycle of schistosomes.

Eggs deposited submucosally, rupture to lumina, pass outside

On reaching the submucosal venules, the worms begin to lay eggs. Each pair deposits 300 (*S mansoni, S haematobium*) to 3000 (*S japonicum*) eggs daily for the remainder of its 4- to 35-year lifespan. Enzymes secreted by the enclosed

miracidium diffuse through the shell and digest the surrounding tissue. Ova lying immediately adjacent to the mucosal surface rupture into the lumen of the bowel (*S mansoni*, *S japonicum*) or bladder (*S haematobium*) and are passed to the outside in the excreta. Here, with appropriate techniques, they may be readily observed and differentiated. The eggs of *S mansoni* are oval, possess a sharp lateral spine, and measure 60 by 140 µm. Those of *S haematobium* differ primarily in the terminal location of their spine. The eggs of *S japonicum*, in contrast, are more nearly circular, measuring 70 by 90 µm. A minute lateral spine can be visualized only with care (Figure 57–1D-F).

Eggs hatch to form miracidia, which invade snails

*** Cercariae from snail traverse human skin, develop into schistosomula that invade vascular system**

The miracidia hatch quickly when the eggs are deposited in fresh water. On finding a snail host appropriate for their species, they invade and are transformed over 1 to 2 months into thousands of forked-tailed cercariae (Figure 57–3B). When released from the snail, these infectious larvae swim about vigorously for a few days. Cercariae coming in contact with human skin during this time attach, discard their tails, and penetrate. During a 1- to 3-day sojourn in the skin, the cercaria with three outer membrane layers develop into schistosomula with seven outer layers, a change that is thought to be critical to the survival of the parasite within the human body. These schistosomula enter small venules and find their way through the right side of the heart to the lung. After a delay of several days, the parasites enter the systemic circulation. Those surviving passage through the pulmonary and intestinal capillary beds return to the portal vein, where they mature to sexually active adults over 1 to 3 months and find a mate of the opposite sex, thus completing the life cycle. Schistosomiasis is primarily a human condition, but may be zoonotic in exceptional circumstances, as demonstrated by the presence of *S japonicum* infection in cattle and water buffalo in southern China.

SCHISTOSOMIASIS (BLOOD FLUKE INFECTION)

EPIDEMIOLOGY

*** Most important helminthic infection**

*** Stopped by modern waste disposal**

Spread by irrigation projects

The widespread distribution and extensive morbidity of schistosomiasis make it the single most important helminthic infection in the world today. Currently, more than 200 million people—roughly 1 in 40 of all humans—are infected worldwide. Of these, roughly 200,000 die annually. The continued transmission of the parasite depends on the disposal of infected human urine and excrement into fresh water, the presence of appropriate snail hosts, and the exposure of humans to water infested with cercariae. The construction of modern sanitation and water purification facilities would break this cycle but exceed the economic resources of many endemic nations. Paradoxically, several massive land irrigation projects launched for the express purpose of speeding economic development have resulted in the dispersion of infection to previously uninvolved areas. *Schistosoma mansoni*, the most widespread of the blood flukes, is the only one present in the Western Hemisphere. Perhaps originally introduced during slavery, *S mansoni* is now found in Venezuela, Brazil, Surinam, Puerto Rico, the Dominican Republic, St. Lucia, and several other Caribbean islands.

Distribution varies with species, depends on snail host

Because a suitable snail host is lacking, transmission of *S mansoni* does not occur within the continental United States; however, many thousands of individuals residing in the United States have acquired schistosomiasis elsewhere. In the Eastern Hemisphere, the prevalence of *S mansoni* infection is highest in the Nile Delta and tropical Africa. Isolated foci are also found in East and South Africa, Yemen, Saudi Arabia, and Israel.

Schistosoma haematobium is largely confined to Africa and the Middle East, where its distribution overlaps that of *S mansoni. S japonicum* affects the agricultural populations of several Southeast Asian countries, including China, the Philippines, and Sulawesi (it was eradicated from Japan in the 1990s). The closely related *S mekongi* is found in the Mekong and Mun River valleys of Vietnam, Thailand, Cambodia, and Laos.

Age-related susceptibility with peak in second decade

Within the endemic areas of schistosomiasis, there are wide variations in both age-specific infection rates and worm loads. In general, both peak in the second decade of life and then decrease with advancing age. This finding has been explained in part by changes in the intensity of water exposure and in part by the gradual development of IgE-mediated immunity. Most infected patients carry fewer than 10 pairs of worms in the vascular system and, accordingly, lack clinical manifestations of disease. Individuals who develop much heavier worm loads as a result of repeated infections may experience serious morbidity or mortality.

PATHOGENESIS

There are three major clinicopathologic stages in schistosomiasis. The first stage is initiated by the penetration and migration of the schistosomula. The second or intermediate stage begins with oviposition and is associated with a complex of clinical manifestations. The third or chronic stage is characterized by granuloma formation and scarring around retained eggs.

IMMUNITY

*** Major disease manifestations from cell-mediated immune response to eggs**

The major clinicopathologic manifestations of schistosomiasis result from the host's cell-mediated immune response to the presence of retained eggs. Not all eggs are excreted into the environment, and those left behind in tissue serve as antigenic stimuli for our immune system, which walls them off in eosinophilic granulomas ("Splendore-Hoeppli reactions"). With time, the intensity of this reaction is muted; granulomas formed in the later stages of infection are smaller and less damaging than those formed early. The mechanisms responsible for this modulation are not fully understood. Present evidence suggests that both suppressor T-lymphocyte activity and antibody blockade are involved. The correlation in humans between human leukocyte antigen (HLA) types A1 and B5 and the development of hepatosplenomegaly suggests that the extent of the immunoregulation is influenced, at least in part, by the genetic background of the host.

Blocking antibodies, adsorption of host molecules provide antigenic

disguise

Concomitant immunity reduces new infections

As evidenced by their prolonged survival, the adult worms are remarkably well tolerated by their hosts. In part, this tolerance may be attributable to the formation of IgG4 blocking antibodies early in the course of infection. Tolerance may also reflect the ability of the developing parasites to disguise themselves by adsorbing host molecules, including immunoglobulins, blood group glycolipids, and histocompatibility complex antigens. Nevertheless, as mentioned earlier, the prevalence and intensity of human infection begin to abate during adolescence, despite continuing exposure to infective cercariae. It has been suggested that schistosomula penetrating the skin after the primary infection are coated with specific antibodies, bound to eosinophils, and destroyed before they can reach the portal system. Although protection is not complete, a 60% to 80% kill rate is highly effective in controlling the intensity of parasitism. This condition, in which adult worms from a primary infection can survive in a host resistant to reinfection, is termed **concomitant immunity.** Eventually, production of blocking antibodies wanes whereas production of protective IgE antibodies active against adult worms increases, leading to a decrease in the host's total worm population.

SCHISTOSOMIASIS (BLOOD FLUKE INFECTION):

CLINICAL ASPECTS

EARLY STAGE

*** Local and systemic hypersensitivity reactions produce rash**

Within 24 hours of penetrating the skin, a large proportion of the schistosomula die. In *S mansoni* and *S haematobium* infections, immediate and delayed hypersensitivity to parasitic antigens results in an intensely pruritic papular skin rash, which increases in severity with repeated exposures to cercariae. As the viable schistosomula begin their migration to the liver, the rash disappears and the patient experiences fever, headache, and abdominal pain for 1 to 2 weeks.

*** Avian schistosomiasis causes swimmer's itch in North America**

Of note, a related condition happens in North America when certain schistosoma species adapted to aquatic birds mistakenly invade the skin of swimmers; unable to penetrate deeper into the human vascular systems, these cercariae remain trapped in the skin. The parasites die there without causing serious harm, but not before causing a localized pruritic, inflammatory reaction called cercarial dermatitis, or “swimmer’s itch.”

INTERMEDIATE STAGE

*** Katayama syndrome: prolonged febrile period with circulating immune complexes**

Intestinal inflammation and encephalitis occur acutely

One to two months after primary exposure, once the sexually mature adult worms begin to lay eggs (oviposition), patients with severe *S mansoni* or *S japonicum* infections may experience an acute febrile illness that bears a striking resemblance to serum sickness. This happens because of relative egg antigen excess, with formation of soluble immune complexes that deposit in host tissues. Indeed, high levels of such complexes have been demonstrated in the peripheral blood and correlate well with the severity of illness. This symptom complex is commonly termed **Katayama syndrome.** In addition to fever and chills, patients experience cough, urticaria, arthralgia, lymphadenopathy, splenomegaly, abdominal pain, and diarrhea. Sigmoidoscopic examination reveals an inflamed colonic mucosa and petechial hemorrhages; occasionally, patients with *S japonicum* infection develop clinical manifestations of encephalitis. Typically, leukocytosis, marked peripheral eosinophilia, and elevated levels of IgM, IgG, and IgE immunoglobulins are present. It is more common and severe in visitors to endemic areas, in whom it may persist for 3 months or more. If untreated, it occasionally results in death.

CHRONIC STAGE

*** Inflammatory, fibrotic reactions to retained eggs cause chronic disease**

Approximately one-half of all deposited eggs reach the lumen of the bowel or bladder and are shed from the body. Retained eggs induce inflammation and

scarring, initiating the final and most morbid phase of schistosomiasis. Soluble antigens excreted by the eggs stimulate the formation of T-lymphocyte–mediated eosinophilic granulomas. Early in the infection, the inflammatory response is vigorous, producing lesions more than 100-fold larger than the inciting egg itself. With time, the host's inflammatory response moderates, leading to a significant decrease in granuloma size. Fibroblasts stimulated by factors released by both retained eggs and the granulomas lay down scar tissue, rendering the earlier, granuloma-induced vascular obstruction permanent. The severity of tissue damage is directly related to the total number of eggs retained.

***S haematobium* bladder lesions with hemorrhage, obstruction**

Urinary carriage may cause *Salmonella* bacteremia

*** Bladder squamous cell carcinoma a serious complication**

In *S haematobium* infection, the bladder mucosa becomes thickened, papillated, and ulcerated. Hematuria and dysuria result; repeated hemorrhages produce anemia. In severe infections, the muscular layers of the bladder are involved, with loss of bladder capacity and contractibility. Vesicoureteral reflux, ureteral obstruction, and hydronephrosis may follow. Progressive obstruction may lead to renal failure and uremia. Calcification of the bladder wall is occasionally seen, and approximately 10% of patients harbor urinary tract calculi. Secondary bacterial infections are common. Chronic *Salmonella* bacteriuria with recurrent bouts of bacteremia has been reported in Egypt, where squamous cell bladder carcinoma is frequently seen as a late complication of disease. Other urogenital organs may also be involved, including the spermatic cord, testes, fallopian tubes, ovaries, and vagina.

Most bladder cancer originates from transitional cells; why is bladder cancer due to *S haematobium* different?

*** Portal hypertension develops without cirrhosis**

Hepatitis B or C superinfection may progress to hepatitis

In *S mansoni* and *S japonicum* infections, the bowel mucosa is congested,

thickened, and ulcerated. Patients experience abdominal pain, diarrhea, and blood in the stool. Eggs deposited in the larger intestinal veins may be carried by the portal blood flow back to the liver, where they lodge in the presinusoidal capillaries. The resulting inflammatory reaction leads to the development of periportal fibrosis and hepatic enlargement. The frequency and severity with which the liver is involved appear to be genetically determined and associated with the patient's HLA type. In contrast to cirrhosis, in most cases of schistosomiasis liver function is well preserved. Infected persons who subsequently acquire hepatitis B or C viruses develop chronic active hepatitis more frequently than those without schistosomiasis. Presinusoidal obstruction of blood flow can result in portal hypertension and serious manifestations of portal obstruction. Eggs that are carried around the liver in the portosystemic collateral vessels may lodge in the small pulmonary arterioles, where they produce interstitial scarring, pulmonary hypertension, and right ventricular failure. Immune complexes shunted to the systemic circulation may induce glomerulonephritis. Occasionally, eggs may be deposited in the central nervous system, where they may cause epilepsy or paraplegia.

Elimination of *Salmonella* requires eradication of parasite

Some differences between the clinical presentation of *S mansoni* and that of *S japonicum* have been noted. Manifestations of the latter disease typically occur earlier in the course of the infection and tend to be more severe. When involvement of the central nervous system develops, it is more likely to occur in the brain than in the spinal cord. On the other hand, immune complex nephropathy and recurrent *Salmonella* bacteremia are more commonly seen in hepatosplenic *S mansoni* infections. The latter phenomenon is apparently related to the ability of *Salmonella* to parasitize the gut and integument of the adult fluke, providing a persistent bacterial focus within the portal system of the infected patient. This focus cannot be eradicated without treatment of the schistosomal infection.

DIAGNOSIS

*** *S haematobium* eggs in urine**

*** *S mansoni* and *S japonicum* eggs in stool and rectal biopsy**

Definitive diagnosis of schistosomiasis requires the recovery of the characteristic

eggs in urine, stool, or biopsy specimens. In *S haematobium* infections, eggs are most numerous in urine samples obtained at midday, especially the last drops voided. When examination of the sediment yields negative results, eggs may sometimes be recovered by filtering the urine through a fine membrane. Cystoscopy with biopsy of the bladder mucosa may be required for the diagnosis of mild infection. Eggs of *S mansoni* and *S japonicum* are passed in the stool. Concentration techniques such as formalin–ether or gravity sedimentation are necessary when the ova are scanty. Results of rectal biopsy may be positive when those of repeated stool examinations are negative.

Determination of egg viability, output useful

Because dead eggs may persist in tissue for a long time after the death of the adult worms, active infection is confirmed only when the eggs are shown to be viable. This may be performed by observing the eggs microscopically for movement of flame cell cilia or by hatching them in water and watching for motile miracidia to emerge. Quantitation of egg output may be useful in estimating the severity of infection and in following response to treatment.

EIA detection of antigens in blood and urine

Conventional serologic tests detect circulating antibodies with sensitivities exceeding 90% but cannot distinguish active from prior infection. Enzyme immunoassay (EIA)-based reagent strip (dipstick) tests, capable of detecting circulating, genus-specific, adult worm antigens in blood and urine, are rapid, simple, and sensitive. They are particularly helpful in the diagnosis of Katayama syndrome in those returning from endemic areas. Moreover, because antigen levels drop rapidly after successful therapy, these tests may prove helpful in distinguishing active from inactive disease.

Think ▸▸ Apply 57-1: This cancer is caused by a prolonged cycle of injury, at locations where eggs lodge in the bladder wall, or where they exit into the urine, triggering inflammation, repair, and scar. Over time, the squamous cells involved may become dysplastic or malignant; in effect, this is a cancer triggered by inflammation.

TREATMENT

No specific therapy is available for the treatment of schistosomal dermatitis or Katayama syndrome. Antihistamines and corticosteroids may be helpful in ameliorating their more severe manifestations. The maturing organisms seem resistant to antiparasitic medications, thus no immediate postexposure prophylaxis after water exposure is possible. In the late stage of schistosomiasis, therapy is directed at interrupting egg deposition by killing or sterilizing the adult worms.

*** Praziquantel drug of choice for schistosomiasis**

*** It kills adult worms, but not immature forms**

Several anthelmintic agents may be used for the chronic stage. Praziquantel, which is active against all three species of schistosomes, is the agent of choice. Use of this drug is relatively contraindicated in early pregnancy. Unfortunately, reports suggest decreased efficacy of this single-dose oral agent in areas where it has been used in mass therapy programs; in this setting, repeat dosing is an option, although *S mansoni* infections acquired in such areas may be treated with oxamniquine (not available in the United States). Artemisinin derivatives have worked well in experimental settings, and may be useful in select cases; fostering *Plasmodium* resistance in patients coinfected with malaria is a real concern.

PREVENTION

Sanitary disposal of feces limited by economic status

Molluscicides effective, but large-scale application difficult

Controlling this deadly disease has proved both difficult and expensive. Programs aimed at interrupting transmission by the provision of pure water supplies and the sanitary disposal of human feces are often beyond the economic reach of nations most seriously affected. Similarly, measures to deny snails access to newly irrigated lands are expensive. Chemical molluscicides have been effective in limited trials, but less successful when used over large areas for prolonged periods. Mass therapy of the infected human population has until recently been severely limited by the toxicity of older agents, or by unanticipated

consequences, such as the unsanitary injection of tartrate emetic in Egypt, an antiparasitic drug that provided little benefit in terms of schistosomiasis but perversely transmitted Hepatitis C to thousands of patients. Oral praziquantel has proved to be more suitable for this purpose, albeit at the risk of selecting drug resistance. Furthermore, without other control measures, discontinuation of mass therapy can result in a rapid rebound of active disease.

Multipronged approach is necessary

In 2009, a report of an extensive controlled study in an area of Southeastern China that was hyperendemic for *S japonicum* yielded remarkable results. These included removal of cattle from snail-infested grasslands, providing mechanized equipment to farmers, improving sanitation of drinking water, building lavatories and latrines, providing boats with fecal matter containers, and implementing intensive health education programs. Infection rates fell dramatically in the intervention villages as compared to nonintervention areas. Thus, a multipronged approach such as this offers the best hope for lasting control.

Vaccines under development

Currently, there is intense interest in developing a vaccine suitable for human use. A vaccine made from irradiated *S bovis* cercariae, which was developed for cattle, appears to confer a significant degree of protection against infection. Although a similar live vaccine would not be practical for human populations, the success of the animal vaccine has provided clues to potential immunoprotective mechanisms in human schistosomiasis. Monoclonal antibodies have been used to identify a number of schistosomula and adult antigens thought to be capable of inducing protective immunity; more than a dozen antigens are now in various stages of investigation as vaccine candidates.

KEY CONCLUSIONS

- Trematode (fluke) infections come in two groups: tissue hermaphrodites and schistosomes.
- Hermaphrodites are acquired by eating larval parasites; schistosomes are acquired via transcutaneous invasion while people bathe in contaminated water, making it more challenging to control.
- For the hermaphrodites, most clinical illness is caused by adult parasites in

visceral organs.

- For the schistosomes, disease is more complex: distinct illnesses happen at the time of initial skin invasion (cercarial dermatitis), at the time of oviposition (Katayama syndrome), and in response to long-egg burden (portal hypertension, granulomatous visceral injury, bladder cancer).

CASE STUDY

The Risks of Adventurous Tourism

A 35-year-old American adventurer returned from a 3-week tour of rural areas in Southeast Asia, which involved hiking forays and sharing meals with local residents. One month after his return to the United States, he developed fever and chills, accompanied by cough, urticaria, arthralgia, abdominal pain, and diarrhea.

Laboratory studies demonstrated leukocytosis and marked eosinophilia, with elevated immunoglobulin levels.

Sigmoidoscopic examination revealed mucosal inflammation and petechial hemorrhages.

QUESTIONS

1. Which of the following is the most likely cause of this man's symptoms?

A. Paragonimiasis
B. Schistosomiasis
C. Clonorchiasis
D. Fascioliasis

2. Which of the following is *not true* regarding Paragonimus infection?

A. Ingestion of crayfish and freshwater crabs is risky.
B. Chest X-ray can mimic tuberculosis.
C. Praziquantel is effective treatment.
D. Biliary tract involvement is prominent.

3. Perpetuation of transmission in *Clonorchis* infections is primarily due to which of the following?

A. Wading in fresh water
B. Refusal to treat with albendazole
C. Lack of careful handwashing
D. Use of human waste as fertilizer

ANSWERS

1. **(B)**
2. **(D)**
3. **(D)**

Practice Questions in USMLE Format

VIRAL DISEASES

V.1 Which one of the following contains lipid in its virion?

A. Adenovirus
B. Parvovirus
C. Picornavirus
D. Coronavirus
E. Retrovirus

V.2 A 30-year-old man has had fever and a sore throat for a week. On examination he has bilateral cervical lymphadenopathy. Which of the following is *least* likely to cause these clinical findings?

A. Epstein-Barr virus
B. Varicella-zoster virus
C. Coxsackie A virus
D. Adenovirus
E. Parainfluenza virus

V.3 Which one of the following is *true* regarding temperate viruses? Temperate viruses:

A. Undergo both productive and nonproductive infections and only establish latent infections
B. Lead to a productive infection called lytic infection
C. Undergo both productive and nonproductive infections and can establish both latent and lytic infections
D. Enter the cells and persist indefinitely with no virus production, called nonproductive responses

V.4 Which one of the following is *true* concerning viral capsids?

A. Viruses acquire host proteins as their capsids.

B. Capsids are virus-specific proteins, which protect their genome and provide shape to viruses.
C. Capsid protein subunits form a helix with the core proteins to mainly provide helical symmetry.
D. Capsids are lipid bilayer membranes containing proteins and/or glycoproteins.

V.5 A young man has returned from a short trip to Mexico where he was bitten by a dog. Eight weeks after returning he developed excessive salivation, aversion to drinking water, and hallucinations and died in cardiac arrest. Which of the following measures might have prevented this death if implemented upon his return?

A. Interleukin 2 infusions
B. Acyclovir prophylaxis
C. Specific vaccine administration
D. Gamma globulin therapy
E. Ciprofloxacin prophylaxis

V.6 Which one of the following statements is *true* regarding the interaction of viruses and cell surface receptors?

A. When receptor sites are occupied the viral infection will be lytic.
B. The interaction can be prevented by neutralizing antibodies to the virus surface protein.
C. The interaction directs host DNA polymerase to synthesize RNA genomes for viral assembly.
D. The interaction determines whether the purified genome of a virus is infectious.

V.7 A transplant patient has developed seizures and an MRI reveals a lesion in the temporal lobe. A biopsy of the area shows multinucleated giant cells with intranuclear inclusions. Which of the following is the most probable etiologic agent?

A. Poliovirus
B. Herpes simplex virus type 1
C. Listeria monocytogenes
D. Toxoplasma
E. Parvovirus

V.8 A 28-year-old woman has developed fever and extreme fatigue over 2 days. She is short of breath and radiographs reveal pulmonary infiltrates. A genetic and biochemical analysis of a virus isolated from her throat that reveals the genome to be composed of eight unequally sized segments of single-stranded RNA, each of which is complementary to viral mRNA in infected cells. Which one of the following statements about this virus is *true*?

A. Several proteins are encoded by each segment of the viral genome.
B. Purified RNA extracted from the virus is infectious because it can interact with the receptor on the host cell.
C. The virus particle contains a virion-associated RNA-dependent RNA polymerase that can copy the RNA genome into its complementary strand.
D. The virus cannot undergo high frequency recombination via reassortment of its RNA segments.
E. The genome can integrate easily into the host chromosome because of being segmented.

V.9 Which of the following statements is *most* characteristic of poliovirus?

A. The genome is double-stranded DNA.
B. Intestinal replication is extensive.
C. Congenital infections are frequent.
D. A skin test can identify previous exposure.
E. Amantadine chemoprophylaxis is effective.

V.10 An emergency room worker suffered a needle stick while caring for an accident victim. The employee health service recommended immediate prophylaxis with zidovudine (ZDV or AZT). This drug's inhibition of reverse transcription is achieved by termination of:

A. Viral RNA elongation
B. Viral RNA transcription
C. Viral DNA integration
D. Viral DNA elongation
E. Viral DNA replication

V.11 An 8-year-old boy has an illness which begins with fever and malaise. Later a rash appears on his cheeks, which makes them look as if he

had been slapped. The virus causing this syndrome has also been linked to aplastic crises in persons with sickle cell disease. Which of the following is most likely?

A. Herpes simplex
B. Parvovirus B19
C. Rubella
D. Rubeola
E. Varicella-zoster

V.12 Each year there are discussions about new formulations of the vaccine for influenza A virus. Why?

A. Because mutations occur mainly in the envelope proteins, hemagglutinin, and neuraminidase.
B. The half-life of the vaccine is a few months and degrades quickly in host cells.
C. The hemagglutinin envelope protein changes but not the neuraminidase protein.
D. Mutations predominantly take place in the matrix protein that interacts with the host cell receptor.
E. Because the vaccine is comprised of several drugs that are active against the virus for one season.

V.13 A 10-month-old infant is brought to the hospital by his mother with a fever, dry cough, and shortness of breath. He has become more restless with a worsening cough over the past day. There is no relevant past medical history and he is up-to-date with his immunization schedule. On examination, a diagnosis of acute bronchiolitis is made. Which one of the following viruses is *most* likely involved?

A. Influenza virus
B. Measles virus
C. Parainfluenza virus
D. Adenovirus
E. Respiratory syncytial virus

V.14 A 28-year-old woman presents with a fever and painful genital ulcers. A culture of the lesions is positive for herpes simplex virus. Which of the following is most characteristic of this infection?

A. Type 1 virus is most common.
B. It is rare if there is a high antibody titer.
C. The initial infection is by the fecal–oral route.
D. It may be reactivated by stress.
E. The brain and visceral organs are typically involved.

V.15 A virus is isolated from the stool of a patient with diarrhea. Detailed analysis reveals that its genome is composed of multiple pieces of double-stranded RNA. Which one of the following statements about this virus is *true*?

A. Each RNA segment encodes a different protein.
B. The virus uses host-encoded RNA-dependent RNA polymerase.
C. The virion contains a lipid bilayer capsid protein.
D. The genome integrates into the host chromosome.
E. This virus has oncogenic potential and further tests should be performed.

V.16 Coxsackieviruses appear worldwide particularly in young persons. Their epidemiology and pathogenesis most closely resembles:

A. Adenoviruses
B. Influenza A
C. Polioviruses
D. Hepatitis A
E. Mumps

V.17 A 35-year-old man was addicted to intravenous drug use and has been a carrier for hepatitis B virus surface antigen (HBsAg) for 10 years. He suddenly develops acute fulminant hepatitis. Which one of the following laboratory tests would contribute *most* to a diagnosis?

A. Antibody to HBsAg
B. HBeAg
C. Antibody to HBcAg
D. Antibody to hepatitis C virus antigen
E. Antibody to hepatitis delta antigen

V.18 In counseling parents about childhood immunizations there are a number of differences between the viral vaccines. Regarding the rubella vaccine all of the following statements are true *except*:

A. Antibodies are induced, which neutralize circulating virus.
B. Induced antibodies prevent reinfection and limit spread.
C. The immunogenic component is killed virus.
D. Vaccine use has reduced both childhood and congenital rubella.
E. Vaccine is often combined with other vaccines.

V.19 A 45-year-old man presented with an acute onset of fever, nausea, and pain in the right upper abdominal quadrant. He had jaundice and dark urine several days earlier. If the correct diagnosis is hepatitis A, then which one of the following statements is *true*?

A. It was parenterally transmitted.
B. Antibody to hepatitis A can be detected during early illness.
C. The patient is most likely to develop chronic hepatitis.
D. The patient is likely to become a chronic carrier.
E. It is the most common sexually transmitted form of hepatitis in the United States.

V.20 A 30-year-old woman is seen with a painful lesion on the vulva and complains of fever, headache, and stiff neck. On pelvic examination, she has several tender ulcers of approximately 4 mm in diameter. She was diagnosed with aseptic meningitis. The *most likely* etiologic agent and the antiviral used for her treatment are:

A. Human papillomavirus infection and ribavirin
B. Cytomegalovirus infection and ganciclovir
C. Herpes simplex virus infection and acyclovir
D. Varicella-zoster virus infection and zidovudine
E. Hepatitis B virus infection and interferon

V.21 Which one of the following statements about retrovirus replication is *true*? By using reverse transcriptase retroviral:

A. Positive stranded RNA is converted to double-stranded DNA, which integrates into the host chromosome after transcription and replication.
B. Positive sense RNA is converted to double-stranded DNA, which integrates into the host chromosome before transcription and replication.
C. Negative sense RNA is converted to DNA, which integrates into the host chromosome before replication.
D. Double-stranded DNA is converted to circular DNA, which integrates

into the viral chromosome after transcription and replication.

V.22 While vacationing in the Caribbean, a man was bitten by *Aedes aegypti* mosquito. He developed fever and severe pain in the back, head, muscles, and joints. An erythematous rash is also seen on his body. The *most likely* diagnosis is:

A. Eastern equine encephalitis
B. St. Louis encephalitis
C. Dengue fever
D. Western equine encephalitis
E. Yellow fever

V.23 A 40-year-old man develops ataxia, slurred speech, and dementia. At autopsy the brain shows widespread neuronal degeneration, a spongy appearance due to many vacuoles between the cells, no inflammation, and no evidence of virus particles. Mice injected with homogenized brain tissue develop similar disease after 6 months. The *most likely* agents of this disease are:

A. Virus-like particles with nucleic acid in their core
B. Herpes-like incomplete viruses
C. Prions resulting from a conformationally rearranged protein
D. Double-stranded DNA virus
E. Single-stranded RNA virus

V.24 A 64-year-old man with chronic lymphocytic leukemia develops progressive deterioration of mental and neuromuscular function. At autopsy the brain shows enlarged oligodendrocytes whose nuclei contain naked, icosahedral virus particles. The *most likely* diagnosis is:

A. Herpes encephalitis
B. Progressive multifocal leukoencephalopathy
C. Rabies encephalitis
D. Creutzfeldt-Jakob disease
E. Subacute sclerosing panencephalitis

V.25 Which one of the following infections peaks mainly in adults?

A. Shingles
B. Rotavirus

C. Respiratory syncytial virus
D. Mumps virus
E. Western equine encephalitis virus

V.26 You have a 25-year-old female patient in your office who had just discovered that her sex partner is HIV positive. She is on birth control pills, so they have not been using condoms. Before she left him this week, they have had sex about 10 to 15 times. You got a blood test done for HIV that came back negative. She is also negative for other sexually transmitted diseases. Which one of the following statements is *true* for this patient?

A. Since the HIV test came back negative, she is not infected and there is no need to test her again.
B. The risk of HIV transmission through heterosexual route is so remote that this patient should not be concerned anymore.
C. She needs to be tested again in 6 months and if negative, she is probably uninfected.
D. She should be tested again in 6 months and if negative, she is definitely uninfected and need not be tested again.
E. Since she is using birth control pills, she should not be concerned because HIV is inactivated by birth control pills.

V.27 You have decided to do a 6-month clinical rotation in a teaching hospital situated in the Indian subcontinent and will be accompanied by your spouse and a 1-year-old child. Your child is up-to-date with all the routine immunizations. In addition, you will take other recommended immunizations before traveling. Which one of following statements is *true* about a viral disease that may affect one of you?

A. Rotavirus infections are more common in infants than adults.
B. Norwalk-like viruses causing diarrhea are seen generally in women.
C. The incubation period for astroviruses is very long because they are DNA viruses and establish latent infection.
D. Viruses of diarrhea are not a major concern in the Indian subcontinent.
E. Enteroviruses that are the major cause of diarrhea can be prevented by boiling the drinking water.

V.28 A 10-year-old girl has developed fever and loss of appetite. By the time

she is seen by her physician, she has tender swelling in the area of both parotid glands. What are other features typical of this infection and its agent?

A. It is maintained in domestic animals.
B. It is preventable by immunization.
C. Progression to the central nervous system is common.
D. Recurrences are common.
E. A helical DNA virus is the cause.

V.29 A young woman presents with malaise, fever, and loss of appetite. On examination her sclera reveals jaundice. Initial testing reveals negative tests for HBs antigen and anti-HBs antibody. Which of the following tests would be most useful in establishing a diagnosis of infection with hepatitis B virus?

A. Delta antigen
B. Anti-HBc antibody
C. Anti-HBe antibody
D. HBe antigen
E. Alanine aminotransferase (ALT)

Answers

V.1 (E), **V.2** (B), **V.3** (C), **V.4** (B), **V.5** (C), **V.6** (B), **V.7** (B), **V.8** (C), **V.9** (B), **V.10** (D), **V.11** (B), **V.12** (A), **V.13** (E), **V.14** (D), **V.15** (A), **V.16** (C), **V.17** (E), **V.18** (C), **V.19** (B), **V.20** (C), **V.21** (B), **V.22** (C), **V.23** (C), **V.24** (B), **V.25** (A), **V.26** (C), **V.27** (A), **V.28** (B), **V.29** (B)

BACTERIAL DISEASES

B.1 Five post office workers have all come down with a similar respiratory illness characterized by low-grade fever, chills, cough, dyspnea on exertion, and generalized malaise. A chest radiograph taken on one of them shows mediastinal edema and a sputum Gram stain shows WBCs and large Gram-positive rods. A blood culture also shows Gram-positive rods. This infection was most likely acquired by:

A. Inhalation of vegetative bacteria
B. Inhalation of conidia

C. Inhalation of spores
D. Traumatic inoculation of vegetative bacteria
E. Traumatic inoculation of spores

B.2 **A young girl in the former Soviet Republic of Georgia has a severe sore throat and multiple white plaques in the back of her throat. She is acutely ill and has a heart murmur. She has had only one set of her childhood immunizations because the supplies in the village where she lives had run out. The manifestations in her throat and heart are due to a toxin which:**

A. Stimulates adenylate cyclase
B. Inserts into sarcolemmal membranes
C. Inhibits protein synthesis
D. Inhibits acetylcholine release
E. Stimulates cytokine release

B.3 **Over half the persons attending a banquet developed a vague febrile illness 2 to 5 days later. Most of those who sought medical aid had the same organism isolated from their bloodstream. Food histories incriminate dairy products but it appears certain they were kept refrigerated right up to the serving time. Which of the following is most likely to be the cause?**

A. *Escherichia coli* O:157:H7
B. *Salmonella enterica*
C. *Salmonella* serotype Typhi
D. *Clostridium perfringens*
E. *Listeria monocytogenes*

B.4 **A newborn was delivered at home without medical assistance. The umbilical cord was cut with kitchen shears. The baby initially did fine but in the third week of life began to have involuntary muscle contractions. The infant now has generalized muscle contractions and difficulty breathing. The abnormal muscle spasms are due to a toxin which:**

A. Stimulates neuromuscular synapses
B. Stimulates neurotransmission in the spinal cord
C. Blocks postsynaptic inhibition in the spinal cord

D. Blocks acetylcholine release in the spinal cord
E. Blocks acetylcholine release at neuromuscular junctions

B.5 **An emergency call to a neighbor leads to an entire family with apparent paralysis of ocular and respiratory muscles. They had just embarked on a project of home canning and had consumed one of their own products (green beans) the evening before. It is most likely they consumed a toxin which:**

A. Stimulates neuromuscular synapses
B. Stimulates neurotransmission in the spinal cord
C. Blocks postsynaptic inhibition in the spinal cord
D. Blocks acetylcholine release in the spinal cord
E. Blocks acetylcholine release at neuromuscular junctions

B.6 **A woman has been in the hospital for 3 weeks due to complications following surgery for colon cancer. Five days into a course of ceftriaxone for suspected pneumonia she developed diarrhea. Colonoscopy revealed multiple plaques on the mucosa which are composed of fibrin and WBS. Stool examinations for *Salmonella, Shigella, Campylobacter*, and amoebas are negative. The diarrhea and plaques are most likely produced by:**

A. Endotoxin from clostridial spores
B. Exotoxin from clostridial spores
C. Exotoxin from clostridial cells
D. Exotoxin from *E coli* cells
E. Endotoxin from *E coli* cells

B.7 **Two isolates of *Neisseria gonorrhoeae* have been obtained from a woman with disseminated gonococcal infection (DGI). One is from the cervix, the other from the blood. Detailed studies of these isolates show that antibody directed against the pili of the cervical isolate neutralize its binding to epithelial cells but the same antibodies have no effect on the blood isolate. The most likely explanation for these observations is:**

A. She is infected with two strains from different partners.
B. The cervical isolate has a plasmid which was lost in the blood.
C. A translational frame shift has shut off the pili of the blood isolate.
D. Recombination between pilin genes has altered the pili.

E. The cervical isolate has a transposon lacking in the blood isolate.

B.8 A young woman has been identified as a sexual partner of a man recently diagnosed with gonococcal urethritis. She is in good health with no genital pain or discharge. The best way to determine if she has gonorrhea is:

A. Pilin serology
B. Opa serology
C. Gram stain
D. Vaginal culture
E. Cervical culture

B.9 Most cases of meningococcal meningitis occur between the ages of 6 months and 5 years (peak 18 months). The best explanation for this age distribution is:

A. This is the age when exposure is most likely.
B. The T-cell-dependent immune response is poorly developed at this age.
C. Antimeningococcal antibody is less likely to be present at this age.
D. Maternal antibody persists through this period.
E. Maternal antibody is not protective.

B.10 A small college has adopted an aggressive immunization policy which includes use of the newest Hib, meningococcal, and pneumococcal vaccines. Despite this, an outbreak of meningitis has developed on campus with clear evidence of transmission between roommates. Which of the following would have the greatest potential to produce an outbreak under these circumstances?

A. *Haemophilus influenzae*, type b
B. *Haemophilus influenzae*, type a
C. *Neisseria meningitidis*, group A
D. *Neisseria meningitidis*, group B
E. *Streptococcus pneumoniae*, type 24

B.11 An outbreak of diarrhea has spread through a day-care center caring for 3- to 5-year-old children. No food is served in the center. Which of the following organisms is most likely to be spread directly from child to child by the fecal–oral mechanism?

A. *Shigella*
B. *Salmonella* serotypes
C. *Salmonella* serotype Typhi
D. Enterotoxigenic *E coli*
E. *Listeria*

B.12 If an *E coli* is introduced into the urinary bladder by mechanical disruption of the perineal flora, which of the following characteristics would give it the best chance to produce pyelonephritis?

A. Alpha hemolysin
B. CFA pili
C. P (gal–gal) pili
D. Type 1 pili
A. LPS endotoxin

B.13 An elderly man with an enlarged prostate has frequent and painful urination. Suddenly he develops fever and chills. Examination reveals hypotension (blood pressure 55/10 mm Hg) and a blood culture is positive for *Klebsiella pneumoniae.* The fever, chills, and hypotension likely derive from the bacterial:

A. Alpha toxin
B. Outer membrane
C. Capsule
D. Endoplasmic reticulum
E. Polysaccharide capsule

B.14 A child has had abdominal pain and diarrhea for 2 days. A stained preparation of the stool demonstrates polymorphonuclear leukocytes. Which of the following is *least likely* to produce these findings?

A. *Vibrio cholerae*
B. *Shigella sonnei*
C. *Shigella dysenteriae*
D. *Salmonella* serotype Typhimurium
E. *Campylobacter jejuni*

B.15 A 6-month-old infant presents with fever, hoarseness, and difficult breathing. Examination reveals a red, swollen, epiglottis. The

laboratory reports that a blood culture is growing Gram-negative coccobacilli. Immunity to infection with this organism is provided by antibodies directed against:

A. Cytotoxic T cells
B. M protein
C. Polyribitol phosphate
D. Surface pili
E. Outer membrane proteins

B.16 A 3-month-old infant was admitted to the hospital with a 10-day history of repetitive coughing and choking spells. His white blood cell count was 30,000/mm^3 (normal <10,000/mm^3) with 70% lymphocytes. The child's chest radiograph was clear. The most sensitive method for making a diagnosis is:

A. Sputum culture on blood agar
B. Nasopharyngeal culture on special medium
C. "Cough plate" culture on special medium
D. Sputum Gram stain
E. Sputum acid-fast stain

B.17 A 56-year-old man has had a cough with hemoptysis for 6 weeks and has lost 25 pounds. His chest X-ray reveals a right upper lobe cavity. His sputum shows multiple slender acid-fast bacilli. The primary mechanism of injury to his lung is:

A. Lipopolysaccharide endotoxin
B. Protein exotoxin
C. Pore-forming toxin
D. Delayed type hypersensitivity
E. Immune complex deposition

B.18 The characteristic of the organism which causes tuberculosis which best distinguishes it from other genera is:

A. Thick peptidoglycan
B. High cell wall lipid content
C. Impermeable outer membrane
D. Injection secretion system

E. Lancefield carbohydrate

B.19 As part of an annual evaluation, a 30-year-old medical resident's tuberculin skin test shows 16 mm induration. She has always had negative tests in the past including one a year earlier. She is afebrile, feels well, and her chest X-ray is clear. The best course of action at this point is:

A. Sputum acid-fast stain
B. Sputum TB culture
C. Bronchoalveolar lavage (BAL) with culture
D. 3 drug TB therapy
E. Isoniazid chemoprophylaxis

B.20 An immunocompromised patient reported chest pains and weight loss. Sputum showed branching, filamentous Gram-positive rods which were weakly acid-fast. This organism was most probably acquired from:

A. Oropharyngeal flora
B. Family member
C. Domestic pet
D. Insect vector
E. Soil

B.21 A 9-year-old boy returned home after attending summer camp in Rhode Island. Upon his return he had complaints of recurrent fever, muscle aches, severe headaches, and fatigue. The patient also had an annular (ring-like) rash on his left arm and later developed a facial palsy. In order to consider a diagnosis of Lyme disease what additional history would be most helpful?

A. Food consumption
B. Swimming in lakes or streams
C. Sexual contact
D. Hiking locales
E. Illness of friends

B.22 A sexually active, 30-year-old male patient has a history of genital ulcer which healed several weeks ago. He now presents with a

maculopapular rash over his entire body, extending to the palms, soles, and face. Examination of one of the skin lesions by what method would be most likely to demonstrate the causative agent of this infection?

A. Gram stain
B. Darkfield microscopy
C. Modified acid-fast stain
D. Acid-fast stain
E. Culture

B.23 A 40-year-old man has dysuria and copious amounts of pus coming from the urethra. He has been with multiple sexual partners in the past 2 months. A Gram stain of the pus shows many Gram-negative diplococci both in and outside neutrophils. He is also discovered to have a positive fluorescent treponemal antibody (FTA-ABS) test but a negative nontreponemal (RPR) test. What best describes his disease(s) state?

A. Gonorrhea (active)
B. Syphilis (active)
C. Gonorrhea (active) and syphilis (active)
D. Gonorrhea (active) and syphilis (previous)
E. Gonorrhea (previous) and syphilis (previous)

B.24 A 29-year-old man presents with a 2-day history of burning on urination and a thin, watery urethral discharge. He had unprotected sex with a new female partner 4 weeks ago. A Gram stain reveals 50% polymorphonuclear (PMN) and 50% mononuclear leukocytes. No microorganisms were visible and a culture for gonococci was negative. Transmission to another sexual partner would be by acquisition of:

A. Elementary body
B. Reticulate body
C. Outer membrane protein
D. Pili
E. Invasin

B.25 A purified polysaccharide vaccine was successful in preventing invasive meningococcal disease in military populations but not in children under 2 years of age. The most probable explanation for this

involves:

A. Maternal IgG transfer at birth
B. CD4+ T-cell function
C. Bone marrow stem cells
D. Maturation of T-cell–dependent responses
E. Maturation of T-cell–independent responses

B.26 Plague continues to exist in many parts of the world. Select the combination from the list that most favors this persistence?

A. Fleas and deer
B. Ticks and wild rodents
C. Fleas and wild rodents
D. Mosquitoes and urban rats
E. Fleas and urban rats

B.27 A number of residents of a migratory worker camp in Arizona have developed fever and night sweats that seem to come and go each day. For some it has been going on more than a month. There are no signs which point to any organ system but most had eaten from a large supply of cheese brought by one of them from Mexico. The best way to establish a diagnosis in these workers is:

A. Blood culture
B. Gram stain
C. Sputum culture
D. CSF culture
E. Serology

B.28 A 30-year-old man presents with fever, headache, and a decline in mental status. He was previously healthy and had received the standard immunizations in school. A lumbar puncture reveals more than 100 white blood cells per milliliter of cerebrospinal fluid (CSF). If a CSF Gram stain reveals Gram-negative diplococci, which of the following actions would best prevent spread of the infection to others in the family?

A. Penicillin chemoprophylaxis
B. Rifampin chemoprophylaxis

C. Polysaccharide vaccine
D. Wearing masks
E. Handwashing

B.29 A 25-year-old student has developed diarrhea with 8 to 10 stools a day. He was healthy 2 days earlier and has no known immune deficits. If the infection developed while traveling in a developing country and the stool contains neither red or white blood cells, the diarrhea is most likely due to:

A. Shiga toxin (Stx)
B. A protein synthesis inhibiting toxin
C. An ADP-ribosylating toxin
D. A pore-forming toxin
E. An invading bacterium

B.30 An 8-year-old boy has been listless and irritable for a week. The mother says he had a sore throat 3 weeks ago but did not see a physician because the family lacks healthcare coverage and "it wasn't that bad." Examination reveals arthritis in two joints and a heart murmur. His antistreptolysin O (ASO) titer is elevated. His cardiac findings are most likely due to antibody stimulated by:

A. Pyrogenic exotoxin
B. M protein
C. Streptolysin O
D. Lipoteichoic acid
E. Fibronectin

B.31 A man presents to urgent care with a history of fever, a shaking chill, and the production of reddish-colored sputum. The X-ray shows consolidation of the right middle lobe of the lung, and a Gram stain of the sputum shows numerous neutrophils and lancet-shaped Gram-positive diplococci. External to the cell wall of this organism_____is typically found:

A. Flagella
B. Pili
C. Lipopolysaccharide
D. Polysaccharide

E. Exotoxin

B.32 Twelve hours after birth a newborn is lethargic and feeding poorly. A blood culture reveals Gram-positive cocci in short chains which are catalase negative. The cell wall of this organism most certainly contains:

A. Pili
B. Flagella
C. Lipopolysaccharide
D. Outer membrane
E. Peptidoglycan

B.33 A teenage boy has developed a tender, painful, lump in his axilla. The lesion eventually came to a "point" and drained purulent material. A Gram stain of the pus revealed WBCs and Gram-positive cocci. Which of the following would be the most probable source of this infection?

A. Resident microbiota
B. Food
C. Insect bite
D. Swimming pool
E. Pet

B.34 An elderly woman recovering from surgery had been in the hospital receiving intravenous fluids for 6 days. On the fifth hospital day she developed a low-grade fever. Physical examination and radiographs revealed no obvious source but a 3 of 3 blood cultures taken were positive for Gram-positive cocci which were catalase positive and coagulase negative. When her IV line was removed, the fever went away. What virulence feature of the organism facilitated this episode?

A. Pili adherent to epithelial cells
B. Pili adherent to plastic
C. Polysaccharide adherent to epithelial cells
D. Polysaccharide adherent to plastic
E. Pore-forming toxin

B.35 A transient man is seen in the emergency room for fever, chills, and a productive cough. The episode began suddenly with a severe shaking

chill. A Gram stain of his sputum shows Gram-positive cocci in pairs and his chest X-ray shows consolidation of the right middle lobe. Which feature of the bacterium was most important in the *initiation* of this infection?

A. Pili adhering to tracheal mucosa
B. Polysaccharide interference with complement
C. Catalase generating superoxide ions
D. Superantigen generation of cytokines
E. Cell injury by pore-forming toxin

B.36 A 5-year-old girl has a sore throat. She is febrile and has a scant exudate on one tonsillar pillar. The most sensitive way to detect whether this infection is due to group A streptococci is:

A. Throat culture
B. Streptococcal group A antigen detection
C. Streptococcal M protein antigen detection
D. Gram stain
E. ASO titer

B.37 A few days after birth, a newborn developed an umbilical infection from which Gram-positive cocci in clusters were isolated. The next day he appeared "sunburned" and the superficial layers of his skin peeled away. Except for elevated WBC count routine, hematologic and chemistry tests were normal. The cutaneous findings, in this case, are most likely due to:

A. Endotoxin
B. Pyrogenic exotoxin
C. Exfoliatin
D. Peptidoglycan
E. Coagulase

B.38 A major difference between the structure of the Gram-positive and Gram-negative cell wall is that the Gram-negative wall contains:

A. Peptidoglycan
B. Pili
C. Flagella

D. Outer membrane
E. Capsule

B.39 During a urinary tract infection, a 30-year-old woman developed hypotension, shock, and purpura. Gram-negative rods were discovered in the bloodstream. The shock state is most due to the action of:

A. Lipopolysaccharide (LPS) lipid A
B. LPS side chains
C. Peptidoglycan
D. Cytoplasmic membrane
E. Pyrogenic exotoxin

B.40 A research microbiologist is said to have caused a fatal pneumonia by sending bacterial spores through the mail. These spores are:

A. Structures for sexual reproduction
B. Packets of toxin
C. Concentrated peptidoglycan
D. Concentrated endotoxin
E. Inert survival forms

B.41 The bacterial structure most likely to be acquired by one bacterial cell from another using the conjugation mechanism is:

A. Circular chromosome
B. Bacteriophage
C. Plasmid
D. DNA fragment
E. Transposon

B.42 A bacterial strain has acquired a set of genes by transduction. The process entered the lysogenic cycle and the bacterial cells have gone through a cycle of reproduction. In the daughter cells these genes will be found in:

A. Bacteriophage
B. Plasmid
C. Chromosome
D. Transposon

E. Cytosol

B.43 A human cell has been brought in contact with a bacterial A/B toxin. The cell type is known to be susceptible to the toxin. The most important determinant of the type of physiologic effect of the toxin on the cell is:

A. Surface-binding receptors
B. Ribosomal receptor sites
C. Endocytotic vacuole
D. Type of enzymatic reaction
E. Function of target protein

B.44 Which of the following biologic substances functions commonly as the *receptor* for bacterial adherence?

A. Ribosome
B. Fibronectin
C. Cholesterol
D. Polysaccharide
E. Pili

B.45 A 12-year-old girl woke up saying it hurt to swallow. Her mother took her to a physician who said it looked like a viral pharyngitis and performed a rapid strep antigen test which was negative. Three weeks later she became listless and irritable. Physical examination revealed a febrile girl with arthritis in two joints and a heart murmur. Her antistreptolysin O (ASO) titer was elevated. Her cardiac findings are most likely due to antibody directed against:

A. Pyrogenic exotoxin
B. Streptolysin O
C. Sarcolemmal membranes
D. Lipoteichoic acid
E. Adhesive pili

B.46 A young woman has developed fever and hypotension 3 days into her menstrual cycle. Laboratory findings include leukocytosis and an elevated blood urea nitrogen. Blood cultures were negative but a vaginal culture grew Gram-positive cocci which were catalase and

coagulase positive. The systemic findings are most likely due to production of:

A. Endotoxin
B. A/B toxin
C. Superantigen exotoxin
D. Pore-forming toxin
E. Peptidoglycan
F. Coagulase

FUNGAL DISEASES

F.1 **A young Phoenix woman has developed fever, cough, and after 1 month of illness has an infiltrate in the upper lobe of her right lung. A sputum specimen digested with KOH was negative but the culture grew a mold with alternating arthroconidia.**

This infection was most likely acquired by inhalation of:

A. Spherules
B. Yeasts
C. Sexual, macroconidia
D. Asexual, arthroconidia
E. Asexual chlamydoconidia

F.2 **A young woman who recently moved to Arizona has developed fever and malaise which have lasted for 3 weeks. Her chest radiograph is clear and her physician has diagnosed “valley fever.” Which of the following tests, using a specific preparation of the infecting agent, would raise the greatest concerns about her disease disseminating**

outside the lung?

A. Positive skin test
B. High levels of IgG antibody
C. Absent IgM antibody
D. Absent IgG antibody
E. High levels of capsular antigen

F.3 **A young woman has developed fever and diffuse pulmonary infiltrates 1 week after undergoing a bone marrow transplant. She is on immunosuppressive therapy. Material collected in a bronchoalveolar lavage has demonstrated septate branching hyphae and she was placed on amphotericin B. The target of this therapy is:**

A. Cell wall mannoprotein
B. Nucleic acids
C. Cytoplasmic membrane
D. Mitotic spindle fibers
E. Cell wall glucan

F.4 **You are asked to evaluate the antifungal therapy of a patient with an enlarged liver and spleen. The laboratory finding shows that culture of a lymph node biopsy yielded a small (4 mm) yeast at 35°C, which at 25°C grew as a mold with tuberculate macroconidia. The patient most probably acquired this infection in:**

A. Semitropical regions of North and South America
B. Ohio and Mississippi River valleys
C. Arid deserts of America and Africa
D. Lower Sonoran life zone
E. Worldwide

F.5 **A 75-year-old man presents with headache and confusion. He has a low-grade fever and 10 lymphocytes in his cerebrospinal fluid (CSF). Cultures of sputum, urine, blood, and CSF yielded no pathogens. For which of the following fungal agents would detection of circulating antigen be a useful diagnostic test?**

A. *Candida albicans*
B. *Aspergillus fumigatus*

C. *Histoplasma capsulatum*
D. *Coccidioides immitis*
E. *Cryptococcus neoformans*

F.6 **A diabetic patient has developed fever and swelling around the eye. Material taken from the adjacent nasal sinus shows large nonseptate hyphae. Which of the following agents is the most probable cause?**

A. Candida
B. Aspergillus
C. Trichophyton
D. Rhizopus
E. Sporothrix

F.7 **Human-to-human transmission is most likely to occur with:**

A. *Coccidioides immitis*
B. *Epidermophyton floccosum*
C. *Cryptococcus neoformans*
D. *Aspergillus flavus*
E. *Histoplasma capsulatum*

F.8 **A 25-year-old woman suffers from vaginal discharge and itching. A Gram smear of the discharge demonstrates abundant yeast cells. Culture of the vaginal discharge yielded yeast cells, which readily formed germ tubes (hyphae) when incubated in serum. The feature of this organism which facilitates its initial binding to vaginal epithelial cells is:**

A. Mannoprotein
B. Hyphae
C. Ergosterol
D. Conidia
E. Chlamydoconidia

F.9 **Skin scrapings have been collected from the advancing edge of a ring-like lesion on the arm of a child. Which of the following observations is diagnostic of dermatophyte infection in a direct KOH preparation?**

A. Arthroconidia

B. Chlamydoconidia
C. Macroconidia
D. Septate hyphae
E. Nonseptate hyphae

F.10 A 27-year-old man has experienced malaise over a 2-week period. On examination he has fever and is short of breath. A chest radiograph shows bilateral diffuse pulmonary infiltrates and a bronchoalveolar massage revealed delicate 5-8 mm cystic structures, some of which were folded and had nuclei. He improved with trimethoprim/sulfamethoxazole therapy. The most likely etiologic agent is:

A. *Candida*
B. *Aspergillus*
C. *Pneumocystis*
D. *Ascaris*
E. *Coccidioides*

Answers

F.1 (D), **F.2** (B), **F.3** (C), **F.4** (B), **F.5** (E), **F.6** (D), **F.7** (B),**F.8** (A), **F.9** (D), **F.10** (C)

PARASITIC DISEASES

P.1 A traveler developed diarrhea 2 weeks after returning from a trip to Moscow and St. Petersburg, Russia. The diarrhea has lasted for over 3 weeks and his stools are greasy and foul-smelling. Which of the following is the most probable etiologic agent?

A. Toxoplasma
B. Giardia
C. Trichinella
D. Entamoeba
E. Toxocara

P.2 A 45-year-old African man suffers from chronic fatigue and weakness. At a routine examination at his village clinic he was found to be

profoundly anemic. Which of the following agents is most likely to be responsible?

A. *Diphyllobothrium latum*
B. *Strongyloides stercoralis*
C. *Ascaris lumbricoides*
D. *Enterobius vermicularis*
E. *Ancylostoma duodenale*

P.3 **An Indonesian man has vague complains of epigastric pain and abdominal tenderness. An evaluation for a peptic ulcer was negative. A diagnosis of strongyloidiasis has been suggested. The best way to confirm this diagnosis is:**

A. Finding eggs in the feces
B. Finding adult worms in the feces
C. Finding larval worms in the feces
D. X-ray evidence of pneumonia

P.4 **A man who moved to the United States from Ethiopia 10 years ago has been well but over the past year has lost significant weight. He reports a healthy appetite and no change in his food consumption. If he has a tapeworm, it was acquired by ingesting tissue containing:**

A. Cysticerci
B. Cercariae
C. Copepods (crustaceans)
D. Hydatid cysts
E. Microfilariae

P.5 **A child presents with a prolapsed rectum, a history of diarrhea and a fondness for eating dirt. She is anemic and looks malnourished. A stool examination reveals barrel-shaped eggs with “plugs” at either end. She is most likely infected with:**

A. *Ascaris lumbricoides*
B. *Enterobius vermicularis*
C. *Trichuris trichiura*
D. *Necator americanus*
E. *Strongyloides stercoralis*

P.6 **At a party, a student consumed sushi which contained fish from Canada. If a parasite becomes established from this raw fish consumption, which of the following problems is most likely?**

A. Diarrhea
B. Formation of hydatid cysts
C. Formation of cercaria that will infect other hosts
D. Formation of oocysts
E. Vitamin B_{12} deficiency

P.7 **A 29-year-old woman has persistent vaginal discharge and itching. Which one of the following would establish a diagnosis of trichomoniasis?**

A. Vaginal clue cells seen by cytology
B. Visualization of organisms by KOH
C. Stool for ova and parasites (O and P)
D. Visualization of motile organisms in vaginal fluid
E. White blood cells with no organisms seen in vaginal fluid

P.8 **A man just returned from a mission around the world that included visits to poverty-stricken rural regions of Thailand, India, Kenya, Nigeria, and Brazil. He recalls numerous evenings when he was bitten by mosquitoes. He took chloroquine during the trip and is still taking it. He now presents with fever and chills, and on examination he has an enlarged spleen. A blood smear reveals ring-shaped structures within erythrocytes. This infection was most likely acquired by the bite of:**

A. *Anopheles* mosquito
B. Tsetse fly
C. Sand fly
D. *Aedes* mosquito
E. Reduviid (kissing, triatomine) bug

P.9 **An immigrant from Bolivia complains of abdominal pain and cramping. Two months prior he passed numerous bloody stools. On examination he has right upper quadrant pain and hepatomegally. If this is a liver abscess, which of the following might have caused it?**

A. Ascaris

B. Entamoeba
C. Balantidium
D. Taenia
E. Acanthamoeba

P.10 Which one of the following can complete its entire life cycle in the human host?

A. *Toxoplasma gondii*
B. *Cryptosporidium parvum*
C. *Plasmodium falciparum*
D. *Trypanosoma cruzi*
E. *Trypanosoma brucei*

P.11 Which of the following parasites primarily infects macrophages?

A. Plasmodium falciparum
B. Trypanosoma cruzi
C. Trichomonas vaginalis
D. Leishmania donovani
E. Echinococcus granulosus

P.12 A man returned 4 weeks ago from Tanzania, East Africa, where he was on a safari. Earlier, he had an ulcer on the back of his neck. He now has headaches, fevers, and decreased level of consciousness. Which one of the following could *most readily* explain his symptoms?

A. *Plasmodium vivax*
B. *Trypanosoma brucei rhodesiense*
C. *Toxoplasma gondii*
D. *Trypanosoma cruzi*
E. *Leishmania donovani*

P.13 Which one of the following may explain the chronicity of infection caused by African trypanosomes?

A. Antigenic variation
B. Inhibition of macrophage phagosome–lysosome fusion
C. Resistance to complement lysis
D. Ingestion of neutrophils

E. Formation of tissue cysts

P.14 Which one of the following may explain the long latency of infection caused by *Toxoplasma gondii*?

A. Antigenic variation
B. Intraerythrocytic survival
C. Resistance to complement lysis
D. Ingestion of neutrophils
E. Formation of tissue cysts

P.15 A young man noticed deterioration of vision after storing his contact lenses in tap water. An ophthalmologist diagnosed severe retinitis. Examination of the water and vitreous fluid would most likely reveal which of the following?

A. Babesia
B. Entamoeba
C. Naegleria
D. Acanthamoeba
E. Cryptosporidium

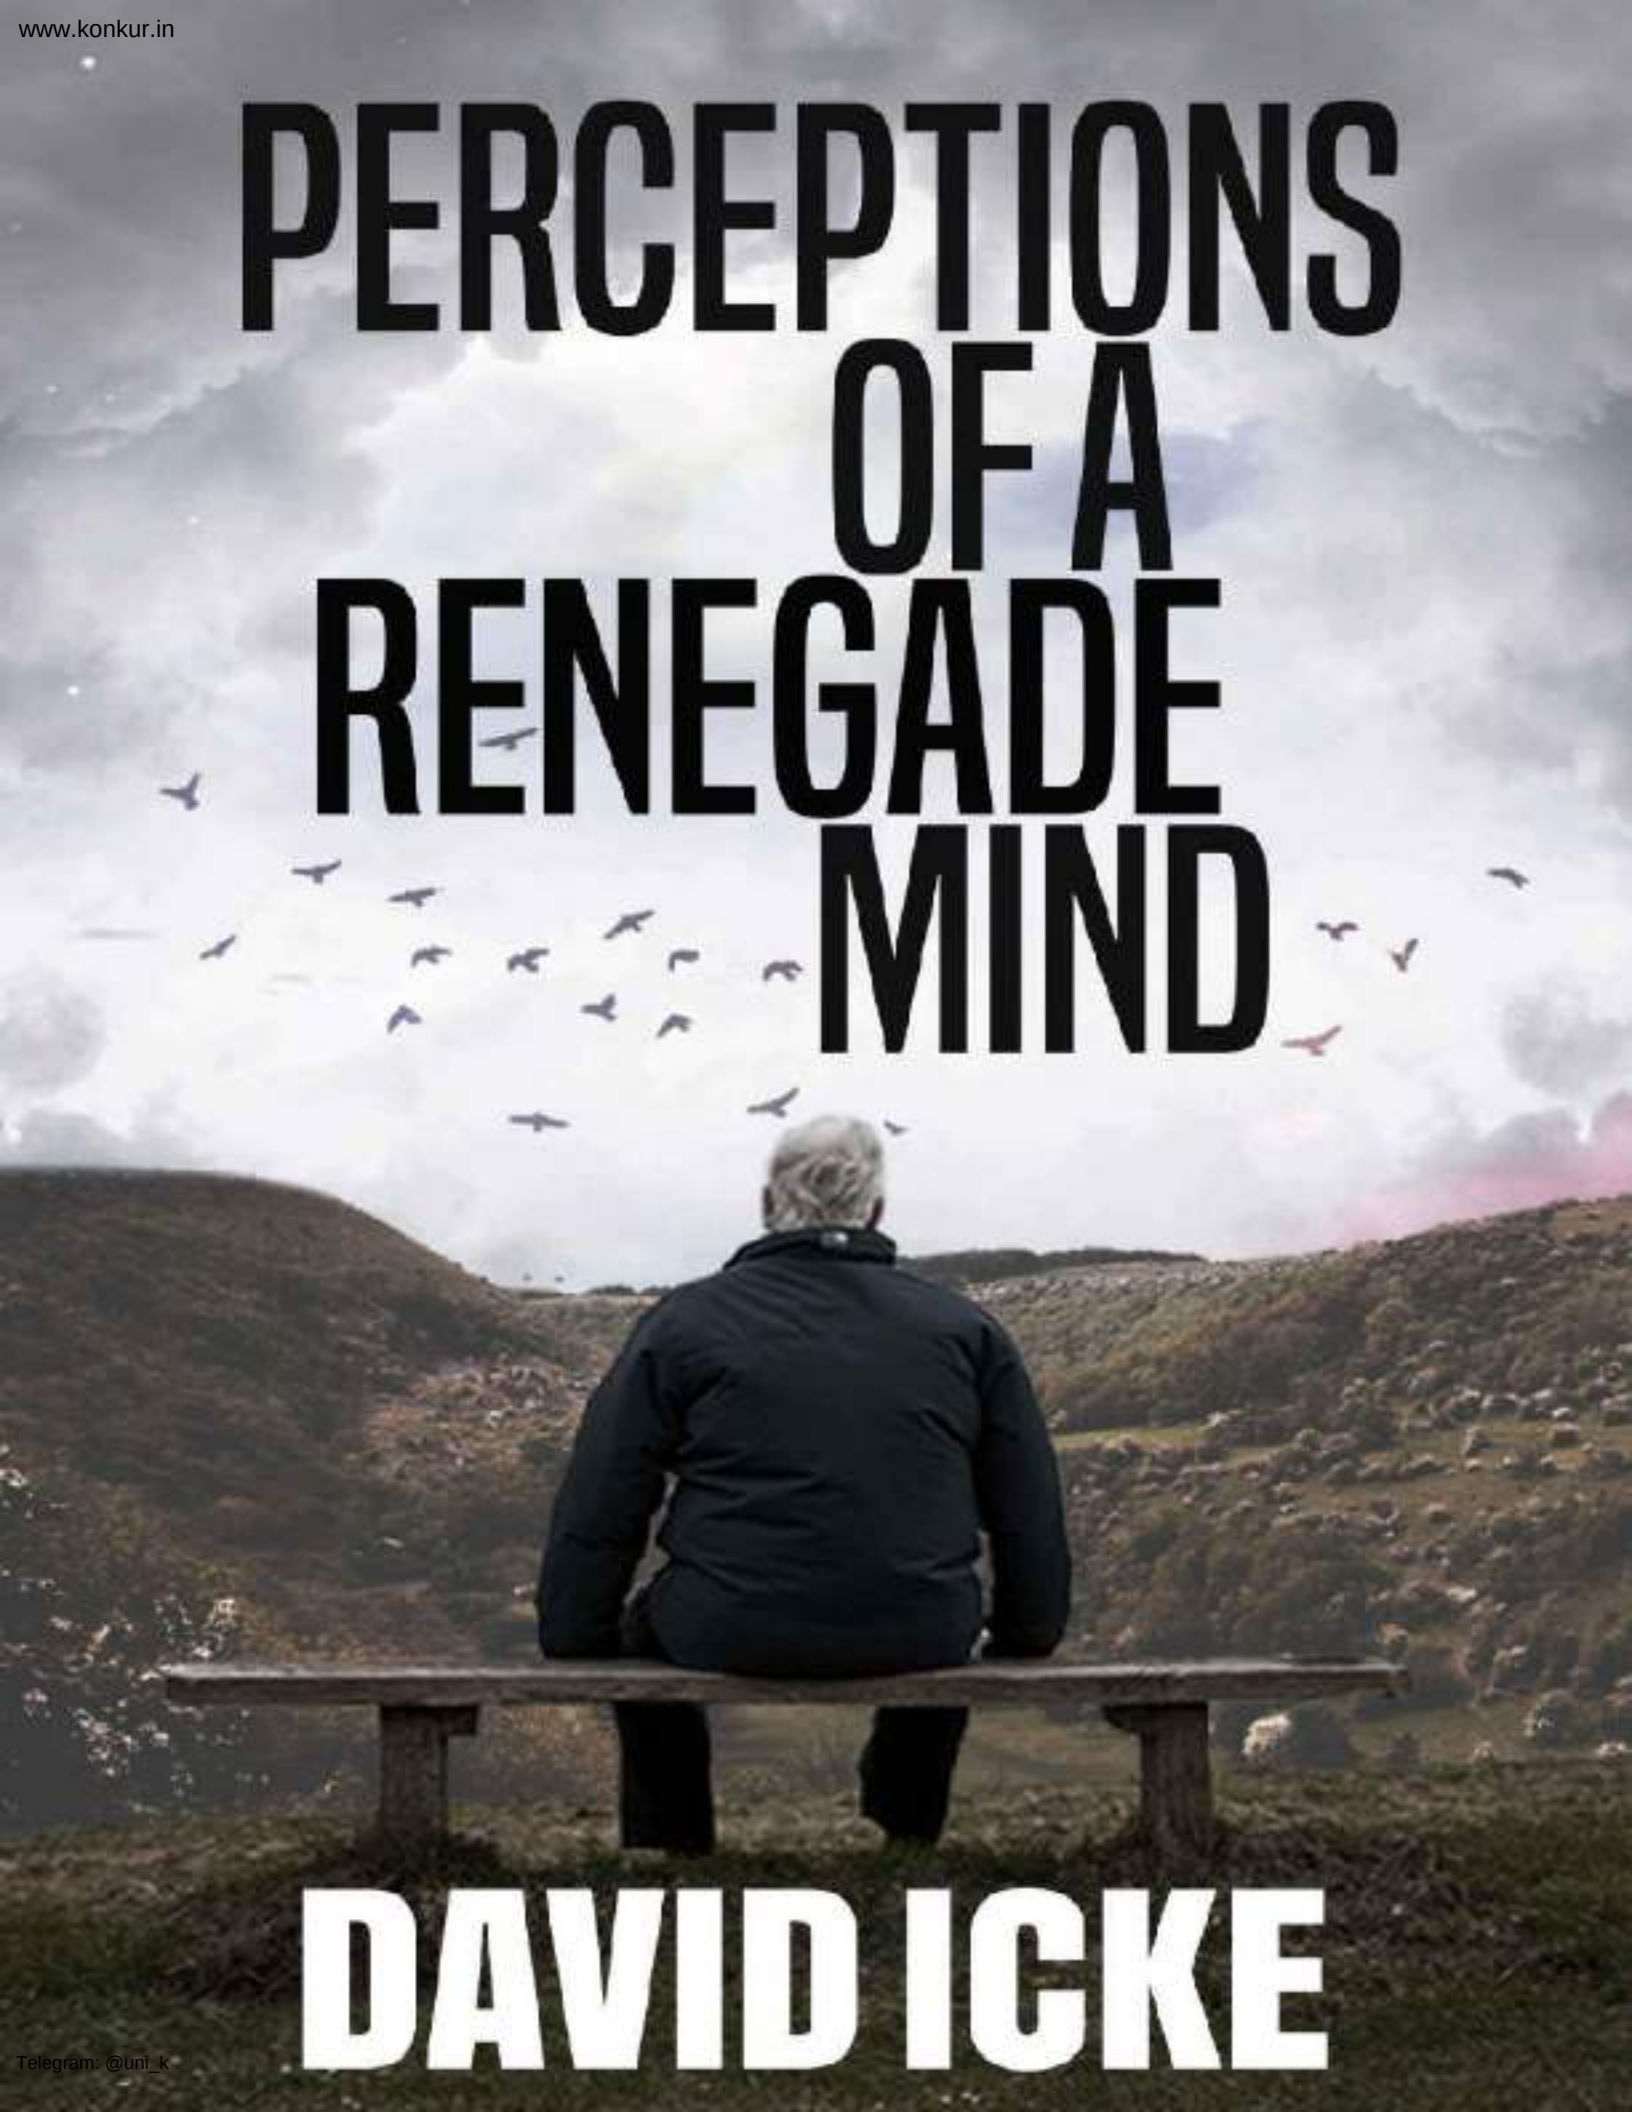
PERCEPTIONS OF A RENEGADE MIND



DAVID ICKE

Dedication:

To *Freeeeeedom!*

Renegade:
Adjective
'Having rejected tradition: Unconventional.'
Merriam-Webster Dictionary

Acquiescence to tyranny is the death of the spirit

You may be 38 years old, as I happen to be. And one day, some great opportunity stands before you and calls you to stand up for some great principle, some great issue, some great cause. And you refuse to do it because you are afraid … You refuse to do it because you want to live longer … You're afraid that you will lose your job, or you are afraid that you will be criticised or that you will lose your popularity, or you're afraid that somebody will stab you, or shoot at you or bomb your house; so you refuse to take the stand.

Well, you may go on and live until you are 90, but you're just as dead at 38 as you would be at 90. And the cessation of breathing in your life is but the belated announcement of an earlier death of the spirit.

Martin Luther King

How the few control the many and always have – the many do whatever they're told

'Forward, the Light Brigade!'
Was there a man dismayed?
Not though the soldier knew
Someone had blundered.
Theirs not to make reply,
Theirs not to reason why,
Theirs but to do and die.
Into the valley of Death
Rode the six hundred.

Cannon to right of them,
Cannon to left of them,
Cannon in front of them
Volleyed and thundered;
Stormed at with shot and shell,
Boldly they rode and well,
Into the jaws of Death,
Into the mouth of hell
Rode the six hundred

Alfred Lord Tennyson (1809-1892)

The mist is lifting slowly
I can see the way ahead
And I've left behind the empty streets
That once inspired my life
And the strength of the emotion
Is like thunder in the air
'Cos the promise that we made each other
Haunts me to the end

The secret of your beauty
And the mystery of your soul
I've been searching for in everyone I meet
And the times I've been mistaken
It's impossible to say
And the grass is growing
Underneath our feet

The words that I remember
From my childhood still are true
That there's none so blind
As those who will not see
And to those who lack the courage
And say it's dangerous to try
Well they just don't know
That love eternal will not be denied

I know you're out there somewhere
Somewhere, somewhere
I know you're out there somewhere

Somewhere you can hear my voice
I know I'll find you somehow
Somehow, somehow
I know I'll find you somehow
And somehow I'll return again to you

The Moody Blues

Are you a gutless wonder - or a Renegade Mind?

Monuments put from pen to paper,
Turns me into a gutless wonder,
And if you tolerate this,
Then your children will be next.
Gravity keeps my head down,
Or is it maybe shame ...

Manic Street Preachers

Rise like lions after slumber
In unvanquishable number.
Shake your chains to earth like dew
Which in sleep have fallen on you.
Ye are many – they are few.

Percy Shelley

Contents

CHAPTER ONE

I'm thinking' – Oh, but *are* you?

Think for yourself and let others enjoy the privilege of doing so too
Voltaire

French-born philosopher, mathematician and scientist René Descartes became famous for his statement in Latin in the 17th century which translates into English as: 'I think, therefore I am.'

On the face of it that is true. Thought reflects perception and perception leads to both behaviour and self-identity. In that sense 'we' are what we think. But who or what is doing the thinking and is thinking the only route to perception? Clearly, as we shall see, 'we' are not always the source of 'our' perception, indeed with regard to humanity as a whole this is rarely the case; and thinking is far from the only means of perception. Thought is the village idiot compared with other expressions of consciousness that we all have the potential to access and tap into. This has to be true when we *are* those other expressions of consciousness which are infinite in nature. We have forgotten this, or, more to the point, been manipulated to forget.

These are not just the esoteric musings of the navel. The whole foundation of human control and oppression is control of perception. Once perception is hijacked then so is behaviour which is dictated by perception. Collective perception becomes collective behaviour and collective behaviour is what we call human society. Perception is all and those behind human control know that which is

why perception is the target 24/7 of the psychopathic manipulators that I call the Global Cult. They know that if they dictate perception they will dictate behaviour and collectively dictate the nature of human society. They are further aware that perception is formed from information received and if they control the circulation of information they will to a vast extent direct human behaviour. Censorship of information and opinion has become globally Nazi-like in recent years and never more blatantly than since the illusory 'virus pandemic' was triggered out of China in 2019 and across the world in 2020. Why have billions submitted to house arrest and accepted fascistic societies in a way they would have never believed possible? Those controlling the information spewing from government, mainstream media and Silicon Valley (all controlled by the same Global Cult networks) told them they were in danger from a 'deadly virus' and only by submitting to house arrest and conceding their most basic of freedoms could they and their families be protected. This monumental and provable lie became the *perception* of the billions and therefore the *behaviour* of the billions. In those few words you have the whole structure and modus operandi of human control. Fear is a perception – **F**alse **E**motion **A**ppearing **R**eal – and fear is the currency of control. In short … get them by the balls (or give them the impression that you have) and their hearts and minds will follow. Nothing grips the dangly bits and freezes the rear-end more comprehensively than fear.

World number 1

There are two 'worlds' in what appears to be one 'world' and the prime difference between them is knowledge. First we have the mass of human society in which the population is maintained in coldly-calculated ignorance through control of information and the 'education' (indoctrination) system. That's all you really need to control to enslave billions in a perceptual delusion in which what are perceived to be *their* thoughts and opinions are ever-repeated mantras that the system has been downloading all their lives through 'education', media, science, medicine, politics and academia

in which the personnel and advocates are themselves overwhelmingly the perceptual products of the same repetition. Teachers and academics in general are processed by the same programming machine as everyone else, but unlike the great majority they never leave the 'education' program. It gripped them as students and continues to grip them as programmers of subsequent generations of students. The programmed become the programmers – the programmed programmers. The same can largely be said for scientists, doctors and politicians and not least because as the American writer Upton Sinclair said: 'It is difficult to get a man to understand something when his salary depends upon his not understanding it.' If your career and income depend on thinking the way the system demands then you will – bar a few free-minded exceptions – concede your mind to the Perceptual Mainframe that I call the Postage Stamp Consensus. This is a tiny band of perceived knowledge and possibility 'taught' (downloaded) in the schools and universities, pounded out by the mainstream media and on which all government policy is founded. Try thinking, and especially speaking and acting, outside of the 'box' of consensus and see what that does for your career in the Mainstream Everything which bullies, harasses, intimidates and ridicules the population into compliance. Here we have the simple structure which enslaves most of humanity in a perceptual prison cell for an entire lifetime and I'll go deeper into this process shortly. Most of what humanity is taught as fact is nothing more than programmed belief. American science fiction author Frank Herbert was right when he said: 'Belief can be manipulated. Only knowledge is dangerous.' In the 'Covid' age belief is promoted and knowledge is censored. It was always so, but never to the extreme of today.

World number 2

A 'number 2' is slang for 'doing a poo' and how appropriate that is when this other 'world' is doing just that on humanity every minute of every day. World number 2 is a global network of secret societies and semi-secret groups dictating the direction of society via

governments, corporations and authorities of every kind. I have spent more than 30 years uncovering and exposing this network that I call the Global Cult and knowing its agenda is what has made my books so accurate in predicting current and past events. Secret societies are secret for a reason. They want to keep their hoarded knowledge to themselves and their chosen initiates and to hide it from the population which they seek through ignorance to control and subdue. The whole foundation of the division between World 1 and World 2 is *knowledge*. What number 1 knows number 2 must not. Knowledge they have worked so hard to keep secret includes (a) the agenda to enslave humanity in a centrally-controlled global dictatorship, and (b) the nature of reality and life itself. The latter (b) must be suppressed to allow the former (a) to prevail as I shall be explaining. The way the Cult manipulates and interacts with the population can be likened to a spider's web. The 'spider' sits at the centre in the shadows and imposes its will through the web with each strand represented in World number 2 by a secret society, satanic or semi-secret group, and in World number 1 – the world of the seen – by governments, agencies of government, law enforcement, corporations, the banking system, media conglomerates and Silicon Valley (Fig 1 overleaf). The spider and the web connect and coordinate all these organisations to pursue the same global outcome while the population sees them as individual entities working randomly and independently. At the level of the web governments *are* the banking system *are* the corporations *are* the media *are* Silicon Valley *are* the World Health Organization working from their inner cores as one unit. Apparently unconnected countries, corporations, institutions, organisations and people are on the *same team* pursuing the same global outcome. Strands in the web immediately around the spider are the most secretive and exclusive secret societies and their membership is emphatically restricted to the Cult inner-circle emerging through the generations from particular bloodlines for reasons I will come to. At the core of the core you would get them in a single room. That's how many people are dictating the direction of human society and its transformation

through the 'Covid' hoax and other means. As the web expands out from the spider we meet the secret societies that many people will be aware of – the Freemasons, Knights Templar, Knights of Malta, Opus Dei, the inner sanctum of the Jesuit Order, and such like. Note how many are connected to the Church of Rome and there is a reason for that. The Roman Church was established as a revamp, a rebranding, of the relocated 'Church' of Babylon and the Cult imposing global tyranny today can be tracked back to Babylon and Sumer in what is now Iraq.

Figure 1: The global web through which the few control the many. (Image Neil Hague.)

Inner levels of the web operate in the unseen away from the public eye and then we have what I call the cusp organisations located at the point where the hidden meets the seen. They include a series of satellite organisations answering to a secret society founded in London in the late 19th century called the Round Table and among them are the Royal Institute of International Affairs (UK, founded in 1920); Council on Foreign Relations (US, 1921); Bilderberg Group (worldwide, 1954); Trilateral Commission (US/worldwide, 1972); and the Club of Rome (worldwide, 1968) which was created to exploit environmental concerns to justify the centralisation of global power to 'save the planet'. The Club of Rome instigated with others the human-caused climate change hoax which has led to all the 'green

new deals' demanding that very centralisation of control. Cusp organisations, which include endless 'think tanks' all over the world, are designed to coordinate a single global policy between political and business leaders, intelligence personnel, media organisations and anyone who can influence the direction of policy in their own sphere of operation. Major players and regular attenders will know what is happening – or some of it – while others come and go and are kept overwhelmingly in the dark about the big picture. I refer to these cusp groupings as semi-secret in that they can be publicly identified, but what goes on at the inner-core is kept very much 'in house' even from most of their members and participants through a fiercely-imposed system of compartmentalisation. Only let them know what they need to know to serve your interests and no more. The structure of secret societies serves as a perfect example of this principle. Most Freemasons never get higher than the bottom three levels of 'degree' (degree of knowledge) when there are 33 official degrees of the Scottish Rite. Initiates only qualify for the next higher 'compartment' or degree if those at that level choose to allow them. Knowledge can be carefully assigned only to those considered 'safe'. I went to my local Freemason's lodge a few years ago when they were having an 'open day' to show how cuddly they were and when I chatted to some of them I was astonished at how little the rank and file knew even about the most ubiquitous symbols they use. The mushroom technique – keep them in the dark and feed them bullshit – applies to most people in the web as well as the population as a whole. Sub-divisions of the web mirror in theme and structure transnational corporations which have a headquarters somewhere in the world dictating to all their subsidiaries in different countries. Subsidiaries operate in their methodology and branding to the same centrally-dictated plan and policy in pursuit of particular ends. The Cult web functions in the same way. Each country has its own web as a subsidiary of the global one. They consist of networks of secret societies, semi-secret groups and bloodline families and their job is to impose the will of the spider and the global web in their particular country. Subsidiary networks control and manipulate the national political system, finance, corporations, media, medicine, etc. to

ensure that they follow the globally-dictated Cult agenda. These networks were the means through which the 'Covid' hoax could be played out with almost every country responding in the same way.

The 'Yessir' pyramid

Compartmentalisation is the key to understanding how a tiny few can dictate the lives of billions when combined with a top-down sequence of imposition and acquiescence. The inner core of the Cult sits at the peak of the pyramidal hierarchy of human society (Fig 2 overleaf). It imposes its will – its agenda for the world – on the level immediately below which acquiesces to that imposition. This level then imposes the Cult will on the level below them which acquiesces and imposes on the next level. Very quickly we meet levels in the hierarchy that have no idea there even is a Cult, but the sequence of imposition and acquiescence continues down the pyramid in just the same way. 'I don't know why we are doing this but the order came from "on-high" and so we better just do it.' Alfred Lord Tennyson said of the cannon fodder levels in his poem *The Charge of the Light Brigade*: 'Theirs not to reason why; theirs but to do and die.' The next line says that 'into the valley of death rode the six hundred' and they died because they obeyed without question what their perceived 'superiors' told them to do. In the same way the population capitulated to 'Covid'. The whole hierarchical pyramid functions like this to allow the very few to direct the enormous many. Eventually imposition-acquiescence-imposition-acquiescence comes down to the mass of the population at the foot of the pyramid. If they acquiesce to those levels of the hierarchy imposing on them (governments/law enforcement/doctors/media) a circuit is completed between the population and the handful of super-psychopaths in the Cult inner core at the top of the pyramid. Without a circuit-breaking refusal to obey, the sequence of imposition and acquiescence allows a staggeringly few people to impose their will upon the entirety of humankind. We are looking at the very sequence that has subjugated billions since the start of 2020. Our freedom has not been taken from us. Humanity has given it

away. Fascists do not impose fascism because there are not enough of them. Fascism is imposed by the population acquiescing to fascism. Put another way allowing their perceptions to be programmed to the extent that leads to the population giving their freedom away by giving their perceptions – their mind – away. If this circuit is not broken by humanity ceasing to cooperate with their own enslavement then nothing can change. For that to happen people have to critically think and see through the lies and window dressing and then summon the backbone to act upon what they see. The Cult spends its days working to stop either happening and its methodology is systematic and highly detailed, but it can be overcome and that is what this book is all about.

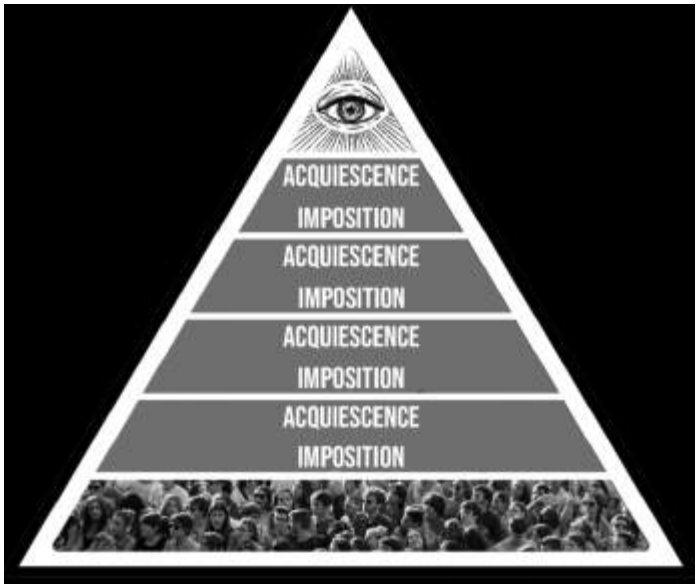

Figure 2: The simple sequence of imposition and compliance that allows a handful of people at the peak of the pyramid to dictate the lives of billions.

The Life Program

Okay, back to world number 1 or the world of the 'masses'. Observe the process of what we call 'life' and it is a perceptual download from cradle to grave. The Cult has created a global structure in which perception can be programmed and the program continually topped-up with what appears to be constant confirmation that the program is indeed true reality. The important word here is 'appears'.

This is the structure, the fly-trap, the Postage Stamp Consensus or Perceptual Mainframe, which represents that incredibly narrow band of perceived possibility delivered by the 'education' system, mainstream media, science and medicine. From the earliest age the download begins with parents who have themselves succumbed to the very programming their children are about to go through. Most parents don't do this out of malevolence and mostly it is quite the opposite. They do what they believe is best for their children and that is what the program has told them is best. Within three or four years comes the major transition from parental programming to full-blown state (Cult) programming in school, college and university where perceptually-programmed teachers and academics pass on their programming to the next generations. Teachers who resist are soon marginalised and their careers ended while children who resist are called a problem child for whom Ritalin may need to be prescribed. A few years after entering the 'world' children are under the control of authority figures representing the state telling them when they have to be there, when they can leave and when they can speak, eat, even go to the toilet. This is calculated preparation for a lifetime of obeying authority in all its forms. Reflex-action fear of authority is instilled by authority from the start. Children soon learn the carrot and stick consequences of obeying or defying authority which is underpinned daily for the rest of their life. Fortunately I daydreamed through this crap and never obeyed authority simply because it told me to. This approach to my alleged 'betters' continues to this day. There can be consequences of pursuing open-minded freedom in a world of closed-minded conformity. I spent a lot of time in school corridors after being ejected from the classroom for not taking some of it seriously and now I spend a lot of time being ejected from Facebook, YouTube and Twitter. But I can tell you that being true to yourself and not compromising your self-respect is far more exhilarating than bowing to authority for authority's sake. You don't have to be a sheep to the shepherd (authority) and the sheep dog (fear of not obeying authority).

The perceptual download continues throughout the formative years in school, college and university while script-reading 'teachers', 'academics' 'scientists', 'doctors' and 'journalists' insist that ongoing generations must be as programmed as they are. Accept the program or you will not pass your 'exams' which confirm your 'degree' of programming. It is tragic to think that many parents pressure their offspring to work hard at school to download the program and qualify for the next stage at college and university. The late, great, American comedian George Carlin said: 'Here's a bumper sticker I'd like to see: We are proud parents of a child who has resisted his teachers' attempts to break his spirit and bend him to the will of his corporate masters.' Well, the best of luck finding many of those, George. Then comes the moment to leave the formal programming years in academia and enter the 'adult' world of work. There you meet others in your chosen or prescribed arena who went through the same Postage Stamp Consensus program before you did. There is therefore overwhelming agreement between almost everyone on the basic foundations of Postage Stamp reality and the rejection, even contempt, of the few who have a mind of their own and are prepared to use it. This has two major effects. Firstly, the consensus confirms to the programmed that their download is really how things are. I mean, everyone knows that, right? Secondly, the arrogance and ignorance of Postage Stamp adherents ensure that anyone questioning the program will have unpleasant consequences for seeking their own truth and not picking their perceptions from the shelf marked: 'Things you must believe without question and if you don't you're a dangerous lunatic conspiracy theorist and a harebrained nutter'.

Every government, agency and corporation is founded on the same Postage Stamp prison cell and you can see why so many people believe the same thing while calling it their own 'opinion'. Fusion of governments and corporations in pursuit of the same agenda was the definition of fascism described by Italian dictator Benito Mussolini. The pressure to conform to perceptual norms downloaded for a lifetime is incessant and infiltrates society right

down to family groups that become censors and condemners of their own 'black sheep' for not, ironically, being sheep. We have seen an explosion of that in the 'Covid' era. Cult-owned global media unleashes its propaganda all day every day in support of the Postage Stamp and targets with abuse and ridicule anyone in the public eye who won't bend their mind to the will of the tyranny. Any response to this is denied (certainly in my case). They don't want to give a platform to expose official lies. Cult-owned-and-created Internet giants like Facebook, Google, YouTube and Twitter delete you for having an unapproved opinion. Facebook boasts that its AI censors delete 97-percent of 'hate speech' before anyone even reports it. Much of that 'hate speech' will simply be an opinion that Facebook and its masters don't want people to see. Such perceptual oppression is widely known as fascism. Even Facebook executive Benny Thomas, a 'CEO Global Planning Lead', said in comments secretly recorded by investigative journalism operation Project Veritas that Facebook is 'too powerful' and should be broken up:

> I mean, no king in history has been the ruler of two billion people, but Mark Zuckerberg is … And he's 36. That's too much for a 36-year-old ... You should not have power over two billion people. I just think that's wrong.

Thomas said Facebook-owned platforms like Instagram, Oculus, and WhatsApp needed to be separate companies. 'It's too much power when they're all one together'. That's the way the Cult likes it, however. We have an executive of a Cult organisation in Benny Thomas that doesn't know there is a Cult such is the compartmentalisation. Thomas said that Facebook and Google 'are no longer companies, they're countries'. Actually they are more powerful than countries on the basis that if you control information you control perception and control human society.

I love my oppressor

Another expression of this psychological trickery is for those who realise they are being pressured into compliance to eventually

convince themselves to believe the official narratives to protect their self-respect from accepting the truth that they have succumbed to meek and subservient compliance. Such people become some of the most vehement defenders of the system. You can see them everywhere screaming abuse at those who prefer to think for themselves and by doing so reminding the compliers of their own capitulation to conformity. 'You are talking dangerous nonsense you Covidiot!!' Are you trying to convince me or yourself? It is a potent form of Stockholm syndrome which is defined as: 'A psychological condition that occurs when a victim of abuse identifies and attaches, or bonds, positively with their abuser.' An example is hostages bonding and even 'falling in love' with their kidnappers. The syndrome has been observed in domestic violence, abused children, concentration camp inmates, prisoners of war and many and various Satanic cults. These are some traits of Stockholm syndrome listed at goodtherapy.org:

- Positive regard towards perpetrators of abuse or captor [see 'Covid'].
- Failure to cooperate with police and other government authorities when it comes to holding perpetrators of abuse or kidnapping accountable [or in the case of 'Covid' cooperating with the police to enforce and defend their captors' demands].
- Little or no effort to escape [see 'Covid'].
- Belief in the goodness of the perpetrators or kidnappers [see 'Covid'].
- Appeasement of captors. This is a manipulative strategy for maintaining one's safety. As victims get rewarded – perhaps with less abuse or even with life itself – their appeasing behaviours are reinforced [see 'Covid'].
- Learned helplessness. This can be akin to 'if you can't beat 'em, join 'em'. As the victims fail to escape the abuse or captivity, they may start giving up and soon realize it's just easier for everyone if they acquiesce all their power to their captors [see 'Covid'].

- Feelings of pity toward the abusers, believing they are actually victims themselves. Because of this, victims may go on a crusade or mission to 'save' [protect] their abuser [see the venom unleashed on those challenging the official 'Covid' narrative].
- Unwillingness to learn to detach from their perpetrators and heal. In essence, victims may tend to be less loyal to themselves than to their abuser [*definitely* see 'Covid'].

Ponder on those traits and compare them with the behaviour of great swathes of the global population who have defended governments and authorities which have spent every minute destroying their lives and livelihoods and those of their children and grandchildren since early 2020 with fascistic lockdowns, house arrest and employment deletion to 'protect' them from a 'deadly virus' that their abusers' perceptually created to bring about this very outcome. We are looking at mass Stockholm syndrome. All those that agree to concede their freedom will believe those perceptions are originating in their own independent 'mind' when in fact by conceding their reality to Stockholm syndrome they have by definition conceded any independence of mind. Listen to the 'opinions' of the acquiescing masses in this 'Covid' era and what gushes forth is the repetition of the official version of everything delivered unprocessed, unfiltered and unquestioned. The whole programming dynamic works this way. I must be free because I'm told that I am and so I think that I am.

You can see what I mean with the chapter theme of 'I'm thinking – Oh, but *are* you?' The great majority are not thinking, let alone for themselves. They are repeating what authority has told them to believe which allows them to be controlled. Weaving through this mentality is the fear that the 'conspiracy theorists' are right and this again explains the often hysterical abuse that ensues when you dare to contest the official narrative of anything. Denial is the mechanism of hiding from yourself what you don't want to be true. Telling people what they want to hear is easy, but it's an infinitely greater challenge to tell them what they would rather not be happening.

One is akin to pushing against an open door while the other is met with vehement resistance no matter what the scale of evidence. I don't want it to be true so I'll convince myself that it's not. Examples are everywhere from the denial that a partner is cheating despite all the signs to the reflex-action rejection of any idea that world events in which country after country act in exactly the same way are centrally coordinated. To accept the latter is to accept that a force of unspeakable evil is working to destroy your life and the lives of your children with nothing too horrific to achieve that end. Who the heck wants that to be true? But if we don't face reality the end is duly achieved and the consequences are far worse and ongoing than breaking through the walls of denial today with the courage to make a stand against tyranny.

Connect the dots – but how?

A crucial aspect of perceptual programming is to portray a world in which everything is random and almost nothing is connected to anything else. Randomness cannot be coordinated by its very nature and once you perceive events as random the idea they could be connected is waved away as the rantings of the tinfoil-hat brigade. You can't plan and coordinate random you idiot! No, you can't, but you can hide the coldly-calculated and long-planned behind the *illusion* of randomness. A foundation manifestation of the Renegade Mind is to scan reality for patterns that connect the apparently random and turn pixels and dots into pictures. This is the way I work and have done so for more than 30 years. You look for similarities in people, modus operandi and desired outcomes and slowly, then ever quicker, the picture forms. For instance: There would seem to be no connection between the 'Covid pandemic' hoax and the human-caused global-warming hoax and yet they are masks (appropriately) on the same face seeking the same outcome. Those pushing the global warming myth through the Club of Rome and other Cult agencies are driving the lies about 'Covid' – Bill Gates is an obvious one, but they are endless. Why would the same people be involved in both when they are clearly not connected? Oh, but they

are. Common themes with personnel are matched by common goals. The 'solutions' to both 'problems' are centralisation of global power to impose the will of the few on the many to 'save' humanity from 'Covid' and save the planet from an 'existential threat' (we need 'zero Covid' and 'zero carbon emissions'). These, in turn, connect with the 'dot' of globalisation which was coined to describe the centralisation of global power in every area of life through incessant political and corporate expansion, trading blocks and superstates like the European Union. If you are the few and you want to control the many you have to centralise power and decision-making. The more you centralise power the more power the few at the centre will have over the many; and the more that power is centralised the more power those at the centre have to centralise even quicker. The momentum of centralisation gets faster and faster which is exactly the process we have witnessed. In this way the hoaxed 'pandemic' and the fakery of human-caused global warming serve the interests of globalisation and the seizure of global power in the hands of the Cult inner-circle which is behind 'Covid', 'climate change' *and* globalisation. At this point random 'dots' become a clear and obvious picture or pattern.

Klaus Schwab, the classic Bond villain who founded the Cult's Gates-funded World Economic Forum, published a book in 2020, *The Great Reset*, in which he used the 'problem' of 'Covid' to justify a total transformation of human society to 'save' humanity from 'climate change'. Schwab said: 'The pandemic represents a rare but narrow window of opportunity to reflect, reimagine, and reset our world.' What he didn't mention is that the Cult he serves is behind both hoaxes as I show in my book *The Answer*. He and the Cult don't have to reimagine the world. They know precisely what they want and that's why they destroyed human society with 'Covid' to 'build back better' in their grand design. Their job is not to imagine, but to get humanity to imagine and agree with their plans while believing it's all random. It must be pure coincidence that 'The Great Reset' has long been the Cult's code name for the global imposition of fascism and replaced previous code-names of the 'New World

Order' used by Cult frontmen like Father George Bush and the 'New Order of the Ages' which emerged from Freemasonry and much older secret societies. New Order of the Ages appears on the reverse of the Great Seal of the United States as 'Novus ordo seclorum' underneath the Cult symbol used since way back of the pyramid and all seeing-eye (Fig 3). The pyramid is the hierarchy of human control headed by the illuminated eye that symbolises the force behind the Cult which I will expose in later chapters. The term 'Annuit Coeptis' translates as 'He favours our undertaking'. We are told the 'He' is the Christian god, but 'He' is not as I will be explaining.

Figure 3: The all-seeing eye of the Cult 'god' on the Freemason-designed Great Seal of the United States and also on the dollar bill.

Having you on

Two major Cult techniques of perceptual manipulation that relate to all this are what I have called since the 1990s Problem-Reaction-Solution (PRS) and the Totalitarian Tiptoe (TT). They can be uncovered by the inquiring mind with a simple question: Who benefits? The answer usually identifies the perpetrators of a given action or happening through the concept of 'he who most benefits from a crime is the one most likely to have committed it'. The Latin 'Cue bono?' – Who benefits? – is widely attributed to the Roman orator and statesman Marcus Tullius Cicero. No wonder it goes back so far when the concept has been relevant to human behaviour since

history was recorded. Problem-Reaction-Solution is the technique used to manipulate us every day by covertly creating a problem (or the illusion of one) and offering the solution to the problem (or the illusion of one). In the first phase you create the problem and blame someone or something else for why it has happened. This may relate to a financial collapse, terrorist attack, war, global warming or pandemic, anything in fact that will allow you to impose the 'solution' to change society in the way you desire at that time. The 'problem' doesn't have to be real. PRS is manipulation of perception and all you need is the population to believe the problem is real. Human-caused global warming and the 'Covid pandemic' only have to be *perceived* to be real for the population to accept the 'solutions' of authority. I refer to this technique as NO-Problem-Reaction-Solution. Billions did not meekly accept house arrest from early 2020 because there was a real deadly 'Covid pandemic' but because they perceived – believed – that to be the case. The antidote to Problem-Reaction-Solution is to ask who benefits from the proposed solution. Invariably it will be anyone who wants to justify more control through deletion of freedom and centralisation of power and decision-making.

The two world wars were Problem-Reaction-Solutions that transformed and realigned global society. Both were manipulated into being by the Cult as I have detailed in books since the mid-1990s. They dramatically centralised global power, especially World War Two, which led to the United Nations and other global bodies thanks to the overt and covert manipulations of the Rockefeller family and other Cult bloodlines like the Rothschilds. The UN is a stalking horse for full-blown world government that I will come to shortly. The land on which the UN building stands in New York was donated by the Rockefellers and the same Cult family was behind Big Pharma scalpel and drug 'medicine' and the creation of the World Health Organization as part of the UN. They have been stalwarts of the eugenics movement and funded Hitler's race-purity expert' Ernst Rudin. The human-caused global warming hoax has been orchestrated by the Club of Rome through the UN which is

manufacturing both the 'problem' through its Intergovernmental Panel on Climate Change and imposing the 'solution' through its Agenda 21 and Agenda 2030 which demand the total centralisation of global power to 'save the world' from a climate hoax the United Nations is itself perpetrating. What a small world the Cult can be seen to be particularly among the inner circles. The bedfellow of Problem-Reaction-Solution is the Totalitarian Tiptoe which became the Totalitarian Sprint in 2020. The technique is fashioned to hide the carefully-coordinated behind the cover of apparently random events. You start the sequence at 'A' and you know you are heading for 'Z'. You don't want people to know that and each step on the journey is presented as a random happening while all the steps strung together lead in the same direction. The speed may have quickened dramatically in recent times, but you can still see the incremental approach of the Tiptoe in the case of 'Covid' as each new imposition takes us deeper into fascism. Tell people they have to do this or that to get back to 'normal', then this and this and this. With each new demand adding to the ones that went before the population's freedom is deleted until it disappears. The spider wraps its web around the flies more comprehensively with each new diktat. I'll highlight this in more detail when I get to the 'Covid' hoax and how it has been pulled off. Another prime example of the Totalitarian Tiptoe is how the Cult-created European Union went from a 'free-trade zone' to a centralised bureaucratic dictatorship through the Tiptoe of incremental centralisation of power until nations became mere administrative units for Cult-owned dark suits in Brussels.

The antidote to ignorance is knowledge which the Cult seeks vehemently to deny us, but despite the systematic censorship to that end the Renegade Mind can overcome this by vociferously seeking out the facts no matter the impediments put in the way. There is also a method of thinking and perceiving – *knowing* – that doesn't even need names, dates, place-type facts to identify the patterns that reveal the story. I'll get to that in the final chapter. All you need to know about the manipulation of human society and to what end is still out there – *at the time of writing* – in the form of books, videos

and websites for those that really want to breach the walls of programmed perception. To access this knowledge requires the abandonment of the mainstream media as a source of information in the awareness that this is owned and controlled by the Cult and therefore promotes mass perceptions that suit the Cult. Mainstream media lies all day, every day. That is its function and very reason for being. Where it does tell the truth, here and there, is only because the truth and the Cult agenda very occasionally coincide. If you look for fact and insight to the BBC, CNN and virtually all the rest of them you are asking to be conned and perceptually programmed.

Know the outcome and you'll see the journey

Events seem random when you have no idea where the world is being taken. Once you do the random becomes the carefully planned. Know the outcome and you'll see the journey is a phrase I have been using for a long time to give context to daily happenings that appear unconnected. Does a problem, or illusion of a problem, trigger a proposed 'solution' that further drives society in the direction of the outcome? Invariably the answer will be yes and the random – *abracadabra* – becomes the clearly coordinated. So what is this outcome that unlocks the door to a massively expanded understanding of daily events? I will summarise its major aspects – the fine detail is in my other books – and those new to this information will see that the world they thought they were living in is a very different place. The foundation of the Cult agenda is the incessant centralisation of power and all such centralisation is ultimately in pursuit of Cult control on a global level. I have described for a long time the planned world structure of top-down dictatorship as the Hunger Games Society. The term obviously comes from the movie series which portrayed a world in which a few living in military-protected hi-tech luxury were the overlords of a population condemned to abject poverty in isolated 'sectors' that were not allowed to interact. 'Covid' lockdowns and travel bans anyone? The 'Hunger Games' pyramid of structural control has the inner circle of the Cult at the top with pretty much the entire

population at the bottom under their control through dependency for survival on the Cult. The whole structure is planned to be protected and enforced by a military-police state (Fig 4).

Here you have the reason for the global lockdowns of the fake pandemic to coldly destroy independent incomes and livelihoods and make everyone dependent on the 'state' (the Cult that controls the 'states'). I have warned in my books for many years about the plan to introduce a 'guaranteed income' – a barely survivable pittance – designed to impose dependency when employment was destroyed by AI technology and now even more comprehensively at great speed by the 'Covid' scam. Once the pandemic was played and lockdown consequences began to delete independent income the authorities began to talk right on cue about the need for a guaranteed income and a 'Great Reset'. Guaranteed income will be presented as benevolent governments seeking to help a desperate people – desperate as a direct result of actions of the same governments. The truth is that such payments are a trap. You will only get them if you do exactly what the authorities demand including mass vaccination (genetic manipulation). We have seen this theme already in Australia where those dependent on government benefits have them reduced if parents don't agree to have their children vaccinated according to an insane health-destroying government-dictated schedule. Calculated economic collapse applies to governments as well as people. The Cult wants rid of countries through the creation of a world state with countries broken up into regions ruled by a world government and super states like the European Union. Countries must be bankrupted, too, to this end and it's being achieved by the trillions in 'rescue packages' and furlough payments, trillions in lost taxation, and money-no-object spending on 'Covid' including constant all-medium advertising (programming) which has made the media dependent on government for much of its income. The day of reckoning is coming – as planned – for government spending and given that it has been made possible by printing money and not by production/taxation there is inflation on the way that has the

potential to wipe out monetary value. In that case there will be no need for the Cult to steal your money. It just won't be worth anything (see the German Weimar Republic before the Nazis took over). Many have been okay with lockdowns while getting a percentage of their income from so-called furlough payments without having to work. Those payments are dependent, however, on people having at least a theoretical job with a business considered non-essential and ordered to close. As these business go under because they are closed by lockdown after lockdown the furlough stops and it will for everyone eventually. Then what? The 'then what?' is precisely the idea.

Figure 4: The Hunger Games Society structure I have long warned was planned and now the 'Covid' hoax has made it possible. This is the real reason for lockdowns.

Hired hands

Between the Hunger Games Cult elite and the dependent population is planned to be a vicious military-police state (a fusion of the two into one force). This has been in the making for a long time with police looking ever more like the military and carrying weapons to match. The pandemic scam has seen this process accelerate so fast as

lockdown house arrest is brutally enforced by carefully recruited fascist minds and gormless system-servers. The police and military are planned to merge into a centrally-directed world army in a global structure headed by a world government which wouldn't be elected even by the election fixes now in place. The world army is not planned even to be human and instead wars would be fought, primarily against the population, using robot technology controlled by artificial intelligence. I have been warning about this for decades and now militaries around the world are being transformed by this very AI technology. The global regime that I describe is a particular form of fascism known as a technocracy in which decisions are not made by clueless and co-opted politicians but by unelected technocrats – scientists, engineers, technologists and bureaucrats. Cult-owned-and-controlled Silicon Valley giants are examples of technocracy and they already have far more power to direct world events than governments. They are with their censorship *selecting* governments. I know that some are calling the 'Great Reset' a Marxist communist takeover, but fascism and Marxism are different labels for the same tyranny. Tell those who lived in fascist Germany and Stalinist Russia that there was a difference in the way their freedom was deleted and their lives controlled. I could call it a fascist technocracy or a Marxist technocracy and they would be equally accurate. The Hunger Games society with its world government structure would oversee a world army, world central bank and single world cashless currency imposing its will on a microchipped population (Fig 5). Scan its different elements and see how the illusory pandemic is forcing society in this very direction at great speed. Leaders of 23 countries and the World Health Organization (WHO) backed the idea in March, 2021, of a global treaty for 'international cooperation' in 'health emergencies' and nations should 'come together as a global community for peaceful cooperation that extends beyond this crisis'. Cut the Orwellian bullshit and this means another step towards global government. The plan includes a cashless digital money system that I first warned about in 1993. Right at the start of 'Covid' the deeply corrupt Tedros

Adhanom Ghebreyesus, the crooked and merely gofer 'head' of the World Health Organization, said it was possible to catch the 'virus' by touching cash and it was better to use cashless means. The claim was ridiculous nonsense and like the whole 'Covid' mind-trick it was nothing to do with 'health' and everything to do with pushing every aspect of the Cult agenda. As a result of the Tedros lie the use of cash has plummeted. The Cult script involves a single world digital currency that would eventually be technologically embedded in the body. China is a massive global centre for the Cult and if you watch what is happening there you will know what is planned for everywhere. The Chinese government is developing a digital currency which would allow fines to be deducted immediately via AI for anyone caught on camera breaking its fantastic list of laws and the money is going to be programmable with an expiry date to ensure that no one can accrue wealth except the Cult and its operatives.

Figure 5: The structure of global control the Cult has been working towards for so long and this has been enormously advanced by the 'Covid' illusion.

Serfdom is so smart

The Cult plan is far wider, extreme, and more comprehensive than even most conspiracy researchers appreciate and I will come to the true depths of deceit and control in the chapters 'Who controls the

Cult?' and 'Escaping Wetiko'. Even the world that we know is crazy enough. We are being deluged with ever more sophisticated and controlling technology under the heading of 'smart'. We have smart televisions, smart meters, smart cards, smart cars, smart driving, smart roads, smart pills, smart patches, smart watches, smart skin, smart borders, smart pavements, smart streets, smart cities, smart communities, smart environments, smart growth, smart planet ... smart *everything* around us. Smart technologies and methods of operation are designed to interlock to create a global Smart Grid connecting the entirety of human society including human minds to create a centrally-dictated 'hive' mind. 'Smart cities' is code for densely-occupied megacities of total surveillance and control through AI. Ever more destructive frequency communication systems like 5G have been rolled out without any official testing for health and psychological effects (colossal). 5G/6G/7G systems are needed to run the Smart Grid and each one becomes more destructive of body and mind. Deleting independent income is crucial to forcing people into these AI-policed prisons by ending private property ownership (except for the Cult elite). The Cult's Great Reset now openly foresees a global society in which no one will own any possessions and everything will be rented while the Cult would own literally everything under the guise of government and corporations. The aim has been to use the lockdowns to destroy sources of income on a mass scale and when the people are destitute and in unrepayable amounts of debt (problem) Cult assets come forward with the pledge to write-off debt in return for handing over all property and possessions (solution). Everything – literally everything including people – would be connected to the Internet via AI. I was warning years ago about the coming Internet of Things (IoT) in which all devices and technology from your car to your fridge would be plugged into the Internet and controlled by AI. Now we are already there with much more to come. The next stage is the Internet of Everything (IoE) which is planned to include the connection of AI to the human brain and body to replace the human mind with a centrally-controlled AI mind. Instead of perceptions

being manipulated through control of information and censorship those perceptions would come direct from the Cult through AI. What do you think? You think whatever AI decides that you think. In human terms there would be no individual 'think' any longer. Too incredible? The ravings of a lunatic? Not at all. Cult-owned crazies in Silicon Valley have been telling us the plan for years without explaining the real motivation and calculated implications. These include Google executive and 'futurist' Ray Kurzweil who highlights the year 2030 for when this would be underway. He said:

Our thinking ... will be a hybrid of biological and non-biological thinking ... humans will be able to extend their limitations and 'think in the cloud' ... We're going to put gateways to the cloud in our brains ... We're going to gradually merge and enhance ourselves ... In my view, that's the nature of being human – we transcend our limitations.

As the technology becomes vastly superior to what we are then the small proportion that is still human gets smaller and smaller and smaller until it's just utterly negligible.

The sales-pitch of Kurzweil and Cult-owned Silicon Valley is that this would make us 'super-human' when the real aim is to make us post-human and no longer 'human' in the sense that we have come to know. The entire global population would be connected to AI and become the centrally-controlled 'hive-mind' of externally-delivered perceptions. The Smart Grid being installed to impose the Cult's will on the world is being constructed to allow particular locations – even one location – to control the whole global system. From these prime control centres, which absolutely include China and Israel, anything connected to the Internet would be switched on or off and manipulated at will. Energy systems could be cut, communication via the Internet taken down, computer-controlled driverless autonomous vehicles driven off the road, medical devices switched off, the potential is limitless given how much AI and Internet connections now run human society. We have seen nothing yet if we allow this to continue. Autonomous vehicle makers are working with law enforcement to produce cars designed to automatically pull over if they detect a police or emergency vehicle flashing from up to 100 feet away. At a police stop the car would be unlocked and the

window rolled down automatically. Vehicles would only take you where the computer (the state) allowed. The end of petrol vehicles and speed limiters on all new cars in the UK and EU from 2022 are steps leading to electric computerised transport over which ultimately you have no control. The picture is far bigger even than the Cult global network or web and that will become clear when I get to the nature of the 'spider'. There is a connection between all these happenings and the instigation of DNA-manipulating 'vaccines' (which aren't 'vaccines') justified by the 'Covid' hoax. That connection is the unfolding plan to transform the human body from a biological to a synthetic biological state and this is why synthetic biology is such a fast-emerging discipline of mainstream science. 'Covid vaccines' are infusing self-replicating synthetic genetic material into the cells to cumulatively take us on the Totalitarian Tiptoe from Human 1.0 to the synthetic biological Human 2.0 which will be physically and perceptually attached to the Smart Grid to one hundred percent control every thought, perception and deed. Humanity needs to wake up and *fast*.

This is the barest explanation of where the 'outcome' is planned to go but it's enough to see the journey happening all around us. Those new to this information will already see 'Covid' in a whole new context. I will add much more detail as we go along, but for the minutiae evidence see my mega-works, *The Answer, The Trigger* and *Everything You Need to Know But Have Never Been Told*.

Now – how does a Renegade Mind see the 'world'?

CHAPTER TWO

Renegade Perception

It is one thing to be clever and another to be wise
George R.R. Martin

A simple definition of the difference between a programmed mind and a Renegade Mind would be that one sees only dots while the other connects them to see the picture. Reading reality with accuracy requires the observer to (a) know the planned outcome and (b) realise that everything, but *everything*, is connected.

The entirety of infinite reality is connected – that's its very nature – and with human society an expression of infinite reality the same must apply. Simple cause and effect is a connection. The effect is triggered by the cause and the effect then becomes the cause of another effect. Nothing happens in isolation because it *can't*. Life in whatever reality is simple choice and consequence. We make choices and these lead to consequences. If we don't like the consequences we can make different choices and get different consequences which lead to other choices and consequences. The choice and the consequence are not only connected they are indivisible. You can't have one without the other as an old song goes. A few cannot control the world unless those being controlled allow that to happen – cause and effect, choice and consequence. Control – who has it and who doesn't – is a two-way process, a symbiotic relationship, involving the controller and controlled. 'They took my freedom away!!' Well, yes, but you also gave it to them. Humanity is

subjected to mass control because humanity has acquiesced to that control. This is all cause and effect and literally a case of give and take. In the same way world events of every kind are connected and the Cult works incessantly to sell the illusion of the random and coincidental to maintain the essential (to them) perception of dots that hide the picture. Renegade Minds know this and constantly scan the world for patterns of connection. This is absolutely pivotal in understanding the happenings in the world and without that perspective clarity is impossible. First you know the planned outcome and then you identify the steps on the journey – the day-by-day apparently random which, when connected in relation to the outcome, no longer appear as individual events, but as the proverbial *chain* of events leading in the same direction. I'll give you some examples:

Political puppet show

We are told to believe that politics is 'adversarial' in that different parties with different beliefs engage in an endless tussle for power. There may have been some truth in that up to a point – and only a point – but today divisions between 'different' parties are rhetorical not ideological. Even the rhetorical is fusing into one-speak as the parties eject any remaining free thinkers while others succumb to the ever-gathering intimidation of anyone with the 'wrong' opinion. The Cult is not a new phenomenon and can be traced back thousands of years as my books have documented. Its intergenerational initiates have been manipulating events with increasing effect the more that global power has been centralised. In ancient times the Cult secured control through the system of monarchy in which 'special' bloodlines (of which more later) demanded the right to rule as kings and queens simply by birthright and by vanquishing others who claimed the same birthright. There came a time, however, when people had matured enough to see the unfairness of such tyranny and demanded a say in who governed them. Note the word – *governed* them. Not served them – *governed* them, hence government defined as 'the political direction and control exercised over the

actions of the members, citizens, or inhabitants of communities, societies, and states; direction of the affairs of a state, community, etc.' Governments exercise control over rather than serve just like the monarchies before them. Bizarrely there are still countries like the United Kingdom which are ruled by a monarch *and* a government that officially answers to the monarch. The UK head of state and that of Commonwealth countries such as Canada, Australia and New Zealand is 'selected' by who in a *single family* had unprotected sex with whom and in what order. Pinch me it can't be true. Ouch! Shit, it is. The demise of monarchies in most countries offered a potential vacuum in which some form of free and fair society could arise and the Cult had that base covered. Monarchies had served its interests but they couldn't continue in the face of such widespread opposition and, anyway, replacing a 'royal' dictatorship that people could see with a dictatorship 'of the people' hiding behind the concept of 'democracy' presented far greater manipulative possibilities and ways of hiding coordinated tyranny behind the illusion of 'freedom'.

Democracy is quite wrongly defined as government selected by the population. This is not the case at all. It is government selected by *some* of the population (and then only in theory). This 'some' doesn't even have to be the majority as we have seen so often in first-past-the-post elections in which the so-called majority party wins fewer votes than the 'losing' parties combined. Democracy can give total power to a party in government from a minority of the votes cast. It's a sleight of hand to sell tyranny as freedom. Seventy-four million Trump-supporting Americans didn't vote for the 'Democratic' Party of Joe Biden in the distinctly dodgy election in 2020 and yet far from acknowledging the wishes and feelings of that great percentage of American society the Cult-owned Biden government set out from day one to destroy them and their right to a voice and opinion. Empty shell Biden and his Cult handlers said they were doing this to 'protect democracy'. Such is the level of lunacy and sickness to which politics has descended. Connect the dots and relate them to the desired outcome – a world government run by self-appointed technocrats and no longer even elected

politicians. While operating through its political agents in government the Cult is at the same time encouraging public distain for politicians by putting idiots and incompetents in theoretical power on the road to deleting them. The idea is to instil a public reaction that says of the technocrats: 'Well, they couldn't do any worse than the pathetic politicians.' It's all about controlling perception and Renegade Minds can see through that while programmed minds cannot when they are ignorant of both the planned outcome and the manipulation techniques employed to secure that end. This knowledge can be learned, however, and fast if people choose to get informed.

Politics may at first sight appear very difficult to control from a central point. I mean look at the 'different' parties and how would you be able to oversee them all and their constituent parts? In truth, it's very straightforward because of their structure. We are back to the pyramid of imposition and acquiescence. Organisations are structured in the same way as the system as a whole. Political parties are not open forums of free expression. They are hierarchies. I was a national spokesman for the British Green Party which claimed to be a different kind of politics in which influence and power was devolved; but I can tell you from direct experience – and it's far worse now – that Green parties are run as hierarchies like all the others however much they may try to hide that fact or kid themselves that it's not true. A very few at the top of all political parties are directing policy and personnel. They decide if you are elevated in the party or serve as a government minister and to do that you have to be a yes man or woman. Look at all the maverick political thinkers who never ascended the greasy pole. If you want to progress within the party or reach 'high-office' you need to fall into line and conform. Exceptions to this are rare indeed. Should you want to run for parliament or Congress you have to persuade the local or state level of the party to select you and for that you need to play the game as dictated by the hierarchy. If you secure election and wish to progress within the greater structure you need to go on conforming to what is acceptable to those running the hierarchy

from the peak of the pyramid. Political parties are perceptual gulags and the very fact that there are party 'Whips' appointed to 'whip' politicians into voting the way the hierarchy demands exposes the ridiculous idea that politicians are elected to serve the people they are supposed to represent. Cult operatives and manipulation has long seized control of major parties that have any chance of forming a government and at least most of those that haven't. A new party forms and the Cult goes to work to infiltrate and direct. This has reached such a level today that you see video compilations of 'leaders' of all parties whether Democrats, Republicans, Conservative, Labour and Green parroting the same Cult mantra of 'Build Back Better' and the 'Great Reset' which are straight off the Cult song-sheet to describe the transformation of global society in response to the Cult-instigated hoaxes of the 'Covid pandemic' and human-caused 'climate change'. To see Caroline Lucas, the Green Party MP that I knew when I was in the party in the 1980s, speaking in support of plans proposed by Cult operative Klaus Schwab representing the billionaire global elite is a real head-shaker.

Many parties – one master

The party system is another mind-trick and was instigated to change the nature of the dictatorship by swapping 'royalty' for dark suits that people believed – though now ever less so – represented their interests. Understanding this trick is to realise that a single force (the Cult) controls all parties either directly in terms of the major ones or through manipulation of perception and ideology with others. You don't need to manipulate Green parties to demand your transformation of society in the name of 'climate change' when they are obsessed with the lie that this is essential to 'save the planet'. You just give them a platform and away they go serving your interests while believing they are being environmentally virtuous. America's political structure is a perfect blueprint for how the two or multi-party system is really a one-party state. The Republican Party is controlled from one step back in the shadows by a group made up of billionaires and their gofers known as neoconservatives or Neocons.

I have exposed them in fine detail in my books and they were the driving force behind the policies of the imbecilic presidency of Boy George Bush which included 9/11 (see *The Trigger* for a comprehensive demolition of the official story), the subsequent 'war on terror' (war *of* terror) and the invasions of Afghanistan and Iraq. The latter was a No-Problem-Reaction-Solution based on claims by Cult operatives, including Bush and British Prime Minister Tony Blair, about Saddam Hussein's 'weapons of mass destruction' which did not exist as war criminals Bush and Blair well knew.

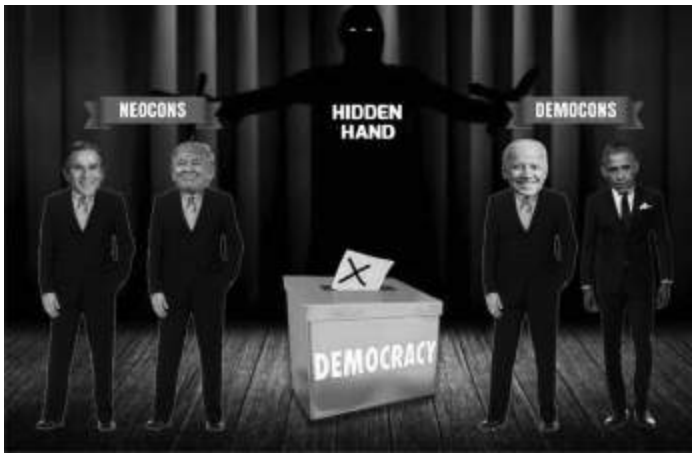

Figure 6: Different front people, different parties – same control system.

The Democratic Party has its own 'Neocon' group controlling from the background which I call the 'Democons' and here's the penny-drop – the Neocons and Democons answer to the same masters one step further back into the shadows (Fig 6). At that level of the Cult the Republican and Democrat parties are controlled by the same people and no matter which is in power the Cult is in power. This is how it works in almost every country and certainly in Britain with Conservative, Labour, Liberal Democrat and Green parties now all on the same page whatever the rhetoric may be in their feeble attempts to appear different. Neocons operated at the time of Bush through a think tank called The Project for the New American Century which in September, 2000, published a document entitled *Rebuilding America's Defenses: Strategies, Forces, and Resources*

For a New Century demanding that America fight 'multiple, simultaneous major theatre wars' as a 'core mission' to force regime-change in countries including Iraq, Libya and Syria. Neocons arranged for Bush ('Republican') and Blair ('Labour Party') to front-up the invasion of Iraq and when they departed the Democons orchestrated the targeting of Libya and Syria through Barack Obama ('Democrat') and British Prime Minister David Cameron ('Conservative Party'). We have 'different' parties and 'different' people, but the same unfolding script. The more the Cult has seized the reigns of parties and personnel the more their policies have transparently pursued the same agenda to the point where the fascist 'Covid' impositions of the Conservative junta of Jackboot Johnson in Britain were opposed by the Labour Party because they were not fascist enough. The Labour Party is likened to the US Democrats while the Conservative Party is akin to a British version of the Republicans and on both sides of the Atlantic they all speak the same language and support the direction demanded by the Cult although some more enthusiastically than others. It's a similar story in country after country because it's all centrally controlled. Oh, but what about Trump? I'll come to him shortly. Political 'choice' in the 'party' system goes like this: You vote for Party A and they get into government. You don't like what they do so next time you vote for Party B and they get into government. You don't like what they do when it's pretty much the same as Party A and why wouldn't that be with both controlled by the same force? Given that only two, sometimes three, parties have any chance of forming a government to get rid of Party B that you don't like you have to vote again for Party A which … you don't like. This, ladies and gentlemen, is what they call 'democracy' which we are told – wrongly – is a term interchangeable with 'freedom'.

The cult of cults

At this point I need to introduce a major expression of the Global Cult known as Sabbatian-Frankism. Sabbatian is also spelt as Sabbatean. I will summarise here. I have published major exposés

and detailed background in other works. Sabbatian-Frankism combines the names of two frauds posing as 'Jewish' men, Sabbatai Zevi (1626-1676), a rabbi, black magician and occultist who proclaimed he was the Jewish messiah; and Jacob Frank (1726-1791), the Polish 'Jew', black magician and occultist who said he was the reincarnation of 'messiah' Zevi and biblical patriarch Jacob. They worked across two centuries to establish the Sabbatian-Frankist cult that plays a major, indeed central, role in the manipulation of human society by the Global Cult which has its origins much further back in history than Sabbatai Zevi. I should emphasise two points here in response to the shrill voices that will scream 'anti-Semitism': (1) Sabbatian-Frankists are NOT Jewish and only pose as such to hide their cult behind a Jewish façade; and (2) my information about this cult has come from Jewish sources who have long realised that their society and community has been infiltrated and taken over by interloper Sabbatian-Frankists. Infiltration has been the foundation technique of Sabbatian-Frankism from its official origin in the 17th century. Zevi's Sabbatian sect attracted a massive following described as the biggest messianic movement in Jewish history, spreading as far as Africa and Asia, and he promised a return for the Jews to the 'Promised Land' of Israel. Sabbatianism was not Judaism but an inversion of everything that mainstream Judaism stood for. So much so that this sinister cult would have a feast day when Judaism had a fast day and whatever was forbidden in Judaism the Sabbatians were encouraged and even commanded to do. This included incest and what would be today called Satanism. Members were forbidden to marry outside the sect and there was a system of keeping their children ignorant of what they were part of until they were old enough to be trusted not to unknowingly reveal anything to outsiders. The same system is employed to this day by the Global Cult in general which Sabbatian-Frankism has enormously influenced and now largely controls.

Zevi and his Sabbatians suffered a setback with the intervention by the Sultan of the Islamic Ottoman Empire in the Middle East and what is now the Republic of Turkey where Zevi was located. The

Sultan gave him the choice of proving his 'divinity', converting to Islam or facing torture and death. Funnily enough Zevi chose to convert or at least appear to. Some of his supporters were disillusioned and drifted away, but many did not with 300 families also converting – only in theory – to Islam. They continued behind this Islamic smokescreen to follow the goals, rules and rituals of Sabbatianism and became known as 'crypto-Jews' or the 'Dönmeh' which means 'to turn'. This is rather ironic because they didn't 'turn' and instead hid behind a fake Islamic persona. The process of appearing to be one thing while being very much another would become the calling card of Sabbatianism especially after Zevi's death and the arrival of the Satanist Jacob Frank in the 18th century when the cult became Sabbatian-Frankism and plumbed still new depths of depravity and infiltration which included – still includes – human sacrifice and sex with children. Wherever Sabbatians go paedophilia and Satanism follow and is it really a surprise that Hollywood is so infested with child abuse and Satanism when it was established by Sabbatian-Frankists and is still controlled by them? Hollywood has been one of the prime vehicles for global perceptual programming and manipulation. How many believe the version of 'history' portrayed in movies when it is a travesty and inversion (again) of the truth? Rabbi Marvin Antelman describes Frankism in his book, *To Eliminate the Opiate*, as 'a movement of complete evil' while Jewish professor Gershom Scholem said of Frank in *The Messianic Idea in Judaism*: 'In all his actions [he was] a truly corrupt and degenerate individual ... one of the most frightening phenomena in the whole of Jewish history.' Frank was excommunicated by traditional rabbis, as was Zevi, but Frank was undeterred and enjoyed vital support from the House of Rothschild, the infamous banking dynasty whose inner-core are Sabbatian-Frankists and not Jews. Infiltration of the Roman Church and Vatican was instigated by Frank with many Dönmeh 'turning' again to convert to Roman Catholicism with a view to hijacking the reins of power. This was the ever-repeating modus operandi and continues to be so. Pose as an advocate of the religion, culture or country that you want to control and then

manipulate your people into the positions of authority and influence largely as advisers, administrators and Svengalis for those that appear to be in power. They did this with Judaism, Christianity (Christian Zionism is part of this), Islam and other religions and nations until Sabbatian-Frankism spanned the world as it does today.

Sabbatian Saudis and the terror network

One expression of the Sabbatian-Frankist Dönmeh within Islam is the ruling family of Saudi Arabia, the House of Saud, through which came the vile distortion of Islam known as Wahhabism. This is the violent creed followed by terrorist groups like Al-Qaeda and ISIS or Islamic State. Wahhabism is the hand-chopping, head-chopping 'religion' of Saudi Arabia which is used to keep the people in a constant state of fear so the interloper House of Saud can continue to rule. Al-Qaeda and Islamic State were lavishly funded by the House of Saud while being created and directed by the Sabbatian-Frankist network in the United States that operates through the Pentagon, CIA and the government in general of whichever 'party'. The front man for the establishment of Wahhabism in the middle of the 18th century was a Sabbatian-Frankist 'crypto-Jew' posing as Islamic called Muhammad ibn Abd al-Wahhab. His daughter would marry the son of Muhammad bin Saud who established the first Saudi state before his death in 1765 with support from the British Empire. Bin Saud's successors would establish modern Saudi Arabia in league with the British and Americans in 1932 which allowed them to seize control of Islam's major shrines in Mecca and Medina. They have dictated the direction of Sunni Islam ever since while Iran is the major centre of the Shiite version and here we have the source of at least the public conflict between them. The Sabbatian network has used its Wahhabi extremists to carry out Problem-Reaction-Solution terrorist attacks in the name of 'Al-Qaeda' and 'Islamic State' to justify a devastating 'war on terror', ever-increasing surveillance of the population and to terrify people into compliance. Another insight of the Renegade Mind is the streetwise understanding that

just because a country, location or people are attacked doesn't mean that those apparently representing that country, location or people are not behind the attackers. Often they are *orchestrating* the attacks because of the societal changes that can be then justified in the name of 'saving the population from terrorists'.

I show in great detail in *The Trigger* how Sabbatian-Frankists were the real perpetrators of 9/11 and not '19 Arab hijackers' who were blamed for what happened. Observe what was justified in the name of 9/11 alone in terms of Middle East invasions, mass surveillance and control that fulfilled the demands of the Project for the New American Century document published by the Sabbatian Neocons. What appear to be enemies are on the deep inside players on the same Sabbatian team. Israel and Arab 'royal' dictatorships are all ruled by Sabbatians and the recent peace agreements between Israel and Saudi Arabia, the United Arab Emirates (UAE) and others are only making formal what has always been the case behind the scenes. Palestinians who have been subjected to grotesque tyranny since Israel was bombed and terrorised into existence in 1948 have never stood a chance. Sabbatian-Frankists have controlled Israel (so the constant theme of violence and war which Sabbatians love) and they have controlled the Arab countries that Palestinians have looked to for real support that never comes. 'Royal families' of the Arab world in Saudi Arabia, Bahrain, UAE, etc., are all Sabbatians with allegiance to the aims of the cult and not what is best for their Arabic populations. They have stolen the oil and financial resources from their people by false claims to be 'royal dynasties' with a genetic right to rule and by employing vicious militaries to impose their will.

Satanic 'illumination'

The Satanist Jacob Frank formed an alliance in 1773 with two other Sabbatians, Mayer Amschel Rothschild (1744-1812), founder of the Rothschild banking dynasty, and Jesuit-educated fraudulent Jew, Adam Weishaupt, and this led to the formation of the Bavarian Illuminati, firstly under another name, in 1776. The Illuminati would

be the manipulating force behind the French Revolution (1789-1799) and was also involved in the American Revolution (1775-1783) before and after the Illuminati's official creation. Weishaupt would later become (in public) a Protestant Christian in archetypal Sabbatian style. I read that his name can be decoded as Adam-Weishaupt or 'the first man to lead those who know'. He wasn't a leader in the sense that he was a subordinate, but he did lead those below him in a crusade of transforming human society that still continues today. The theme was confirmed as early as 1785 when a horseman courier called Lanz was reported to be struck by lighting and extensive Illuminati documents were found in his saddlebags. They made the link to Weishaupt and detailed the plan for world takeover. Current events with 'Covid' fascism have been in the making for a very long time. Jacob Frank was jailed for 13 years by the Catholic Inquisition after his arrest in 1760 and on his release he headed for Frankfurt, Germany, home city and headquarters of the House of Rothschild where the alliance was struck with Mayer Amschel Rothschild and Weishaupt. Rothschild arranged for Frank to be given the title of Baron and he became a wealthy nobleman with a big following of Jews in Germany, the Austro-Hungarian Empire and other European countries. Most of them would have believed he was on their side.

The name 'Illuminati' came from the Zohar which is a body of works in the Jewish mystical 'bible' called the Kabbalah. 'Zohar' is the foundation of Sabbatian-Frankist belief and in Hebrew 'Zohar' means 'splendour', 'radiance', 'illuminated', and so we have 'Illuminati'. They claim to be the 'Illuminated Ones' from their knowledge systematically hidden from the human population and passed on through generations of carefully-chosen initiates in the global secret society network or Cult. Hidden knowledge includes an awareness of the Cult agenda for the world and the nature of our collective reality that I will explore later. Cult 'illumination' is symbolised by the torch held by the Statue of Liberty which was gifted to New York by French Freemasons in Paris who knew exactly what it represents. 'Liberty' symbolises the goddess worshipped in

Babylon as Queen Semiramis or Ishtar. The significance of this will become clear. Notice again the ubiquitous theme of inversion with the Statue of 'Liberty' really symbolising mass control (Fig 7). A mirror-image statute stands on an island in the River Seine in Paris from where New York Liberty originated (Fig 8). A large replica of the Liberty flame stands on top of the Pont de l'Alma tunnel in Paris where Princess Diana died in a Cult ritual described in *The Biggest Secret*. Lucifer 'the light bringer' is related to all this (and much more as we'll see) and 'Lucifer' is a central figure in Sabbatian-Frankism and its associated Satanism. Sabbatians reject the Jewish Torah, or Pentateuch, the 'five books of Moses' in the Old Testament known as Genesis, Exodus, Leviticus, Numbers, and Deuteronomy which are claimed by Judaism and Christianity to have been dictated by 'God' to Moses on Mount Sinai. Sabbatians say these do not apply to them and they seek to replace them with the Zohar to absorb Judaism and its followers into their inversion which is an expression of a much greater global inversion. They want to delete all religions and force humanity to worship a one-world religion – Sabbatian Satanism that also includes worship of the Earth goddess. Satanic themes are being more and more introduced into mainstream society and while Christianity is currently the foremost target for destruction the others are planned to follow.

Figure 7: The Cult goddess of Babylon disguised as the Statue of Liberty holding the flame of Lucifer the 'light bringer'.

Figure 8: Liberty's mirror image in Paris where the New York version originated.

Marx brothers

Rabbi Marvin Antelman connects the Illuminati to the Jacobins in *To Eliminate the Opiate* and Jacobins were the force behind the French Revolution. He links both to the Bund der Gerechten, or League of the Just, which was the network that inflicted communism/Marxism on the world. Antelman wrote:

> The original inner circle of the Bund der Gerechten consisted of born Catholics, Protestants and Jews [Sabbatian-Frankist infiltrators], and those representatives of respective subdivisions formulated schemes for the ultimate destruction of their faiths. The heretical Catholics laid plans which they felt would take a century or more for the ultimate destruction of the church; the apostate Jews for the ultimate destruction of the Jewish religion.

Sabbatian-created communism connects into this anti-religion agenda in that communism does not allow for the free practice of religion. The Sabbatian 'Bund' became the International Communist Party and Communist League and in 1848 'Marxism' was born with the Communist Manifesto of Sabbatian assets Karl Marx and Friedrich Engels. It is absolutely no coincidence that Marxism, just a different name for fascist and other centrally-controlled tyrannies, is being imposed worldwide as a result of the 'Covid' hoax and nor that Marxist/fascist China was the place where the hoax originated. The reason for this will become very clear in the chapter 'Covid: The calculated catastrophe'. The so-called 'Woke' mentality has hijacked

traditional beliefs of the political left and replaced them with far-right make-believe 'social justice' better known as Marxism. Woke will, however, be swallowed by its own perceived 'revolution' which is really the work of billionaires and billionaire corporations feigning being 'Woke'. Marxism is being touted by Wokers as a replacement for 'capitalism' when we don't have 'capitalism'. We have cartelism in which the market is stitched up by the very Cult billionaires and corporations bankrolling Woke. Billionaires love Marxism which keeps the people in servitude while they control from the top. Terminally naïve Wokers think they are 'changing the world' when it's the Cult that is doing the changing and when they have played their vital part and become surplus to requirements they, too, will be targeted. The Illuminati-Jacobins were behind the period known as 'The Terror' in the French Revolution in 1793 and 1794 when Jacobin Maximillian de Robespierre and his Orwellian 'Committee of Public Safety' killed 17,000 'enemies of the Revolution' who had once been 'friends of the Revolution'. Karl Marx (1818-1883), whose Sabbatian creed of Marxism has cost the lives of at least 100 million people, is a hero once again to Wokers who have been systematically kept ignorant of real history by their 'education' programming. As a result they now promote a Sabbatian 'Marxist' abomination destined at some point to consume them. Rabbi Antelman, who spent decades researching the Sabbatian plot, said of the League of the Just and Karl Marx:

> Contrary to popular opinion Karl Marx did not originate the Communist Manifesto. He was paid for his services by the League of the Just, which was known in its country of origin, Germany, as the Bund der Geaechteten.

Antelman said the text attributed to Marx was the work of other people and Marx 'was only repeating what others already said'. Marx was 'a hired hack – lackey of the wealthy Illuminists'. Marx famously said that religion was the 'opium of the people' (part of the Sabbatian plan to demonise religion) and Antelman called his books, *To Eliminate the Opiate*. Marx was born Jewish, but his family converted to Christianity (Sabbatian modus operandi) and he

attacked Jews, not least in his book, *A World Without Jews*. In doing so he supported the Sabbatian plan to destroy traditional Jewishness and Judaism which we are clearly seeing today with the vindictive targeting of orthodox Jews by the Sabbatian government of Israel over 'Covid' laws. I don't follow any religion and it has done much damage to the world over centuries and acted as a perceptual straightjacket. Renegade Minds, however, are always asking *why* something is being done. It doesn't matter if they agree or disagree with what is happening – *why* is it happening is the question. The 'why?' can be answered with regard to religion in that religions create interacting communities of believers when the Cult wants to dismantle all discourse, unity and interaction (see 'Covid' lockdowns) and the ultimate goal is to delete all religions for a one-world religion of Cult Satanism worshipping their 'god' of which more later. We see the same 'why?' with gun control in America. I don't have guns and don't want them, but why is the Cult seeking to disarm the population at the same time that law enforcement agencies are armed to their molars and why has every tyrant in history sought to disarm people before launching the final takeover? They include Hitler, Stalin, Pol Pot and Mao who followed confiscation with violent seizing of power. You know it's a Cult agenda by the people who immediately race to the microphones to exploit dead people in multiple shootings. Ultra-Zionist Cult lackey Senator Chuck Schumer was straight on the case after ten people were killed in Boulder, Colorado in March, 2121. Simple rule … if Schumer wants it the Cult wants it and the same with his ultra-Zionist mate the wild-eyed Senator Adam Schiff. At the same time they were calling for the disarmament of Americans, many of whom live a long way from a police response, Schumer, Schiff and the rest of these pampered clowns were sitting on Capitol Hill behind a razor-wired security fence protected by thousands of armed troops in addition to their own armed bodyguards. Mom and pop in an isolated home? They're just potential mass shooters.

Zion Mainframe

Sabbatian-Frankists and most importantly the Rothschilds were behind the creation of 'Zionism', a political movement that demanded a Jewish homeland in Israel as promised by Sabbatai Zevi. The very symbol of Israel comes from the German meaning of the name Rothschild. Dynasty founder Mayer Amschel Rothschild changed the family name from Bauer to Rothschild, or 'Red-Shield' in German, in deference to the six-pointed 'Star of David' hexagram displayed on the family's home in Frankfurt. The symbol later appeared on the flag of Israel after the Rothschilds were centrally involved in its creation. Hexagrams are not a uniquely Jewish symbol and are widely used in occult ('hidden') networks often as a symbol for Saturn (see my other books for why). Neither are Zionism and Jewishness interchangeable. Zionism is a political movement and philosophy and not a 'race' or a people. Many Jews oppose Zionism and many non-Jews, including US President Joe Biden, call themselves Zionists as does Israel-centric Donald Trump. America's support for the Israel government is pretty much a gimme with ultra-Zionist billionaires and corporations providing fantastic and dominant funding for both political parties. Former Congresswoman Cynthia McKinney has told how she was approached immediately she ran for office to 'sign the pledge' to Israel and confirm that she would always vote in that country's best interests. All American politicians are approached in this way. Anyone who refuses will get no support or funding from the enormous and all-powerful Zionist lobby that includes organisations like mega-lobby group AIPAC, the American Israel Public Affairs Committee. Trump's biggest funder was ultra-Zionist casino and media billionaire Sheldon Adelson while major funders of the Democratic Party include ultra-Zionist George Soros and ultra-Zionist financial and media mogul, Haim Saban. Some may reel back at the suggestion that Soros is an Israel-firster (Sabbatian-controlled Israel-firster), but Renegade Minds watch the actions not the words and everywhere Soros donates his billions the Sabbatian agenda benefits. In the spirit of Sabbatian inversion Soros pledged $1 billion for a new university network to promote 'liberal values and tackle intolerance'. He made the announcement during his annual speech

at the Cult-owned World Economic Forum in Davos, Switzerland, in January, 2020, after his 'harsh criticism' of 'authoritarian rulers' around the world. You can only laugh at such brazen mendacity. How *he* doesn't laugh is the mystery. Translated from the Orwellian 'liberal values and tackle intolerance' means teaching non-white people to hate white people and for white people to loathe themselves for being born white. The reason for that will become clear.

The 'Anti-Semitism' fraud

Zionists support the Jewish homeland in the land of Palestine which has been the Sabbatian-Rothschild goal for so long, but not for the benefit of Jews. Sabbatians and their global Anti-Semitism Industry have skewed public and political opinion to equate opposing the violent extremes of Zionism to be a blanket attack and condemnation of all Jewish people. Sabbatians and their global Anti-Semitism Industry have skewed public and political opinion to equate opposing the violent extremes of Zionism to be a blanket attack and condemnation of all Jewish people. This is nothing more than a Sabbatian protection racket to stop legitimate investigation and exposure of their agendas and activities. The official definition of 'anti-Semitism' has more recently been expanded to include criticism of Zionism – a *political movement* – and this was done to further stop exposure of Sabbatian infiltrators who created Zionism as we know it today in the 19th century. Renegade Minds will talk about these subjects when they know the shit that will come their way. People must decide if they want to know the truth or just cower in the corner in fear of what others will say. Sabbatians have been trying to label me as 'anti-Semitic' since the 1990s as I have uncovered more and more about their background and agendas. Useless, gutless, fraudulent 'journalists' then just repeat the smears without question and on the day I was writing this section a pair of unquestioning repeaters called Ben Quinn and Archie Bland (how appropriate) outright called me an 'anti-Semite' in the establishment propaganda sheet, the London *Guardian*, with no supporting evidence. The

Sabbatian Anti-Semitism Industry said so and who are they to question that? They wouldn't dare. Ironically 'Semitic' refers to a group of languages in the Middle East that are almost entirely Arabic. 'Anti-Semitism' becomes 'anti-Arab' which if the consequences of this misunderstanding were not so grave would be hilarious. Don't bother telling Quinn and Bland. I don't want to confuse them, bless 'em. One reason I am dubbed 'anti-Semitic' is that I wrote in the 1990s that Jewish operatives (Sabbatians) were heavily involved in the Russian Revolution when Sabbatians overthrew the Romanov dynasty. This apparently made me 'anti-Semitic'. Oh, really? Here is a section from *The Trigger*:

British journalist Robert Wilton confirmed these themes in his 1920 book *The Last Days of the Romanovs* when he studied official documents from the Russian government to identify the members of the Bolshevik ruling elite between 1917 and 1919. The Central Committee included 41 Jews among 62 members; the Council of the People's Commissars had 17 Jews out of 22 members; and 458 of the 556 most important Bolshevik positions between 1918 and 1919 were occupied by Jewish people. Only 17 were Russian. Then there were the 23 Jews among the 36 members of the vicious Cheka Soviet secret police established in 1917 who would soon appear all across the country.

Professor Robert Service of Oxford University, an expert on 20th century Russian history, found evidence that ['Jewish'] Leon Trotsky had sought to make sure that Jews were enrolled in the Red Army and were disproportionately represented in the Soviet civil bureaucracy that included the Cheka which performed mass arrests, imprisonment and executions of 'enemies of the people'. A US State Department Decimal File (861.00/5339) dated November 13th, 1918, names [Rothschild banking agent in America] Jacob Schiff and a list of ultra-Zionists as funders of the Russian Revolution leading to claims of a 'Jewish plot', but the key point missed by all is they were not 'Jews' – they were Sabbatian-Frankists.

Britain's Winston Churchill made the same error by mistake or otherwise. He wrote in a 1920 edition of the *Illustrated Sunday Herald* that those behind the Russian revolution were part of a 'worldwide conspiracy for the overthrow of civilisation and for the reconstitution of society on the basis of arrested development, of envious malevolence, and impossible equality' (see 'Woke' today because that has been created by the same network). Churchill said there was no need to exaggerate the part played in the creation of Bolshevism and in the actual bringing about of the Russian

Revolution 'by these international and for the most part atheistical Jews' ['atheistical Jews' = Sabbatians]. Churchill said it is certainly a very great one and probably outweighs all others: 'With the notable exception of Lenin, the majority of the leading figures are Jews.' He went on to describe, knowingly or not, the Sabbatian modus operandi of placing puppet leaders nominally in power while they control from the background:

> Moreover, the principal inspiration and driving power comes from the Jewish leaders. Thus Tchitcherin, a pure Russian, is eclipsed by his nominal subordinate, Litvinoff, and the influence of Russians like Bukharin or Lunacharski cannot be compared with the power of Trotsky, or of Zinovieff, the Dictator of the Red Citadel (Petrograd), or of Krassin or Radek – all Jews. In the Soviet institutions the predominance of Jews is even more astonishing. And the prominent, if not indeed the principal, part in the system of terrorism applied by the Extraordinary Commissions for Combatting Counter-Revolution has been taken by Jews, and in some notable cases by Jewesses.

What I said about seriously disproportionate involvement in the Russian Revolution by Jewish 'revolutionaries' (Sabbatians) is provable fact, but truth is no defence against the Sabbatian Anti-Semitism Industry, its repeater parrots like Quinn and Bland, and the now breathtaking network of so-called 'Woke' 'anti-hate' groups with interlocking leaderships and funding which have the role of discrediting and silencing anyone who gets too close to exposing the Sabbatians. We have seen 'truth is no defence' confirmed in legal judgements with the Saskatchewan Human Rights Commission in Canada decreeing this: 'Truthful statements can be presented in a manner that would meet the definition of hate speech, and not all truthful statements must be free from restriction.' Most 'anti-hate' activists, who are themselves consumed by hatred, are too stupid and ignorant of the world to know how they are being used. They are far too far up their own virtue-signalling arses and it's far too dark for them to see anything.

The 'revolution' game

The background and methods of the 'Russian' Revolution are straight from the Sabbatian playbook seen in the French Revolution

and endless others around the world that appear to start as a revolution of the people against tyrannical rule and end up with a regime change to more tyrannical rule overtly or covertly. Wars, terror attacks and regime overthrows follow the Sabbatian cult through history with its agents creating them as Problem-Reaction-Solutions to remove opposition on the road to world domination. Sabbatian dots connect the Rothschilds with the Illuminati, Jacobins of the French Revolution, the 'Bund' or League of the Just, the International Communist Party, Communist League and the Communist Manifesto of Karl Marx and Friedrich Engels that would lead to the Rothschild-funded Russian Revolution. The sequence comes under the heading of 'creative destruction' when you advance to your global goal by continually destroying the status quo to install a new status quo which you then also destroy. The two world wars come to mind. With each new status quo you move closer to your planned outcome. Wars and mass murder are to Sabbatians a collective blood sacrifice ritual. They are obsessed with death for many reasons and one is that death is an inversion of life. Satanists and Sabbatians are obsessed with death and often target churches and churchyards for their rituals. Inversion-obsessed Sabbatians explain the use of inverted symbolism including the *inverted* pentagram and *inverted* cross. The inversion of the cross has been related to targeting Christianity, but the cross was a religious symbol long before Christianity and its inversion is a statement about the Sabbatian mentality and goals more than any single religion.

Sabbatians operating in Germany were behind the rise of the occult-obsessed Nazis and the subsequent Jewish exodus from Germany and Europe to Palestine and the United States after World War Two. The Rothschild dynasty was at the forefront of this both as political manipulators and by funding the operation. Why would Sabbatians help to orchestrate the horrors inflicted on Jews by the Nazis and by Stalin after they organised the Russian Revolution? Sabbatians hate Jews and their religion, that's why. They pose as Jews and secure positions of control within Jewish society and play the 'anti-Semitism' card to protect themselves from exposure

through a global network of organisations answering to the Sabbatian-created-and-controlled globe-spanning intelligence network that involves a stunning web of military-intelligence operatives and operations for a tiny country of just nine million. Among them are Jewish assets who are not Sabbatians but have been convinced by them that what they are doing is for the good of Israel and the Jewish community to protect them from what they have been programmed since childhood to believe is a Jew-hating hostile world. The Jewish community is just a highly convenient cover to hide the true nature of Sabbatians. Anyone getting close to exposing their game is accused by Sabbatian place-people and gofers of 'anti-Semitism' and claiming that all Jews are part of a plot to take over the world. I am not saying that. I am saying that Sabbatians – the *real* Jew-haters – have infiltrated the Jewish community to use them both as a cover and an 'anti-Semitic' defence against exposure. Thus we have the Anti-Semitism Industry targeted researchers in this way and most Jewish people think this is justified and genuine. They don't know that their 'Jewish' leaders and institutions of state, intelligence and military are not controlled by Jews at all, but cultists and stooges of Sabbatian-Frankism. I once added my name to a pro-Jewish freedom petition online and the next time I looked my name was gone and text had been added to the petition blurb to attack me as an 'anti-Semite' such is the scale of perceptual programming.

Moving on America

I tell the story in *The Trigger* and a chapter called 'Atlantic Crossing' how particularly after Israel was established the Sabbatians moved in on the United States and eventually grasped control of government administration, the political system via both Democrats and Republicans, the intelligence community like the CIA and National Security Agency (NSA), the Pentagon and mass media. Through this seriously compartmentalised network Sabbatians and their operatives in Mossad, Israeli Defense Forces (IDF) and US agencies pulled off 9/11 and blamed it on 19 'Al-Qaeda hijackers' dominated by men from, or connected to, Sabbatian-ruled Saudi

Arabia. The '19' were not even on the planes let alone flew those big passenger jets into buildings while being largely incompetent at piloting one-engine light aircraft. 'Hijacker' Hani Hanjour who is said to have flown American Airlines Flight 77 into the Pentagon with a turn and manoeuvre most professional pilots said they would have struggled to do was banned from renting a small plane by instructors at the Freeway Airport in Bowie, Maryland, just *six weeks* earlier on the grounds that he was an incompetent pilot. The Jewish population of the world is just 0.2 percent with even that almost entirely concentrated in Israel (75 percent Jewish) and the United States (around two percent). This two percent and globally 0.2 percent refers to *Jewish* people and not Sabbatian interlopers who are a fraction of that fraction. What a sobering thought when you think of the fantastic influence on world affairs of tiny Israel and that the Project for the New America Century (PNAC) which laid out the blueprint in September, 2000, for America's war on terror and regime change wars in Iraq, Libya and Syria was founded and dominated by Sabbatians known as 'Neocons'. The document conceded that this plan would not be supported politically or publicly without a major attack on American soil and a Problem-Reaction-Solution excuse to send troops to war across the Middle East. Sabbatian Neocons said:

> ... [The] process of transformation ... [war and regime change] ... is likely to be a long one, absent some catastrophic and catalysing event – like a new Pearl Harbor.

Four months later many of those who produced that document came to power with their inane puppet George Bush from the long-time Sabbatian Bush family. They included Sabbatian Dick Cheney who was officially vice-president, but really de-facto president for the entirety of the 'Bush' government. Nine months after the 'Bush' inauguration came what Bush called at the time 'the Pearl Harbor of the 21st century' and with typical Sabbatian timing and symbolism 2001 was the 60th anniversary of the attack in 1941 by the Japanese Air Force on Pearl Harbor, Hawaii, which allowed President Franklin Delano Roosevelt to take the United States into a Sabbatian-

instigated Second World War that he said in his election campaign that he never would. The evidence is overwhelming that Roosevelt and his military and intelligence networks knew the attack was coming and did nothing to stop it, but they did make sure that America's most essential naval ships were not in Hawaii at the time. Three thousand Americans died in the Pearl Harbor attacks as they did on September 11th. By the 9/11 year of 2001 Sabbatians had widely infiltrated the US government, military and intelligence operations and used their compartmentalised assets to pull off the 'Al-Qaeda' attacks. If you read *The Trigger* it will blow your mind to see the utterly staggering concentration of 'Jewish' operatives (Sabbatian infiltrators) in essential positions of political, security, legal, law enforcement, financial and business power before, during, and after the attacks to make them happen, carry them out, and then cover their tracks – and I do mean *staggering* when you think of that 0.2 percent of the world population and two percent of Americans which are Jewish while Sabbatian infiltrators are a fraction of that. A central foundation of the 9/11 conspiracy was the hijacking of government, military, Air Force and intelligence computer systems in real time through 'back-door' access made possible by Israeli (Sabbatian) 'cyber security' software. Sabbatian-controlled Israel is on the way to rivalling Silicon Valley for domination of cyberspace and is becoming the dominant force in cyber-security which gives them access to entire computer systems and their passcodes across the world. Then add to this that Zionists head (officially) Silicon Valley giants like Google (Larry Page and Sergey Brin), Google-owned YouTube (Susan Wojcicki), Facebook (Mark Zuckerberg and Sheryl Sandberg), and Apple (Chairman Arthur D. Levinson), and that ultra-Zionist hedge fund billionaire Paul Singer has a $1 billion stake in Twitter which is only nominally headed by 'CEO' pothead Jack Dorsey. As cable news host Tucker Carlson said of Dorsey: 'There used to be debate in the medical community whether dropping a ton of acid had permanent effects and I think that debate has now ended.' Carlson made the comment after Dorsey told a hearing on Capitol Hill (if you cut through his bullshit) that he

believed in free speech so long as he got to decide what you can hear and see. These 'big names' of Silicon Valley are only front men and women for the Global Cult, not least the Sabbatians, who are the true controllers of these corporations. Does anyone still wonder why these same people and companies have been ferociously censoring and banning people (like me) for exposing any aspect of the Cult agenda and especially the truth about the 'Covid' hoax which Sabbatians have orchestrated?

The Jeffrey Epstein paedophile ring was a Sabbatian operation. He was officially 'Jewish' but he was a Sabbatian and women abused by the ring have told me about the high number of 'Jewish' people involved. The Epstein horror has Sabbatian written all over it and matches perfectly their modus operandi and obsession with sex and ritual. Epstein was running a Sabbatian blackmail ring in which famous people with political and other influence were provided with young girls for sex while everything was being filmed and recorded on hidden cameras and microphones at his New York house, Caribbean island and other properties. Epstein survivors have described this surveillance system to me and some have gone public. Once the famous politician or other figure knew he or she was on video they tended to do whatever they were told. Here we go again …when you've got them by the balls their hearts and minds will follow. Sabbatians use this blackmail technique on a wide scale across the world to entrap politicians and others they need to act as demanded. Epstein's private plane, the infamous 'Lolita Express', had many well-known passengers including Bill Clinton while Bill Gates has flown on an Epstein plane and met with him four years after Epstein had been jailed for paedophilia. They subsequently met many times at Epstein's home in New York according to a witness who was there. Epstein's infamous side-kick was Ghislaine Maxwell, daughter of Mossad agent and ultra-Zionist mega-crooked British businessman, Bob Maxwell, who at one time owned the *Daily Mirror* newspaper. Maxwell was murdered at sea on his boat in 1991 by Sabbatian-controlled Mossad when he became a liability with his

business empire collapsing as a former Mossad operative has confirmed (see *The Trigger*).

Money, money, money, funny money ...

Before I come to the Sabbatian connection with the last three US presidents I will lay out the crucial importance to Sabbatians of controlling banking and finance. Sabbatian Mayer Amschel Rothschild set out to dominate this arena in his family's quest for total global control. What is freedom? It is, in effect, choice. The more choices you have the freer you are and the fewer your choices the more you are enslaved. In the global structure created over centuries by Sabbatians the biggest decider and restrictor of choice is … money. Across the world if you ask people what they would like to do with their lives and why they are not doing that they will reply 'I don't have the money'. This is the idea. A global elite of multi-billionaires are described as 'greedy' and that is true on one level; but control of money – who has it and who doesn't – is not primarily about greed. It's about control. Sabbatians have seized ever more control of finance and sucked the wealth of the world out of the hands of the population. We talk now, after all, about the 'One-percent' and even then the wealthiest are a lot fewer even than that. This has been made possible by a money scam so outrageous and so vast it could rightly be called the scam of scams founded on creating 'money' out of nothing and 'loaning' that with interest to the population. Money out of nothing is called 'credit'. Sabbatians have asserted control over governments and banking ever more completely through the centuries and secured financial laws that allow banks to lend hugely more than they have on deposit in a confidence trick known as fractional reserve lending. Imagine if you could lend money that doesn't exist and charge the recipient interest for doing so. You would end up in jail. Bankers by contrast end up in mansions, private jets, Malibu and Monaco.

Banks are only required to keep a fraction of their deposits and wealth in their vaults and they are allowed to lend 'money' they don't have called 'credit. Go into a bank for a loan and if you succeed

the banker will not move any real wealth into your account. They will type into your account the amount of the agreed 'loan' – say £100,000. This is not wealth that really exists; it is non-existent, fresh-air, created-out-of-nothing 'credit' which has never, does not, and will never exist except in theory. Credit is backed by nothing except wind and only has buying power because people think that it has buying power and accept it in return for property, goods and services. I have described this situation as like those cartoon characters you see chasing each other and when they run over the edge of a cliff they keep running forward on fresh air until one of them looks down, realises what's happened, and they all crash into the ravine. The whole foundation of the Sabbatian financial system is to stop people looking down except for periodic moments when they want to crash the system (as in 2008 and 2020 ongoing) and reap the rewards from all the property, businesses and wealth their borrowers had signed over as 'collateral' in return for a 'loan' of fresh air. Most people think that money is somehow created by governments when it comes into existence from the start as a debt through banks 'lending' illusory money called credit. Yes, the very currency of exchange is a *debt* from day one issued as an interest-bearing loan. Why don't governments create money interest-free and lend it to their people interest-free? Governments are controlled by Sabbatians and the financial system is controlled by Sabbatians for whom interest-free money would be a nightmare come true. Sabbatians underpin their financial domination through their global network of central banks, including the privately-owned US Federal Reserve and Britain's Bank of England, and this is orchestrated by a privately-owned central bank coordination body called the Bank for International Settlements in Basle, Switzerland, created by the usual suspects including the Rockefellers and Rothschilds. Central bank chiefs don't answer to governments or the people. They answer to the Bank for International Settlements or, in other words, the Global Cult which is dominated today by Sabbatians.

Built-in disaster

There are so many constituent scams within the overall banking scam. When you take out a loan of thin-air credit only the amount of that loan is theoretically brought into circulation to add to the amount in circulation; but you are paying back the principle plus interest. The additional interest is not created and this means that with every 'loan' there is a shortfall in the money in circulation between what is borrowed and what has to be paid back. There is never even close to enough money in circulation to repay all outstanding public and private debt including interest. Coldly weaved in the very fabric of the system is the certainty that some will lose their homes, businesses and possessions to the banking 'lender'. This is less obvious in times of 'boom' when the amount of money in circulation (and the debt) is expanding through more people wanting and getting loans. When a downturn comes and the money supply contracts it becomes painfully obvious that there is not enough money to service all debt and interest. This is less obvious in times of 'boom' when the amount of money in circulation (and the debt) is expanding through more people wanting and getting loans. When a downturn comes and the money supply contracts and it becomes painfully obvious – as in 2008 and currently – that there is not enough money to service all debt and interest. Sabbatian banksters have been leading the human population through a calculated series of booms (more debt incurred) and busts (when the debt can't be repaid and the banks get the debtor's tangible wealth in exchange for non-existent 'credit'). With each 'bust' Sabbatian bankers have absorbed more of the world's tangible wealth and we end up with the One-percent. Governments are in bankruptcy levels of debt to the same system and are therefore owned by a system they do not control. The Federal Reserve, 'America's central bank', is privately-owned and American presidents only nominally appoint its chairman or woman to maintain the illusion that it's an arm of government. It's not. The 'Fed' is a cartel of private banks which handed billions to its associates and friends after the crash of 2008 and has been Sabbatian-controlled since it was manipulated into being in 1913 through the covert trickery of Rothschild banking agents Jacob Schiff and Paul

Warburg, and the Sabbatian Rockefeller family. Somehow from a Jewish population of two-percent and globally 0.2 percent (Sabbatian interlopers remember are far smaller) ultra-Zionists headed the Federal Reserve for 31 years between 1987 and 2018 in the form of Alan Greenspan, Bernard Bernanke and Janet Yellen (now Biden's Treasury Secretary) with Yellen's deputy chairman a Israeli-American duel citizen and ultra-Zionist Stanley Fischer, a former governor of the Bank of Israel. Ultra-Zionist Fed chiefs spanned the presidencies of Ronald Reagan ('Republican'), Father George Bush ('Republican'), Bill Clinton ('Democrat'), Boy George Bush ('Republican') and Barack Obama ('Democrat'). We should really add the pre-Greenspan chairman, Paul Adolph Volcker, 'appointed' by Jimmy Carter ('Democrat') who ran the Fed between 1979 and 1987 during the Carter and Reagan administrations before Greenspan took over. Volcker was a long-time associate and business partner of the Rothschilds. No matter what the 'party' officially in power the United States economy was directed by the same force. Here are members of the Obama, Trump and Biden administrations and see if you can make out a common theme.

Barack Obama ('Democrat')

Ultra-Zionists Robert Rubin, Larry Summers, and Timothy Geithner ran the US Treasury in the Clinton administration and two of them reappeared with Obama. Ultra-Zionist Fed chairman Alan Greenspan had manipulated the crash of 2008 through deregulation and jumped ship just before the disaster to make way for ultra-Zionist Bernard Bernanke to hand out trillions to Sabbatian 'too big to fail' banks and businesses, including the ubiquitous ultra-Zionist Goldman Sachs which has an ongoing staff revolving door operation between itself and major financial positions in government worldwide. Obama inherited the fallout of the crash when he took office in January, 2009, and fortunately he had the support of his ultra-Zionist White House Chief of Staff Rahm Emmanuel, son of a terrorist who helped to bomb Israel into being in 1948, and his ultra-Zionist senior adviser David Axelrod, chief strategist in Obama's two

successful presidential campaigns. Emmanuel, later mayor of Chicago and former senior fundraiser and strategist for Bill Clinton, is an example of the Sabbatian policy after Israel was established of migrating insider families to America so their children would be born American citizens. 'Obama' chose this financial team throughout his administration to respond to the Sabbatian-instigated crisis:

Timothy Geithner (ultra-Zionist) Treasury Secretary; Jacob J. Lew, Treasury Secretary; Larry Summers (ultra-Zionist), director of the White House National Economic Council; Paul Adolph Volcker (Rothschild business partner), chairman of the Economic Recovery Advisory Board; Peter Orszag (ultra-Zionist), director of the Office of Management and Budget overseeing all government spending; Penny Pritzker (ultra-Zionist), Commerce Secretary; Jared Bernstein (ultra-Zionist), chief economist and economic policy adviser to Vice President Joe Biden; Mary Schapiro (ultra-Zionist), chair of the Securities and Exchange Commission (SEC); Gary Gensler (ultra-Zionist), chairman of the Commodity Futures Trading Commission (CFTC); Sheila Bair (ultra-Zionist), chair of the Federal Deposit Insurance Corporation (FDIC); Karen Mills (ultra-Zionist), head of the Small Business Administration (SBA); Kenneth Feinberg (ultra-Zionist), Special Master for Executive [bail-out] Compensation. Feinberg would be appointed to oversee compensation (with strings) to 9/11 victims and families in a campaign to stop them having their day in court to question the official story. At the same time ultra-Zionist Bernard Bernanke was chairman of the Federal Reserve and these are only some of the ultra-Zionists with allegiance to Sabbatian-controlled Israel in the Obama government. Obama's biggest corporate donor was ultra-Zionist Goldman Sachs which had employed many in his administration.

Donald Trump ('Republican')

Trump claimed to be an outsider (he wasn't) who had come to 'drain the swamp'. He embarked on this goal by immediately appointing ultra-Zionist Steve Mnuchin, a Goldman Sachs employee for 17

years, as his Treasury Secretary. Others included Gary Cohn (ultra-Zionist), chief operating officer of Goldman Sachs, his first Director of the National Economic Council and chief economic adviser, who was later replaced by Larry Kudlow (ultra-Zionist). Trump's senior adviser throughout his four years in the White House was his sinister son-in-law Jared Kushner, a life-long friend of Israel Prime Minister Benjamin Netanyahu. Kushner is the son of a convicted crook who was pardoned by Trump in his last days in office. Other ultra-Zionists in the Trump administration included: Stephen Miller, Senior Policy Adviser; Avrahm Berkowitz, Deputy Adviser to Trump and his Senior Adviser Jared Kushner; Ivanka Trump, Adviser to the President, who converted to Judaism when she married Jared Kushner; David Friedman, Trump lawyer and Ambassador to Israel; Jason Greenblatt, Trump Organization executive vice president and chief legal officer, who was made Special Representative for International Negotiations and the Israeli-Palestinian Conflict; Rod Rosenstein, Deputy Attorney General; Elliot Abrams, Special Representative for Venezuela, then Iran; John Eisenberg, National Security Council Legal Adviser and Deputy Council to the President for National Security Affairs; Anne Neuberger, Deputy National Manager, National Security Agency; Ezra Cohen-Watnick, Acting Under Secretary of Defense for Intelligence; Elan Carr, Special Envoy to monitor and combat anti-Semitism; Len Khodorkovsky, Deputy Special Envoy to monitor and combat anti-Semitism; Reed Cordish, Assistant to the President, Intragovernmental and Technology Initiatives. Trump Vice President Mike Pence and Secretary of State Mike Pompeo, both Christian Zionists, were also vehement supporters of Israel and its goals and ambitions.

Donald 'free-speech believer' Trump pardoned a number of financial and violent criminals while ignoring calls to pardon Julian Assange and Edward Snowden whose crimes are revealing highly relevant information about government manipulation and corruption and the widespread illegal surveillance of the American people by US 'security' agencies. It's so good to know that Trump is on the side of freedom and justice and not mega-criminals with

allegiance to Sabbatian-controlled Israel. These included a pardon for Israeli spy Jonathan Pollard who was jailed for life in 1987 under the Espionage Act. Aviem Sella, the Mossad agent who recruited Pollard, was also pardoned by Trump while Assange sat in jail and Snowden remained in exile in Russia. Sella had 'fled' (was helped to escape) to Israel in 1987 and was never extradited despite being charged under the Espionage Act. A Trump White House statement said that Sella's clemency had been 'supported by Benjamin Netanyahu, Ron Dermer, Israel's US Ambassador, David Friedman, US Ambassador to Israel and Miriam Adelson, wife of leading Trump donor Sheldon Adelson who died shortly before. Other friends of Jared Kushner were pardoned along with Sholom Weiss who was believed to be serving the longest-ever white-collar prison sentence of more than 800 years in 2000. The sentence was commuted of Ponzi-schemer Eliyahu Weinstein who defrauded Jews and others out of $200 million. I did mention that Assange and Snowden were ignored, right? Trump gave Sabbatians almost everything they asked for in military and political support, moving the US Embassy from Tel Aviv to Jerusalem with its critical symbolic and literal implications for Palestinian statehood, and the 'deal of the Century' designed by Jared Kushner and David Friedman which gave the Sabbatian Israeli government the green light to substantially expand its already widespread program of building illegal Jewish-only settlements in the occupied land of the West Bank. This made a two-state 'solution' impossible by seizing all the land of a potential Palestinian homeland and that had been the plan since 1948 and then 1967 when the Arab-controlled Gaza Strip, West Bank, Sinai Peninsula and Syrian Golan Heights were occupied by Israel. All the talks about talks and road maps and delays have been buying time until the West Bank was physically occupied by Israeli real estate. Trump would have to be a monumentally ill-informed idiot not to see that this was the plan he was helping to complete. The Trump administration was in so many ways the Kushner administration which means the Netanyahu administration which means the Sabbatian administration. I understand why many opposing Cult fascism in all its forms gravitated to Trump, but he

was a crucial part of the Sabbatian plan and I will deal with this in the next chapter.

Joe Biden ('Democrat')

A barely cognitive Joe Biden took over the presidency in January, 2021, along with his fellow empty shell, Vice-President Kamala Harris, as the latest Sabbatian gofers to enter the White House. Names on the door may have changed and the 'party' – the force behind them remained the same as Zionists were appointed to a stream of pivotal areas relating to Sabbatian plans and policy. They included: Janet Yellen, Treasury Secretary, former head of the Federal Reserve, and still another ultra-Zionist running the US Treasury after Mnuchin (Trump), Lew and Geithner (Obama), and Summers and Rubin (Clinton); Anthony Blinken, Secretary of State; Wendy Sherman, Deputy Secretary of State (so that's 'Biden's' Sabbatian foreign policy sorted); Jeff Zients, White House coronavirus coordinator; Rochelle Walensky, head of the Centers for Disease Control; Rachel Levine, transgender deputy health secretary (that's 'Covid' hoax policy under control); Merrick Garland, Attorney General; Alejandro Mayorkas, Secretary of Homeland Security; Cass Sunstein, Homeland Security with responsibility for new immigration laws; Avril Haines, Director of National Intelligence; Anne Neuberger, National Security Agency cybersecurity director (note, cybersecurity); David Cohen, CIA Deputy Director; Ronald Klain, Biden's Chief of Staff (see Rahm Emanuel); Eric Lander, a 'leading geneticist', Office of Science and Technology Policy director (see Smart Grid, synthetic biology agenda); Jessica Rosenworcel, acting head of the Federal Communications Commission (FCC) which controls Smart Grid technology policy and electromagnetic communication systems including 5G. How can it be that so many pivotal positions are held by two-percent of the American population and 0.2 percent of the world population administration after administration no matter who is the president and what is the party? It's a coincidence? Of course it's not and this is why Sabbatians have built their colossal global web of interlocking 'anti-

hate' hate groups to condemn anyone who asks these glaring questions as an 'anti-Semite'. The way that Jewish people horrifically abused in Sabbatian-backed Nazi Germany are exploited to this end is stomach-turning and disgusting beyond words.

Political fusion

Sabbatian manipulation has reversed the roles of Republicans and Democrats and the same has happened in Britain with the Conservative and Labour Parties. Republicans and Conservatives were always labelled the 'right' and Democrats and Labour the 'left', but look at the policy positions now and the Democrat-Labour 'left' has moved further to the 'right' than Republicans and Conservatives under the banner of 'Woke', the Cult-created far-right tyranny. Where once the Democrat-Labour 'left' defended free speech and human rights they now seek to delete them and as I said earlier despite the 'Covid' fascism of the Jackboot Johnson Conservative government in the UK the Labour Party of leader Keir Starmer demanded even more extreme measures. The Labour Party has been very publicly absorbed by Sabbatians after a political and media onslaught against the previous leader, the weak and inept Jeremy Corbyn, over made-up allegations of 'anti-Semitism' both by him and his party. The plan was clear with this 'anti-Semite' propaganda and what was required in response was a swift and decisive 'fuck off' from Corbyn and a statement to expose the Anti-Semitism Industry (Sabbatian) attempt to silence Labour criticism of the Israeli government (Sabbatians) and purge the party of all dissent against the extremes of ultra-Zionism (Sabbatians). Instead Corbyn and his party fell to their knees and appeased the abusers which, by definition, is impossible. Appeasing one demand leads only to a new demand to be appeased until takeover is complete. Like I say – 'fuck off' would have been a much more effective policy and I have used it myself with great effect over the years when Sabbatians are on my case which is most of the time. I consider that fact a great compliment, by the way. The outcome of the Labour Party capitulation is that we now have a Sabbatian-controlled

Conservative Party 'opposed' by a Sabbatian-controlled Labour Party in a one-party Sabbatian state that hurtles towards the extremes of tyranny (the Sabbatian cult agenda). In America the situation is the same. Labour's Keir Starmer spends his days on his knees with his tongue out pointing to Tel Aviv, or I guess now Jerusalem, while Boris Johnson has an 'anti-Semitism czar' in the form of former Labour MP John Mann who keeps Starmer company on his prayer mat.

Sabbatian influence can be seen in Jewish members of the Labour Party who have been ejected for criticism of Israel including those from families that suffered in Nazi Germany. Sabbatians despise real Jewish people and target them even more harshly because it is so much more difficult to dub them 'anti-Semitic' although in their desperation they do try.

CHAPTER THREE

The Pushbacker sting

Until you realize how easy it is for your mind to be manipulated, you remain the puppet of someone else's game
Evita Ochel

I will use the presidencies of Trump and Biden to show how the manipulation of the one-party state plays out behind the illusion of political choice across the world. No two presidencies could – on the face of it – be more different and apparently at odds in terms of direction and policy.

A Renegade Mind sees beyond the obvious and focuses on outcomes and consequences and not image, words and waffle. The Cult embarked on a campaign to divide America between those who blindly support its agenda (the mentality known as 'Woke') and those who are pushing back on where the Cult and its Sabbatians want to go. This presents infinite possibilities for dividing and ruling the population by setting them at war with each other and allows a perceptual ring fence of demonisation to encircle the Pushbackers in a modern version of the Little Big Horn in 1876 when American cavalry led by Lieutenant Colonel George Custer were drawn into a trap, surrounded and killed by Native American tribes defending their land of thousands of years from being seized by the government. In this modern version the roles are reversed and it's those defending themselves from the Sabbatian government who are surrounded and the government that's seeking to destroy them. This trap was set years ago and to explain how we must return to 2016

and the emergence of Donald Trump as a candidate to be President of the United States. He set out to overcome the best part of 20 other candidates in the Republican Party before and during the primaries and was not considered by many in those early stages to have a prayer of living in the White House. The Republican Party was said to have great reservations about Trump and yet somehow he won the nomination. When you know how American politics works – politics in general – there is no way that Trump could have become the party's candidate unless the Sabbatian-controlled 'Neocons' that run the Republican Party wanted that to happen. We saw the proof in emails and documents made public by WikiLeaks that the Democratic Party hierarchy, or Democons, systematically undermined the campaign of Bernie Sanders to make sure that Sabbatian gofer Hillary Clinton won the nomination to be their presidential candidate. If the Democons could do that then the Neocons in the Republican Party could have derailed Trump in the same way. But they didn't and at that stage I began to conclude that Trump could well be the one chosen to be president. If that was the case the 'why' was pretty clear to see – the goal of dividing America between Cult agenda-supporting Wokers and Pushbackers who gravitated to Trump because he was telling them what they wanted to hear. His constituency of support had been increasingly ignored and voiceless for decades and profoundly through the eight years of Sabbatian puppet Barack Obama. Now here was someone speaking their language of pulling back from the incessant globalisation of political and economic power, the exporting of American jobs to China and elsewhere by 'American' (Sabbatian) corporations, the deletion of free speech, and the mass immigration policies that had further devastated job opportunities for the urban working class of all races and the once American heartlands of the Midwest.

Beware the forked tongue

Those people collectively sighed with relief that at last a political leader was apparently on their side, but another trait of the Renegade Mind is that you look even harder at people telling you

what you want to hear than those who are telling you otherwise. Obviously as I said earlier people wish what they want to hear to be true and genuine and they are much more likely to believe that than someone saying what they don't want to here and don't want to be true. Sales people are taught to be skilled in eliciting by calculated questioning what their customers want to hear and repeating that back to them as their own opinion to get their targets to like and trust them. Assets of the Cult are also sales people in the sense of selling perception. To read Cult manipulation you have to play the long and expanded game and not fall for the Vaudeville show of party politics. Both American parties are vehicles for the Cult and they exploit them in different ways depending on what the agenda requires at that moment. Trump and the Republicans were used to be the focus of dividing America and isolating Pushbackers to open the way for a Biden presidency to become the most extreme in American history by advancing the full-blown Woke (Cult) agenda with the aim of destroying and silencing Pushbackers now labelled Nazi Trump supporters and white supremacists.

Sabbatians wanted Trump in office for the reasons described by ultra-Zionist Saul Alinsky (1909-1972) who was promoting the Woke philosophy through 'community organising' long before anyone had heard of it. In those days it still went by its traditional name of Marxism. The reason for the manipulated Trump phenomenon was laid out in Alinsky's 1971 book, *Rules for Radicals*, which was his blueprint for overthrowing democratic and other regimes and replacing them with Sabbatian Marxism. Not surprisingly his to-do list was evident in the Sabbatian French and Russian 'Revolutions' and that in China which will become very relevant in the next chapter about the 'Covid' hoax. Among Alinsky's followers have been the deeply corrupt Barack Obama, House Speaker Nancy Pelosi and Hillary Clinton who described him as a 'hero'. All three are Sabbatian stooges with Pelosi personifying the arrogant corrupt idiocy that so widely fronts up for the Cult inner core. Predictably as a Sabbatian advocate of the 'light-bringer' Alinsky features Lucifer on the dedication page of his book as the original radical who gained

his own kingdom ('Earth' as we shall see). One of Alinsky's golden radical rules was to pick an individual and focus all attention, hatred and blame on them and not to target faceless bureaucracies and corporations. *Rules for Radicals* is really a Sabbatian handbook with its contents repeatedly employed all over the world for centuries and why wouldn't Sabbatians bring to power their designer-villain to be used as the individual on which all attention, hatred and blame was bestowed? This is what they did and the only question for me is how much Trump knew that and how much he was manipulated. A bit of both, I suspect. This was Alinsky's Trump technique from a man who died in 1972. The technique has spanned history:

Pick the target, freeze it, personalize it, polarize it. Don't try to attack abstract corporations or bureaucracies. Identify a responsible individual. Ignore attempts to shift or spread the blame.

From the moment Trump came to illusory power everything was about him. It wasn't about Republican policy or opinion, but all about Trump. Everything he did was presented in negative, derogatory and abusive terms by the Sabbatian-dominated media led by Cult operations such as CNN, MSNBC, *The New York Times* and the Jeff Bezos-owned *Washington Post* – 'Pick the target, freeze it, personalize it, polarize it.' Trump was turned into a demon to be vilified by those who hated him and a demi-god loved by those who worshipped him. This, in turn, had his supporters, too, presented as equally demonic in preparation for the punchline later down the line when Biden was about to take office. It was here's a Trump, there's a Trump, everywhere a Trump, Trump. Virtually every news story or happening was filtered through the lens of 'The Donald'. You loved him or hated him and which one you chose was said to define you as Satan's spawn or a paragon of virtue. Even supporting some Trump policies or statements and not others was enough for an assault on your character. No shades of grey were or are allowed. Everything is black and white (literally and figuratively). A Californian I knew had her head utterly scrambled by her hatred for Trump while telling people they should love each other. She was so totally consumed by

Trump Derangement Syndrome as it became to be known that this glaring contradiction would never have occurred to her. By definition anyone who criticised Trump or praised his opponents was a hero and this lady described Joe Biden as 'a kind, honest gentleman' when he's a provable liar, mega-crook and vicious piece of work to boot. Sabbatians had indeed divided America using Trump as the fall-guy and all along the clock was ticking on the consequences for his supporters.

In hock to his masters

Trump gave Sabbatians via Israel almost everything they wanted in his four years. Ask and you shall receive was the dynamic between himself and Benjamin Netanyahu orchestrated by Trump's ultra-Zionist son-in-law Jared Kushner, his ultra-Zionist Ambassador to Israel, David Friedman, and ultra-Zionist 'Israel adviser', Jason Greenblatt. The last two were central to the running and protecting from collapse of his business empire, the Trump Organisation, and colossal business failures made him forever beholding to Sabbatian networks that bailed him out. By the start of the 1990s Trump owed $4 billion to banks that he couldn't pay and almost $1billion of that was down to him personally and not his companies. This mega-disaster was the result of building two new casinos in Atlantic City and buying the enormous Taj Mahal operation which led to crippling debt payments. He had borrowed fantastic sums from 72 banks with major Sabbatian connections and although the scale of debt should have had him living in a tent alongside the highway they never foreclosed. A plan was devised to lift Trump from the mire by BT Securities Corporation and Rothschild Inc. and the case was handled by Wilber Ross who had worked for the Rothschilds for 27 years. Ross would be named US Commerce Secretary after Trump's election. Another crucial figure in saving Trump was ultra-Zionist 'investor' Carl Icahn who bought the Taj Mahal casino. Icahn was made special economic adviser on financial regulation in the Trump administration. He didn't stay long but still managed to find time to make a tidy sum of a reported $31.3 million when he sold his

holdings affected by the price of steel three days before Trump imposed a 235 percent tariff on steel imports. What amazing bits of luck these people have. Trump and Sabbatian operatives have long had a close association and his mentor and legal adviser from the early 1970s until 1986 was the dark and genetically corrupt ultra-Zionist Roy Cohn who was chief counsel to Senator Joseph McCarthy's 'communist' witch-hunt in the 1950s. *Esquire* magazine published an article about Cohn with the headline 'Don't mess with Roy Cohn'. He was described as the most feared lawyer in New York and 'a ruthless master of dirty tricks ... [with] ... more than one Mafia Don on speed dial'. Cohn's influence, contacts, support and protection made Trump a front man for Sabbatians in New York with their connections to one of Cohn's many criminal employers, the 'Russian' Sabbatian Mafia. Israel-centric media mogul Rupert Murdoch was introduced to Trump by Cohn and they started a long friendship. Cohn died in 1986 weeks after being disbarred for unethical conduct by the Appellate Division of the New York State Supreme Court. The wheels of justice do indeed run slow given the length of Cohn's crooked career.

QAnon-sense

We are asked to believe that Donald Trump with his fundamental connections to Sabbatian networks and operatives has been leading the fight to stop the Sabbatian agenda for the fascistic control of America and the world. Sure he has. A man entrapped during his years in the White House by Sabbatian operatives and whose biggest financial donor was casino billionaire Sheldon Adelson who was Sabbatian to his DNA?? Oh, do come on. Trump has been used to divide America and isolate Pushbackers on the Cult agenda under the heading of 'Trump supporters', 'insurrectionists' and 'white supremacists'. The US Intelligence/Mossad Psyop or psychological operation known as QAnon emerged during the Trump years as a central pillar in the Sabbatian campaign to lead Pushbackers into the trap set by those that wished to destroy them. I knew from the start that QAnon was a scam because I had seen the same scenario many

times before over 30 years under different names and I had written about one in particular in the books. 'Not again' was my reaction when QAnon came to the fore. The same script is pulled out every few years and a new name added to the letterhead. The story always takes the same form: 'Insiders' or 'the good guys' in the government-intelligence-military 'Deep State' apparatus were going to instigate mass arrests of the 'bad guys' which would include the Rockefellers, Rothschilds, Barack Obama, Hillary Clinton, George Soros, etc., etc. Dates are given for when the 'good guys' are going to move in, but the dates pass without incident and new dates are given which pass without incident. The central message to Pushbackers in each case is that they don't have to do anything because there is 'a plan' and it is all going to be sorted by the 'good guys' on the inside. 'Trust the plan' was a QAnon mantra when the only plan was to misdirect Pushbackers into putting their trust in a Psyop they believed to be real. Beware, beware, those who tell you what you want to hear and always check it out. Right up to Biden's inauguration QAnon was still claiming that 'the Storm' was coming and Trump would stay on as president when Biden and his cronies were arrested and jailed. It was never going to happen and of course it didn't, but what did happen as a result provided that punchline to the Sabbatian Trump/QAnon Psyop.

On January 6th, 2021, a very big crowd of Trump supporters gathered in the National Mall in Washington DC down from the Capitol Building to protest at what they believed to be widespread corruption and vote fraud that stopped Trump being re-elected for a second term as president in November, 2020. I say as someone that does not support Trump or Biden that the evidence is clear that major vote-fixing went on to favour Biden, a man with cognitive problems so advanced he can often hardly string a sentence together without reading the words written for him on the Teleprompter. Glaring ballot discrepancies included serious questions about electronic voting machines that make vote rigging a comparative cinch and hundreds of thousands of paper votes that suddenly appeared during already advanced vote counts and virtually all of

them for Biden. Early Trump leads in crucial swing states suddenly began to close and disappear. The pandemic hoax was used as the excuse to issue almost limitless numbers of mail-in ballots with no checks to establish that the recipients were still alive or lived at that address. They were sent to streams of people who had not even asked for them. Private organisations were employed to gather these ballots and who knows what they did with them before they turned up at the counts. The American election system has been manipulated over decades to become a sick joke with more holes than a Swiss cheese for the express purpose of dictating the results. Then there was the criminal manipulation of information by Sabbatian tech giants like Facebook, Twitter and Google-owned YouTube which deleted pro-Trump, anti-Biden accounts and posts while everything in support of Biden was left alone. Sabbatians wanted Biden to win because after the dividing of America it was time for full-on Woke and every aspect of the Cult agenda to be unleashed.

Hunter gatherer

Extreme Silicon Valley bias included blocking information by the *New York Post* exposing a Biden scandal that should have ended his bid for president in the final weeks of the campaign. Hunter Biden, his monumentally corrupt son, is reported to have sent a laptop to be repaired at a local store and failed to return for it. Time passed until the laptop became the property of the store for non-payment of the bill. When the owner saw what was on the hard drive he gave a copy to the FBI who did nothing even though it confirmed widespread corruption in which the Joe Biden family were using his political position, especially when he was vice president to Obama, to make multiple millions in countries around the world and most notably Ukraine and China. Hunter Biden's one-time business partner Tony Bobulinski went public when the story broke in the *New York Post* to confirm the corruption he saw and that Joe Biden not only knew what was going on he also profited from the spoils. Millions were handed over by a Chinese company with close

connections – like all major businesses in China – to the Chinese communist party of President Xi Jinping. Joe Biden even boasted at a meeting of the Cult's World Economic Forum that as vice president he had ordered the government of Ukraine to fire a prosecutor. What he didn't mention was that the same man just happened to be investigating an energy company which was part of Hunter Biden's corrupt portfolio. The company was paying him big bucks for no other reason than the influence his father had. Overnight Biden's presidential campaign should have been over given that he had lied publicly about not knowing what his son was doing. Instead almost the entire Sabbatian-owned mainstream media and Sabbatian-owned Silicon Valley suppressed circulation of the story. This alone went a mighty way to rigging the election of 2020. Cult assets like Mark Zuckerberg at Facebook also spent hundreds of millions to be used in support of Biden and vote 'administration'.

The Cult had used Trump as the focus to divide America and was now desperate to bring in moronic, pliable, corrupt Biden to complete the double-whammy. No way were they going to let little things like the will of the people thwart their plan. Silicon Valley widely censored claims that the election was rigged because it *was* rigged. For the same reason anyone claiming it was rigged was denounced as a 'white supremacist' including the pathetically few Republican politicians willing to say so. Right across the media where the claim was mentioned it was described as a 'false claim' even though these excuses for 'journalists' would have done no research into the subject whatsoever. Trump won seven million more votes than any sitting president had ever achieved while somehow a cognitively-challenged soon to be 78-year-old who was hidden away from the public for most of the campaign managed to win more votes than any presidential candidate in history. It makes no sense. You only had to see election rallies for both candidates to witness the enthusiasm for Trump and the apathy for Biden. Tens of thousands would attend Trump events while Biden was speaking in empty car parks with often only television crews attending and framing their shots to hide the fact that no one was there. It was pathetic to see

footage come to light of Biden standing at a podium making speeches only to TV crews and party fixers while reading the words written for him on massive Teleprompter screens. So, yes, those protestors on January 6th had a point about election rigging, but some were about to walk into a trap laid for them in Washington by the Cult Deep State and its QAnon Psyop. This was the Capitol Hill riot ludicrously dubbed an 'insurrection'.

The spider and the fly

Renegade Minds know there are not two 'sides' in politics, only one side, the Cult, working through all 'sides'. It's a stage show, a puppet show, to direct the perceptions of the population into focusing on diversions like parties and candidates while missing the puppeteers with their hands holding all the strings. The Capitol Hill 'insurrection' brings us back to the Little Big Horn. Having created two distinct opposing groupings – Woke and Pushbackers – the trap was about to be sprung. Pushbackers were to be encircled and isolated by associating them all in the public mind with Trump and then labelling Trump as some sort of Confederate leader. I knew immediately that the Capitol riot was a set-up because of two things. One was how easy the rioters got into the building with virtually no credible resistance and secondly I could see – as with the 'Covid' hoax in the West at the start of 2020 – how the Cult could exploit the situation to move its agenda forward with great speed. My experience of Cult techniques and activities over more than 30 years has showed me that while they do exploit situations they haven't themselves created this never happens with events of fundamental agenda significance. Every time major events giving cultists the excuse to rapidly advance their plan you find they are manipulated into being for the specific reason of providing that excuse – Problem-Reaction-Solution. Only a tiny minority of the huge crowd of Washington protestors sought to gain entry to the Capitol by smashing windows and breaching doors. That didn't matter. The whole crowd and all Pushbackers, even if they did not support Trump, were going to be lumped together as dangerous

insurrectionists and conspiracy theorists. The latter term came into widespread use through a CIA memo in the 1960s aimed at discrediting those questioning the nonsensical official story of the Kennedy assassination and it subsequently became widely employed by the media. It's still being used by inept 'journalists' with no idea of its origin to discredit anyone questioning anything that authority claims to be true. When you are perpetrating a conspiracy you need to discredit the very word itself even though the dictionary definition of conspiracy is merely 'the activity of secretly planning with other people to do something bad or illegal' and 'a general agreement to keep silent about a subject for the purpose of keeping it secret'. On that basis there are conspiracies almost wherever you look. For obvious reasons the Cult and its lapdog media have to claim there are no conspiracies even though the word appears in state laws as with conspiracy to defraud, to murder, and to corrupt public morals.

Agent provocateurs are widely used by the Cult Deep State to manipulate genuine people into acting in ways that suit the desired outcome. By genuine in this case I mean protestors genuinely supporting Trump and claims that the election was stolen. In among them, however, were agents of the state wearing the garb of Trump supporters and QAnon to pump-prime the Capital riot which some genuine Trump supporters naively fell for. I described the situation as 'Come into my parlour said the spider to the fly'. Leaflets appeared through the Woke paramilitary arm Antifa, the anti-fascist fascists, calling on supporters to turn up in Washington looking like Trump supporters even though they hated him. Some of those arrested for breaching the Capitol Building were sourced to Antifa and its stable mate Black Lives Matter. Both organisations are funded by Cult billionaires and corporations. One man charged for the riot was according to his lawyer a former FBI agent who had held top secret security clearance for 40 years. Attorney Thomas Plofchan said of his client, 66-year-old Thomas Edward Caldwell:

He has held a Top Secret Security Clearance since 1979 and has undergone multiple Special Background Investigations in support of his clearances. After retiring from the Navy, he

worked as a section chief for the Federal Bureau of Investigation from 2009-2010 as a GS-12 [mid-level employee].

He also formed and operated a consulting firm performing work, often classified, for U.S government customers including the US. Drug Enforcement Agency, Department of Housing and Urban Development, the US Coast Guard, and the US Army Personnel Command.

A judge later released Caldwell pending trial in the absence of evidence about a conspiracy or that he tried to force his way into the building. *The New York Post* reported a 'law enforcement source' as saying that 'at least two known Antifa members were spotted' on camera among Trump supporters during the riot while one of the rioters arrested was John Earle Sullivan, a seriously extreme Black Lives Matter Trump-hater from Utah who was previously arrested and charged in July, 2020, over a BLM-Antifa riot in which drivers were threatened and one was shot. Sullivan is the founder of Utah-based Insurgence USA which is an affiliate of the Cult-created-and-funded Black Lives Matter movement. Footage appeared and was then deleted by Twitter of Trump supporters calling out Antifa infiltrators and a group was filmed changing into pro-Trump clothing before the riot. Security at the building was *pathetic* – as planned. Colonel Leroy Fletcher Prouty, a man with long experience in covert operations working with the US security apparatus, once described the tell-tale sign to identify who is involved in an assassination. He said:

No one has to direct an assassination – it happens. The active role is played secretly by permitting it to happen. This is the greatest single clue. Who has the power to call off or reduce the usual security precautions?

This principle applies to many other situations and certainly to the Capitol riot of January 6th, 2021.

The sting

With such a big and potentially angry crowd known to be gathering near the Capitol the security apparatus would have had a major police detail to defend the building with National Guard troops on

standby given the strength of feeling among people arriving from all over America encouraged by the QAnon Psyop and statements by Donald Trump. Instead Capitol Police 'security' was flimsy, weak, and easily breached. The same number of officers was deployed as on a regular day and that is a blatant red flag. They were not staffed or equipped for a possible riot that had been an obvious possibility in the circumstances. No protective and effective fencing worth the name was put in place and there were no contingency plans. The whole thing was basically a case of standing aside and waving people in. Once inside police mostly backed off apart from one Capitol police officer who ridiculously shot dead unarmed Air Force veteran protestor Ashli Babbitt without a warning as she climbed through a broken window. The 'investigation' refused to name or charge the officer after what must surely be considered a murder in the circumstances. They just lifted a carpet and swept. The story was endlessly repeated about five people dying in the 'armed insurrection' when there was no report of rioters using weapons. Apart from Babbitt the other four died from a heart attack, strokes and apparently a drug overdose. Capitol police officer Brian Sicknick was reported to have died after being bludgeoned with a fire extinguisher when he was alive after the riot was over and died later of what the Washington Medical Examiner's Office said was a stroke. Sicknick had no external injuries. The lies were delivered like rapid fire. There was a narrative to build with incessant repetition of the lie until the lie became the accepted 'everybody knows that' truth. The 'Big Lie' technique of Nazi Propaganda Minister Joseph Goebbels is constantly used by the Cult which was behind the Nazis and is today behind the 'Covid' and 'climate change' hoaxes. Goebbels said:

> If you tell a lie big enough and keep repeating it, people will eventually come to believe it. The lie can be maintained only for such time as the State can shield the people from the political, economic and/or military consequences of the lie. It thus becomes vitally important for the State to use all of its powers to repress dissent, for the truth is the mortal enemy of the lie, and thus by extension, the truth is the greatest enemy of the State.

Most protestors had a free run of the Capitol Building. This allowed pictures to be taken of rioters in iconic parts of the building including the Senate chamber which could be used as propaganda images against all Pushbackers. One Congresswoman described the scene as 'the worst kind of non-security anybody could ever imagine'. Well, the first part was true, but someone obviously did imagine it and made sure it happened. Some photographs most widely circulated featured people wearing QAnon symbols and now the Psyop would be used to dub all QAnon followers with the ubiquitous fit-all label of 'white supremacist' and 'insurrectionists'. When a Muslim extremist called Noah Green drove his car at two police officers at the Capitol Building killing one in April, 2021, there was no such political and media hysteria. They were just disappointed he wasn't white.

The witch-hunt

Government prosecutor Michael Sherwin, an aggressive, dark-eyed, professional Rottweiler led the 'investigation' and to call it over the top would be to understate reality a thousand fold. Hundreds were tracked down and arrested for the crime of having the wrong political views and people were jailed who had done nothing more than walk in the building, committed no violence or damage to property, took a few pictures and left. They were labelled a 'threat to the Republic' while Biden sat in the White House signing executive orders written for him that were dismantling 'the Republic'. Even when judges ruled that a mother and son should not be in jail the government kept them there. Some of those arrested have been badly beaten by prison guards in Washington and lawyers for one man said he suffered a fractured skull and was made blind in one eye. Meanwhile a woman is shot dead for no reason by a Capitol Police officer and we are not allowed to know who he is never mind what has happened to him although that will be *nothing*. The Cult's QAnon/Trump sting to identify and isolate Pushbackers and then target them on the road to crushing and deleting them was a resounding success. You would have thought the Russians had

invaded the building at gunpoint and lined up senators for a firing squad to see the political and media reaction. Congresswoman Alexandria Ocasio-Cortez is a child in a woman's body, a terrible-twos, me, me, me, Woker narcissist of such proportions that words have no meaning. She said she thought she was going to die when 'insurrectionists' banged on her office door. It turned out she wasn't even in the Capitol Building when the riot was happening and the 'banging' was a Capitol Police officer. She referred to herself as a 'survivor' which is an insult to all those true survivors of violent and sexual abuse while she lives her pampered and privileged life talking drivel for a living. Her Woke colleague and fellow mega-narcissist Rashida Tlaib broke down describing the devastating effect on her, too, of *not being* in the building when the rioters were there. Ocasio-Cortez and Tlaib are members of a fully-Woke group of Congresswomen known as 'The Squad' along with Ilhan Omar and Ayanna Pressley. The Squad from what I can see can be identified by its vehement anti-white racism, anti-white men agenda, and, as always in these cases, the absence of brain cells on active duty.

The usual suspects were on the riot case immediately in the form of Democrat ultra-Zionist senators and operatives Chuck Schumer and Adam Schiff demanding that Trump be impeached for 'his part in the insurrection'. The same pair of prats had led the failed impeachment of Trump over the invented 'Russia collusion' nonsense which claimed Russia had helped Trump win the 2016 election. I didn't realise that Tel Aviv had been relocated just outside Moscow. I must find an up-to-date map. The Russia hoax was a Sabbatian operation to keep Trump occupied and impotent and to stop any rapport with Russia which the Cult wants to retain as a perceptual enemy to be pulled out at will. Puppet Biden began attacking Russia when he came to office as the Cult seeks more upheaval, division and war across the world. A two-year stage show 'Russia collusion inquiry' headed by the not-very-bright former 9/11 FBI chief Robert Mueller, with support from 19 lawyers, 40 FBI agents plus intelligence analysts, forensic accountants and other

staff, devoured tens of millions of dollars and found no evidence of Russia collusion which a ten-year-old could have told them on day one. Now the same moronic Schumer and Schiff wanted a second impeachment of Trump over the Capitol 'insurrection' (riot) which the arrested development of Schumer called another 'Pearl Harbor' while others compared it with 9/11 in which 3,000 died and, in the case of CNN, with the Rwandan genocide in the 1990s in which an estimated 500,000 to 600,000 were murdered, between 250, 000 and 500,000 women were raped, and populations of whole towns were hacked to death with machetes. To make those comparisons purely for Cult political reasons is beyond insulting to those that suffered and lost their lives and confirms yet again the callous inhumanity that we are dealing with. Schumer is a monumental idiot and so is Schiff, but they serve the Cult agenda and do whatever they're told so they get looked after. Talking of idiots – another inane man who spanned the Russia and Capitol impeachment attempts was Senator Eric Swalwell who had the nerve to accuse Trump of collusion with the Russians while sleeping with a Chinese spy called Christine Fang or 'Fang Fang' which is straight out of a Bond film no doubt starring Klaus Schwab as the bloke living on a secret island and controlling laser weapons positioned in space and pointing at world capitals. Fang Fang plays the part of Bond's infiltrator girlfriend which I'm sure she would enjoy rather more than sharing a bed with the brainless Swalwell, lying back and thinking of China. The FBI eventually warned Swalwell about Fang Fang which gave her time to escape back to the Chinese dictatorship. How very thoughtful of them. The second Trump impeachment also failed and hardly surprising when an impeachment is supposed to remove a sitting president and by the time it happened Trump was no longer president. These people are running your country America, well, officially anyway. Terrifying isn't it?

Outcomes tell the story - always

The outcome of all this – and it's the *outcome* on which Renegade Minds focus, not the words – was that a vicious, hysterical and

obviously pre-planned assault was launched on Pushbackers to censor, silence and discredit them and even targeted their right to earn a living. They have since been condemned as 'domestic terrorists' that need to be treated like Al-Qaeda and Islamic State. 'Domestic terrorists' is a label the Cult has been trying to make stick since the period of the Oklahoma bombing in 1995 which was blamed on 'far-right domestic terrorists'. If you read *The Trigger* you will see that the bombing was clearly a Problem-Reaction-Solution carried out by the Deep State during a Bill Clinton administration so corrupt that no dictionary definition of the term would even nearly suffice. Nearly 30, 000 troops were deployed from all over America to the empty streets of Washington for Biden's inauguration. Ten thousand of them stayed on with the pretext of protecting the capital from insurrectionists when it was more psychological programming to normalise the use of the military in domestic law enforcement in support of the Cult plan for a police-military state. Biden's fascist administration began a purge of 'wrong-thinkers' in the military which means anyone that is not on board with Woke. The Capitol Building was surrounded by a fence with razor wire and the Land of the Free was further symbolically and literally dismantled. The circle was completed with the installation of Biden and the exploitation of the QAnon Psyop.

America had never been so divided since the civil war of the 19th century, Pushbackers were isolated and dubbed terrorists and now, as was always going to happen, the Cult immediately set about deleting what little was left of freedom and transforming American society through a swish of the hand of the most controlled 'president' in American history leading (officially at least) the most extreme regime since the country was declared an independent state on July 4th, 1776. Biden issued undebated, dictatorial executive orders almost by the hour in his opening days in office across the whole spectrum of the Cult wish-list including diluting controls on the border with Mexico allowing thousands of migrants to illegally enter the United States to transform the demographics of America and import an election-changing number of perceived Democrat

voters. Then there were Biden deportation amnesties for the already illegally resident (estimated to be as high as 20 or even 30 million). A bill before Congress awarded American citizenship to anyone who could prove they had worked in agriculture for just 180 days in the previous two years as 'Big Ag' secured its slave labour long-term. There were the plans to add new states to the union such as Puerto Rico and making Washington DC a state. They are all parts of a plan to ensure that the Cult-owned Woke Democrats would be permanently in power.

Border – what border?

I have exposed in detail in other books how mass immigration into the United States and Europe is the work of Cult networks fuelled by the tens of billions spent to this and other ends by George Soros and his global Open Society (open borders) Foundations. The impact can be seen in America alone where the population has increased by *100 million* in little more than 30 years mostly through immigration. I wrote in *The Answer* that the plan was to have so many people crossing the southern border that the numbers become unstoppable and we are now there under Cult-owned Biden. El Salvador in Central America puts the scale of what is happening into context. A third of the population now lives in the United States, much of it illegally, and many more are on the way. The methodology is to crush Central and South American countries economically and spread violence through machete-wielding psychopathic gangs like MS-13 based in El Salvador and now operating in many American cities. Biden-imposed lax security at the southern border means that it is all but open. He said before his 'election' that he wanted to see a surge towards the border if he became president and that was the green light for people to do just that after election day to create the human disaster that followed for both America and the migrants. When that surge came the imbecilic Alexandria Ocasio-Cortez said it wasn't a 'surge' because they are 'children, not insurgents' and the term 'surge' (used by Biden) was a claim of 'white supremacists'.

This disingenuous lady may one day enter the realm of the most basic intelligence, but it won't be any time soon.

Sabbatians and the Cult are in the process of destroying America by importing violent people and gangs in among the genuine to terrorise American cities and by overwhelming services that cannot cope with the sheer volume of new arrivals. Something similar is happening in Europe as Western society in general is targeted for demographic and cultural transformation and upheaval. The plan demands violence and crime to create an environment of intimidation, fear and division and Soros has been funding the election of district attorneys across America who then stop prosecuting many crimes, reduce sentences for violent crimes and free as many violent criminals as they can. Sabbatians are creating the chaos from which order – their order – can respond in a classic Problem-Reaction-Solution. A Freemasonic moto says 'Ordo Ab Chao' (Order out of Chaos) and this is why the Cult is constantly creating chaos to impose a new 'order'. Here you have the reason the Cult is constantly creating chaos. The 'Covid' hoax can be seen with those entering the United States by plane being forced to take a 'Covid' test while migrants flooding through southern border processing facilities do not. Nothing is put in the way of mass migration and if that means ignoring the government's own 'Covid' rules then so be it. They know it's all bullshit anyway. Any pushback on this is denounced as 'racist' by Wokers and Sabbatian fronts like the ultra-Zionist Anti-Defamation League headed by the appalling Jonathan Greenblatt which at the same time argues that Israel should not give citizenship and voting rights to more Palestinian Arabs or the 'Jewish population' (in truth the Sabbatian network) will lose control of the country.

Society-changing numbers

Biden's masters have declared that countries like El Salvador are so dangerous that their people must be allowed into the United States for humanitarian reasons when there are fewer murders in large parts of many Central American countries than in US cities like

Baltimore. That is not to say Central America cannot be a dangerous place and Cult-controlled American governments have been making it so since way back, along with the dismantling of economies, in a long-term plan to drive people north into the United States. Parts of Central America are very dangerous, but in other areas the story is being greatly exaggerated to justify relaxing immigration criteria. Migrants are being offered free healthcare and education in the United States as another incentive to head for the border and there is no requirement to be financially independent before you can enter to prevent the resources of America being drained. You can't blame migrants for seeking what they believe will be a better life, but they are being played by the Cult for dark and nefarious ends. The numbers since Biden took office are huge. In February, 2021, more than 100,000 people were known to have tried to enter the US illegally through the southern border (it was 34,000 in the same month in 2020) and in March it was 170,000 – a 418 percent increase on March, 2020. These numbers are only known people, not the ones who get in unseen. The true figure for migrants illegally crossing the border in a single month was estimated by one congressman at 250,000 and that number will only rise under Biden's current policy. Gangs of murdering drug-running thugs that control the Mexican side of the border demand money – thousands of dollars – to let migrants cross the Rio Grande into America. At the same time gun battles are breaking out on the border several times a week between rival Mexican drug gangs (which now operate globally) who are equipped with sophisticated military-grade weapons, grenades and armoured vehicles. While the Capitol Building was being 'protected' from a non-existent 'threat' by thousands of troops, and others were still deployed at the time in the Cult Neocon war in Afghanistan, the southern border of America was left to its fate. This is not incompetence, it is cold calculation.

By March, 2021, there were 17,000 unaccompanied children held at border facilities and many of them are ensnared by people traffickers for paedophile rings and raped on their journey north to America. This is not conjecture – this is fact. Many of those designated

children are in reality teenage boys or older. Meanwhile Wokers posture their self-purity for encouraging poor and tragic people to come to America and face this nightmare both on the journey and at the border with the disgusting figure of House Speaker Nancy Pelosi giving disingenuous speeches about caring for migrants. The woman's evil. Wokers condemned Trump for having children in cages at the border (so did Obama, *Shhhh*), but now they are sleeping on the floor without access to a shower with one border facility 729 percent over capacity. The Biden insanity even proposed flying migrants from the southern border to the northern border with Canada for 'processing'. The whole shambles is being overseen by ultra-Zionist Secretary of Homeland Security, the moronic liar Alejandro Mayorkas, who banned news cameras at border facilities to stop Americans seeing what was happening. Mayorkas said there was not a ban on news crews; it was just that they were not allowed to film. Alongside him at Homeland Security is another ultra-Zionist Cass Sunstein appointed by Biden to oversee new immigration laws. Sunstein despises conspiracy researchers to the point where he suggests they should be banned or *taxed* for having such views. The man is not bonkers or anything. He's perfectly well-adjusted, but adjusted to what is the question. Criticise what is happening and you are a 'white supremacist' when earlier non-white immigrants also oppose the numbers which effect their lives and opportunities. Black people in poor areas are particularly damaged by uncontrolled immigration and the increased competition for work opportunities with those who will work for less. They are also losing voting power as Hispanics become more dominant in former black areas. It's a downward spiral for them while the billionaires behind the policy drone on about how much they care about black people and 'racism'. None of this is about compassion for migrants or black people – that's just wind and air. Migrants are instead being mercilessly exploited to transform America while the countries they leave are losing their future and the same is true in Europe. Mass immigration may now be the work of Woke Democrats, but it can be traced back to the 1986 Immigration Reform and Control Act (it

wasn't) signed into law by Republican hero President Ronald Reagan which gave amnesty to millions living in the United States illegally and other incentives for people to head for the southern border. Here we have the one-party state at work again.

Save me syndrome

Almost every aspect of what I have been exposing as the Cult agenda was on display in even the first days of 'Biden' with silencing of Pushbackers at the forefront of everything. A Renegade Mind will view the Trump years and QAnon in a very different light to their supporters and advocates as the dots are connected. The QAnon/Trump Psyop has given the Cult all it was looking for. We may not know how much, or little, that Trump realised he was being used, but that's a side issue. This pincer movement produced the desired outcome of dividing America and having Pushbackers isolated. To turn this around we have to look at new routes to empowerment which do not include handing our power to other people and groups through what I will call the 'Save Me Syndrome' – 'I want someone else to do it so that I don't have to'. We have seen this at work throughout human history and the QAnon/Trump Psyop is only the latest incarnation alongside all the others. Religion is an obvious expression of this when people look to a 'god' or priest to save them or tell them how to be saved and then there are 'save me' politicians like Trump. Politics is a diversion and not a 'saviour'. It is a means to block positive change, not make it possible.

Save Me Syndrome always comes with the same repeating theme of handing your power to whom or what you believe will save you while your real 'saviour' stares back from the mirror every morning. Renegade Minds are constantly vigilant in this regard and always asking the question 'What can I do?' rather than 'What can someone else do for me?' Gandhi was right when he said: 'You must be the change you want to see in the world.' We are indeed the people we have been waiting for. We are presented with a constant raft of reasons to concede that power to others and forget where the real power is. Humanity has the numbers and the Cult does not. It has to

use diversion and division to target the unstoppable power that comes from unity. Religions, governments, politicians, corporations, media, QAnon, are all different manifestations of this power-diversion and dilution. Refusing to give your power to governments and instead handing it to Trump and QAnon is not to take a new direction, but merely to recycle the old one with new names on the posters. I will explore this phenomenon as we proceed and how to break the cycles and recycles that got us here through the mists of repeating perception and so repeating history.

For now we shall turn to the most potent example in the entire human story of the consequences that follow when you give your power away. I am talking, of course, of the 'Covid' hoax.

CHAPTER FOUR

‘Covid’: Calculated catastrophe

Facts are threatening to those invested in fraud
DaShanne Stokes

We can easily unravel the real reason for the ‘Covid pandemic’ hoax by employing the Renegade Mind methodology that I have outlined this far. We’ll start by comparing the long-planned Cult outcome with the ‘Covid pandemic’ outcome. Know the outcome and you’ll see the journey.

I have highlighted the plan for the Hunger Games Society which has been in my books for so many years with the very few controlling the very many through ongoing dependency. To create this dependency it is essential to destroy independent livelihoods, businesses and employment to make the population reliant on the state (the Cult) for even the basics of life through a guaranteed pittance income. While independence of income remained these Cult ambitions would be thwarted. With this knowledge it was easy to see where the ‘pandemic’ hoax was going once talk of ‘lockdowns’ began and the closing of all but perceived ‘essential’ businesses to ‘save’ us from an alleged ‘deadly virus’. Cult corporations like Amazon and Walmart were naturally considered ‘essential’ while mom and pop shops and stores had their doors closed by fascist decree. As a result with every new lockdown and new regulation more small and medium, even large businesses not owned by the Cult, went to the wall while Cult giants and their frontmen and women grew financially fatter by the second. Mom and pop were

denied an income and the right to earn a living and the wealth of people like Jeff Bezos (Amazon), Mark Zuckerberg (Facebook) and Sergei Brin and Larry Page (Google/Alphabet) have reached record levels. The Cult was increasing its own power through further dramatic concentrations of wealth while the competition was being destroyed and brought into a state of dependency. Lockdowns have been instigated to secure that very end and were never anything to do with health. My brother Paul spent 45 years building up a bus repair business, but lockdowns meant buses were running at a fraction of normal levels for months on end. Similar stories can told in their hundreds of millions worldwide. Efforts of a lifetime coldly destroyed by Cult multi-billionaires and their lackeys in government and law enforcement who continued to earn their living from the taxation of the people while denying the right of the same people to earn theirs. How different it would have been if those making and enforcing these decisions had to face the same financial hardships of those they affected, but they never do.

Gates of Hell

Behind it all in the full knowledge of what he is doing and why is the psychopathic figure of Cult operative Bill Gates. His puppet Tedros at the World Health Organization declared 'Covid' a pandemic in March, 2020. The WHO had changed the definition of a 'pandemic' in 2009 just a month before declaring the 'swine flu pandemic' which would not have been so under the previous definition. The same applies to 'Covid'. The definition had included… 'an infection by an infectious agent, occurring simultaneously in different countries, with a significant mortality rate relative to the proportion of the population infected'. The new definition removed the need for 'significant mortality'. The 'pandemic' has been fraudulent even down to the definition, but Gates demanded economy-destroying lockdowns, school closures, social distancing, mandatory masks, a 'vaccination' for every man, woman and child on the planet and severe consequences and restrictions for those that refused. Who gave him this power? The

Cult did which he serves like a little boy in short trousers doing what his daddy tells him. He and his psychopathic missus even smiled when they said that much worse was to come (what they knew was planned to come). Gates responded in the matter-of-fact way of all psychopaths to a question about the effect on the world economy of what he was doing:

> Well, it won't go to zero but it will shrink. Global GDP is probably going to take the biggest hit ever [Gates was smiling as he said this] … in my lifetime this will be the greatest economic hit. But you don't have a choice. People act as if you have a choice. People don't feel like going to the stadium when they might get infected … People are deeply affected by seeing these stats, by knowing they could be part of the transmission chain, old people, their parents and grandparents, could be affected by this, and so you don't get to say ignore what is going on here.
>
> There will be the ability to open up, particularly in rich countries, if things are done well over the next few months, but for the world at large normalcy only returns when we have largely vaccinated the entire population.

The man has no compassion or empathy. How could he when he's a psychopath like all Cult players? My own view is that even beyond that he is very seriously mentally ill. Look in his eyes and you can see this along with his crazy flailing arms. You don't do what he has done to the world population since the start of 2020 unless you are mentally ill and at the most extreme end of psychopathic. You especially don't do it when to you know, as we shall see, that cases and deaths from 'Covid' are fakery and a product of monumental figure massaging. 'These stats' that Gates referred to are based on a 'test' that's not testing for the 'virus' as he has known all along. He made his fortune with big Cult support as an infamously ruthless software salesman and now buys global control of 'health' (death) policy without the population he affects having any say. It's a breathtaking outrage. Gates talked about people being deeply affected by fear of 'Covid' when that was because of *him* and his global network lying to them minute-by-minute supported by a lying media that he seriously influences and funds to the tune of hundreds of millions. He's handed big sums to media operations including the BBC, NBC, Al Jazeera, Univision, *PBS NewsHour*,

ProPublica, National Journal, The Guardian, The Financial Times, The Atlantic, Texas Tribune, USA Today publisher Gannett, *Washington Monthly, Le Monde,* Center for Investigative Reporting, Pulitzer Center on Crisis Reporting, National Press Foundation, International Center for Journalists, Solutions Journalism Network, the Poynter Institute for Media Studies, and many more. Gates is everywhere in the 'Covid' hoax and the man must go to prison – or a mental facility – for the rest of his life and his money distributed to those he has taken such enormous psychopathic pleasure in crushing.

The Muscle

The Hunger Games global structure demands a police-military state – a fusion of the two into one force – which viciously imposes the will of the Cult on the population and protects the Cult from public rebellion. In that regard, too, the 'Covid' hoax just keeps on giving. Often unlawful, ridiculous and contradictory 'Covid' rules and regulations have been policed across the world by moronic automatons and psychopaths made faceless by face-nappy masks and acting like the Nazi SS and fascist blackshirts and brownshirts of Hitler and Mussolini. The smallest departure from the rules decreed by the psychos in government and their clueless gofers were jumped upon by the face-nappy fascists. Brutality against public protestors soon became commonplace even on girls, women and old people as the brave men with the batons – the Face-Nappies as I call them – broke up peaceful protests and handed out fines like confetti to people who couldn't earn a living let alone pay hundreds of pounds for what was once an accepted human right. Robot Face-Nappies of Nottingham police in the English East Midlands fined one group £11,000 for attending a child's birthday party. For decades I charted the transformation of law enforcement as genuine, decent officers were replaced with psychopaths and the brain dead who would happily and brutally do whatever their masters told them. Now they were let loose on the public and I would emphasise the point that none of this just happened. The step-by-step change in the dynamic between police and public was orchestrated from the shadows by

those who knew where this was all going and the same with the perceptual reframing of those in all levels of authority and official administration through 'training courses' by organisations such as Common Purpose which was created in the late 1980s and given a massive boost in Blair era Britain until it became a global phenomenon. Supposed public 'servants' began to view the population as the enemy and the same was true of the police. This was the start of the explosion of behaviour manipulation organisations and networks preparing for the all-war on the human psyche unleashed with the dawn of 2020. I will go into more detail about this later in the book because it is a core part of what is happening.

Police desecrated beauty spots to deter people gathering and arrested women for walking in the countryside alone 'too far' from their homes. We had arrogant, clueless sergeants in the Isle of Wight police where I live posting on Facebook what they insisted the population must do or else. A schoolmaster sergeant called Radford looked young enough for me to ask if his mother knew he was out, but he was posting what he *expected* people to do while a Sergeant Wilkinson boasted about fining lads for meeting in a McDonald's car park where they went to get a lockdown takeaway. Wilkinson added that he had even cancelled their order. What a pair of prats these people are and yet they have increasingly become the norm among Jackboot Johnson's Yellowshirts once known as the British police. This was the theme all over the world with police savagery common during lockdown protests in the United States, the Netherlands, and the fascist state of Victoria in Australia under its tyrannical and again moronic premier Daniel Andrews. Amazing how tyrannical and moronic tend to work as a team and the same combination could be seen across America as arrogant, narcissistic Woke governors and mayors such as Gavin Newsom (California), Andrew Cuomo (New York), Gretchen Whitmer (Michigan), Lori Lightfoot (Chicago) and Eric Garcetti (Los Angeles) did their Nazi and Stalin impressions with the full support of the compliant brutality of their enforcers in uniform as they arrested small business owners defying

fascist shutdown orders and took them to jail in ankle shackles and handcuffs. This happened to bistro owner Marlena Pavlos-Hackney in Gretchen Whitmer's fascist state of Michigan when police arrived to enforce an order by a state-owned judge for 'putting the community at risk' at a time when other states like Texas were dropping restrictions and migrants were pouring across the southern border without any 'Covid' questions at all. I'm sure there are many officers appalled by what they are ordered to do, but not nearly enough of them. If they were truly appalled they would not do it. As the months passed every opportunity was taken to have the military involved to make their presence on the streets ever more familiar and 'normal' for the longer-term goal of police-military fusion.

Another crucial element to the Hunger Games enforcement network has been encouraging the public to report neighbours and others for 'breaking the lockdown rules'. The group faced with £11,000 in fines at the child's birthday party would have been dobbed-in by a neighbour with a brain the size of a pea. The technique was most famously employed by the Stasi secret police in communist East Germany who had public informants placed throughout the population. A police chief in the UK says his force doesn't need to carry out 'Covid' patrols when they are flooded with so many calls from the public reporting other people for visiting the beach. Dorset police chief James Vaughan said people were so enthusiastic about snitching on their fellow humans they were now operating as an auxiliary arm of the police: 'We are still getting around 400 reports a week from the public, so we will respond to reports …We won't need to be doing hotspot patrols because people are very quick to pick the phone up and tell us.' Vaughan didn't say that this is a pillar of all tyrannies of whatever complexion and the means to hugely extend the reach of enforcement while spreading distrust among the people and making them wary of doing anything that might get them reported. Those narcissistic Isle of Wight sergeants Radford and Wilkinson never fail to add a link to their Facebook posts where the public can inform on their fellow slaves.

Neither would be self-aware enough to realise they were imitating the Stasi which they might well never have heard of. Government psychologists that I will expose later laid out a policy to turn communities against each other in the same way.

A coincidence? Yep, and I can knit fog

I knew from the start of the alleged pandemic that this was a Cult operation. It presented limitless potential to rapidly advance the Cult agenda and exploit manipulated fear to demand that every man, woman and child on the planet was 'vaccinated' in a process never used on humans before which infuses self-replicating *synthetic* material into human cells. Remember the plan to transform the human body from a biological to a synthetic biological state. I'll deal with the 'vaccine' (that's not actually a vaccine) when I focus on the genetic agenda. Enough to say here that mass global 'vaccination' justified by this 'new virus' set alarms ringing after 30 years of tracking these people and their methods. The 'Covid' hoax officially beginning in China was also a big red flag for reasons I will be explaining. The agenda potential was so enormous that I could dismiss any idea that the 'virus' appeared naturally. Major happenings with major agenda implications never occur without Cult involvement in making them happen. My questions were twofold in early 2020 as the media began its campaign to induce global fear and hysteria: Was this alleged infectious agent released on purpose by the Cult or did it even exist at all? I then did what I always do in these situations. I sat, observed and waited to see where the evidence and information would take me. By March and early April synchronicity was strongly – and ever more so since then – pointing me in the direction of *there is no 'virus'*. I went public on that with derision even from swathes of the alternative media that voiced a scenario that the Chinese government released the 'virus' in league with Deep State elements in the United States from a top-level bio-lab in Wuhan where the 'virus' is said to have first appeared. I looked at that possibility, but I didn't buy it for several reasons. Deaths from the 'virus' did not in any way match what they

would have been with a ‘deadly bioweapon’ and it is much more effective if you sell the *illusion* of an infectious agent rather than having a real one unless you can control through injection who has it and who doesn’t. Otherwise you lose control of events. A made-up ‘virus’ gives you a blank sheet of paper on which you can make it do whatever you like and have any symptoms or mutant ‘variants’ you choose to add while a real infectious agent would limit you to what it actually does. A phantom disease allows you to have endless ludicrous ‘studies’ on the ‘Covid’ dollar to widen the perceived impact by inventing ever more ‘at risk’ groups including one study which said those who walk slowly may be almost four times more likely to die from the ‘virus’. People are in psychiatric wards for less.

A real ‘deadly bioweapon’ can take out people in the hierarchy that are not part of the Cult, but essential to its operation. Obviously they don’t want that. Releasing a real disease means you immediately lose control of it. Releasing an illusory one means you don’t. Again it’s vital that people are extra careful when dealing with what they want to hear. A bioweapon unleashed from a Chinese laboratory in collusion with the American Deep State may fit a conspiracy narrative, but is it true? Would it not be far more effective to use the excuse of a ‘virus’ to justify the real bioweapon – the ‘vaccine’? That way your disease agent does not have to be transmitted and arrives directly through a syringe. I saw a French virologist Luc Montagnier quoted in the alternative media as saying he had discovered that the alleged ‘new’ severe acute respiratory syndrome coronavirus , or SARS-CoV-2, was made artificially and included elements of the human immunodeficiency ‘virus’ (HIV) and a parasite that causes malaria. SARS-CoV-2 is alleged to trigger an alleged illness called Covid-19. I remembered Montagnier’s name from my research years before into claims that an HIV ‘retrovirus’ causes AIDs – claims that were demolished by Berkeley virologist Peter Duesberg who showed that no one had ever proved that HIV causes acquired immunodeficiency syndrome or AIDS. Claims that become accepted as fact, publicly and medically, with no proof whatsoever are an ever-recurring story that profoundly applies to

'Covid'. Nevertheless, despite the lack of proof, Montagnier's team at the Pasteur Institute in Paris had a long dispute with American researcher Robert Gallo over which of them discovered and isolated the HIV 'virus' and with *no evidence* found it to cause AIDS. You will see later that there is also no evidence that any 'virus' causes any disease or that there is even such a thing as a 'virus' in the way it is said to exist. The claim to have 'isolated' the HIV 'virus' will be presented in its real context as we come to the shocking story – and it is a story – of SARS-CoV-2 and so will Montagnier's assertion that he identified the full SARS-CoV-2 genome.

Hoax in the making

We can pick up the 'Covid' story in 2010 and the publication by the Rockefeller Foundation of a document called 'Scenarios for the Future of Technology and International Development'. The inner circle of the Rockefeller family has been serving the Cult since John D. Rockefeller (1839-1937) made his fortune with Standard Oil. It is less well known that the same Rockefeller – the Bill Gates of his day – was responsible for establishing what is now referred to as 'Big Pharma', the global network of pharmaceutical companies that make outrageous profits dispensing scalpel and drug 'medicine' and are obsessed with pumping vaccines in ever-increasing number into as many human arms and backsides as possible. John D. Rockefeller was the driving force behind the creation of the 'education' system in the United States and elsewhere specifically designed to program the perceptions of generations thereafter. The Rockefeller family donated exceptionally valuable land in New York for the United Nations building and were central in establishing the World Health Organization in 1948 as an agency of the UN which was created from the start as a Trojan horse and stalking horse for world government. Now enter Bill Gates. His family and the Rockefellers have long been extremely close and I have seen genealogy which claims that if you go back far enough the two families fuse into the same bloodline. Gates has said that the Bill and Melinda Gates Foundation was inspired by the Rockefeller Foundation and why not

when both are serving the same Cult? Major tax-exempt foundations are overwhelmingly criminal enterprises in which Cult assets fund the Cult agenda in the guise of 'philanthropy' while avoiding tax in the process. Cult operatives can become mega-rich in their role of front men and women for the psychopaths at the inner core and they, too, have to be psychopaths to knowingly serve such evil. Part of the deal is that a big percentage of the wealth gleaned from representing the Cult has to be spent advancing the ambitions of the Cult and hence you have the Rockefeller Foundation, Bill and Melinda Gates Foundation (and *so* many more) and people like George Soros with his global Open Society Foundations spending their billions in pursuit of global Cult control. Gates is a global public face of the Cult with his interventions in world affairs including Big Tech influence; a central role in the 'Covid' and 'vaccine' scam; promotion of the climate change shakedown; manipulation of education; geoengineering of the skies; and his food-control agenda as the biggest owner of farmland in America, his GMO promotion and through other means. As one writer said: 'Gates monopolizes or wields disproportionate influence over the tech industry, global health and vaccines, agriculture and food policy (including biopiracy and fake food), weather modification and other climate technologies, surveillance, education and media.' The almost limitless wealth secured through Microsoft and other not-allowed-to-fail ventures (including vaccines) has been ploughed into a long, long list of Cult projects designed to enslave the entire human race. Gates and the Rockefellers have been working as one unit with the Rockefeller-established World Health Organization leading global 'Covid' policy controlled by Gates through his mouth-piece Tedros. Gates became the WHO's biggest funder when Trump announced that the American government would cease its donations, but Biden immediately said he would restore the money when he took office in January, 2021. The Gates Foundation (the Cult) owns through limitless funding the world health system and the major players across the globe in the 'Covid' hoax.

Okay, with that background we return to that Rockefeller Foundation document of 2010 headed 'Scenarios for the Future of Technology and International Development' and its 'imaginary' epidemic of a virulent and deadly influenza strain which infected 20 percent of the global population and killed eight million in seven months. The Rockefeller scenario was that the epidemic destroyed economies, closed shops, offices and other businesses and led to governments imposing fierce rules and restrictions that included mandatory wearing of face masks and body-temperature checks to enter communal spaces like railway stations and supermarkets. The document predicted that even after the height of the Rockefeller-envisaged epidemic the authoritarian rule would continue to deal with further pandemics, transnational terrorism, environmental crises and rising poverty. Now you may think that the Rockefellers are our modern-day seers or alternatively, and rather more likely, that they well knew what was planned a few years further on. Fascism had to be imposed, you see, to 'protect citizens from risk and exposure'. The Rockefeller scenario document said:

During the pandemic, national leaders around the world flexed their authority and imposed airtight rules and restrictions, from the mandatory wearing of face masks to body-temperature checks at the entries to communal spaces like train stations and supermarkets. Even after the pandemic faded, this more authoritarian control and oversight of citizens and their activities stuck and even intensified. In order to protect themselves from the spread of increasingly global problems – from pandemics and transnational terrorism to environmental crises and rising poverty – leaders around the world took a firmer grip on power.

At first, the notion of a more controlled world gained wide acceptance and approval. Citizens willingly gave up some of their sovereignty – and their privacy – to more paternalistic states in exchange for greater safety and stability. Citizens were more tolerant, and even eager, for top-down direction and oversight, and national leaders had more latitude to impose order in the ways they saw fit.

In developed countries, this heightened oversight took many forms: biometric IDs for all citizens, for example, and tighter regulation of key industries whose stability was deemed vital to national interests. In many developed countries, enforced cooperation with a suite of new regulations and agreements slowly but steadily restored both order and, importantly, economic growth.

There we have the prophetic Rockefellers in 2010 and three years later came their paper for the Global Health Summit in Beijing, China, when government representatives, the private sector, international organisations and groups met to discuss the next 100 years of 'global health'. The Rockefeller Foundation-funded paper was called 'Dreaming the Future of Health for the Next 100 Years and more prophecy ensued as it described a dystopian future: 'The abundance of data, digitally tracking and linking people may mean the 'death of privacy' and may replace physical interaction with transient, virtual connection, generating isolation and raising questions of how values are shaped in virtual networks.' Next in the 'Covid' hoax preparation sequence came a 'table top' simulation in 2018 for another 'imaginary' pandemic of a disease called Clade X which was said to kill 900 million people. The exercise was organised by the Gates-funded Johns Hopkins University's Center for Health Security in the United States and this is the very same university that has been compiling the disgustingly and systematically erroneous global figures for 'Covid' cases and deaths. Similar Johns Hopkins health crisis scenarios have included the Dark Winter exercise in 2001 and Atlantic Storm in 2005.

Nostradamus 201

For sheer predictive genius look no further prophecy-watchers than the Bill Gates-funded Event 201 held only six weeks before the 'coronavirus pandemic' is supposed to have broken out in China and Event 201 was based on a scenario of a global 'coronavirus pandemic'. Melinda Gates, the great man's missus, told the BBC that he had 'prepared for years' for a coronavirus pandemic which told us what we already knew. Nostradamugates had predicted in a TED talk in 2015 that a pandemic was coming that would kill a lot of people and demolish the world economy. My god, the man is a machine – possibly even literally. Now here he was only weeks before the real thing funding just such a simulated scenario and involving his friends and associates at Johns Hopkins, the World Economic Forum Cult-front of Klaus Schwab, the United Nations,

Johnson & Johnson, major banks, and officials from China and the Centers for Disease Control in the United States. What synchronicity – Johns Hopkins would go on to compile the fraudulent 'Covid' figures, the World Economic Forum and Schwab would push the 'Great Reset' in response to 'Covid', the Centers for Disease Control would be at the forefront of 'Covid' policy in the United States, Johnson & Johnson would produce a 'Covid vaccine', and everything would officially start just weeks later in China. Spooky, eh? They were even accurate in creating a simulation of a 'virus' pandemic because the 'real thing' would also be a simulation. Event 201 was not an exercise preparing for something that might happen; it was a rehearsal for what those in control knew was *going* to happen and very shortly. Hours of this simulation were posted on the Internet and the various themes and responses mirrored what would soon be imposed to transform human society. News stories were inserted and what they said would be commonplace a few weeks later with still more prophecy perfection. Much discussion focused on the need to deal with misinformation and the 'anti-vax movement' which is exactly what happened when the 'virus' arrived – was said to have arrived – in the West.

Cult-owned social media banned criticism and exposure of the official 'virus' narrative and when I said there *was* no 'virus' in early April, 2020, I was banned by one platform after another including YouTube, Facebook and later Twitter. The mainstream broadcast media in Britain was in effect banned from interviewing me by the Tony-Blair-created government broadcasting censor Ofcom headed by career government bureaucrat Melanie Dawes who was appointed just as the 'virus' hoax was about to play out in January, 2020. At the same time the Ickonic media platform was using Vimeo, another ultra-Zionist-owned operation, while our own player was being created and they deleted in an instant hundreds of videos, documentaries, series and shows to confirm their unbelievable vindictiveness. We had copies, of course, and they had to be restored one by one when our player was ready. These people have no class. Sabbatian Facebook promised free advertisements for the Gates-

controlled World Health Organization narrative while deleting 'false claims and conspiracy theories' to stop 'misinformation' about the alleged coronavirus. All these responses could be seen just a short while earlier in the scenarios of Event 201. Extreme censorship was absolutely crucial for the Cult because the official story was so ridiculous and unsupportable by the evidence that it could never survive open debate and the free-flow of information and opinion. If you can't win a debate then don't have one is the Cult's approach throughout history. Facebook's little boy front man – front boy – Mark Zuckerberg equated 'credible and accurate information' with official sources and exposing their lies with 'misinformation'.

Silencing those that can see

The censorship dynamic of Event 201 is now the norm with an army of narrative-supporting 'fact-checker' organisations whose entire reason for being is to tell the public that official narratives are true and those exposing them are lying. One of the most appalling of these 'fact-checkers' is called NewsGuard founded by ultra-Zionist Americans Gordon Crovitz and Steven Brill. Crovitz is a former publisher of *The Wall Street Journal*, former Executive Vice President of Dow Jones, a member of the Council on Foreign Relations (CFR), and on the board of the American Association of Rhodes Scholars. The CFR and Rhodes Scholarships, named after Rothschild agent Cecil Rhodes who plundered the gold and diamonds of South Africa for his masters and the Cult, have featured widely in my books. NewsGuard don't seem to like me for some reason – I really can't think why – and they have done all they can to have me censored and discredited which is, to quote an old British politician, like being savaged by a dead sheep. They are, however, like all in the censorship network, very well connected and funded by organisations themselves funded by, or connected to, Bill Gates. As you would expect with anything associated with Gates NewsGuard has an offshoot called HealthGuard which 'fights online health care hoaxes'. How very kind. Somehow the NewsGuard European Managing Director Anna-Sophie Harling, a remarkably young-

looking woman with no broadcasting experience and little hands-on work in journalism, has somehow secured a position on the 'Content Board' of UK government broadcast censor Ofcom. An executive of an organisation seeking to discredit dissidents of the official narratives is making decisions for the government broadcast 'regulator' about content?? Another appalling 'fact-checker' is Full Fact funded by George Soros and global censors Google and Facebook.

It's amazing how many activists in the 'fact-checking', 'anti-hate', arena turn up in government-related positions – people like UK Labour Party activist Imran Ahmed who heads the Center for Countering Digital Hate founded by people like Morgan McSweeney, now chief of staff to the Labour Party's hapless and useless 'leader' Keir Starmer. Digital Hate – which is what it really is – uses the American spelling of Center to betray its connection to a transatlantic network of similar organisations which in 2020 shapeshifted from attacking people for 'hate' to attacking them for questioning the 'Covid' hoax and the dangers of the 'Covid vaccine'. It's just a coincidence, you understand. This is one of Imran Ahmed's hysterical statements: 'I would go beyond calling anti-vaxxers conspiracy theorists to say they are an extremist group that pose a national security risk.' No one could ever accuse this prat of understatement and he's including in that those parents who are now against vaccines after their children were damaged for life or killed by them. He's such a nice man. Ahmed does the rounds of the Woke media getting soft-ball questions from spineless 'journalists' who never ask what right he has to campaign to destroy the freedom of speech of others while he demands it for himself. There also seems to be an overrepresentation in Ofcom of people connected to the narrative-worshipping BBC. This incredible global network of narrative-support was super-vital when the 'Covid' hoax was played in the light of the mega-whopper lies that have to be defended from the spotlight cast by the most basic intelligence.

Setting the scene

The Cult plays the long game and proceeds step-by-step ensuring that everything is in place before major cards are played and they don't come any bigger than the 'Covid' hoax. The psychopaths can't handle events where the outcome isn't certain and as little as possible – preferably nothing – is left to chance. Politicians, government and medical officials who would follow direction were brought to illusory power in advance by the Cult web whether on the national stage or others like state governors and mayors of America. For decades the dynamic between officialdom, law enforcement and the public was changed from one of service to one of control and dictatorship. Behaviour manipulation networks established within government were waiting to impose the coming 'Covid' rules and regulations specifically designed to subdue and rewire the psyche of the people in the guise of protecting health. These included in the UK the Behavioural Insights Team part-owned by the British government Cabinet Office; the Scientific Pandemic Insights Group on Behaviours (SPI-B); and a whole web of intelligence and military groups seeking to direct the conversation on social media and control the narrative. Among them are the cyberwarfare (on the people) 77th Brigade of the British military which is also coordinated through the Cabinet Office as civilian and military leadership continues to combine in what they call the Fusion Doctrine. The 77th Brigade is a British equivalent of the infamous Israeli (Sabbatian) military cyberwarfare and Internet manipulation operation Unit 8200 which I expose at length in *The Trigger*. Also carefully in place were the medical and science advisers to government – many on the payroll past or present of Bill Gates – and a whole alternative structure of unelected government stood by to take control when elected parliaments were effectively closed down once the 'Covid' card was slammed on the table. The structure I have described here and so much more was installed in every major country through the Cult networks. The top-down control hierarchy looks like this: The Cult – Cult-owned Gates – the World Health Organization and Tedros – Gates-funded or controlled chief medical officers and science 'advisers' (dictators) in each country –

political 'leaders'– law enforcement – The People. Through this simple global communication and enforcement structure the policy of the Cult could be imposed on virtually the entire human population so long as they acquiesced to the fascism. With everything in place it was time for the button to be pressed in late 2019/early 2020.

These were the prime goals the Cult had to secure for its will to prevail:

1) Locking down economies, closing all but designated 'essential' businesses (Cult-owned corporations were 'essential'), and putting the population under house arrest was an imperative to destroy independent income and employment and ensure dependency on the Cult-controlled state in the Hunger Games Society. Lockdowns had to be established as the global blueprint from the start to respond to the 'virus' and followed by pretty much the entire world.

2) The global population had to be terrified into believing in a deadly 'virus' that didn't actually exist so they would unquestioningly obey authority in the belief that authority must know how best to protect them and their families. Software salesman Gates would suddenly morph into the world's health expert and be promoted as such by the Cult-owned media.

3) A method of testing that wasn't testing for the 'virus', but was only claimed to be, had to be in place to provide the illusion of 'cases' and subsequent 'deaths' that had a very different cause to the 'Covid-19' that would be scribbled on the death certificate.

4) Because there was no 'virus' and the great majority testing positive with a test not testing for the 'virus' would have no symptoms of anything the lie had to be sold that people without symptoms (without the 'virus') could still pass it on to others. This was crucial to justify for the first time quarantining – house arresting – healthy people. Without this the economy-destroying lockdown of *everybody* could not have been credibly sold.

5) The 'saviour' had to be seen as a vaccine which beyond evil drug companies were working like angels of mercy to develop as quickly as possible, with all corners cut, to save the day. The public must absolutely not know that the 'vaccine' had nothing to do with a 'virus' or that the contents were ready and waiting with a very different motive long before the 'Covid' card was even lifted from the pack.

I said in March, 2020, that the 'vaccine' would have been created way ahead of the 'Covid' hoax which justified its use and the following December an article in the New York *Intelligencer* magazine said the Moderna 'vaccine' had been 'designed' by

January, 2020. This was 'before China had even acknowledged that the disease could be transmitted from human to human, more than a week before the first confirmed coronavirus case in the United States'. The article said that by the time the first American death was announced a month later 'the vaccine had already been manufactured and shipped to the National Institutes of Health for the beginning of its Phase I clinical trial'. The 'vaccine' was actually 'designed' long before that although even with this timescale you would expect the article to ask how on earth it could have been done that quickly. Instead it asked why the 'vaccine' had not been rolled out then and not months later. Journalism in the mainstream is truly dead. I am going to detail in the next chapter why the 'virus' has never existed and how a hoax on that scale was possible, but first the foundation on which the Big Lie of 'Covid' was built.

The test that doesn't test

Fraudulent 'testing' is the bottom line of the whole 'Covid' hoax and was the means by which a 'virus' that did not exist *appeared* to exist. They could only achieve this magic trick by using a test not testing for the 'virus'. To use a test that *was* testing for the 'virus' would mean that every test would come back negative given there was no 'virus'. They chose to exploit something called the RT-PCR test invented by American biochemist Kary Mullis in the 1980s who said publicly that his PCR test … *cannot detect infectious disease*. Yes, the 'test' used worldwide to detect infectious 'Covid' to produce all the illusory 'cases' and 'deaths' compiled by Johns Hopkins and others *cannot detect infectious disease*. This fact came from the mouth of the man who invented PCR and was awarded the Nobel Prize in Chemistry in 1993 for doing so. Sadly, and incredibly conveniently for the Cult, Mullis died in August, 2019, at the age of 74 just before his test would be fraudulently used to unleash fascism on the world. He was said to have died from pneumonia which was an irony in itself. A few months later he would have had 'Covid-19' on his death certificate. I say the timing of his death was convenient because had he lived Mullis, a brilliant, honest and decent man, would have been

vociferously speaking out against the use of his test to detect 'Covid' when it was never designed, or able, to do that. I know that to be true given that Mullis made the same point when his test was used to 'detect' – not detect – HIV. He had been seriously critical of the Gallo/Montagnier claim to have isolated the HIV 'virus' and shown it to cause AIDS for which Mullis said there was no evidence. AIDS is actually not a disease but a series of diseases from which people die all the time. When they die from those *same diseases* after a positive 'test' for HIV then AIDS goes on their death certificate. I think I've heard that before somewhere. Countries instigated a policy with 'Covid' that anyone who tested positive with a test not testing for the 'virus' and died of any other cause within 28 days and even longer 'Covid-19' had to go on the death certificate. Cases have come from the test that can't test for infectious disease and the deaths are those who have died of *anything* after testing positive with a test not testing for the 'virus'. I'll have much more later about the death certificate scandal.

Mullis was deeply dismissive of the now US 'Covid' star Anthony Fauci who he said was a liar who didn't know anything about anything – 'and I would say that to his face – nothing.' He said of Fauci: 'The man thinks he can take a blood sample, put it in an electron microscope and if it's got a virus in there you'll know it – he doesn't understand electron microscopy and he doesn't understand medicine and shouldn't be in a position like he's in.' That position, terrifyingly, has made him the decider of 'Covid' fascism policy on behalf of the Cult in his role as director since 1984 of the National Institute of Allergy and Infectious Diseases (NIAID) while his record of being wrong is laughable; but being wrong, so long as it's the *right kind* of wrong, is why the Cult loves him. He'll say anything the Cult tells him to say. Fauci was made Chief Medical Adviser to the President immediately Biden took office. Biden was installed in the White House by Cult manipulation and one of his first decisions was to elevate Fauci to a position of even more control. This is a coincidence? Yes, and I identify as a flamenco dancer called Lola. How does such an incompetent criminal like Fauci remain in that

pivotal position in American health since *the 1980s*? When you serve the Cult it looks after you until you are surplus to requirements. Kary Mullis said prophetically of Fauci and his like: 'Those guys have an agenda and it's not an agenda we would like them to have … they make their own rules, they change them when they want to, and Tony Fauci does not mind going on television in front of the people who pay his salary and lie directly into the camera.' Fauci has done that almost daily since the 'Covid' hoax began. Lying is in Fauci's DNA. To make the situation crystal clear about the PCR test this is a direct quote from its inventor Kary Mullis:

> It [the PCR test] doesn't tell you that you're sick and doesn't tell you that the thing you ended up with was really going to hurt you ...'

Ask yourself why governments and medical systems the world over have been using this very test to decide who is 'infected' with the SARS-CoV-2 'virus' and the alleged disease it allegedly causes, 'Covid-19'. The answer to that question will tell you what has been going on. By the way, here's a little show-stopper – the 'new' SARS-CoV-2 'virus' was 'identified' as such right from the start using … *the PCR test not testing for the 'virus'*. If you are new to this and find that shocking then stick around. I have hardly started yet. Even worse, other 'tests', like the 'Lateral Flow Device' (LFD), are considered so useless that they have to be *confirmed* by the PCR test! Leaked emails written by Ben Dyson, adviser to UK 'Health' Secretary Matt Hancock, said they were 'dangerously unreliable'. Dyson, executive director of strategy at the Department of Health, wrote: 'As of today, someone who gets a positive LFD result in (say) London has at best a 25 per cent chance of it being a true positive, but if it is a self-reported test potentially as low as 10 per cent (on an optimistic assumption about specificity) or as low as 2 per cent (on a more pessimistic assumption).' These are the 'tests' that schoolchildren and the public are being urged to have twice a week or more and have to isolate if they get a positive. Each fake positive goes in the statistics as a 'case' no matter how ludicrously inaccurate and the

'cases' drive lockdown, masks and the pressure to 'vaccinate'. The government said in response to the email leak that the 'tests' were accurate which confirmed yet again what shocking bloody liars they are. The real false positive rate is *100 percent* as we'll see. In another 'you couldn't make it up' the UK government agreed to pay £2.8 billion to California's Innova Medical Group to supply the irrelevant lateral flow tests. The company's primary test-making centre is in China. Innova Medical Group, established in March, 2020, is owned by Pasaca Capital Inc, chaired by Chinese-American millionaire Charles Huang who was born in Wuhan.

How it works – and how it doesn't

The RT-PCR test, known by its full title of Polymerase chain reaction, is used across the world to make millions, even billions, of copies of a DNA/RNA genetic information sample. The process is called 'amplification' and means that a tiny sample of genetic material is amplified to bring out the detailed content. I stress that it is not testing for an infectious disease. It is simply amplifying a sample of genetic material. In the words of Kary Mullis: 'PCR is … just a process that's used to make a whole lot of something out of something.' To emphasise the point companies that make the PCR tests circulated around the world to 'test' for 'Covid' warn on the box that it can't be used to detect 'Covid' or infectious disease and is for research purposes only. It's okay, rest for a minute and you'll be fine. This is the test that produces the 'cases' and 'deaths' that have been used to destroy human society. All those global and national medical and scientific 'experts' demanding this destruction to 'save us' *KNOW* that the test is not testing for the 'virus' and the cases and deaths they claim to be real are an almost unimaginable fraud. Every one of them and so many others including politicians and psychopaths like Gates and Tedros must be brought before Nuremburg-type trials and jailed for the rest of their lives. The more the genetic sample is amplified by PCR the more elements of that material become sensitive to the test and by that I don't mean sensitive for a 'virus' but for elements of the genetic material which

is *naturally* in the body or relates to remnants of old conditions of various kinds lying dormant and causing no disease. Once the amplification of the PCR reaches a certain level *everyone* will test positive. So much of the material has been made sensitive to the test that everyone will have some part of it in their body. Even lying criminals like Fauci have said that once PCR amplifications pass 35 cycles everything will be a false positive that cannot be trusted for the reasons I have described. I say, like many proper doctors and scientists, that 100 percent of the 'positives' are false, but let's just go with Fauci for a moment.

He says that any amplification over 35 cycles will produce false positives and yet the US Centers for Disease Control (CDC) and Food and Drug Administration (FDA) have recommended up to *40 cycles* and the National Health Service (NHS) in Britain admitted in an internal document for staff that it was using *45 cycles* of amplification. A long list of other countries has been doing the same and at least one 'testing' laboratory has been using *50 cycles*. Have you ever heard a doctor, medical 'expert' or the media ask what level of amplification has been used to claim a 'positive'. The 'test' comes back 'positive' and so you have the 'virus', end of story. Now we can see how the government in Tanzania could send off samples from a goat and a pawpaw fruit under human names and both came back positive for 'Covid-19'. Tanzania president John Magufuli mocked the 'Covid' hysteria, the PCR test and masks and refused to import the DNA-manipulating 'vaccine'. The Cult hated him and an article sponsored by the Bill Gates Foundation appeared in the London *Guardian* in February, 2021, headed 'It's time for Africa to rein in Tanzania's anti-vaxxer president'. Well, 'reined in' he shortly was. Magufuli appeared in good health, but then, in March, 2021, he was dead at 61 from 'heart failure'. He was replaced by Samia Hassan Suhulu who is connected to Klaus Schwab's World Economic Forum and she immediately reversed Magufuli's 'Covid' policy. A sample of cola tested positive for 'Covid' with the PCR test in Germany while American actress and singer-songwriter Erykah Badu tested positive in one nostril and negative in the other. Footballer Ronaldo called

the PCR test 'bullshit' after testing positive three times and being forced to quarantine and miss matches when there was nothing wrong with him. The mantra from Tedros at the World Health Organization and national governments (same thing) has been test, test, test. They know that the more tests they can generate the more fake 'cases' they have which go on to become 'deaths' in ways I am coming to. The UK government has its Operation Moonshot planned to test multiple millions every day in workplaces and schools with free tests for everyone to use twice a week at home in line with the Cult plan from the start to make testing part of life. A government advertisement for an 'Interim Head of Asymptomatic Testing Communication' said the job included responsibility for delivering a 'communications strategy' (propaganda) 'to support the expansion of asymptomatic testing that *'normalises testing as part of everyday life*'. More tests means more fake 'cases', 'deaths' and fascism. I have heard of, and from, many people who booked a test, couldn't turn up, and yet got a positive result through the post for a test they'd never even had. The whole thing is crazy, but for the Cult there's method in the madness. Controlling and manipulating the level of amplification of the test means the authorities can control whenever they want the number of apparent 'cases' and 'deaths'. If they want to justify more fascist lockdown and destruction of livelihoods they keep the amplification high. If they want to give the illusion that lockdowns and the 'vaccine' are working then they lower the amplification and 'cases' and 'deaths' will appear to fall. In January, 2021, the Cult-owned World Health Organization suddenly warned laboratories about over-amplification of the test and to lower the threshold. Suddenly headlines began appearing such as: 'Why ARE "Covid" cases plummeting?' This was just when the vaccine rollout was underway and I had predicted months before they would make cases appear to fall through amplification tampering when the 'vaccine' came. These people are so predictable.

Cow vaccines?

The question must be asked of what is on the test swabs being poked far up the nose of the population to the base of the brain? A nasal swab punctured one woman's brain and caused it to leak fluid. Most of these procedures are being done by people with little training or medical knowledge. Dr Lorraine Day, former orthopaedic trauma surgeon and Chief of Orthopaedic Surgery at San Francisco General Hospital, says the tests are really a *'vaccine'*. Cows have long been vaccinated this way. She points out that masks have to cover the nose and the mouth where it is claimed the 'virus' exists in saliva. Why then don't they take saliva from the mouth as they do with a DNA test instead of pushing a long swab up the nose towards the brain? The ethmoid bone separates the nasal cavity from the brain and within that bone is the cribriform plate. Dr Day says that when the swab is pushed up against this plate and twisted the procedure is 'depositing things back there'. She claims that among these 'things' are nanoparticles that can enter the brain. Researchers have noted that a team at the Gates-funded Johns Hopkins have designed tiny, star-shaped micro-devices that can latch onto intestinal mucosa and release drugs into the body. Mucosa is the thin skin that covers the inside surface of parts of the body such as *the nose* and mouth and produces mucus to protect them. The Johns Hopkins micro-devices are called 'theragrippers' and were 'inspired' by a parasitic worm that digs its sharp teeth into a host's intestines. Nasal swabs are also coated in the sterilisation agent ethylene oxide. The US National Cancer Institute posts this explanation on its website:

At room temperature, ethylene oxide is a flammable colorless gas with a sweet odor. It is used primarily to produce other chemicals, including antifreeze. In smaller amounts, ethylene oxide is used as a pesticide and a sterilizing agent. The ability of ethylene oxide to damage DNA makes it an effective sterilizing agent but also accounts for its cancer-causing activity.

The Institute mentions lymphoma and leukaemia as cancers most frequently reported to be associated with occupational exposure to ethylene oxide along with stomach and breast cancers. How does anyone think this is going to work out with the constant testing

regime being inflicted on adults and children at home and at school that will accumulate in the body anything that's on the swab?

Doctors know best

It is vital for people to realise that 'hero' doctors 'know' only what the Big Pharma-dominated medical authorities tell them to 'know' and if they refuse to 'know' what they are told to 'know' they are out the door. They are mostly not physicians or healers, but repeaters of the official narrative – or else. I have seen alleged professional doctors on British television make shocking statements that we are supposed to take seriously. One called 'Dr' Amir Khan, who is actually telling patients how to respond to illness, said that men could take the birth pill to 'help slow down the effects of Covid-19'. In March, 2021, another ridiculous 'Covid study' by an American doctor proposed injecting men with the female sex hormone progesterone as a 'Covid' treatment. British doctor Nighat Arif told the BBC that face coverings were now going to be part of ongoing normal. Yes, the vaccine protects you, she said (evidence?) … but the way to deal with viruses in the community was always going to come down to hand washing, face covering and keeping a physical distance. That's not what we were told before the 'vaccine' was circulating. Arif said she couldn't imagine ever again going on the underground or in a lift without a mask. I was just thanking my good luck that she was not my doctor when she said – in March, 2021 – that if 'we are *behaving* and we are doing all the right things' she thought we could 'have our nearest and dearest around us at home … around *Christmas* and N*ew Year!* Her patronising delivery was the usual school teacher talking to six-year-olds as she repeated every government talking point and probably believed them all. If we have learned anything from the 'Covid' experience surely it must be that humanity's perception of doctors needs a fundamental rethink. NHS 'doctor' Sara Kayat told her television audience that the 'Covid vaccine' would '100 percent prevent hospitalisation and death'. Not even Big Pharma claimed that. We have to stop taking 'experts' at their word without question when so many of them are

clueless and only repeating the party line on which their careers depend. That is not to say there are not brilliants doctors – there are and I have spoken to many of them since all this began – but you won't see them in the mainstream media or quoted by the psychopaths and yes-people in government.

Remember the name – Christian Drosten

German virologist Christian Drosten, Director of Charité Institute of Virology in Berlin, became a national star after the pandemic hoax began. He was feted on television and advised the German government on 'Covid' policy. Most importantly to the wider world Drosten led a group that produced the 'Covid' testing protocol for the PCR test. What a remarkable feat given the PCR cannot test for infectious disease and even more so when you think that Drosten said that his method of testing for SARS-CoV-2 was developed 'without having virus material available'. *He developed a test for a 'virus' that he didn't have and had never seen*. Let that sink in as you survey the global devastation that came from what he did. The whole catastrophe of Drosten's 'test' was based on the alleged genetic sequence published by Chinese scientists on the Internet. We will see in the next chapter that this alleged 'genetic sequence' has never been produced by China or anyone and cannot be when there *is no* SARS-CoV-2. Drosten, however, doesn't seem to let little details like that get in the way. He was the lead author with Victor Corman from the same Charité Hospital of the paper 'Detection of 2019 novel coronavirus (2019-nCoV) by real-time PCR' published in a magazine called *Eurosurveillance*. This became known as the Corman-Drosten paper. In November, 2020, with human society devastated by the effects of the Corman-Drosten test baloney, the protocol was publicly challenged by 22 international scientists and independent researchers from Europe, the United States, and Japan. Among them were senior molecular geneticists, biochemists, immunologists, and microbiologists. They produced a document headed 'External peer review of the RTPCR test to detect SARS-Cov-2 Reveals 10 Major Flaws At The Molecular and Methodological Level: Consequences

For False-Positive Results'. The flaws in the Corman-Drosten test included the following:

- The test is non-specific because of erroneous design
- Results are enormously variable
- The test is unable to discriminate between the whole 'virus' and viral fragments
- It doesn't have positive or negative controls
- The test lacks a standard operating procedure
- It is unsupported by proper peer view

The scientists said the PCR 'Covid' testing protocol was not founded on science and they demanded the Corman-Drosten paper be retracted by *Eurosurveillance*. They said all present and previous Covid deaths, cases, and 'infection rates' should be subject to a massive retroactive inquiry. Lockdowns and travel restrictions should be reviewed and relaxed and those diagnosed through PCR to have 'Covid-19' should not be forced to isolate. Dr Kevin Corbett, a health researcher and nurse educator with a long academic career producing a stream of peer-reviewed publications at many UK universities, made the same point about the PCR test debacle. He said of the scientists' conclusions: 'Every scientific rationale for the development of that test has been totally destroyed by this paper. It's like Hiroshima/Nagasaki to the Covid test.' He said that China hadn't given them an isolated 'virus' when Drosten developed the test. Instead they had developed the test from *a sequence in a gene bank*.' Put another way … *they made it up*! The scientists were supported in this contention by a Portuguese appeals court which ruled in November, 2020, that PCR tests are unreliable and it is unlawful to quarantine people based solely on a PCR test. The point about China not providing an isolated virus must be true when the 'virus' has never been isolated to this day and the consequences of that will become clear. Drosten and company produced this useless 'protocol' right on cue in January, 2020, just as the 'virus' was said to

be moving westward and it somehow managed to successfully pass a peer-review in 24 hours. In other words there was no peer-review for a test that would be used to decide who had 'Covid' and who didn't across the world. The Cult-created, Gates-controlled World Health Organization immediately recommended all its nearly 200 member countries to use the Drosten PCR protocol to detect 'cases' and 'deaths'. The sting was underway and it continues to this day.

So who is this Christian Drosten that produced the means through which death, destruction and economic catastrophe would be justified? His education background, including his doctoral thesis, would appear to be somewhat shrouded in mystery and his track record is dire as with another essential player in the 'Covid' hoax, the Gates-funded Professor Neil Ferguson at the Gates-funded Imperial College in London of whom more shortly. Drosten predicted in 2003 that the alleged original SARS 'virus' (SARS-1') was an epidemic that could have serious effects on economies and an effective vaccine would take at least two years to produce. Drosten's answer to every alleged 'outbreak' is a vaccine which you won't be shocked to know. What followed were just 774 official deaths worldwide and none in Germany where there were only nine cases. That is even if you believe there ever was a SARS 'virus' when the evidence is zilch and I will expand on this in the next chapter. Drosten claims to be co-discoverer of 'SARS-1' and developed a test for it in 2003. He was screaming warnings about 'swine flu' in 2009 and how it was a widespread infection far more severe than any dangers from a vaccine could be and people should get vaccinated. It would be helpful for Drosten's vocal chords if he simply recorded the words 'the virus is deadly and you need to get vaccinated' and copies could be handed out whenever the latest made-up threat comes along. Drosten's swine flu epidemic never happened, but Big Pharma didn't mind with governments spending hundreds of millions on vaccines that hardly anyone bothered to use and many who did wished they hadn't. A study in 2010 revealed that the risk of dying from swine flu, or H1N1, was no higher than that of the annual seasonal flu which is what at least most of 'it' really was as in

the case of 'Covid-19'. A media investigation into Drosten asked how with such a record of inaccuracy he could be *the* government adviser on these issues. The answer to that question is the same with Drosten, Ferguson and Fauci – they keep on giving the authorities the 'conclusions' and 'advice' they want to hear. Drosten certainly produced the goods for them in January, 2020, with his PCR protocol garbage and provided the foundation of what German internal medicine specialist Dr Claus Köhnlein, co-author of *Virus Mania*, called the 'test pandemic'. The 22 scientists in the *Eurosurveillance* challenge called out conflicts of interest within the Drosten 'protocol' group and with good reason. Olfert Landt, a regular co-author of Drosten 'studies', owns the biotech company TIB Molbiol Syntheselabor GmbH in Berlin which manufactures and sells the tests that Drosten and his mates come up with. They have done this with SARS, Enterotoxigenic E. coli (ETEC), MERS, Zika 'virus', yellow fever, and now 'Covid'. Landt told the *Berliner Zeitung* newspaper:

> The testing, design and development came from the Charité [Drosten and Corman]. We simply implemented it immediately in the form of a kit. And if we don't have the virus, which originally only existed in Wuhan, we can make a synthetic gene to simulate the genome of the virus. That's what we did very quickly.

This is more confirmation that the Drosten test was designed without access to the 'virus' and only a synthetic simulation which is what SARS-CoV-2 really is – a computer-generated synthetic fiction. It's quite an enterprise they have going here. A Drosten team decides what the test for something should be and Landt's biotech company flogs it to governments and medical systems across the world. His company must have made an absolute fortune since the 'Covid' hoax began. Dr Reiner Fuellmich, a prominent German consumer protection trial lawyer in Germany and California, is on Drosten's case and that of Tedros at the World Health Organization for crimes against humanity with a class-action lawsuit being prepared in the United States and other legal action in Germany.

Why China?

Scamming the world with a 'virus' that doesn't exist would seem impossible on the face of it, but not if you have control of the relatively few people that make policy decisions and the great majority of the global media. Remember it's not about changing 'real' reality it's about controlling *perception* of reality. You don't have to make something happen you only have make people *believe* that it's happening. Renegade Minds understand this and are therefore much harder to swindle. 'Covid-19' is not a 'real' 'virus'. It's a mind virus, like a computer virus, which has infected the minds, not the bodies, of billions. It all started, publically at least, in China and that alone is of central significance. The Cult was behind the revolution led by its asset Mao Zedong, or Chairman Mao, which established the People's Republic of China on October 1st, 1949. It should have been called The Cult's Republic of China, but the name had to reflect the recurring illusion that vicious dictatorships are run by and for the people (see all the 'Democratic Republics' controlled by tyrants). In the same way we have the 'Biden' Democratic Republic of America officially ruled by a puppet tyrant (at least temporarily) on behalf of Cult tyrants. The creation of Mao's merciless communist/fascist dictatorship was part of a frenzy of activity by the Cult at the conclusion of World War Two which, like the First World War, it had instigated through its assets in Germany, Britain, France, the United States and elsewhere. Israel was formed in 1948; the Soviet Union expanded its 'Iron Curtain' control, influence and military power with the Warsaw Pact communist alliance in 1955; the United Nations was formed in 1945 as a Cult precursor to world government; and a long list of world bodies would be established including the World Health Organization (1948), World Trade Organization (1948 under another name until 1995), International Monetary Fund (1945) and World Bank (1944). Human society was redrawn and hugely centralised in the global Problem-Reaction-Solution that was World War Two. All these changes were significant. Israel would become the headquarters of the Sabbatians

and the revolution in China would prepare the ground and control system for the events of 2019/2020.

Renegade Minds know there are no borders except for public consumption. The Cult is a seamless, borderless global entity and to understand the game we need to put aside labels like borders, nations, countries, communism, fascism and democracy. These delude the population into believing that countries are ruled within their borders by a government of whatever shade when these are mere agencies of a global power. America's illusion of democracy and China's communism/fascism are subsidiaries – vehicles – for the same agenda. We may hear about conflict and competition between America and China and on the lower levels that will be true; but at the Cult level they are branches of the same company in the way of the McDonald's example I gave earlier. I have tracked in the books over the years support by US governments of both parties for Chinese Communist Party infiltration of American society through allowing the sale of land, even military facilities, and the acquisition of American business and university influence. All this is underpinned by the infamous stealing of intellectual property and technological know-how. Cult-owned Silicon Valley corporations waive their fraudulent 'morality' to do business with human-rights-free China; Cult-controlled Disney has become China's PR department; and China in effect owns 'American' sports such as basketball which depends for much of its income on Chinese audiences. As a result any sports player, coach or official speaking out against China's horrific human rights record is immediately condemned or fired by the China-worshipping National Basketball Association. One of the first acts of China-controlled Biden was to issue an executive order telling federal agencies to stop making references to the 'virus' by the 'geographic location of its origin'. Long-time Congressman Jerry Nadler warned that criticising China, America's biggest rival, leads to hate crimes against Asian people in the United States. So shut up you bigot. China is fast closing in on Israel as a country that must not be criticised which is apt, really, given that Sabbatians control them both. The two countries have

developed close economic, military, technological and strategic ties which include involvement in China's 'Silk Road' transport and economic initiative to connect China with Europe. Israel was the first country in the Middle East to recognise the establishment of Mao's tyranny in 1950 months after it was established.

Project Wuhan – the 'Covid' Psyop

I emphasise again that the Cult plays the long game and what is happening to the world today is the result of centuries of calculated manipulation following a script to take control step-by-step of every aspect of human society. I will discuss later the common force behind all this that has spanned those centuries and thousands of years if the truth be told. Instigating the Mao revolution in China in 1949 with a 2020 'pandemic' in mind is not only how they work – the 71 years between them is really quite short by the Cult's standards of manipulation preparation. The reason for the Cult's Chinese revolution was to create a fiercely-controlled environment within which an extreme structure for human control could be incubated to eventually be unleashed across the world. We have seen this happen since the 'pandemic' emerged from China with the Chinese control-structure founded on AI technology and tyrannical enforcement sweep across the West. Until the moment when the Cult went for broke in the West and put its fascism on public display Western governments had to pay some lip-service to freedom and democracy to not alert too many people to the tyranny-in-the-making. Freedoms were more subtly eroded and power centralised with covert government structures put in place waiting for the arrival of 2020 when that smokescreen of 'freedom' could be dispensed with. The West was not able to move towards tyranny before 2020 anything like as fast as China which was created as a tyranny and had no limits on how fast it could construct the Cult's blueprint for global control. When the time came to impose that structure on the world it was the same Cult-owned Chinese communist/fascist government that provided the excuse – the 'Covid pandemic'. It was absolutely crucial to the Cult plan for the Chinese response to the 'pandemic' –

draconian lockdowns of the entire population – to become the blueprint that Western countries would follow to destroy the livelihoods and freedom of their people. This is why the Cult-owned, Gates-owned, WHO Director-General Tedros said early on:

The Chinese government is to be congratulated for the extraordinary measures it has taken to contain the outbreak. China is actually setting a new standard for outbreak response and it is not an exaggeration.

Forbes magazine said of China: '… those measures protected untold millions from getting the disease'. The Rockefeller Foundation 'epidemic scenario' document in 2010 said 'prophetically':

However, a few countries did fare better – China in particular. The Chinese government's quick imposition and enforcement of mandatory quarantine for all citizens, as well as its instant and near-hermetic sealing off of all borders, saved millions of lives, stopping the spread of the virus far earlier than in other countries and enabling a swifter post-pandemic recovery.

Once again – *spooky*.

The first official story was the 'bat theory' or rather the bat diversion. The source of the 'virus outbreak' we were told was a ''wet market' in Wuhan where bats and other animals are bought and eaten in horrifically unhygienic conditions. Then another story emerged through the alternative media that the 'virus' had been released on purpose or by accident from a BSL-4 (biosafety level 4) laboratory in Wuhan not far from the wet market. The lab was reported to create and work with lethal concoctions and bioweapons. Biosafety level 4 is the highest in the World Health Organization system of safety and containment. Renegade Minds are aware of what I call designer manipulation. The ideal for the Cult is for people to buy its prime narrative which in the opening salvoes of the 'pandemic' was the wet market story. It knows, however, that there is now a considerable worldwide alternative media of researchers sceptical of anything governments say and they are often given a version of events in a form they can perceive as credible while misdirecting them from the real truth. In this case let them

think that the conspiracy involved is a 'bioweapon virus' released from the Wuhan lab to keep them from the real conspiracy – *there is no 'virus'*. The WHO's current position on the source of the outbreak at the time of writing appears to be: 'We haven't got a clue, mate.' This is a good position to maintain mystery and bewilderment. The inner circle will know where the 'virus' came from – *nowhere*. The bottom line was to ensure the public believed there *was* a 'virus' and it didn't much matter if they thought it was natural or had been released from a lab. The belief that there was a 'deadly virus' was all that was needed to trigger global panic and fear. The population was terrified into handing their power to authority and doing what they were told. They had to or they were 'all gonna die'.

In March, 2020, information began to come my way from real doctors and scientists and my own additional research which had my intuition screaming: 'Yes, that's it! *There is no virus*.' The 'bioweapon' was not the 'virus'; it was the *'vaccine'* already being talked about that would be the bioweapon. My conclusion was further enhanced by happenings in Wuhan. The 'virus' was said to be sweeping the city and news footage circulated of people collapsing in the street (which they've never done in the West with the same 'virus'). The Chinese government was building 'new hospitals' in a matter of ten days to 'cope with demand' such was the virulent nature of the 'virus'. Yet in what seemed like no time the 'new hospitals' closed – even if they even opened – and China declared itself 'virus-free'. It was back to business as usual. This was more propaganda to promote the Chinese draconian lockdowns in the West as the way to 'beat the virus'. Trouble was that we subsequently had lockdown after lockdown, but never business as usual. As the people of the West and most of the rest of the world were caught in an ever-worsening spiral of lockdown, social distancing, masks, isolated old people, families forced apart, and livelihood destruction, it was party-time in Wuhan. Pictures emerged of thousands of people enjoying pool parties and concerts. It made no sense until you realised there never was a 'virus' and the

whole thing was a Cult set-up to transform human society out of one its major global strongholds – China.

How is it possible to deceive virtually the entire world population into believing there is a deadly virus when there is not even a 'virus' let alone a deadly one? It's nothing like as difficult as you would think and that's clearly true because it happened.

Postscript: See end of book Postscript for more on the 'Wuhan lab virus release' story which the authorities and media were pushing heavily in the summer of 2021 to divert attention from the truth that the 'Covid virus' is pure invention.

CHAPTER FIVE

There *is no* 'virus'

You can fool some of the people all of the time, and all of the people some of the time, but you cannot fool all of the people all of the time
Abraham Lincoln

The greatest form of mind control is repetition. The more you repeat the same mantra of alleged 'facts' the more will accept them to be true. It becomes an 'everyone knows that, mate'. If you can also censor any other version or alternative to your alleged 'facts' you are pretty much home and cooking.

By the start of 2020 the Cult owned the global mainstream media almost in its entirety to spew out its 'Covid' propaganda and ignore or discredit any other information and view. Cult-owned social media platforms in Cult-owned Silicon Valley were poised and ready to unleash a campaign of ferocious censorship to obliterate all but the official narrative. To complete the circle many demands for censorship by Silicon Valley were led by the mainstream media as 'journalists' became full-out enforcers for the Cult both as propagandists and censors. Part of this has been the influx of young people straight out of university who have become 'journalists' in significant positions. They have no experience and a headful of programmed perceptions from their years at school and university at a time when today's young are the most perceptually-targeted generations in known human history given the insidious impact of technology. They enter the media perceptually prepared and ready to repeat the narratives of the system that programmed them to

repeat its narratives. The BBC has a truly pathetic 'specialist disinformation reporter' called Marianna Spring who fits this bill perfectly. She is clueless about the world, how it works and what is really going on. Her role is to discredit anyone doing the job that a proper journalist would do and system-serving hacks like Spring wouldn't dare to do or even see the need to do. They are too busy licking the arse of authority which can never be wrong and, in the case of the BBC propaganda programme, *Panorama*, contacting payments systems such as PayPal to have a donations page taken down for a film company making documentaries questioning vaccines. Even the BBC soap opera *EastEnders* included a disgracefully biased scene in which an inarticulate white working class woman was made to look foolish for questioning the 'vaccine' while a well-spoken black man and Asian woman promoted the government narrative. It ticked every BBC box and the fact that the black and minority community was resisting the 'vaccine' had nothing to do with the way the scene was written. The BBC has become a disgusting tyrannical propaganda and censorship operation that should be defunded and disbanded and a free media take its place with a brief to stop censorship instead of demanding it. A BBC 'interview' with Gates goes something like: 'Mr Gates, sir, if I can call you sir, would you like to tell our audience why you are such a great man, a wonderful humanitarian philanthropist, and why you should absolutely be allowed as a software salesman to decide health policy for approaching eight billion people? Thank you, sir, please sir.' Propaganda programming has been incessant and merciless and when all you hear is the same story from the media, repeated by those around you who have only heard the same story, is it any wonder that people on a grand scale believe absolute mendacious garbage to be true? You are about to see, too, why this level of information control is necessary when the official 'Covid' narrative is so nonsensical and unsupportable by the evidence.

Structure of Deceit

The pyramid structure through which the 'Covid' hoax has been manifested is very simple and has to be to work. As few people as possible have to be involved with full knowledge of what they are doing – and why – or the real story would get out. At the top of the pyramid are the inner core of the Cult which controls Bill Gates who, in turn, controls the World Health Organization through his pivotal funding and his puppet Director-General mouthpiece, Tedros. Before he was appointed Tedros was chair of the Gates-founded Global Fund to 'fight against AIDS, tuberculosis and malaria', a board member of the Gates-funded 'vaccine alliance' GAVI, and on the board of another Gates-funded organisation. Gates owns him and picked him for a specific reason – Tedros is a crook and worse. 'Dr' Tedros (he's not a medical doctor, the first WHO chief not to be) was a member of the tyrannical Marxist government of Ethiopia for decades with all its human rights abuses. He has faced allegations of corruption and misappropriation of funds and was exposed three times for covering up cholera epidemics while Ethiopia's health minister. Tedros appointed the mass-murdering genocidal Zimbabwe dictator Robert Mugabe as a WHO goodwill ambassador for public health which, as with Tedros, is like appointing a psychopath to run a peace and love campaign. The move was so ridiculous that he had to drop Mugabe in the face of widespread condemnation. American economist David Steinman, a Nobel peace prize nominee, lodged a complaint with the International Criminal Court in The Hague over alleged genocide by Tedros when he was Ethiopia's foreign minister. Steinman says Tedros was a 'crucial decision maker' who directed the actions of Ethiopia's security forces from 2013 to 2015 and one of three officials in charge when those security services embarked on the 'killing' and 'torturing' of Ethiopians. You can see where Tedros is coming from and it's sobering to think that he has been the vehicle for Gates and the Cult to direct the global response to 'Covid'. Think about that. A psychopathic Cult dictates to psychopath Gates who dictates to psychopath Tedros who dictates how countries of the world must respond to a 'Covid virus' never scientifically shown to exist. At the same time psychopathic Cult-owned Silicon Valley information

giants like Google, YouTube, Facebook and Twitter announced very early on that they would give the Cult/Gates/Tedros/WHO version of the narrative free advertising and censor those who challenged their intelligence-insulting, mendacious story.

The next layer in the global 'medical' structure below the Cult, Gates and Tedros are the chief medical officers and science 'advisers' in each of the WHO member countries which means virtually all of them. Medical officers and arbiters of science (they're not) then take the WHO policy and recommended responses and impose them on their country's population while the political 'leaders' say they are deciding policy (they're clearly not) by 'following the science' on the advice of the 'experts' – the same medical officers and science 'advisers' (dictators). In this way with the rarest of exceptions the entire world followed the same policy of lockdown, people distancing, masks and 'vaccines' dictated by the psychopathic Cult, psychopathic Gates and psychopathic Tedros who we are supposed to believe give a damn about the health of the world population they are seeking to enslave. That, amazingly, is all there is to it in terms of crucial decision-making. Medical staff in each country then follow like sheep the dictates of the shepherds at the top of the national medical hierarchies – chief medical officers and science 'advisers' who themselves follow like sheep the shepherds of the World Health Organization and the Cult. Shepherds at the national level often have major funding and other connections to Gates and his Bill and Melinda Gates Foundation which carefully hands out money like confetti at a wedding to control the entire global medical system from the WHO down.

Follow the money

Christopher Whitty, Chief Medical Adviser to the UK Government at the centre of 'virus' policy, a senior adviser to the government's Scientific Advisory Group for Emergencies (SAGE), and Executive Board member of the World Health Organization, was gifted a grant of $40 million by the Bill and Melinda Gates Foundation for malaria research in Africa. The BBC described the unelected Whitty as 'the

official who will probably have the greatest impact on our everyday lives of any individual policymaker in modern times' and so it turned out. What Gates and Tedros have said Whitty has done like his equivalents around the world. Patrick Vallance, co-chair of SAGE and the government's Chief Scientific Adviser, is a former executive of Big Pharma giant GlaxoSmithKline with its fundamental financial and business connections to Bill Gates. In September, 2020, it was revealed that Vallance owned a deferred bonus of shares in GlaxoSmithKline worth £600,000 while the company was 'developing' a 'Covid vaccine'. Move along now – nothing to see here – what could possibly be wrong with that? Imperial College in London, a major player in 'Covid' policy in Britain and elsewhere with its 'Covid-19' Response Team, is funded by Gates and has big connections to China while the now infamous Professor Neil Ferguson, the useless 'computer modeller' at Imperial College is also funded by Gates. Ferguson delivered the dramatically inaccurate excuse for the first lockdowns (much more in the next chapter). The Institute for Health Metrics and Evaluation (IHME) in the United States, another source of outrageously false 'Covid' computer models to justify lockdowns, is bankrolled by Gates who is a vehement promotor of lockdowns. America's version of Whitty and Vallance, the again now infamous Anthony Fauci, has connections to 'Covid vaccine' maker Moderna as does Bill Gates through funding from the Bill and Melinda Gates Foundation. Fauci is director of the National Institute of Allergy and Infectious Diseases (NIAID), a major recipient of Gates money, and they are very close. Deborah Birx who was appointed White House Coronavirus Response Coordinator in February, 2020, is yet another with ties to Gates. Everywhere you look at the different elements around the world behind the coordination and decision making of the 'Covid' hoax there is Bill Gates and his money. They include the World Health Organization; Centers for Disease Control (CDC) in the United States; National Institutes of Health (NIH) of Anthony Fauci; Imperial College and Neil Ferguson; the London School of Hygiene where Chris Whitty worked; Regulatory agencies like the UK Medicines & Healthcare products Regulatory Agency (MHRA)

which gave emergency approval for 'Covid vaccines'; Wellcome Trust; GAVI, the Vaccine Alliance; the Coalition for Epidemic Preparedness Innovations (CEPI); Johns Hopkins University which has compiled the false 'Covid' figures; and the World Economic Forum. A Nationalfile.com article said:

> Gates has a lot of pull in the medical world, he has a multi-million dollar relationship with Dr. Fauci, and Fauci originally took the Gates line supporting vaccines and casting doubt on [the drug hydroxychloroquine]. Coronavirus response team member Dr. Deborah Birx, appointed by former president Obama to serve as United States Global AIDS Coordinator, also sits on the board of a group that has received billions from Gates' foundation, and Birx reportedly used a disputed Bill Gates-funded model for the White House's Coronavirus effort. Gates is a big proponent for a population lockdown scenario for the Coronavirus outbreak.

Another funder of Moderna is the Defense Advanced Research Projects Agency (DARPA), the technology-development arm of the Pentagon and one of the most sinister organisations on earth. DARPA had a major role with the CIA covert technology-funding operation In-Q-Tel in the development of Google and social media which is now at the centre of global censorship. Fauci and Gates are extremely close and openly admit to talking regularly about 'Covid' policy, but then why wouldn't Gates have a seat at every national 'Covid' table after his Foundation committed $1.75 billion to the 'fight against Covid-19'. When passed through our Orwellian Translation Unit this means that he has bought and paid for the Cult-driven 'Covid' response worldwide. Research the major 'Covid' response personnel in your own country and you will find the same Gates funding and other connections again and again. Medical and science chiefs following World Health Organization 'policy' sit atop a medical hierarchy in their country of administrators, doctors and nursing staff. These 'subordinates' are told they must work and behave in accordance with the policy delivered from the 'top' of the national 'health' pyramid which is largely the policy delivered by the WHO which is the policy delivered by Gates and the Cult. The whole 'Covid' narrative has been imposed on medical staff by a climate of fear although great numbers don't even need that to comply. They do so through breathtaking levels of ignorance and

include doctors who go through life simply repeating what Big Pharma and their hierarchical masters tell them to say and believe. No wonder Big Pharma 'medicine' is one of the biggest killers on Planet Earth.

The same top-down system of intimidation operates with regard to the Cult Big Pharma cartel which also dictates policy through national and global medical systems in this way. The Cult and Big Pharma agendas are the same because the former controls and owns the latter. 'Health' administrators, doctors, and nursing staff are told to support and parrot the dictated policy or they will face consequences which can include being fired. How sad it's been to see medical staff meekly repeating and imposing Cult policy without question and most of those who can see through the deceit are only willing to speak anonymously off the record. They know what will happen if their identity is known. This has left the courageous few to expose the lies about the 'virus', face masks, overwhelmed hospitals that aren't, and the dangers of the 'vaccine' that isn't a vaccine. When these medical professionals and scientists, some renowned in their field, have taken to the Internet to expose the truth their articles, comments and videos have been deleted by Cult-owned Facebook, Twitter and YouTube. What a real head-shaker to see YouTube videos with leading world scientists and highly qualified medical specialists with an added link underneath to the notorious Cult propaganda website *Wikipedia* to find the 'facts' about the same subject.

HIV – the 'Covid' trial-run

I'll give you an example of the consequences for health and truth that come from censorship and unquestioning belief in official narratives. The story was told by PCR inventor Kary Mullis in his book *Dancing Naked in the Mind Field*. He said that in 1984 he accepted as just another scientific fact that Luc Montagnier of France's Pasteur Institute and Robert Gallo of America's National Institutes of Health had independently discovered that a 'retrovirus' dubbed HIV (human immunodeficiency virus) caused AIDS. They

were, after all, Mullis writes, specialists in retroviruses. This is how the medical and science pyramids work. Something is announced or *assumed* and then becomes an everybody-knows-that purely through repetition of the assumption as if it is fact. Complete crap becomes accepted truth with no supporting evidence and only repetition of the crap. This is how a 'virus' that doesn't exist became the 'virus' that changed the world. The HIV-AIDS fairy story became a multi-billion pound industry and the media poured out propaganda terrifying the world about the deadly HIV 'virus' that caused the lethal AIDS. By then Mullis was working at a lab in Santa Monica, California, to detect retroviruses with his PCR test in blood donations received by the Red Cross. In doing so he asked a virologist where he could find a reference for HIV being the cause of AIDS. 'You don't need a reference,' the virologist said … *'Everybody knows it.'* Mullis said he wanted to quote a reference in the report he was doing and he said he felt a little funny about not knowing the source of such an important discovery when everyone else seemed to. The virologist suggested he cite a report by the Centers for Disease Control and Prevention (CDC) on morbidity and mortality. Mullis read the report, but it only said that an organism had been identified and did not say how. The report did not identify the original scientific work. Physicians, however, *assumed* (key recurring theme) that if the CDC was convinced that HIV caused AIDS then proof must exist. Mullis continues:

I did computer searches. Neither Montagnier, Gallo, nor anyone else had published papers describing experiments which led to the conclusion that HIV probably caused AIDS. I read the papers in Science for which they had become well known as AIDS doctors, but all they had said there was that they had found evidence of a past infection by something which was probably HIV in some AIDS patients.

They found antibodies. Antibodies to viruses had always been considered evidence of past disease, not present disease. Antibodies signaled that the virus had been defeated. The patient had saved himself. There was no indication in these papers that this virus caused a disease. They didn't show that everybody with the antibodies had the disease. In fact they found some healthy people with antibodies.

Mullis asked why their work had been published if Montagnier and Gallo hadn't really found this evidence, and why had they been fighting so hard to get credit for the discovery? He says he was hesitant to write 'HIV is the probable cause of AIDS' until he found published evidence to support that. 'Tens of thousands of scientists and researchers were spending billions of dollars a year doing research based on this idea,' Mullis writes. 'The reason had to be there somewhere; otherwise these people would not have allowed their research to settle into one narrow channel of investigation.' He said he lectured about PCR at numerous meetings where people were always talking about HIV and he asked them how they knew that HIV was the cause of AIDS:

> Everyone said something. Everyone had the answer at home, in the office, in some drawer. They all knew, and they would send me the papers as soon as they got back. But I never got any papers. Nobody ever sent me the news about how AIDS was caused by HIV.

Eventually Mullis was able to ask Montagnier himself about the reference proof when he lectured in San Diego at the grand opening of the University of California AIDS Research Center. Mullis says this was the last time he would ask his question without showing anger. Montagnier said he should reference the CDC report. 'I read it', Mullis said, and it didn't answer the question. 'If Montagnier didn't know the answer who the hell did?' Then one night Mullis was driving when an interview came on National Public Radio with Peter Duesberg, a prominent virologist at Berkeley and a California Scientist of the Year. Mullis says he finally understood why he could not find references that connected HIV to AIDS – *there weren't any!* No one had ever proved that HIV causes AIDS even though it had spawned a multi-billion pound global industry and the media was repeating this as fact every day in their articles and broadcasts terrifying the shit out of people about AIDS and giving the impression that a positive test for HIV (see 'Covid') was a death sentence. Duesberg was a threat to the AIDS gravy train and the agenda that underpinned it. He was therefore abused and castigated after he told the Proceedings of the National Academy of Sciences

there was no good evidence implicating the new 'virus'. Editors rejected his manuscripts and his research funds were deleted. Mullis points out that the CDC has defined AIDS as one of more than 30 diseases *if accompanied* by a positive result on a test that detects antibodies to HIV; but those same diseases are not defined as AIDS cases when antibodies are not detected:

> If an HIV-positive woman develops uterine cancer, for example, she is considered to have AIDS. If she is not HIV positive, she simply has uterine cancer. An HIV-positive man with tuberculosis has AIDS; if he tests negative he simply has tuberculosis. If he lives in Kenya or Colombia, where the test for HIV antibodies is too expensive, he is simply presumed to have the antibodies and therefore AIDS, and therefore he can be treated in the World Health Organization's clinic. It's the only medical help available in some places. And it's free, because the countries that support WHO are worried about AIDS.

Mullis accuses the CDC of continually adding new diseases (see ever more 'Covid symptoms') to the grand AIDS definition and of virtually doctoring the books to make it appear as if the disease continued to spread. He cites how in 1993 the CDC enormously broadened its AIDS definition and county health authorities were delighted because they received $2,500 per year from the Federal government for every reported AIDS case. Ladies and gentlemen, I have just described, via Kary Mullis, the 'Covid pandemic' of 2020 and beyond. Every element is the same and it's been pulled off in the same way by the same networks.

The 'Covid virus' exists? Okay – prove it. Er … still waiting

What Kary Mullis described with regard to 'HIV' has been repeated with 'Covid'. A claim is made that a new, or 'novel', infection has been found and the entire medical system of the world repeats that as fact exactly as they did with HIV and AIDS. No one in the mainstream asks rather relevant questions such as 'How do you know?' and 'Where is your proof?' The SARS-Cov-2 'virus' and the 'Covid-19 disease' became an overnight 'everybody-knows-that'. The origin could be debated and mulled over, but what you could not suggest was that 'SARS-Cov-2' didn't exist. That would be

ridiculous. 'Everybody knows' the 'virus' exists. Well, I didn't for one along with American proper doctors like Andrew Kaufman and Tom Cowan and long-time American proper journalist Jon Rappaport. We dared to pursue the obvious and simple question: 'Where's the evidence?' The overwhelming majority in medicine, journalism and the general public did not think to ask that. After all, *everyone knew* there was a new 'virus'. Everyone was saying so and I heard it on the BBC. Some would eventually argue that the 'deadly virus' was nothing like as deadly as claimed, but few would venture into the realms of its very existence. Had they done so they would have found that the evidence for that claim had gone AWOL as with HIV causes AIDS. In fact, not even that. For something to go AWOL it has to exist in the first place and scientific proof for a 'SARS-Cov-2' can be filed under nothing, nowhere and zilch.

Dr Andrew Kaufman is a board-certified forensic psychiatrist in New York State, a Doctor of Medicine and former Assistant Professor and Medical Director of Psychiatry at SUNY Upstate Medical University, and Medical Instructor of Hematology and Oncology at the Medical School of South Carolina. He also studied biology at the Massachusetts Institute of Technology (MIT) and trained in Psychiatry at Duke University. Kaufman is retired from allopathic medicine, but remains a consultant and educator on natural healing, I saw a video of his very early on in the 'Covid' hoax in which he questioned claims about the 'virus' in the absence of any supporting evidence and with plenty pointing the other way. I did everything I could to circulate his work which I felt was asking the pivotal questions that needed an answer. I can recommend an excellent pull-together interview he did with the website The Last Vagabond entitled *Dr Andrew Kaufman: Virus Isolation, Terrain Theory and Covid-19* and his website is andrewkaufmanmd.com. Kaufman is not only a forensic psychiatrist; he is forensic in all that he does. He always reads original scientific papers, experiments and studies instead of second-third-fourth-hand reports about the 'virus' in the media which are repeating the repeated repetition of the narrative. When he did so with the original Chinese 'virus' papers Kaufman

realised that there was no evidence of a 'SARS-Cov-2'. They had never – from the start – shown it to exist and every repeat of this claim worldwide was based on the accepted existence of proof that was nowhere to be found – see Kary Mullis and HIV. Here we go again.

Let's postulate

Kaufman discovered that the Chinese authorities immediately concluded that the cause of an illness that broke out among about 200 initial patients in Wuhan was a 'new virus' when there were no grounds to make that conclusion. The alleged 'virus' was not isolated from other genetic material in their samples and then shown through a system known as Koch's postulates to be the causative agent of the illness. The world was told that the SARS-Cov-2 'virus' caused a disease they called 'Covid-19' which had 'flu-like' symptoms and could lead to respiratory problems and pneumonia. If it wasn't so tragic it would almost be funny. *'Flu-like' symptoms'? Pneumonia? Respiratory disease?* What in *CHINA* and particularly in *Wuhan*, one of the most polluted cities in the world with a resulting epidemic of respiratory disease?? Three hundred thousand people get pneumonia in China every year and there are nearly a billion cases worldwide of 'flu-like symptoms'. These have a whole range of causes – including pollution in Wuhan – but no other possibility was credibly considered in late 2019 when the world was told there was a new and deadly 'virus'. The global prevalence of pneumonia and 'flu-like systems' gave the Cult networks unlimited potential to re-diagnose these other causes as the mythical 'Covid-19' and that is what they did from the very start. Kaufman revealed how Chinese medical and science authorities (all subordinates to the Cult-owned communist government) took genetic material from the lungs of only a few of the first patients. The material contained their own cells, bacteria, fungi and other microorganisms living in their bodies. The only way you could prove the existence of the 'virus' and its responsibility for the alleged 'Covid-19' was to isolate the virus from all the other material – a process also known as 'purification' – and

then follow the postulates sequence developed in the late 19th century by German physician and bacteriologist Robert Koch which became the 'gold standard' for connecting an alleged causation agent to a disease:

1. The microorganism (bacteria, fungus, virus, etc.) must be present in every case of the disease and all patients must have the same symptoms. It must also *not be present in healthy individuals*.

2. The microorganism must be isolated from the host with the disease. If the microorganism is a bacteria or fungus it must be grown in a pure culture. If it is a virus, it must be purified (i.e. containing no other material except the virus particles) from a clinical sample.

3. The specific disease, with all of its characteristics, must be reproduced when the infectious agent (the purified virus or a pure culture of bacteria or fungi) is inoculated into a healthy, susceptible host.

4. The microorganism must be recoverable from the experimentally infected host as in step 2.

Not one of these criteria has been met in the case of 'SARS-Cov-2' and 'Covid-19'. Not ONE. *EVER*. Robert Koch refers to bacteria and not viruses. What are called 'viral particles' are so minute (hence masks are useless by any definition) that they could only be seen after the invention of the electron microscope in the 1930s and can still only be observed through that means. American bacteriologist and virologist Thomas Milton Rivers, the so-called 'Father of Modern Virology' who was very significantly director of the Rockefeller Institute for Medical Research in the 1930s, developed a less stringent version of Koch's postulates to identify 'virus' causation known as 'Rivers criteria'. 'Covid' did not pass that process either. Some even doubt whether any 'virus' can be isolated from other particles containing genetic material in the Koch method. Freedom of Information requests in many countries asking for scientific proof that the 'Covid virus' has been purified and isolated and shown to exist have all come back with a 'we don't have that' and when this happened with a request to the UK Department of Health they added this comment:

However, outside of the scope of the [Freedom of Information Act] and on a discretionary basis, the following information has been advised to us, which may be of interest. Most infectious diseases are caused by viruses, bacteria or fungi. Some bacteria or fungi have the capacity to grow on their own in isolation, for example in colonies on a petri dish. Viruses are different in that they are what we call 'obligate pathogens' – that is, they cannot survive or reproduce without infecting a host ...

… For some diseases, it is possible to establish causation between a microorganism and a disease by isolating the pathogen from a patient, growing it in pure culture and reintroducing it to a healthy organism. These are known as 'Koch's postulates' and were developed in 1882. However, as our understanding of disease and different disease-causing agents has advanced, these are no longer the method for determining causation [Andrew Kaufman asks why in that case are there two published articles falsely claiming to satisfy Koch's postulates].

It has long been known that viral diseases cannot be identified in this way as viruses cannot be grown in 'pure culture'. When a patient is tested for a viral illness, this is normally done by looking for the presence of antigens, or viral genetic code in a host with molecular biology techniques [Kaufman asks how you could know the origin of these chemicals without having a pure culture for comparison].

For the record 'antigens' are defined so:

Invading microorganisms have antigens on their surface that the human body can recognise as being foreign – meaning not belonging to it. When the body recognises a foreign antigen, lymphocytes (white blood cells) produce antibodies, which are complementary in shape to the antigen.

Notwithstanding that this is open to question in relation to 'SARS-Cov-2' the presence of 'antibodies' can have many causes and they are found in people that are perfectly well. Kary Mullis said: 'Antibodies … had always been considered evidence of past disease, not present disease.'

'Covid' really is a *computer* 'virus'

Where the UK Department of Health statement says 'viruses' are now 'diagnosed' through a 'viral genetic code in a host with molecular biology techniques', they mean … *the PCR test* which its inventor said cannot test for infectious disease. They have no credible method of connecting a 'virus' to a disease and we will see that there is no scientific proof that any 'virus' causes any disease or there is any such thing as a 'virus' in the way that it is described. Tenacious Canadian researcher Christine Massey and her team made

some 40 Freedom of Information requests to national public health agencies in different countries asking for proof that SARS-CoV-2 has been isolated and not one of them could supply that information. Massey said of her request in Canada: 'Freedom of Information reveals Public Health Agency of Canada has no record of 'SARS-COV-2' isolation performed by anyone, anywhere, ever.' If you accept the comment from the UK Department of Health it's because they can't isolate a 'virus'. Even so many 'science' papers claimed to have isolated the 'Covid virus' until they were questioned and had to admit they hadn't. A reply from the Robert Koch Institute in Germany was typical: 'I am not aware of a paper which purified isolated SARS-CoV-2.' So what the hell was Christian Drosten and his gang using to design the 'Covid' testing protocol that has produced all the illusory Covid' cases and 'Covid' deaths when the head of the Chinese version of the CDC admitted there was a problem right from the start in that the 'virus' had never been isolated/purified? Breathe deeply: What they are calling 'Covid' is actually created by a *computer program* i.e. *they made it up* – er, that's it. They took lung fluid, with many sources of genetic material, from one single person alleged to be infected with Covid-19 by a PCR test which they *claimed*, without clear evidence, contained a 'virus'. They used several computer programs to create a model of a theoretical virus genome sequence from more than fifty-six million small sequences of RNA, each of an unknown source, assembling them like a puzzle with no known solution. The computer filled in the gaps with sequences from bits in the gene bank to make it look like a bat SARS-like coronavirus! A wave of the magic wand and poof, an in silico (computer-generated) genome, a scientific fantasy, was created. UK health researcher Dr Kevin Corbett made the same point with this analogy:

> … It's like giving you a few bones and saying that's your fish. It could be any fish. Not even a skeleton. Here's a few fragments of bones. That's your fish … It's all from gene bank and the bits of the virus sequence that weren't there they made up.
>
> They synthetically created them to fill in the blanks. That's what genetics is; it's a code. So it's ABBBCCDDD and you're missing some what you think is EEE so you put it in. It's all

synthetic. You just manufacture the bits that are missing. This is the end result of the geneticization of virology. This is basically a computer virus.

Further confirmation came in an email exchange between British citizen journalist Frances Leader and the government's Medicines & Healthcare Products Regulatory Agency (the Gates-funded MHRA) which gave emergency permission for untested 'Covid vaccines' to be used. The agency admitted that the 'vaccine' is not based on an isolated 'virus', but comes from a *computer-generated model*. Frances Leader was naturally banned from Cult-owned fascist Twitter for making this exchange public. The process of creating computer-generated alleged 'viruses' is called 'in silico' or 'in silicon' – computer chips – and the term 'in silico' is believed to originate with biological experiments using only a computer in 1989. 'Vaccines' involved with 'Covid' are also produced 'in silico' or by computer not a natural process. If the original 'virus' is nothing more than a made-up computer model how can there be 'new variants' of something that never existed in the first place? They are not new 'variants'; they are new *computer models* only minutely different to the original program and designed to further terrify the population into having the 'vaccine' and submitting to fascism. You want a 'new variant'? Click, click, enter – there you go. Tell the medical profession that you have discovered a 'South African variant', 'UK variants' or a 'Brazilian variant' and in the usual HIV-causes-AIDS manner they will unquestioningly repeat it with no evidence whatsoever to support these claims. They will go on television and warn about the dangers of 'new variants' while doing nothing more than repeating what they have been told to be true and knowing that any deviation from that would be career suicide. Big-time insiders will know it's a hoax, but much of the medical community is clueless about the way they are being played and themselves play the public without even being aware they are doing so. What an interesting 'coincidence' that AstraZeneca and Oxford University were conducting 'Covid vaccine trials' in the three countries – the UK, South Africa and Brazil – where the first three 'variants' were claimed to have 'broken out'.

Here's your 'virus' – it's a unicorn

Dr Andrew Kaufman presented a brilliant analysis describing how the 'virus' was imagined into fake existence when he dissected an article published by *Nature* and written by 19 authors detailing *alleged* 'sequencing of a complete viral genome' of the 'new SARS-CoV-2 virus'. This computer-modelled *in silico* genome was used as a template for all subsequent genome sequencing experiments that resulted in the so-called variants which he said now number more than *6,000*. The fake genome was constructed from more than 56 million individual short strands of RNA. Those little pieces were assembled into longer pieces by finding areas of overlapping sequences. The computer programs created over two million possible combinations from which the authors simply chose the longest one. They then compared this to a 'bat virus' and the computer 'alignment' rearranged the sequence and filled in the gaps! They called this computer-generated abomination the 'complete genome'. Dr Tom Cowan, a fellow medical author and collaborator with Kaufman, said such computer-generation constitutes scientific fraud and he makes this superb analogy:

> Here is an equivalency: A group of researchers claim to have found a unicorn because they found a piece of a hoof, a hair from a tail, and a snippet of a horn. They then add that information into a computer and program it to re-create the unicorn, and they then claim this computer re-creation is the real unicorn. Of course, they had never actually seen a unicorn so could not possibly have examined its genetic makeup to compare their samples with the actual unicorn's hair, hooves and horn.
>
> The researchers claim they decided which is the real genome of SARS-CoV-2 by 'consensus', sort of like a vote. Again, different computer programs will come up with different versions of the imaginary 'unicorn', so they come together as a group and decide which is the real imaginary unicorn.

This is how the 'virus' that has transformed the world was brought into fraudulent 'existence'. Extraordinary, yes, but as the Nazis said the bigger the lie the more will believe it. Cowan, however, wasn't finished and he went on to identify what he called the real blockbuster in the paper. He quotes this section from a paper written

by virologists and published by the CDC and then explains what it means:

> Therefore, we examined the capacity of SARS-CoV-2 to infect and replicate in several common primate and human cell lines, including human adenocarcinoma cells (A549), human liver cells (HUH 7.0), and human embryonic kidney cells (HEK-293T). In addition to Vero E6 and Vero CCL81 cells. ... Each cell line was inoculated at high multiplicity of infection and examined 24h post-infection.
>
> No CPE was observed in any of the cell lines except in Vero cells, which grew to greater than 10 to the 7th power at 24 h post-infection. In contrast, HUH 7.0 and 293T showed only modest viral replication, and A549 cells were incompatible with SARS CoV-2 infection.

Cowan explains that when virologists attempt to prove infection they have three possible 'hosts' or models on which they can test. The first was humans. Exposure to humans was generally not done for ethical reasons and has never been done with SARS-CoV-2 or any coronavirus. The second possible host was animals. Cowan said that forgetting for a moment that they never actually use purified virus when exposing animals they do use solutions that they *claim* contain the virus. Exposure to animals has been done with SARS-CoV-2 in an experiment involving mice and this is what they found: *None of the wild (normal) mice got sick*. In a group of genetically-modified mice, a statistically insignificant number lost weight and had slightly bristled fur, but they experienced nothing like the illness called 'Covid-19'. Cowan said the third method – the one they mostly rely on – is to inoculate solutions they *say* contain the virus onto a variety of tissue cultures. This process had never been shown to kill tissue *unless* the sample material was starved of nutrients and poisoned as *part of the process*. Yes, incredibly, in tissue experiments designed to show the 'virus' is responsible for killing the tissue they starve the tissue of nutrients and add toxic drugs including antibiotics and they do not have control studies to see if it's the starvation and poisoning that is degrading the tissue rather than the 'virus' they allege to be in there somewhere. You want me to pinch you? Yep, I understand. Tom Cowan said this about the whole nonsensical farce as he explains what that quote from the CDC paper really means:

The shocking thing about the above quote is that using their own methods, the virologists found that solutions containing SARS-CoV-2 – even in high amounts – were NOT, I repeat NOT, infective to any of the three human tissue cultures they tested. In plain English, this means they proved, on their terms, that this 'new coronavirus' is not infectious to human beings. It is ONLY infective to monkey kidney cells, and only then when you add two potent drugs (gentamicin and amphotericin), known to be toxic to kidneys, to the mix.

My friends, read this again and again. These virologists, published by the CDC, performed a clear proof, on their terms, showing that the SARS-CoV-2 virus is harmless to human beings. That is the only possible conclusion, but, unfortunately, this result is not even mentioned in their conclusion. They simply say they can provide virus stocks cultured only on monkey Vero cells, thanks for coming.

Cowan concluded: 'If people really understood how this "science" was done, I would hope they would storm the gates and demand honesty, transparency and truth.' Dr Michael Yeadon, former Vice President and Chief Scientific Adviser at drug giant Pfizer has been a vocal critic of the 'Covid vaccine' and its potential for multiple harm. He said in an interview in April, 2021, that 'not one [vaccine] has the virus. He was asked why vaccines normally using a 'dead' version of a disease to activate the immune system were not used for 'Covid' and instead we had the synthetic methods of the 'mRNA Covid vaccine'. Yeadon said that to do the former 'you'd have to have some of [the virus] wouldn't you?' He added: 'No-one's got any – seriously.' Yeadon said that surely they couldn't have fooled the whole world for a year without having a virus, 'but oddly enough ask around – no one's got it'. He didn't know why with all the 'great labs' around the world that the virus had not been isolated – 'Maybe they've been too busy running bad PCR tests and vaccines that people don't need.' What is today called 'science' is not 'science' at all. Science is no longer what is, but whatever people can be manipulated to *believe* that it is. Real science has been hijacked by the Cult to dispense and produce the 'expert scientists' and contentions that suit the agenda of the Cult. How big-time this has happened with the 'Covid' hoax which is entirely based on fake science delivered by fake 'scientists' and fake 'doctors'. The human-caused climate change hoax is also entirely based on fake science delivered by fake 'scientists' and fake 'climate experts'. In both cases real

scientists, climate experts and doctors have their views suppressed and deleted by the Cult-owned science establishment, media and Silicon Valley. This is the 'science' that politicians claim to be 'following' and a common denominator of 'Covid' and climate are Cult psychopaths Bill Gates and his mate Klaus Schwab at the Gates-funded World Economic Forum. But, don't worry, it's all just a coincidence and absolutely nothing to worry about. *Zzzzzzzz*.

What is a 'virus' REALLY?

Dr Tom Cowan is one of many contesting the very existence of viruses let alone that they cause disease. This is understandable when there is no scientific evidence for a disease-causing 'virus'. German virologist Dr Stefan Lanka won a landmark case in 2017 in the German Supreme Court over his contention that there is no such thing as a measles virus. He had offered a big prize for anyone who could prove there is and Lanka won his case when someone sought to claim the money. There is currently a prize of more than 225,000 euros on offer from an Isolate Truth Fund for anyone who can prove the isolation of SARS-CoV-2 and its genetic substance. Lanka wrote in an article headed 'The Misconception Called Virus' that scientists think a 'virus' is causing tissue to become diseased and degraded when in fact it is the *processes they are using* which do that – not a 'virus'. Lanka has done an important job in making this point clear as Cowan did in his analysis of the CDC paper. Lanka says that all claims about viruses as disease-causing pathogens are wrong and based on 'easily recognisable, understandable and verifiable misinterpretations.' Scientists believed they were working with 'viruses' in their laboratories when they were really working with 'typical particles of specific dying tissues or cells …' Lanka said that the tissue decaying process claimed to be caused by a 'virus' still happens when no alleged 'virus' is involved. It's the *process* that does the damage and not a 'virus'. The genetic sample is deprived of nutrients, removed from its energy supply through removal from the body and then doused in toxic antibiotics to remove any bacteria. He confirms again that establishment scientists do not (pinch me)

conduct control experiments to see if this is the case and if they did they would see the claims that 'viruses' are doing the damage is nonsense. He adds that during the measles 'virus' court case he commissioned an independent laboratory to perform just such a control experiment and the result was that the tissues and cells died in the exact same way as with alleged 'infected' material. This is supported by a gathering number of scientists, doctors and researchers who reject what is called 'germ theory' or the belief in the body being infected by contagious sources emitted by other people. Researchers Dawn Lester and David Parker take the same stance in their highly-detailed and sourced book *What Really Makes You Ill – Why everything you thought you knew about disease is wrong* which was recommended to me by a number of medical professionals genuinely seeking the truth. Lester and Parker say there is no provable scientific evidence to show that a 'virus' can be transmitted between people or people and animals or animals and people:

> The definition also claims that viruses are the cause of many diseases, as if this has been definitively proven. But this is not the case; there is no original scientific evidence that definitively demonstrates that any virus is the cause of any disease. The burden of proof for any theory lies with those who proposed it; but none of the existing documents provides 'proof' that supports the claim that 'viruses' are pathogens.

Dr Tom Cowan employs one of his clever analogies to describe the process by which a 'virus' is named as the culprit for a disease when what is called a 'virus' is only material released by cells detoxing themselves from infiltration by chemical or radiation poisoning. The tidal wave of technologically-generated radiation in the 'smart' modern world plus all the toxic food and drink are causing this to happen more than ever. Deluded 'scientists' misread this as a gathering impact of what they wrongly label 'viruses'.

Paper can infect houses

Cowan said in an article for davidicke.com – with his tongue only mildly in his cheek – that he believed he had made a tremendous

discovery that may revolutionise science. He had discovered that small bits of paper are alive, 'well alive-ish', can 'infect' houses, and then reproduce themselves inside the house. The result was that this explosion of growth in the paper inside the house causes the house to explode, blowing it to smithereens. His evidence for this new theory is that in the past months he had carefully examined many of the houses in his neighbourhood and found almost no scraps of paper on the lawns and surrounds of the house. There was an occasional stray label, but nothing more. Then he would return to these same houses a week or so later and with a few, not all of them, particularly the old and decrepit ones, he found to his shock and surprise they were littered with stray bits of paper. He knew then that the paper had infected these houses, made copies of itself, and blew up the house. A young boy on a bicycle at one of the sites told him he had seen a demolition crew using dynamite to explode the house the previous week, but Cowan dismissed this as the idle thoughts of silly boys because 'I was on to something big'. He was on to how 'scientists' mistake genetic material in the detoxifying process for something they call a 'virus'. Cowan said of his house and paper story:

> If this sounds crazy to you, it's because it should. This scenario is obviously nuts. But consider this admittedly embellished, for effect, current viral theory that all scientists, medical doctors and virologists currently believe.

He takes the example of the 'novel SARS-Cov2' virus to prove the point. First they take someone with an undefined illness called 'Covid-19' and don't even attempt to find any virus in their sputum. Never mind the scientists still describe how this 'virus', which they have not located attaches to a cell receptor, injects its genetic material, in 'Covid's' case, RNA, into the cell. The RNA once inserted exploits the cell to reproduce itself and makes 'thousands, nay millions, of copies of itself … Then it emerges victorious to claim its next victim':

If you were to look in the scientific literature for proof, actual scientific proof, that uniform SARS-CoV2 viruses have been properly isolated from the sputum of a sick person, that actual spike proteins could be seen protruding from the virus (which has not been found), you would find that such evidence doesn't exist.

If you go looking in the published scientific literature for actual pictures, proof, that these spike proteins or any viral proteins are ever attached to any receptor embedded in any cell membrane, you would also find that no such evidence exists. If you were to look for a video or documented evidence of the intact virus injecting its genetic material into the body of the cell, reproducing itself and then emerging victorious by budding off the cell membrane, you would find that no such evidence exists.

The closest thing you would find is electron micrograph pictures of cellular particles, possibly attached to cell debris, both of which to be seen were stained by heavy metals, a process that completely distorts their architecture within the living organism. This is like finding bits of paper stuck to the blown-up bricks, thereby proving the paper emerged by taking pieces of the bricks on its way out.

The Enders baloney

Cowan describes the 'Covid' story as being just as make-believe as his paper story and he charts back this fantasy to a Nobel Prize winner called John Enders (1897-1985), an American biomedical scientist who has been dubbed 'The Father of Modern Vaccines'. Enders is claimed to have 'discovered' the process of the viral culture which 'proved' that a 'virus' caused measles. Cowan explains how Enders did this 'by using the EXACT same procedure that has been followed by every virologist to find and characterize every new virus since 1954'. Enders took throat swabs from children with measles and immersed them in 2ml of milk. Penicillin (100u/ml) and the antibiotic streptomycin (50,g/ml) were added and the whole mix was centrifuged – rotated at high speed to separate large cellular debris from small particles and molecules as with milk and cream, for example. Cowan says that if the aim is to find little particles of genetic material ('viruses') in the snot from children with measles it would seem that the last thing you would do is mix the snot with other material – milk –that also has genetic material. 'How are you ever going to know whether whatever you found came from the snot or the milk?' He points out that streptomycin is a 'nephrotoxic' or poisonous-to-the-kidney drug. You will see the relevance of that

shortly. Cowan says that it gets worse, much worse, when Enders describes the culture medium upon which the virus 'grows': 'The culture medium consisted of bovine amniotic fluid (90%), beef embryo extract (5%), horse serum (5%), antibiotics and phenol red as an indicator of cell metabolism.' Cowan asks incredulously: 'Did he just say that the culture medium also contained fluids and tissues that are themselves rich sources of genetic material?' The genetic cocktail, or 'medium', is inoculated onto tissue and cells from rhesus monkey *kidney* tissue. This is where the importance of streptomycin comes in and currently-used antimicrobials and other drugs that are *poisonous to kidneys* and used in ALL modern viral cultures (e.g. gentamicin, streptomycin, and amphotericin). Cowan asks: 'How are you ever going to know from this witch's brew where any genetic material comes from as we now have five different sources of rich genetic material in our mix?' Remember, he says, that all genetic material, whether from monkey kidney tissues, bovine serum, milk, etc., is made from the exact same components. The same central question returns: 'How are you possibly going to know that it was the virus that killed the kidney tissue and not the toxic antibiotic and starvation rations on which you are growing the tissue?' John Enders answered the question himself – *you can't*:

A second agent was obtained from an uninoculated culture of monkey kidney cells. The cytopathic changes [death of the cells] it induced in the unstained preparations could not be distinguished with confidence from the viruses isolated from measles.

The death of the cells ('cytopathic changes') happened in exactly the same manner, whether they inoculated the kidney tissue with the measles snot or not, Cowan says. 'This is evidence that the destruction of the tissue, the very proof of viral causation of illness, was not caused by anything in the snot because they saw the same destructive effect when the snot was not even used … the cytopathic, i.e., cell-killing, changes come from the process of the culture itself, not from any virus in any snot, period.' Enders quotes in his 1957 paper a virologist called Ruckle as reporting similar findings 'and in addition has isolated an agent from monkey kidney tissue that is so

far indistinguishable from human measles virus'. In other words, Cowan says, these particles called 'measles viruses' are simply and clearly breakdown products of the starved and poisoned tissue. For measles 'virus' see all 'viruses' including the so-called 'Covid virus'. Enders, the 'Father of Modern Vaccines', also said:

There is a potential risk in employing cultures of primate cells for the production of vaccines composed of attenuated virus, since the presence of other agents possibly latent in primate tissues cannot be definitely excluded by any known method.

Cowan further quotes from a paper published in the journal *Viruses* in May, 2020, while the 'Covid pandemic' was well underway in the media if not in reality. 'EVs' here refers to particles of genetic debris from our own tissues, such as exosomes of which more in a moment: 'The remarkable resemblance between EVs and viruses has caused quite a few problems in the studies focused on the analysis of EVs released during viral infections.' Later the paper adds that to date a reliable method that can actually guarantee a complete separation (of EVs from viruses) DOES NOT EXIST. This was published at a time when a fairy tale 'virus' was claimed in total certainty to be causing a fairy tale 'viral disease' called 'Covid-19' – a fairy tale that was already well on the way to transforming human society in the image that the Cult has worked to achieve for so long. Cowan concludes his article:

To summarize, there is no scientific evidence that pathogenic viruses exist. What we think of as 'viruses' are simply the normal breakdown products of dead and dying tissues and cells. When we are well, we make fewer of these particles; when we are starved, poisoned, suffocated by wearing masks, or afraid, we make more.

There is no engineered virus circulating and making people sick. People in laboratories all over the world are making genetically modified products to make people sick. These are called vaccines. There is no virome, no 'ecosystem' of viruses, viruses are not 8%, 50% or 100 % of our genetic material. These are all simply erroneous ideas based on the misconception called a virus.

What is 'Covid'? Load of bollocks

The background described here by Cowan and Lanka was emphasised in the first video presentation that I saw by Dr Andrew Kaufman when he asked whether the 'Covid virus' was in truth a natural defence mechanism of the body called 'exosomes'. These are released by cells when in states of toxicity – see the same themes returning over and over. They are released ever more profusely as chemical and radiation toxicity increases and think of the potential effect therefore of 5G alone as its destructive frequencies infest the human energetic information field with a gathering pace (5G went online in Wuhan in 2019 as the 'virus' emerged). I'll have more about this later. Exosomes transmit a warning to the rest of the body that 'Houston, we have a problem'. Kaufman presented images of exosomes and compared them with 'Covid' under an electron microscope and the similarity was remarkable. They both attach to the same cell receptors (*claimed* in the case of 'Covid'), contain the same genetic material in the form of RNA or ribonucleic acid, and both are found in 'viral cell cultures' with damaged or dying cells. James Hildreth MD, President and Chief Executive Officer of the Meharry Medical College at Johns Hopkins, said: 'The virus is fully an exosome in every sense of the word.' Kaufman's conclusion was that there is no 'virus': 'This entire pandemic is a completely manufactured crisis … there is no evidence of anyone dying from [this] illness.' Dr Tom Cowan and Sally Fallon Morell, authors of *The Contagion Myth*, published a statement with Dr Kaufman in February, 2021, explaining why the 'virus' does not exist and you can read it that in full in the Appendix.

'Virus' theory can be traced to the 'cell theory' in 1858 of German physician Rudolf Virchow (1821-1920) who contended that disease originates from a single cell infiltrated by a 'virus'. Dr Stefan Lanka said that findings and insights with respect to the structure, function and central importance of tissues in the creation of life, which were already known in 1858, comprehensively refute the cell theory. Virchow ignored them. We have seen the part later played by John Enders in the 1950s and Lanka notes that infection theories were only established as a global dogma through the policies and

eugenics of the Third Reich in Nazi Germany (creation of the same Sabbatian cult behind the 'Covid' hoax). Lanka said: 'Before 1933, scientists dared to contradict this theory; after 1933, these critical scientists were silenced'. Dr Tom Cowan's view is that ill-heath is caused by too much of something, too little of something, or toxification from chemicals and radiation – not contagion. We must also highlight as a major source of the 'virus' theology a man still called the 'Father of Modern Virology' – Thomas Milton Rivers (1888-1962). There is no way given the Cult's long game policy that it was a coincidence for the 'Father of Modern Virology' to be director of the Rockefeller Institute for Medical Research from 1937 to 1956 when he is credited with making the Rockefeller Institute a leader in 'viral research'. Cult Rockefellers were the force behind the creation of Big Pharma 'medicine', established the World Health Organisation in 1948, and have long and close associations with the Gates family that now runs the WHO during the pandemic hoax through mega-rich Cult gofer and psychopath Bill Gates.

Only a Renegade Mind can see through all this bullshit by asking the questions that need to be answered, not taking 'no' or prevarication for an answer, and certainly not hiding from the truth in fear of speaking it. Renegade Minds have always changed the world for the better and they will change this one no matter how bleak it may currently appear to be.

CHAPTER SIX

Sequence of deceit

If you tell the truth, you don't have to remember anything
Mark Twain

Against the background that I have laid out this far the sequence that took us from an invented 'virus' in Cult-owned China in late 2019 to the fascist transformation of human society can be seen and understood in a whole new context.

We were told that a deadly disease had broken out in Wuhan and the world media began its campaign (coordinated by behavioural psychologists as we shall see) to terrify the population into unquestioning compliance. We were shown images of Chinese people collapsing in the street which never happened in the West with what was supposed to be the same condition. In the earliest days when alleged cases and deaths were few the fear register was hysterical in many areas of the media and this would expand into the common media narrative across the world. The real story was rather different, but we were never told that. The Chinese government, one of the Cult's biggest centres of global operation, said they had discovered a new illness with flu-like and pneumonia-type symptoms in a city with such toxic air that it is overwhelmed with flu-like symptoms, pneumonia and respiratory disease. Chinese scientists said it was a new – 'novel' – coronavirus which they called Sars-Cov-2 and that it caused a disease they labelled 'Covid-19'. There was no evidence for this and the 'virus' has never to this day been isolated, purified and its genetic code established from that. It

was from the beginning a computer-generated fiction. Stories of Chinese whistleblowers saying the number of deaths was being supressed or that the 'new disease' was related to the Wuhan bio-lab misdirected mainstream and alternative media into cul-de-sacs to obscure the real truth – there was no 'virus'.

Chinese scientists took genetic material from the lung fluid of just a few people and said they had found a 'new' disease when this material had a wide range of content. There was no evidence for a 'virus' for the very reasons explained in the last two chapters. The 'virus' has never been shown to (a) exist and (b) cause any disease. People were diagnosed on symptoms that are so widespread in Wuhan and polluted China and with a PCR test that can't detect infectious disease. On this farce the whole global scam was sold to the rest of the world which would also diagnose respiratory disease as 'Covid-19' from symptoms alone or with a PCR test not testing for a 'virus'. Flu miraculously disappeared *worldwide* in 2020 and into 2021 as it was redesignated 'Covid-19'. It was really the same old flu with its 'flu-like' symptoms attributed to 'flu-like' 'Covid-19'. At the same time with very few exceptions the Chinese response of draconian lockdown and fascism was the chosen weapon to respond across the West as recommended by the Cult-owned Tedros at the Cult-owned World Health Organization run by the Cult-owned Gates. All was going according to plan. Chinese scientists – everything in China is controlled by the Cult-owned government – compared their contaminated RNA lung-fluid material with other RNA sequences and said it appeared to be just under 80 percent identical to the SARS-CoV-1 'virus' claimed to be the cause of the SARS (severe acute respiratory syndrome) 'outbreak' in 2003. They decreed that because of this the 'new virus' had to be related and they called it SARS-CoV-2. There are some serious problems with this assumption and *assumption* was all it was. Most 'factual' science turns out to be assumptions repeated into everyone-knows-that. A match of under 80-percent is meaningless. Dr Kaufman makes the point that there's a *96 percent* genetic correlation between humans and chimpanzees, but 'no one would say our genetic material is part

of the chimpanzee family'. Yet the Chinese authorities were claiming that a much lower percentage, less than 80 percent, proved the existence of a new 'coronavirus'. For goodness sake human DNA is 60 percent similar to a *banana*.

You are feeling sleepy

The entire 'Covid' hoax is a global Psyop, a psychological operation to program the human mind into believing and fearing a complete fantasy. A crucial aspect of this was what *appeared* to happen in Italy. It was all very well streaming out daily images of an alleged catastrophe in Wuhan, but to the Western mind it was still on the other side of the world in a very different culture and setting. A reaction of 'this could happen to me and my family' was still nothing like as intense enough for the mind-doctors. The Cult needed a Western example to push people over that edge and it chose Italy, one of its major global locations going back to the Roman Empire. An Italian 'Covid' crisis was manufactured in a particular area called Lombardy which just happens to be notorious for its toxic air and therefore respiratory disease. Wuhan, China, déjà vu. An hysterical media told horror stories of Italians dying from 'Covid' in their droves and how Lombardy hospitals were being overrun by a tidal wave of desperately ill people needing treatment after being struck down by the 'deadly virus'. Here was the psychological turning point the Cult had planned. Wow, if this is happening in Italy, the Western mind concluded, this indeed could happen to me and my family. Another point is that Italian authorities responded by following the Chinese blueprint so vehemently recommended by the Cult-owned World Health Organization. They imposed fascistic lockdowns on the whole country viciously policed with the help of surveillance drones sweeping through the streets seeking out anyone who escaped from mass house arrest. Livelihoods were destroyed and psychology unravelled in the way we have witnessed since in all lockdown countries. Crucial to the plan was that Italy responded in this way to set the precedent of suspending freedom and imposing fascism in a 'Western liberal democracy'. I emphasised in an

animated video explanation on davidicke.com posted in the summer of 2020 how important it was to the Cult to expand the Chinese lockdown model across the West. Without this, and the bare-faced lie that non-symptomatic people could still transmit a 'disease' they didn't have, there was no way locking down the whole population, sick and not sick, could be pulled off. At just the right time and with no evidence Cult operatives and gofers claimed that people without symptoms could pass on the 'disease'. In the name of protecting the 'vulnerable' like elderly people, who lockdowns would kill by the tens of thousands, we had for the first time healthy people told to isolate as well as the sick. The great majority of people who tested positive had no symptoms because there was nothing wrong with them. It was just a trick made possible by a test not testing for the 'virus'.

Months after my animated video the Gates-funded Professor Neil Ferguson at the Gates-funded Imperial College confirmed that I was right. He didn't say it in those terms, naturally, but he did say it. Ferguson will enter the story shortly for his outrageously crazy 'computer models' that led to Britain, the United States and many other countries following the Chinese and now Italian methods of response. Put another way, following the Cult script. Ferguson said that SAGE, the UK government's scientific advisory group which has controlled 'Covid' policy from the start, wanted to follow the Chinese lockdown model (while they all continued to work and be paid), but they wondered if they could possibly, in Ferguson's words, 'get away with it in Europe'. 'Get away with it'? Who the hell do these moronic, arrogant people think they are? This appalling man Ferguson said that once Italy went into national lockdown they realised they, too, could mimic China:

> It's a communist one-party state, we said. We couldn't get away with it in Europe, we thought … and then Italy did it. And we realised we could. Behind this garbage from Ferguson is a simple fact: Doing the same as China in every country was the plan from the start and Ferguson's 'models' would play a central role in achieving that. It's just a coincidence, of course, and absolutely nothing to worry your little head about.

Oops, sorry, our mistake

Once the Italian segment of the Psyop had done the job it was designed to do a very different story emerged. Italian authorities revealed that 99 percent of those who had 'died from Covid-19' in Italy had one, two, three, or more 'co-morbidities' or illnesses and health problems that could have ended their life. The US Centers for Disease Control and Prevention (CDC) published a figure of 94 percent for Americans dying of 'Covid' while having other serious medical conditions – on average two to three (some five or six) other potential causes of death. In terms of death from an unproven 'virus' I say it is 100 percent. The other one percent in Italy and six percent in the US would presumably have died from 'Covid's' flu-like symptoms with a range of other possible causes in conjunction with a test not testing for the 'virus'. Fox News reported that even more startling figures had emerged in one US county in which 410 of 422 deaths attributed to 'Covid-19' had other potentially deadly health conditions. The Italian National Health Institute said later that the average age of people dying with a 'Covid-19' diagnosis in Italy was about 81. Ninety percent were over 70 with ten percent over 90. In terms of other reasons to die some 80 percent had two or more chronic diseases with half having three or more including cardiovascular problems, diabetes, respiratory problems and cancer. Why is the phantom 'Covid-19' said to kill overwhelmingly old people and hardly affect the young? Old people continually die of many causes and especially respiratory disease which you can re-diagnose 'Covid-19' while young people die in tiny numbers by comparison and rarely of respiratory disease. Old people 'die of Covid' because they die of other things that can be redesignated 'Covid' and it really is that simple.

Flu has flown

The blueprint was in place. Get your illusory 'cases' from a test not testing for the 'virus' and redesignate other causes of death as 'Covid-19'. You have an instant 'pandemic' from something that is nothing more than a computer-generated fiction. With near-on a

billion people having 'flu-like' symptoms every year the potential was limitless and we can see why flu quickly and apparently miraculously disappeared *worldwide* by being diagnosed 'Covid-19'. The painfully bloody obvious was explained away by the childlike media in headlines like this in the UK '*Independent*': 'Not a single case of flu detected by Public Health England this year as Covid restrictions suppress virus'. I kid you not. The masking, social distancing and house arrest that did not make the 'Covid virus' disappear somehow did so with the 'flu virus'. Even worse the article, by a bloke called Samuel Lovett, suggested that maybe the masking, sanitising and other 'Covid' measures should continue to keep the flu away. With a ridiculousness that disturbs your breathing (it's 'Covid-19') the said Lovett wrote: 'With widespread social distancing and mask-wearing measures in place throughout the UK, the usual routes of transmission for influenza have been blocked.' He had absolutely no evidence to support that statement, but look at the consequences of him acknowledging the obvious. With flu not disappearing at all and only being relabelled 'Covid-19' he would have to contemplate that 'Covid' was a hoax on a scale that is hard to imagine. You need guts and commitment to truth to even go there and that's clearly something Samuel Lovett does not have in abundance. He would never have got it through the editors anyway.

Tens of thousands die in the United States alone every winter from flu including many with pneumonia complications. CDC figures record *45 million* Americans diagnosed with flu in 2017-2018 of which 61,000 died and some reports claim 80,000. Where was the same hysteria then that we have seen with 'Covid-19'? Some 250,000 Americans are admitted to hospital with pneumonia every year with about 50,000 cases proving fatal. About 65 million suffer respiratory disease every year and three million deaths makes this the third biggest cause of death worldwide. You only have to redesignate a portion of all these people 'Covid-19' and you have an instant global pandemic or the *appearance* of one. Why would doctors do this? They are told to do this and all but a few dare not refuse those who must be obeyed. Doctors in general are not researching their own

knowledge and instead take it direct and unquestioned from the authorities that own them and their careers. The authorities say they must now diagnose these symptoms 'Covid-19' and not flu, or whatever, and they do it. Dark suits say put 'Covid-19' on death certificates no matter what the cause of death and the doctors do it. Renegade Minds don't fall for the illusion that doctors and medical staff are all highly-intelligent, highly-principled, seekers of medical truth. *Some are*, but not the majority. They are repeaters, gofers, and yes sir, no sir, purveyors of what the system demands they purvey. The 'Covid' con is not merely confined to diseases of the lungs. Instructions to doctors to put 'Covid-19' on death certificates for anyone dying of *anything* within 28 days (or much more) of a positive test not testing for the 'virus' opened the floodgates. The term dying *with* 'Covid' and not *of* 'Covid' was coined to cover the truth. Whether it was a *with* or an *of* they were all added to the death numbers attributed to the 'deadly virus' compiled by national governments and globally by the Gates-funded Johns Hopkins operation in the United States that was so involved in those 'pandemic' simulations. Fraudulent deaths were added to the ever-growing list of fraudulent 'cases' from false positives from a false test. No wonder Professor Walter Ricciardi, scientific advisor to the Italian minister of health, said after the Lombardy hysteria had done its job that 'Covid' death rates were due to Italy having the second oldest population in the world and to *how hospitals record deaths*:

> The way in which we code deaths in our country is very generous in the sense that all the people who die in hospitals with the coronavirus are deemed to be dying of the coronavirus. On re-evaluation by the National Institute of Health, only 12 per cent of death certificates have shown a direct causality from coronavirus, while 88 per cent of patients who have died have at least one pre-morbidity – many had two or three.

This is extraordinary enough when you consider the propaganda campaign to use Italy to terrify the world, but how can they even say twelve percent were genuine when the 'virus' has not been shown to exist, its 'code' is a computer program, and diagnosis comes from a test not testing for it? As in China, and soon the world, 'Covid-19' in

Italy was a redesignation of diagnosis. Lies and corruption were to become the real 'pandemic' fuelled by a pathetically-compliant medical system taking its orders from the tiny few at the top of their national hierarchy who answered to the World Health Organization which answers to Gates and the Cult. Doctors were told – ordered – to diagnose a particular set of symptoms 'Covid-19' and put that on the death certificate for any cause of death if the patient had tested positive with a test not testing for the virus or had 'Covid' symptoms like the flu. The United States even introduced big financial incentives to manipulate the figures with hospitals receiving £4,600 from the Medicare system for diagnosing someone with regular pneumonia, $13,000 if they made the diagnosis from the same symptoms 'Covid-19' pneumonia, and $39, 000 if they put a 'Covid' diagnosed patient on a ventilator that would almost certainly kill them. A few – painfully and pathetically few – medical whistleblowers revealed (before Cult-owned YouTube deleted their videos) that they had been instructed to 'let the patient crash' and put them straight on a ventilator instead of going through a series of far less intrusive and dangerous methods as they would have done before the pandemic hoax began and the financial incentives kicked in. We are talking cold-blooded murder given that ventilators are so damaging to respiratory systems they are usually the last step before heaven awaits. Renegade Minds never fall for the belief that people in white coats are all angels of mercy and cannot be full-on psychopaths. I have explained in detail in *The Answer* how what I am describing here played out across the world coordinated by the World Health Organization through the medical hierarchies in almost every country.

Medical scientist calls it

Information about the non-existence of the 'virus' began to emerge for me in late March, 2020, and mushroomed after that. I was sent an email by Sir Julian Rose, a writer, researcher, and organic farming promotor, from a medical scientist friend of his in the United States. Even at that early stage in March the scientist was able to explain

how the 'Covid' hoax was being manipulated. He said there were no reliable tests for a specific 'Covid-19 virus' and nor were there any reliable agencies or media outlets for reporting numbers of actual 'Covid-19' cases. We have seen in the long period since then that he was absolutely right. 'Every action and reaction to Covid-19 is based on totally flawed data and we simply cannot make accurate assessments,' he said. Most people diagnosed with 'Covid-19' were showing nothing more than cold and flu-like symptoms 'because most coronavirus strains *are* nothing more than cold/flu-like symptoms'. We had farcical situations like an 84-year-old German man testing positive for 'Covid-19' and his nursing home ordered to quarantine only for him to be found to have a common cold. The scientist described back then why PCR tests and what he called the 'Mickey Mouse test kits' were useless for what they were claimed to be identifying. 'The idea these kits can isolate a specific virus like Covid-19 is nonsense,' he said. Significantly, he pointed out that 'if you want to create a totally false panic about a totally false pandemic – pick a coronavirus'. This is exactly what the Cult-owned Gates, World Economic Forum and Johns Hopkins University did with their Event 201 'simulation' followed by their real-life simulation called the 'pandemic'. The scientist said that all you had to do was select the sickest of people with respiratory-type diseases in a single location – 'say Wuhan' – and administer PCR tests to them. You can then claim that anyone showing 'viral sequences' similar to a coronavirus 'which will inevitably be quite a few' is suffering from a 'new' disease:

> Since you already selected the sickest flu cases a fairly high proportion of your sample will go on to die. You can then say this 'new' virus has a CFR [case fatality rate] higher than the flu and use this to infuse more concern and do more tests which will of course produce more 'cases', which expands the testing, which produces yet more 'cases' and so on and so on. Before long you have your 'pandemic', and all you have done is use a simple test kit trick to convert the worst flu and pneumonia cases into something new that doesn't ACTUALLY EXIST [my emphasis].

He said that you then 'just run the same scam in other countries' and make sure to keep the fear message running high 'so that people

will feel panicky and less able to think critically'. The only problem to overcome was the fact *there is no* actual new deadly pathogen and only regular sick people. This meant that deaths from the 'new deadly pathogen' were going to be way too low for a real new deadly virus pandemic, but he said this could be overcome in the following ways – all of which would go on to happen:

1. You can claim this is just the beginning and more deaths are imminent [you underpin this with fantasy 'computer projections']. Use this as an excuse to quarantine everyone and then claim the quarantine prevented the expected millions of dead.

2. You can [say that people] 'minimizing' the dangers are irresponsible and bully them into not talking about numbers.

3. You can talk crap about made up numbers hoping to blind people with pseudoscience.

4. You can start testing well people (who, of course, will also likely have shreds of coronavirus [RNA] in them) and thus inflate your 'case figures' with 'asymptomatic carriers' (you will of course have to spin that to sound deadly even though any virologist knows the more symptom-less cases you have the less deadly is your pathogen).

The scientist said that if you take these simple steps 'you can have your own entirely manufactured pandemic up and running in weeks'. His analysis made so early in the hoax was brilliantly prophetic of what would actually unfold. Pulling all the information together in these recent chapters we have this is simple 1, 2, 3, of how you can delude virtually the entire human population into believing in a 'virus' that doesn't exist:

- A 'Covid case' is someone who tests positive with a test not testing for the 'virus'.

- A 'Covid death' is someone who dies of *any cause* within 28 days (or much longer) of testing positive with a test not testing for the 'virus.

- Asymptomatic means there is nothing wrong with you, but they claim you can pass on what you don't have to justify locking

down (quarantining) healthy people in totality.

The foundations of the hoax are that simple. A study involving ten million people in Wuhan, published in November, 2020, demolished the whole lie about those without symptoms passing on the 'virus'. They found '300 asymptomatic cases' and traced their contacts to find that not one of them was detected with the 'virus'. 'Asymptomatic' patients and their contacts were isolated for no less than two weeks and nothing changed. I know it's all crap, but if you are going to claim that those without symptoms can transmit 'the virus' then you must produce evidence for that and they never have. Even World Health Organization official Dr Maria Van Kerkhove, head of the emerging diseases and zoonosis unit, said as early as June, 2020, that she doubted the validity of asymptomatic transmission. She said that 'from the data we have, it still seems to be rare that an asymptomatic person actually transmits onward to a secondary individual' and by 'rare' she meant that she couldn't cite any case of asymptomatic transmission.

The Ferguson factor

The problem for the Cult as it headed into March, 2020, when the script had lockdown due to start, was that despite all the manipulation of the case and death figures they still did not have enough people alleged to have died from 'Covid' to justify mass house arrest. This was overcome in the way the scientist described: 'You can claim this is just the beginning and more deaths are imminent … Use this as an excuse to quarantine everyone and then claim the quarantine prevented the expected millions of dead.' Enter one Professor Neil Ferguson, the Gates-funded 'epidemiologist' at the Gates-funded Imperial College in London. Ferguson is Britain's Christian Drosten in that he has a dire record of predicting health outcomes, but is still called upon to advise government on the next health outcome when another 'crisis' comes along. This may seem to be a strange and ridiculous thing to do. Why would you keep turning for policy guidance to people who have a history of being

monumentally wrong? Ah, but it makes sense from the Cult point of view. These 'experts' keep on producing predictions that suit the Cult agenda for societal transformation and so it was with Neil Ferguson as he revealed his horrific (and clearly insane) computer model predictions that allowed lockdowns to be imposed in Britain, the United States and many other countries. Ferguson does not have even an A-level in biology and would appear to have no formal training in computer modelling, medicine or epidemiology, according to Derek Winton, an MSc in Computational Intelligence. He wrote an article somewhat aghast at what Ferguson did which included taking no account of respiratory disease 'seasonality' which means it is far worse in the winter months. Who would have thought that respiratory disease could be worse in the winter? Well, certainly not Ferguson.

The massively China-connected Imperial College and its bizarre professor provided the excuse for the long-incubated Chinese model of human control to travel westward at lightning speed. Imperial College confirms on its website that it collaborates with the Chinese Research Institute; publishes more than 600 research papers every year with Chinese research institutions; has 225 Chinese staff; 2,600 Chinese students – the biggest international group; 7,000 former students living in China which is the largest group outside the UK; and was selected for a tour by China's President Xi Jinping during his state visit to the UK in 2015. The college takes major donations from China and describes itself as the UK's number one university collaborator with Chinese research institutions. The China communist/fascist government did not appear phased by the woeful predictions of Ferguson and Imperial when during the lockdown that Ferguson induced the college signed a five-year collaboration deal with China tech giant Huawei that will have Huawei's indoor 5G network equipment installed at the college's West London tech campus along with an 'AI cloud platform'. The deal includes Chinese sponsorship of Imperial's Venture Catalyst entrepreneurship competition. Imperial is an example of the enormous influence the Chinese government has within British and North American

universities and research centres – and further afield. Up to 200 academics from more than a dozen UK universities are being investigated on suspicion of 'unintentionally' helping the Chinese government build weapons of mass destruction by 'transferring world-leading research in advanced military technology such as aircraft, missile designs and cyberweapons'. Similar scandals have broken in the United States, but it's all a coincidence. Imperial College serves the agenda in many other ways including the promotion of every aspect of the United Nations Agenda 21/2030 (the Great Reset) and produced computer models to show that human-caused 'climate change' is happening when in the real world it isn't. Imperial College is driving the climate agenda as it drives the 'Covid' agenda (both Cult hoaxes) while Patrick Vallance, the UK government's Chief Scientific Adviser on 'Covid', was named Chief Scientific Adviser to the UN 'climate change' conference known as COP26 hosted by the government in Glasgow, Scotland. 'Covid' and 'climate' are fundamentally connected.

Professor Woeful

From Imperial's bosom came Neil Ferguson still advising government despite his previous disasters and it was announced early on that he and other key people like UK Chief Medical Adviser Chris Whitty had caught the 'virus' as the propaganda story was being sold. Somehow they managed to survive and we had Prime Minister Boris Johnson admitted to hospital with what was said to be a severe version of the 'virus' in this same period. His whole policy and demeanour changed when he returned to Downing Street. It's a small world with these government advisors – especially in their communal connections to Gates – and Ferguson had partnered with Whitty to write a paper called 'Infectious disease: Tough choices to reduce Ebola transmission' which involved another scare-story that didn't happen. Ferguson's 'models' predicted that up to150, 000 could die from 'mad cow disease', or BSE, and its version in sheep if it was transmitted to humans. BSE was not transmitted and instead triggered by an organophosphate pesticide used to treat a pest on

cows. Fewer than 200 deaths followed from the human form. Models by Ferguson and his fellow incompetents led to the unnecessary culling of millions of pigs, cattle and sheep in the foot and mouth outbreak in 2001 which destroyed the lives and livelihoods of farmers and their families who had often spent decades building their herds and flocks. Vast numbers of these animals did not have foot and mouth and had no contact with the infection. Another 'expert' behind the cull was Professor Roy Anderson, a computer modeller at Imperial College specialising in the epidemiology of *human*, not animal, disease. Anderson has served on the Bill and Melinda Gates Grand Challenges in Global Health advisory board and chairs another Gates-funded organisation. Gates is everywhere.

In a precursor to the 'Covid' script Ferguson backed closing schools 'for prolonged periods' over the swine flu 'pandemic' in 2009 and said it would affect a third of the world population if it continued to spread at the speed he claimed to be happening. His mates at Imperial College said much the same and a news report said: 'One of the authors, the epidemiologist and disease modeller Neil Ferguson, who sits on the World Health Organisation's emergency committee for the outbreak, said the virus had "full pandemic potential".' Professor Liam Donaldson, the Chris Whitty of his day as Chief Medical Officer, said the worst case could see 30 percent of the British people infected by swine flu with 65,000 dying. Ferguson and Donaldson were indeed proved correct when at the end of the year the number of deaths attributed to swine flu was 392. The term 'expert' is rather liberally applied unfortunately, not least to complete idiots. Swine flu 'projections' were great for GlaxoSmithKline (GSK) as millions rolled in for its Pandemrix influenza vaccine which led to brain damage with children most affected. The British government (taxpayers) paid out more than £60 million in compensation after GSK was given immunity from prosecution. Yet another 'Covid' déjà vu. Swine flu was supposed to have broken out in Mexico, but Dr Wolfgang Wodarg, a German doctor, former member of parliament and critic of the 'Covid' hoax, observed 'the spread of swine flu' in Mexico City at the time. He

said: 'What we experienced in Mexico City was a very mild flu which did not kill more than usual – which killed even fewer people than usual.' Hyping the fear against all the facts is not unique to 'Covid' and has happened many times before. Ferguson is reported to have over-estimated the projected death toll of bird flu (H5N1) by some three million-fold, but bird flu vaccine makers again made a killing from the scare. This is some of the background to the Neil Ferguson who produced the perfectly-timed computer models in early 2020 predicting that half a million people would die in Britain without draconian lockdown and 2.2 million in the United States. Politicians panicked, people panicked, and lockdowns of alleged short duration were instigated to 'flatten the curve' of cases gleaned from a test not testing for the 'virus'. I said at the time that the public could forget the 'short duration' bit. This was an agenda to destroy the livelihoods of the population and force them into mass control through dependency and there was going to be nothing 'short' about it. American researcher Daniel Horowitz described the consequences of the 'models' spewed out by Gates-funded Ferguson and Imperial College:

> What led our government and the governments of many other countries into panic was a single Imperial College of UK study, funded by global warming activists, that predicted 2.2 million deaths if we didn't lock down the country. In addition, the reported 8-9% death rate in Italy scared us into thinking there was some other mutation of this virus that they got, which might have come here.
>
> Together with the fact that we were finally testing and had the ability to actually report new cases, we thought we were headed for a death spiral. But again … we can't flatten a curve if we don't know when the curve started.

How about it *never* started?

Giving them what they want

An investigation by German news outlet *Welt Am Sonntag (World on Sunday)* revealed how in March, 2020, the German government gathered together 'leading scientists from several research institutes and universities' and 'together, they were to produce a [modelling]

paper that would serve as legitimization for further tough political measures'. The Cult agenda was justified by computer modelling not based on evidence or reality; it was specifically constructed to justify the Cult demand for lockdowns all over the world to destroy the independent livelihoods of the global population. All these modellers and everyone responsible for the 'Covid' hoax have a date with a trial like those in Nuremberg after World War Two when Nazis faced the consequences of their war crimes. These corrupt-beyond-belief 'modellers' wrote the paper according to government instructions and it said that that if lockdown measures were lifted then up to one million Germans would die from 'Covid-19' adding that some would die 'agonizingly at home, gasping for breath' unable to be treated by hospitals that couldn't cope. All lies. No matter – it gave the Cult all that it wanted. What did long-time government 'modeller' Neil Ferguson say? If the UK and the United States didn't lockdown half a million would die in Britain and 2.2 million Americans. Anyone see a theme here? 'Modellers' are such a crucial part of the lockdown strategy that we should look into their background and follow the money. Researcher Rosemary Frei produced an excellent article headlined 'The Modelling-paper Mafiosi'. She highlights a guy called John Edmunds, a British epidemiologist, and professor in the Faculty of Epidemiology and Population Health at the London School of Hygiene & Tropical Medicine. He studied at Imperial College. Edmunds is a member of government 'Covid' advisory bodies which have been dictating policy, the New and Emerging Respiratory Virus Threats Advisory Group (NERVTAG) and the Scientific Advisory Group for Emergencies (SAGE).

Ferguson, another member of NERVTAG and SAGE, led the way with the original 'virus' and Edmunds has followed in the 'variant' stage and especially the so-called UK or Kent variant known as the 'Variant of Concern' (VOC) B.1.1.7. He said in a co-written report for the Centre for Mathematical modelling of Infectious Diseases at the London School of Hygiene and Tropical Medicine, with input from the Centre's 'Covid-19' Working Group, that there was 'a realistic

possibility that VOC B.1.1.7 is associated with an increased risk of death compared to non-VOC viruses'. Fear, fear, fear, get the vaccine, fear, fear, fear, get the vaccine. Rosemary Frei reveals that almost all the paper's authors and members of the modelling centre's 'Covid-19' Working Group receive funding from the Bill and Melinda Gates Foundation and/or the associated Gates-funded Wellcome Trust. The paper was published by e-journal *Medr χiv* which only publishes papers not peer-reviewed and the journal was established by an organisation headed by Facebook's Mark Zuckerberg and his missus. What a small world it is. Frei discovered that Edmunds is on the Scientific Advisory Board of the Coalition for Epidemic Preparedness Innovations (CEPI) which was established by the Bill and Melinda Gates Foundation, Klaus Schwab's Davos World Economic Forum and Big Pharma giant Wellcome. CEPI was 'launched in Davos [in 2017] to develop vaccines to stop future epidemics', according to its website. 'Our mission is to accelerate the development of vaccines against emerging infectious diseases and enable equitable access to these vaccines for people during outbreaks.' What kind people they are. Rosemary Frei reveals that Public Health England (PHE) director Susan Hopkins is an author of her organisation's non-peer-reviewed reports on 'new variants'. Hopkins is a professor of infectious diseases at London's Imperial College which is gifted tens of millions of dollars a year by the Bill and Melinda Gates Foundation. Gates-funded modelling disaster Neil Ferguson also co-authors Public Health England reports and he spoke in December, 2020, about the potential danger of the B.1.1.7. 'UK variant' promoted by Gates-funded modeller John Edmunds. When I come to the 'Covid vaccines' the 'new variants' will be shown for what they are – bollocks.

Connections, connections

All these people and modellers are lockdown-obsessed or, put another way, they demand what the Cult demands. Edmunds said in January, 2021, that to ease lockdowns too soon would be a disaster and they had to 'vaccinate much, much, much more widely than the

elderly'. Rosemary Frei highlights that Edmunds is married to Jeanne Pimenta who is described in a LinkedIn profile as director of epidemiology at GlaxoSmithKline (GSK) and she held shares in the company. Patrick Vallance, co-chair of SAGE and the government's Chief Scientific Adviser, is a former executive of GSK and has a deferred bonus of shares in the company worth £600,000. GSK has serious business connections with Bill Gates and is collaborating with mRNA-'vaccine' company CureVac to make 'vaccines' for the new variants that Edmunds is talking about. GSK is planning a 'Covid vaccine' with drug giant Sanofi. Puppet Prime Minister Boris Johnson announced in the spring of 2021 that up to 60 million vaccine doses were to be made at the GSK facility at Barnard Castle in the English North East. Barnard Castle, with a population of just 6,000, was famously visited in breach of lockdown rules in April, 2020, by Johnson aide Dominic Cummings who said that he drove there 'to test his eyesight' before driving back to London. Cummings would be better advised to test his integrity – not that it would take long. The GSK facility had nothing to do with his visit then although I'm sure Patrick Vallance would have been happy to arrange an introduction and some tea and biscuits. Ruthless psychopath Gates has made yet another fortune from vaccines in collaboration with Big Pharma companies and gushes at the phenomenal profits to be made from vaccines – more than a 20-to-1 return as he told one interviewer. Gates also tweeted in December, 2019, with the foreknowledge of what was coming: 'What's next for our foundation? I'm particularly excited about what the next year could mean for one of the best buys in global health: vaccines.'

Modeller John Edmunds is a big promotor of vaccines as all these people appear to be. He's the dean of the London School of Hygiene & Tropical Medicine's Faculty of Epidemiology and Population Health which is primarily funded by the Bill and Melinda Gates Foundation and the Gates-established and funded GAVI vaccine alliance which is the Gates vehicle to vaccinate the world. The organisation Doctors Without Borders has described GAVI as being 'aimed more at supporting drug-industry desires to promote new

products than at finding the most efficient and sustainable means for fighting the diseases of poverty'. But then that's why the psychopath Gates created it. John Edmunds said in a video that the London School of Hygiene & Tropical Medicine is involved in every aspect of vaccine development including large-scale clinical trials. He contends that mathematical modelling can show that vaccines protect individuals and society. That's on the basis of shit in and shit out, I take it. Edmunds serves on the UK Vaccine Network as does Ferguson and the government's foremost 'Covid' adviser, the grim-faced, dark-eyed Chris Whitty. The Vaccine Network says it works 'to support the government to identify and shortlist targeted investment opportunities for the most promising vaccines and vaccine technologies that will help combat infectious diseases with epidemic potential, and to address structural issues related to the UK's broader vaccine infrastructure'. Ferguson is acting Director of the Imperial College Vaccine Impact Modelling Consortium which has funding from the Bill and Melina Gates Foundation and the Gates-created GAVI 'vaccine alliance'. Anyone wonder why these characters see vaccines as the answer to every problem? Ferguson is wildly enthusiastic in his support for GAVI's campaign to vaccine children en masse in poor countries. You would expect someone like Gates who has constantly talked about the need to reduce the population to want to fund vaccines to keep more people alive. I'm sure that's why he does it. The John Edmunds London School of Hygiene & Tropical Medicine (LSHTM) has a Vaccines Manufacturing Innovation Centre which develops, tests and commercialises vaccines. Rosemary Frei writes:

> The vaccines centre also performs affiliated activities like combating 'vaccine hesitancy'. The latter includes the Vaccine Confidence Project. The project's stated purpose is, among other things, 'to provide analysis and guidance for early response and engagement with the public to ensure sustained confidence in vaccines and immunisation'. The Vaccine Confidence Project's director is LSHTM professor Heidi Larson. For more than a decade she's been researching how to combat vaccine hesitancy.

How the bloody hell can blokes like John Edmunds and Neil Ferguson with those connections and financial ties model 'virus' case

and death projections for the government and especially in a way that gives their paymasters like Gates exactly what they want? It's insane, but this is what you find throughout the world.

'Covid' is not dangerous, oops, wait, yes it is

Only days before Ferguson's nightmare scenario made Jackboot Johnson take Britain into a China-style lockdown to save us from a deadly 'virus' the UK government website gov.uk was reporting something very different to Ferguson on a page of official government guidance for 'high consequence infectious diseases (HCID)'. It said this about 'Covid-19':

> As of 19 March 2020, COVID-19 *is no longer considered to be a high consequence infectious diseases (HCID) in the UK* [my emphasis]. The 4 nations public health HCID group made an interim recommendation in January 2020 to classify COVID-19 as an HCID. This was based on consideration of the UK HCID criteria about the virus and the disease with information available during the early stages of the outbreak.
>
> Now that more is known about COVID-19, the public health bodies in the UK have reviewed the most up to date information about COVID-19 against the UK HCID criteria. They have determined that several features have now changed; in particular, more information is available about mortality rates (low overall), and there is now greater clinical awareness and a specific and sensitive laboratory test, the availability of which continues to increase. The Advisory Committee on Dangerous Pathogens (ACDP) is also of the opinion that COVID-19 should no longer be classified as an HCID.

Soon after the government had been exposed for downgrading the risk they upgraded it again and everyone was back to singing from the same Cult hymn book. Ferguson and his fellow Gates clones indicated that lockdowns and restrictions would have to continue until a Gates-funded vaccine was developed. Gates said the same because Ferguson and his like were repeating the Gates script which is the Cult script. 'Flatten the curve' became an ongoing nightmare of continuing lockdowns with periods in between of severe restrictions in pursuit of destroying independent incomes and had nothing to do with protecting health about which the Cult gives not a shit. Why wouldn't Ferguson be pushing a vaccine 'solution' when he's owned by vaccine-obsessive Gates who makes a fortune from them and

when Ferguson heads the Vaccine Impact Modelling Consortium at Imperial College funded by the Gates Foundation and GAVI, the 'vaccine alliance', created by Gates as his personal vaccine promotion operation? To compound the human catastrophe that Ferguson's 'models' did so much to create he was later exposed for breaking his own lockdown rules by having sexual liaisons with his married girlfriend Antonia Staats at his home while she was living at another location with her husband and children. Staats was a 'climate' activist and senior campaigner at the Soros-funded Avaaz which I wouldn't trust to tell me that grass is green. Ferguson had to resign as a government advisor over this hypocrisy in May, 2020, but after a period of quiet he was back being quoted by the ridiculous media on the need for more lockdowns and a vaccine rollout. Other government-advising 'scientists' from Imperial College' held the fort in his absence and said lockdown could be indefinite until a vaccine was found. The Cult script was being sung by the payrolled choir. I said there was no intention of going back to 'normal' when the 'vaccine' came because the 'vaccine' is part of a very different agenda that I will discuss in Human 2.0. Why would the Cult want to let the world go back to normal when destroying that normal forever was the whole point of what was happening? House arrest, closing businesses and schools through lockdown, (un)social distancing and masks all followed the Ferguson fantasy models. Again as I predicted (these people are so predictable) when the 'vaccine' arrived we were told that house arrest, lockdown, (un)social distancing and masks would still have to continue. I will deal with the masks in the next chapter because they are of fundamental importance.

Where's the 'pandemic'?

Any mildly in-depth assessment of the figures revealed what was really going on. Cult-funded and controlled organisations still have genuine people working within them such is the number involved. So it is with Genevieve Briand, assistant program director of the Applied Economics master's degree program at Johns Hopkins

University. She analysed the impact that 'Covid-19' had on deaths from *all* causes in the United States using official data from the CDC for the period from early February to early September, 2020. She found that allegedly 'Covid' *related*-deaths exceeded those from heart disease which she found strange with heart disease always the biggest cause of fatalities. Her research became even more significant when she noted the sudden decline in 2020 of *all* non-'Covid' deaths: 'This trend is completely contrary to the pattern observed in all previous years … the total decrease in deaths by other causes almost exactly equals the increase in deaths by Covid-19.' This was such a game, set and match in terms of what was happening that Johns Hopkins University deleted the article on the grounds that it 'was being used to support false and dangerous inaccuracies about the impact of the pandemic'. No – because it exposed the scam from official CDC figures and this was confirmed when those figures were published in January, 2021. Here we can see the effect of people dying from heart attacks, cancer, road accidents and gunshot wounds – *anything* – having 'Covid-19' on the death certificate along with those diagnosed from 'symptoms' who had even not tested positive with a test not testing for the 'virus'. I am not kidding with the gunshot wounds, by the way. Brenda Bock, coroner in Grand County, Colorado, revealed that two gunshot victims tested positive for the 'virus' within the previous 30 days and were therefore classified as 'Covid deaths'. Bock said: 'These two people had tested positive for Covid, but that's not what killed them. A gunshot wound is what killed them.' She said she had not even finished her investigation when the state listed the gunshot victims as deaths due to the 'virus'. The death and case figures for 'Covid-19' are an absolute joke and yet they are repeated like parrots by the media, politicians and alleged medical 'experts'. The official Cult narrative is the only show in town.

Genevieve Briand found that deaths from all causes were not exceptional in 2020 compared with previous years and a Spanish magazine published figures that said the same about Spain which was a 'Covid' propaganda hotspot at one point. *Discovery Salud*, a

health and medicine magazine, quoted government figures which showed how 17,000 *fewer* people died in Spain in 2020 than in 2019 and more than 26,000 fewer than in 2018. The age-standardised mortality rate for England and Wales when age distribution is taken into account was significantly lower in 2020 than the 1970s, 80s and 90s, and was only the ninth highest since 2000. Where is the 'pandemic'?

Post mortems and autopsies virtually disappeared for 'Covid' deaths amid claims that 'virus-infected' bodily fluids posed a risk to those carrying out the autopsy. This was rejected by renowned German pathologist and forensic doctor Klaus Püschel who said that he and his staff had by then done 150 autopsies on 'Covid' patients with no problems at all. He said they were needed to know why some 'Covid' patients suffered blood clots and not severe respiratory infections. The 'virus' is, after all, called SARS or 'severe acute respiratory syndrome'. I highlighted in the spring of 2020 this phenomenon and quoted New York intensive care doctor Cameron Kyle-Sidell who posted a soon deleted YouTube video to say that they had been told to prepare to treat an infectious disease called 'Covid-19', but that was not what they were dealing with. Instead he likened the lung condition of the most severely ill patients to what you would expect with cabin depressurisation in a plane at 30,000 feet or someone dropped on the top of Everest without oxygen or acclimatisation. I have never said this is not happening to a small minority of alleged 'Covid' patients – I am saying this is not caused by a phantom 'contagious virus'. Indeed Kyle-Sidell said that 'Covid-19' was not the disease they were told was coming their way. 'We are operating under a medical paradigm that is untrue,' he said, and he believed they were treating the wrong disease: 'These people are being slowly starved of oxygen.' Patients would take off their oxygen masks in a state of fear and stress and while they were blue in the face on the brink of death. They did not look like patients dying of pneumonia. You can see why they don't want autopsies when their virus doesn't exist and there is another condition in some people that they don't wish to be uncovered. I should add here that

the 5G system of millimetre waves was being rapidly introduced around the world in 2020 and even more so now as they fire 5G at the Earth from satellites. At 60 gigahertz within the 5G range that frequency interacts with the oxygen molecule and stops people breathing in sufficient oxygen to be absorbed into the bloodstream. They are installing 5G in schools and hospitals. The world is not mad or anything. 5G can cause major changes to the lungs and blood as I detail in *The Answer* and these consequences are labelled 'Covid-19', the alleged symptoms of which can be caused by 5G and other electromagnetic frequencies as cells respond to radiation poisoning.

The 'Covid death' scam

Dr Scott Jensen, a Minnesota state senator and medical doctor, exposed 'Covid' Medicare payment incentives to hospitals and death certificate manipulation. He said he was sent a seven-page document by the US Department of Health 'coaching' him on how to fill out death certificates which had never happened before. The document said that he didn't need to have a laboratory test for 'Covid-19' to put that on the death certificate and that shocked him when death certificates are supposed to be about facts. Jensen described how doctors had been 'encouraged, if not pressured' to make a diagnosis of 'Covid-19' if they thought it was probable or *'presumed*'. No positive test was necessary – not that this would have mattered anyway. He said doctors were told to diagnose 'Covid' by symptoms when these were the same as colds, allergies, other respiratory problems, and certainly with influenza which 'disappeared' in the 'Covid' era. A common sniffle was enough to get the dreaded verdict. Ontario authorities decreed that a single care home resident with *one* symptom from a long list must lead to the isolation of the entire home. Other courageous doctors like Jensen made the same point about death figure manipulation and how deaths by other causes were falling while 'Covid-19 deaths' were rising at the same rate due to re-diagnosis. Their videos rarely survive long on YouTube with its Cult-supporting algorithms courtesy of CEO Susan Wojcicki and her bosses at Google. Figure-tampering was so glaring

and ubiquitous that even officials were letting it slip or outright saying it. UK chief scientific adviser Patrick Vallance said on one occasion that 'Covid' on the death certificate doesn't mean 'Covid' was the cause of death (so why the hell is it there?) and we had the rare sight of a BBC reporter telling the truth when she said: 'Someone could be successfully treated for Covid, in say April, discharged, and then in June, get run over by a bus and die … That person would still be counted as a Covid death in England.' Yet the BBC and the rest of the world media went on repeating the case and death figures as if they were real. Illinois Public Health Director Dr Ngozi Ezike revealed the deceit while her bosses must have been clenching their buttocks:

> If you were in a hospice and given a few weeks to live and you were then found to have Covid that would be counted as a Covid death. [There might be] a clear alternate cause, but it is still listed as a Covid death. So everyone listed as a Covid death doesn't mean that was the cause of the death, but that they had Covid at the time of death.

Yes, a 'Covid virus' never shown to exist and tested for with a test not testing for the 'virus'. In the first period of the pandemic hoax through the spring of 2020 the process began of designating almost everything a 'Covid' death and this has continued ever since. I sat in a restaurant one night listening to a loud conversation on the next table where a family was discussing in bewilderment how a relative who had no symptoms of 'Covid', and had died of a long-term problem, could have been diagnosed a death by the 'virus'. I could understand their bewilderment. If they read this book they will know why this medical fraud has been perpetrated the world over.

Some media truth shock

The media ignored the evidence of death certificate fraud until eventually one columnist did speak out when she saw it first-hand. Bel Mooney is a long-time national newspaper journalist in Britain currently working for the *Daily Mail*. Her article on February 19th, 2021, carried this headline: 'My dad Ted passed three Covid tests

and died of a chronic illness yet he's officially one of Britain's 120,000 victims of the virus and is far from alone ... so how many more are there?' She told how her 99-year-old father was in a care home with a long-standing chronic obstructive pulmonary disease and vascular dementia. Maybe, but he was still aware enough to tell her from the start that there was no 'virus' and he refused the 'vaccine' for that reason. His death was not unexpected given his chronic health problems and Mooney said she was shocked to find that 'Covid-19' was declared the cause of death on his death certificate. She said this was a 'bizarre and unacceptable untruth' for a man with long-time health problems who had tested negative twice at the home for the 'virus'. I was also shocked by this story although not by what she said. I had been highlighting the death certificate manipulation for ten months. It was the confirmation that a professional full-time journalist only realised this was going on when it affected her directly and neither did she know that whether her dad tested positive or negative was irrelevant with the test not testing for the 'virus'. Where had she been? She said she did not believe in 'conspiracy theories' without knowing I'm sure that this and 'conspiracy theorists' were terms put into widespread circulation by the CIA in the 1960s to discredit those who did not accept the ridiculous official story of the Kennedy assassination. A blanket statement of 'I don't believe in conspiracy theories' is always bizarre. The dictionary definition of the term alone means the world is drowning in conspiracies. What she said was even more daft when her dad had just been affected by the 'Covid' conspiracy. Why else does she think that 'Covid-19' was going on the death certificates of people who died of something else?

To be fair once she saw from personal experience what was happening she didn't mince words. Mooney was called by the care home on the morning of February 9th to be told her father had died in his sleep. When she asked for the official cause of death what came back was 'Covid-19'. Mooney challenged this and was told there had been deaths from Covid on the dementia floor (confirmed by a test not testing for the 'virus') so they considered it 'reasonable

to assume'. 'But doctor,' Mooney rightly protested, 'an assumption isn't a diagnosis.' She said she didn't blame the perfectly decent and sympathetic doctor – 'he was just doing his job'. Sorry, but that's *bullshit*. He wasn't doing his job at all. He was putting a false cause of death on the death certificate and that is a criminal offence for which he should be brought to account and the same with the millions of doctors worldwide who have done the same. They were not doing their job they were following orders and that must not wash at new Nuremberg trials any more than it did at the first ones. Mooney's doctor was 'assuming' (presuming) as he was told to, but 'just following orders' makes no difference to his actions. A doctor's job is to serve the patient and the truth, not follow orders, but that's what they have done all over the world and played a central part in making the 'Covid' hoax possible with all its catastrophic consequences for humanity. Shame on them and they must answer for their actions. Mooney said her disquiet worsened when she registered her father's death by telephone and was told by the registrar there had been very many other cases like hers where 'the deceased' had not tested positive for 'Covid' yet it was recorded as the cause of death. The test may not matter, but those involved at their level *think* it matters and it shows a callous disregard for accurate diagnosis. The pressure to do this is coming from the top of the national 'health' pyramids which in turn obey the World Health Organization which obeys Gates and the Cult. Mooney said the registrar agreed that this must distort the national figures adding that 'the strangest thing is that every winter we record countless deaths from flu, and this winter there have been none. Not one!' She asked if the registrar thought deaths from flu were being misdiagnosed and lumped together with 'Covid' deaths. The answer was a 'puzzled yes'. Mooney said that the funeral director said the same about 'Covid' deaths which had nothing to do with 'Covid'. They had lost count of the number of families upset by this and other funeral companies in different countries have had the same experience. Mooney wrote:

The nightly shroud-waving and shocking close-ups of pain imposed on us by the TV news bewildered and terrified the population into eager compliance with lockdowns. We were invited to 'save the NHS' and to grieve for strangers – the real-life loved ones behind those shocking death counts. Why would the public imagine what I now fear, namely that the way Covid-19 death statistics are compiled might make the numbers seem greater than they are?

Oh, just a little bit – like 100 percent.

Do the maths

Mooney asked why a country would wish to skew its mortality figures by wrongly certifying deaths? What had been going on? Well, if you don't believe in conspiracies you will never find the answer which is that *it's a conspiracy*. She did, however, describe what she had discovered as a 'national scandal'. In reality it's a global scandal and happening everywhere. Pillars of this conspiracy were all put into place before the button was pressed with the Drosten PCR protocol and high amplifications to produce the cases and death certificate changes to secure illusory 'Covid' deaths. Mooney notes that normally two doctors were needed to certify a death, with one having to know the patient, and how the rules were changed in the spring of 2020 to allow one doctor to do this. In the same period 'Covid deaths' were decreed to be all cases where Covid-19 was put on the death certificate even without a positive test or any symptoms. Mooney asked: 'How many of the 30,851 (as of January 15) care home resident deaths with Covid-19 on the certificate (32.4 per cent of all deaths so far) were based on an assumption, like that of my father? And what has that done to our national psyche?'All of them is the answer to the first question and it has devastated and dismantled the national psyche, actually the global psyche, on a colossal scale. In the UK case and death data is compiled by organisations like Public Health England (PHE) and the Office for National Statistics (ONS). Mooney highlights the insane policy of counting a death from any cause as 'Covid-19' if this happens within 28 days of a positive test (with a test not testing for the 'virus') and she points out that ONS statistics reflect deaths 'involving Covid' 'or due to Covid' which meant in practice any

death where 'Covid-19' was mentioned on the death certificate. She described the consequences of this fraud:

> Most people will accept the narrative they are fed, so panicky governments here and in Europe witnessed the harsh measures enacted in totalitarian China and jumped into lockdown. Headlines about Covid deaths tolled like the knell that would bring doomsday to us all. Fear stalked our empty streets. Politicians parroted the frankly ridiculous aim of 'zero Covid' and shut down the economy, while most British people agreed that lockdown was essential and (astonishingly to me, as a patriotic Brit) even wanted more restrictions.
>
> For what? Lies on death certificates? Never mind the grim toll of lives ruined, suicides, schools closed, rising inequality, depression, cancelled hospital treatments, cancer patients in a torture of waiting, poverty, economic devastation, loneliness, families kept apart, and so on. How many lives have been lost as a direct result of lockdown?

She said that we could join in a national chorus of shock and horror at reaching the 120,000 death toll which was surely certain to have been totally skewed all along, but what about the human cost of lockdown justified by these 'death figures'? *The British Medical Journal* had reported a 1,493 percent increase in cases of children taken to Great Ormond Street Hospital with abusive head injuries alone and then there was the effect on families:

> Perhaps the most shocking thing about all this is that families have been kept apart – and obeyed the most irrational, changing rules at the whim of government – because they believed in the statistics. They succumbed to fear, which his generation rejected in that war fought for freedom. Dad (God rest his soul) would be angry. And so am I.

Another theme to watch is that in the winter months when there are more deaths from all causes they focus on 'Covid' deaths and in the summer when the British Lung Foundation says respiratory disease plummets by 80 percent they rage on about 'cases'. Either way fascism on population is always the answer.

Nazi eugenics in the 21st century

Elderly people in care homes have been isolated from their families month after lonely month with no contact with relatives and grandchildren who were banned from seeing them. We were told

that lockdown fascism was to 'protect the vulnerable' like elderly people. At the same time Do Not Resuscitate (DNR) orders were placed on their medical files so that if they needed resuscitation it wasn't done and 'Covid-19' went on their death certificates. Old people were not being 'protected' they were being culled – murdered in truth. DNR orders were being decreed for disabled and young people with learning difficulties or psychological problems. The UK Care Quality Commission, a non-departmental body of the Department of Health and Social Care, found that 34 percent of those working in health and social care were pressured into placing 'do not attempt cardiopulmonary resuscitation' orders on 'Covid' patients who suffered from disabilities and learning difficulties without involving the patient or their families in the decision. UK judges ruled that an elderly woman with dementia should have the DNA-manipulating 'Covid vaccine' against her son's wishes and that a man with severe learning difficulties should have the jab despite his family's objections. Never mind that many had already died. The judiciary always supports doctors and government in fascist dictatorships. They wouldn't dare do otherwise. A horrific video was posted showing fascist officers from Los Angeles police forcibly giving the 'Covid' shot to women with special needs who were screaming that they didn't want it. The same fascists are seen giving the jab to a sleeping elderly woman in a care home. This is straight out of the Nazi playbook. Hitler's Nazis committed mass murder of the mentally ill and physically disabled throughout Germany and occupied territories in the programme that became known as Aktion T4, or just T4. Sabbatian-controlled Hitler and his grotesque crazies set out to kill those they considered useless and unnecessary. The Reich Committee for the Scientific Registering of Hereditary and Congenital Illnesses registered the births of babies identified by physicians to have 'defects'. By 1941 alone more than 5,000 children were murdered by the state and it is estimated that in total the number of innocent people killed in Aktion T4 was between 275,000 and 300,000. Parents were told their children had been sent away for 'special treatment' never to return. It is rather pathetic to see claims about plans for new extermination camps being dismissed today

when the same force behind current events did precisely that 80 years ago. Margaret Sanger was a Cult operative who used 'birth control' to sanitise her programme of eugenics. Organisations she founded became what is now Planned Parenthood. Sanger proposed that 'the whole dysgenic population would have its choice of segregation or sterilization'. These included epileptics, 'feeble-minded', and prostitutes. Sanger opposed charity because it perpetuated 'human waste'. She reveals the Cult mentality and if anyone thinks that extermination camps are a 'conspiracy theory' their naivety is touching if breathtakingly stupid.

If you don't believe that doctors can act with callous disregard for their patients it is worth considering that doctors and medical staff agreed to put government-decreed DNR orders on medical files and do nothing when resuscitation is called for. I don't know what you call such people in your house. In mine they are Nazis from the Josef Mengele School of Medicine. Phenomenal numbers of old people have died worldwide from the effects of lockdown, depression, lack of treatment, the 'vaccine' (more later) and losing the will to live. A common response at the start of the manufactured pandemic was to remove old people from hospital beds and transfer them to nursing homes. The decision would result in a mass cull of elderly people in those homes through lack of treatment – *not* 'Covid'. Care home whistleblowers have told how once the 'Covid' era began doctors would not come to their homes to treat patients and they were begging for drugs like antibiotics that often never came. The most infamous example was ordered by New York governor Andrew Cuomo, brother of a moronic CNN host, who amazingly was given an Emmy Award for his handling of the 'Covid crisis' by the ridiculous Wokers that hand them out. Just how ridiculous could be seen in February, 2021, when a Department of Justice and FBI investigation began into how thousands of old people in New York died in nursing homes after being discharged from hospital to make way for 'Covid' patients on Cuomo's say-so – and how he and his staff covered up these facts. This couldn't have happened to a nicer psychopath. Even then there was a 'Covid' spin. Reports said that

thousands of old people who tested positive for 'Covid' in hospital were transferred to nursing homes to both die of 'Covid' and transmit it to others. No – they were in hospital because they were ill and the fact that they tested positive with a test not testing for the 'virus' is irrelevant. They were ill often with respiratory diseases ubiquitous in old people near the end of their lives. Their transfer out of hospital meant that their treatment stopped and many would go on to die.

They're old. Who gives a damn?

I have exposed in the books for decades the Cult plan to cull the world's old people and even to introduce at some point what they call a 'demise pill' which at a certain age everyone would take and be out of here by law. In March, 2021, Spain legalised euthanasia and assisted suicide following the Netherlands, Belgium, Luxembourg and Canada on the Tiptoe to the demise pill. Treatment of old people by many 'care' homes has been a disgrace in the 'Covid' era. There are many, many, caring staff – I know some. There have, however, been legions of stories about callous treatment of old people and their families. Police were called when families came to take their loved ones home in the light of isolation that was killing them. They became prisoners of the state. Care home residents in insane, fascist Ontario, Canada, were not allowed to leave their *room* once the 'Covid' hoax began. UK staff have even wheeled elderly people away from windows where family members were talking with them. Oriana Criscuolo from Stockport in the English North West dropped off some things for her 80-year-old father who has Parkinson's disease and dementia and she wanted to wave to him through a ground-floor window. She was told that was 'illegal'. When she went anyway they closed the curtains in the middle of the day. Oriana said:

> It's just unbelievable. I cannot understand how care home staff – people who are being paid to care – have become so uncaring. Their behaviour is inhumane and cruel. It's beyond belief.

She was right and this was not a one-off. What a way to end your life in such loveless circumstances. UK registered nurse Nicky Millen, a proper old school nurse for 40 years, said that when she started her career care was based on dignity, choice, compassion and empathy. Now she said 'the things that are important to me have gone out of the window.' She was appalled that people were dying without their loved ones and saying goodbye on iPads. Nicky described how a distressed 89-year-old lady stroked her face and asked her 'how many paracetamol would it take to finish me off'. Life was no longer worth living while not seeing her family. Nicky said she was humiliated in front of the ward staff and patients for letting the lady stroke her face and giving her a cuddle. Such is the dehumanisation that the 'Covid' hoax has brought to the surface. Nicky worked in care homes where patients told her they were being held prisoner. 'I want to live until I die', one said to her. 'I had a lady in tears because she hadn't seen her great-grandson.' Nicky was compassionate old school meeting psychopathic New Normal. She also said she had worked on a 'Covid' ward with no 'Covid' patients. Jewish writer Shai Held wrote an article in March, 2020, which was headlined 'The Staggering, Heartless Cruelty Toward the Elderly'. What he described was happening from the earliest days of lockdown. He said 'the elderly' were considered a group and not unique individuals (the way of the Woke). Shai Held said:

> Notice how the all-too-familiar rhetoric of dehumanization works: 'The elderly' are bunched together as a faceless mass, all of them considered culprits and thus effectively deserving of the suffering the pandemic will inflict upon them. Lost entirely is the fact that the elderly are individual human beings, each with a distinctive face and voice, each with hopes and dreams, memories and regrets, friendships and marriages, loves lost and loves sustained.

'The elderly' have become another dehumanised group for which anything goes and for many that has resulted in cold disregard for their rights and their life. The distinctive face that Held talks about is designed to be deleted by masks until everyone is part of a faceless mass.

'War-zone' hospitals myth

Again and again medical professionals have told me what was really going on and how hospitals 'overrun like war zones' according to the media were virtually empty. The mantra from medical whistleblowers was please don't use my name or my career is over. Citizen journalists around the world sneaked into hospitals to film evidence exposing the 'war-zone' lie. They really *were* largely empty with closed wards and operating theatres. I met a hospital worker in my town on the Isle of Wight during the first lockdown in 2020 who said the only island hospital had never been so quiet. Lockdown was justified by the psychopaths to stop hospitals being overrun. At the same time that the island hospital was near-empty the military arrived here to provide *extra beds*. It was all propaganda to ramp up the fear to ensure compliance with fascism as were never-used temporary hospitals with thousands of beds known as Nightingales and never-used make-shift mortuaries opened by the criminal UK government. A man who helped to install those extra island beds attributed to the army said they were never used and the hospital was empty. Doctors and nurses 'stood around talking or on their phones, wandering down to us to see what we were doing'. There were no masks or social distancing. He accused the useless local island paper, the *County Press*, of 'pumping the fear as if our hospital was overrun and we only have one so it should have been'. He described ambulances parked up with crews outside in deck chairs. When his brother called an ambulance he was told there was a two-hour backlog which he called 'bullshit'. An old lady on the island fell 'and was in a bad way', but a caller who rang for an ambulance was told the situation wasn't urgent enough. Ambulance stations were working under capacity while people would hear ambulances with sirens blaring driving through the streets. When those living near the stations realised what was going on they would follow them as they left, circulated around an urban area with the sirens going, and then came back without stopping. All this was to increase levels of fear and the same goes for the 'ventilator shortage crisis' that cost tens of millions for hastily produced ventilators never to be used.

Ambulance crews that agreed to be exploited in this way for fear propaganda might find themselves a mirror. I wish them well with that. Empty hospitals were the obvious consequence of treatment and diagnoses of non-'Covid' conditions cancelled and those involved handed a death sentence. People have been dying at home from undiagnosed and untreated cancer, heart disease and other life-threatening conditions to allow empty hospitals to deal with a 'pandemic' that wasn't happening.

Death of the innocent

'War-zones' have been laying off nursing staff, even doctors where they can. There was no work for them. Lockdown was justified by saving lives and protecting the vulnerable they were actually killing with DNR orders and preventing empty hospitals being 'overrun'. In Britain the mantra of stay at home to 'save the NHS' was everywhere and across the world the same story was being sold when it was all lies. Two California doctors, Dan Erickson and Artin Massihi at Accelerated Urgent Care in Bakersfield, held a news conference in April, 2020, to say that intensive care units in California were 'empty, essentially', with hospitals shutting floors, not treating patients and laying off doctors. The California health system was working at minimum capacity 'getting rid of doctors because we just don't have the volume'. They said that people with conditions such as heart disease and cancer were not coming to hospital out of fear of 'Covid-19'. Their video was deleted by Susan Wojcicki's Cult-owned YouTube after reaching five million views. Florida governor Ron Desantis, who rejected the severe lockdowns of other states and is being targeted for doing so, said that in March, 2020, every US governor was given models claiming they would run out of hospital beds in days. That was never going to happen and the 'modellers' knew it. Deceit can be found at every level of the system. Urgent children's operations were cancelled including fracture repairs and biopsies to spot cancer. Eric Nicholls, a consultant paediatrician, said 'this is obviously concerning and we need to return to normal operating and to increase capacity as soon as possible'. Psychopaths

in power were rather less concerned *because* they are psychopaths. Deletion of urgent care and diagnosis has been happening all over the world and how many kids and others have died as a result of the actions of these cold and heartless lunatics dictating 'health' policy? The number must be stratospheric. Richard Sullivan, professor of cancer and global health at King's College London, said people feared 'Covid' more than cancer such was the campaign of fear. 'Years of lost life will be quite dramatic', Sullivan said, with 'a huge amount of avoidable mortality'. Sarah Woolnough, executive director for policy at Cancer Research UK, said there had been a 75 percent drop in urgent referrals to hospitals by family doctors of people with suspected cancer. Sullivan said that 'a lot of services have had to scale back – we've seen a dramatic decrease in the amount of elective cancer surgery'. Lockdown deaths worldwide has been absolutely fantastic with the *New York Post* reporting how data confirmed that 'lockdowns end more lives than they save':

> There was a sharp decline in visits to emergency rooms and an increase in fatal heart attacks because patients didn't receive prompt treatment. Many fewer people were screened for cancer. Social isolation contributed to excess deaths from dementia and Alzheimer's.
>
> Researchers predicted that the social and economic upheaval would lead to tens of thousands of "deaths of despair" from drug overdoses, alcoholism and suicide. As unemployment surged and mental-health and substance-abuse treatment programs were interrupted, the reported levels of anxiety, depression and suicidal thoughts increased dramatically, as did alcohol sales and fatal drug overdoses.

This has been happening while nurses and other staff had so much time on their hands in the 'war-zones' that Tic-Tok dancing videos began appearing across the Internet with medical staff dancing around in empty wards and corridors as people died at home from causes that would normally have been treated in hospital.

Mentions in dispatches

One brave and truth-committed whistleblower was Louise Hampton, a call handler with the UK NHS who made a viral Internet video saying she had done 'fuck all' during the 'pandemic'

which was ‘a load of bollocks’. She said that ‘Covid-19’ was rebranded flu and of course she lost her job. This is what happens in the medical and endless other professions now when you tell the truth. Louise filmed inside ‘war-zone’ accident and emergency departments to show they were empty and I mean *empty* as in no one there. The mainstream media could have done the same and blown the gaff on the whole conspiracy. They haven’t to their eternal shame. Not that most ‘journalists’ seem capable of manifesting shame as with the psychopaths they slavishly repeat without question. The relative few who were admitted with serious health problems were left to die alone with no loved ones allowed to see them because of ‘Covid’ rules and they included kids dying without the comfort of mum and dad at their bedside while the evil behind this couldn’t give a damn. It was all good fun to them. A Scottish NHS staff nurse publicly quit in the spring of 2021 saying: ‘I can no longer be part of the lies and the corruption by the government.’ She said hospitals ‘aren’t full, the beds aren’t full, beds have been shut, wards have been shut’. Hospitals were never busy throughout ‘Covid’. The staff nurse said that Nicola Sturgeon, tragically the leader of the Scottish government, was on television saying save the hospitals and the NHS – ‘but the beds are empty’ and ‘we’ve not seen flu, we always see flu every year’. She wrote to government and spoke with her union Unison (the unions are Cult-compromised and *useless*, but nothing changed. Many of her colleagues were scared of losing their jobs if they spoke out as they wanted to. She said nursing staff were being affected by wearing masks all day and ‘my head is splitting every shift from wearing a mask’. The NHS is part of the fascist tyranny and must be dismantled so we can start again with human beings in charge. (Ironically, hospitals were reported to be busier again when official ‘Covid’ cases *fell* in spring/summer of 2021 and many other conditions required treatment at the same time as *the fake vaccine rollout*.)

I will cover the ‘Covid vaccine’ scam in detail later, but it is another indicator of the sickening disregard for human life that I am highlighting here. The DNA-manipulating concoctions do not fulfil

the definition of a 'vaccine', have never been used on humans before and were given only emergency approval because trials were not completed and they continued using the unknowing public. The result was what a NHS senior nurse with responsibility for 'vaccine' procedure said was 'genocide'. She said the 'vaccines' were not 'vaccines'. They had not been shown to be safe and claims about their effectiveness by drug companies were 'poetic licence'. She described what was happening as a 'horrid act of human annihilation'. The nurse said that management had instigated a policy of not providing a Patient Information Leaflet (PIL) before people were 'vaccinated' even though health care professionals are supposed to do this according to protocol. Patients should also be told that they are taking part in an ongoing clinical trial. Her challenges to what is happening had seen her excluded from meetings and ridiculed in others. She said she was told to 'watch my step … or I would find myself surplus to requirements'. The nurse, who spoke anonymously in fear of her career, said she asked her NHS manager why he/she was content with taking part in genocide against those having the 'vaccines'. The reply was that everyone had to play their part and to 'put up, shut up, and get it done'. Government was 'leaning heavily' on NHS management which was clearly leaning heavily on staff. This is how the global 'medical' hierarchy operates and it starts with the Cult and its World Health Organization.

She told the story of a doctor who had the Pfizer jab and when questioned had no idea what was in it. The doctor had never read the literature. We have to stop treating doctors as intellectual giants when so many are moral and medical pygmies. The doctor did not even know that the 'vaccines' were not fully approved or that their trials were ongoing. They were, however, asking their patients if they minded taking part in follow-ups for research purposes – yes, the *ongoing clinical trial*. The nurse said the doctor's ignorance was not rare and she had spoken to a hospital consultant who had the jab without any idea of the background or that the 'trials' had not been completed. Nurses and pharmacists had shown the same ignorance.

'My NHS colleagues have forsaken their duty of care, broken their code of conduct – Hippocratic Oath – and have been brainwashed just the same as the majority of the UK public through propaganda …' She said she had not been able to recruit a single NHS colleague, doctor, nurse or pharmacist to stand with her and speak out. Her union had refused to help. She said that if the genocide came to light she would not hesitate to give evidence at a Nuremberg-type trial against those in power who could have affected the outcomes but didn't.

And all for what?

To put the nonsense into perspective let's say the 'virus' does exist and let's go completely crazy and accept that the official manipulated figures for cases and deaths are accurate. *Even then* a study by Stanford University epidemiologist Dr John Ioannidis published on the World Health Organization website produced an average infection to fatality rate of … *0.23 percent!* Ioannidis said: 'If one could sample equally from all locations globally, the median infection fatality rate might even be substantially lower than the 0.23% observed in my analysis.' For healthy people under 70 it was … *0.05 percent*! This compares with the 3.4 percent claimed by the Cult-owned World Health Organization when the hoax was first played and maximum fear needed to be generated. An updated Stanford study in April, 2021, put the 'infection' to 'fatality' rate at just 0.15 percent. Another team of scientists led by Megan O'Driscoll and Henrik Salje studied data from 45 countries and published their findings on the Nature website. For children and young people the figure is so small it virtually does not register although authorities will be hyping dangers to the young when they introduce DNA-manipulating 'vaccines' for children. The O'Driscoll study produced an average infection-fatality figure of 0.003 for children from birth to four; 0.001 for 5 to 14; 0.003 for 15 to 19; and it was still only 0.456 up to 64. To claim that children must be 'vaccinated' to protect them from 'Covid' is an obvious lie and so there must be another reason and there is. What's more the average age of a 'Covid' death is akin

to the average age that people die in general. The average age of death in England is about 80 for men and 83 for women. The average age of death from alleged 'Covid' is between 82 and 83. California doctors, Dan Erickson and Artin Massihi, said at their April media conference that projection models of millions of deaths had been 'woefully inaccurate'. They produced detailed figures showing that Californians had a 0.03 chance of dying from 'Covid' based on the number of people who tested positive (with a test not testing for the 'virus'). Erickson said there was a 0.1 percent chance of dying from 'Covid' in the *state* of New York, not just the city, and a 0.05 percent chance in Spain, a centre of 'Covid-19' hysteria at one stage. The Stanford studies supported the doctors' data with fatality rate estimates of 0.23 and 0.15 percent. How close are these figures to my estimate of *zero*? Death-rate figures claimed by the World Health Organization at the start of the hoax were some 15 times higher. The California doctors said there was no justification for lockdowns and the economic devastation they caused. Everything they had ever learned about quarantine was that you quarantine the *sick* and not the healthy. They had never seen this before and it made no medical sense.

Why in the in the light of all this would governments and medical systems the world over say that billions must go under house arrest; lose their livelihood; in many cases lose their mind, their health and their life; force people to wear masks dangerous to health and psychology; make human interaction and even family interaction a criminal offence; ban travel; close restaurants, bars, watching live sport, concerts, theatre, and any activity involving human togetherness and discourse; and closing schools to isolate children from their friends and cause many to commit suicide in acts of hopelessness and despair? The California doctors said lockdown consequences included increased child abuse, partner abuse, alcoholism, depression, and other impacts they were seeing every day. Who would do that to the entire human race if not mentally-ill psychopaths of almost unimaginable extremes like Bill Gates? We must face the reality of what we are dealing with and come out of

denial. Fascism and tyranny are made possible only by the target population submitting and acquiescing to fascism and tyranny. The whole of human history shows that to be true. Most people naively and unquestioning believed what they were told about a 'deadly virus' and meekly and weakly submitted to house arrest. Those who didn't believe it – at least in total – still submitted in fear of the consequences of not doing so. For the rest who wouldn't submit draconian fines have been imposed, brutal policing by psychopaths *for* psychopaths, and condemnation from the meek and weak who condemn the Pushbackers on behalf of the very force that has them, too, in its gunsights. 'Pathetic' does not even begin to suffice. Britain's brainless 'Health' Secretary Matt Hancock warned anyone lying to border officials about returning from a list of 'hotspot' countries could face a jail sentence of up to ten years which is more than for racially-aggravated assault, incest and attempting to have sex with a child under 13. Hancock is a lunatic, but he has the state apparatus behind him in a Cult-led chain reaction and the same with UK 'Vaccine Minister' Nadhim Zahawi, a prominent member of the mega-Cult secret society, Le Cercle, which featured in my earlier books. The Cult enforces its will on governments and medical systems; government and medical systems enforce their will on business and police; business enforces its will on staff who enforce it on customers; police enforce the will of the Cult on the population and play their essential part in creating a world of fascist control that their own children and grandchildren will have to live in their entire lives. It is a hierarchical pyramid of imposition and acquiescence and, yes indeedy, of clinical insanity.

Does anyone bright enough to read this book have to ask what the answer is? I think not, but I will reveal it anyway in the fewest of syllables: Tell the psychos and their moronic lackeys to fuck off and let's get on with our lives. We are many – They are few.

CHAPTER SEVEN

War on your mind

One believes things because one has been conditioned to believe them
Aldous Huxley, *Brave New World*

I have described the 'Covid' hoax as a 'Psyop' and that is true in every sense and on every level in accordance with the definition of that term which is psychological warfare. Break down the 'Covid pandemic' to the foundation themes and it is psychological warfare on the human individual and collective mind.

The same can be said for the entire human belief system involving every subject you can imagine. Huxley was right in his contention that people believe what they are conditioned to believe and this comes from the repetition throughout their lives of the same falsehoods. They spew from government, corporations, media and endless streams of 'experts' telling you what the Cult wants you to believe and often believing it themselves (although *far* from always). 'Experts' are rewarded with 'prestigious' jobs and titles and as agents of perceptual programming with regular access to the media. The Cult has to control the narrative – control *information* – or they lose control of the vital, crucial, without-which-they-cannot-prevail public perception of reality. The foundation of that control today is the Internet made possible by the Defense Advanced Research Projects Agency (DARPA), the incredibly sinister technological arm of the Pentagon. The Internet is the result of military technology.

DARPA openly brags about establishing the Internet which has been a long-term project to lasso the minds of the global population. I have said for decades the plan is to control information to such an extreme that eventually no one would see or hear anything that the Cult does not approve. We are closing in on that end with ferocious censorship since the 'Covid' hoax began and in my case it started back in the 1990s in terms of books and speaking venues. I had to create my own publishing company in 1995 precisely because no one else would publish my books even then. I think they're all still running.

Cult Internet

To secure total control of information they needed the Internet in which pre-programmed algorithms can seek out 'unclean' content for deletion and even stop it being posted in the first place. The Cult had to dismantle print and non-Internet broadcast media to ensure the transfer of information to the appropriate-named 'Web' – a critical expression of the *Cult* web. We've seen the ever-quickening demise of traditional media and control of what is left by a tiny number of corporations operating worldwide. Independent journalism in the mainstream is already dead and never was that more obvious than since the turn of 2020. The Cult wants all information communicated via the Internet to globally censor and allow the plug to be pulled any time. Lockdowns and forced isolation has meant that communication between people has been through electronic means and no longer through face-to-face discourse and discussion. Cult psychopaths have targeted the bars, restaurants, sport, venues and meeting places in general for this reason. None of this is by chance and it's to stop people gathering in any kind of privacy or number while being able to track and monitor all Internet communications and block them as necessary. Even private messages between individuals have been censored by these fascists that control Cult fronts like Facebook, Twitter, Google and YouTube which are all officially run by Sabbatian place-people and from the background by higher-level Sabbatian place people.

Facebook, Google, Amazon and their like were seed-funded and supported into existence with money-no-object infusions of funds either directly or indirectly from DARPA and CIA technology arm In-Q-Tel. The Cult plays the long game and prepares very carefully for big plays like 'Covid'. Amazon is another front in the psychological war and pretty much controls the global market in book sales and increasingly publishing. Amazon's limitless funds have deleted fantastic numbers of independent publishers to seize global domination on the way to deciding which books can be sold and circulated and which cannot. Moves in that direction are already happening. Amazon's leading light Jeff Bezos is the grandson of Lawrence Preston Gise who worked with DARPA predecessor ARPA. Amazon has big connections to the CIA and the Pentagon. The plan I have long described went like this:

1. Employ military technology to establish the Internet.

2. Sell the Internet as a place where people can freely communicate without censorship and allow that to happen until the Net becomes the central and irreversible pillar of human society. If the Internet had been highly censored from the start many would have rejected it.

3. Fund and manipulate major corporations into being to control the circulation of information on your Internet using cover stories about geeks in garages to explain how they came about. Give them unlimited funds to expand rapidly with no need to make a profit for years while non-Cult companies who need to balance the books cannot compete. You know that in these circumstances your Googles, YouTubes, Facebooks and Amazons are going to secure near monopolies by either crushing or buying up the opposition.

4. Allow freedom of expression on both the Internet and communication platforms to draw people in until the Internet is the central and irreversible pillar of human society and your communication corporations have reached a stage of near monopoly domination.

5. Then unleash your always-planned frenzy of censorship on the basis of 'where else are you going to go?' and continue to expand that until nothing remains that the Cult does not want its human targets to see.

The process was timed to hit the 'Covid' hoax to ensure the best chance possible of controlling the narrative which they knew they had to do at all costs. They were, after all, about to unleash a 'deadly virus' that didn't really exist. If you do that in an environment of free-flowing information and opinion you would be dead in the

water before you could say Gates is a psychopath. The network was in place through which the Cult-created-and-owned World Health Organization could dictate the 'Covid' narrative and response policy slavishly supported by Cult-owned Internet communication giants and mainstream media while those telling a different story were censored. Google, YouTube, Facebook and Twitter openly announced that they would do this. What else would we expect from Cult-owned operations like Facebook which former executives have confirmed set out to make the platform more addictive than cigarettes and coldly manipulates emotions of its users to sow division between people and groups and scramble the minds of the young? If Zuckerberg lives out the rest of his life without going to jail for crimes against humanity, and most emphatically against the young, it will be a travesty of justice. Still, no matter, cause and effect will catch up with him eventually and the same with Sergey Brin and Larry Page at Google with its CEO Sundar Pichai who fix the Google search results to promote Cult narratives and hide the opposition. Put the same key words into Google and other search engines like DuckDuckGo and you will see how different results can be. Wikipedia is another intensely biased 'encyclopaedia' which skews its content to the Cult agenda. YouTube links to Wikipedia's version of 'Covid' and 'climate change' on video pages in which experts in their field offer a different opinion (even that is increasingly rare with Wojcicki censorship). Into this 'Covid' silence-them network must be added government media censors, sorry 'regulators', such as Ofcom in the UK which imposed tyrannical restrictions on British broadcasters that had the effect of banning me from ever appearing. Just to debate with me about my evidence and views on 'Covid' would mean breaking the fascistic impositions of Ofcom and its CEO career government bureaucrat Melanie Dawes. Gutless British broadcasters tremble at the very thought of fascist Ofcom.

Psychos behind 'Covid'

The reason for the 'Covid' catastrophe in all its facets and forms can be seen by whom and what is driving the policies worldwide in such a coordinated way. Decisions are not being made to protect health, but to target psychology. The dominant group guiding and 'advising' government policy are not medical professionals. They are psychologists and behavioural scientists. Every major country has its own version of this phenomenon and I'll use the British example to show how it works. In many ways the British version has been affecting the wider world in the form of the huge behaviour manipulation network in the UK which operates in other countries. The network involves private companies, government, intelligence and military. The Cabinet Office is at the centre of the government 'Covid' Psyop and part-owns, with 'innovation charity' Nesta, the Behavioural Insights Team (BIT) which claims to be independent of government but patently isn't. The BIT was established in 2010 and its job is to manipulate the psyche of the population to acquiesce to government demands and so much more. It is also known as the 'Nudge Unit', a name inspired by the 2009 book by two ultra-Zionists, Cass Sunstein and Richard Thaler, called *Nudge: Improving Decisions About Health, Wealth, and Happiness*. The book, as with the Behavioural Insights Team, seeks to 'nudge' behaviour (manipulate it) to make the public follow patterns of action and perception that suit those in authority (the Cult). Sunstein is so skilled at this that he advises the World Health Organization and the UK Behavioural Insights Team and was Administrator of the White House Office of Information and Regulatory Affairs in the Obama administration. Biden appointed him to the Department of Homeland Security – another ultra-Zionist in the fold to oversee new immigration laws which is another policy the Cult wants to control. Sunstein is desperate to silence anyone exposing conspiracies and co-authored a 2008 report on the subject in which suggestions were offered to ban 'conspiracy theorizing' or impose 'some kind of tax, financial or otherwise, on those who disseminate such theories'. I guess a psychiatrist's chair is out of the question?

Sunstein's mate Richard Thaler, an 'academic affiliate' of the UK Behavioural Insights Team, is a proponent of 'behavioural economics' which is defined as the study of 'the effects of psychological, cognitive, emotional, cultural and social factors on the decisions of individuals and institutions'. Study the effects so they can be manipulated to be what you want them to be. Other leading names in the development of behavioural economics are ultra-Zionists Daniel Kahneman and Robert J. Shiller and they, with Thaler, won the Nobel Memorial Prize in Economic Sciences for their work in this field. The Behavioural Insights Team is operating at the heart of the UK government and has expanded globally through partnerships with several universities including Harvard, Oxford, Cambridge, University College London (UCL) and Pennsylvania. They claim to have 'trained' (reframed) 20,000 civil servants and run more than 750 projects involving 400 randomised controlled trials in dozens of countries' as another version of mind reframers Common Purpose. BIT works from its office in New York with cities and their agencies, as well as other partners, across the United States and Canada – this is a company part-owned by the British government Cabinet Office. An executive order by President Cult-servant Obama established a US Social and Behavioral Sciences Team in 2015. They all have the same reason for being and that's to brainwash the population directly and by brainwashing those in positions of authority.

'Covid' mind game

Another prime aspect of the UK mind-control network is the 'independent' [joke] Scientific Pandemic Insights Group on Behaviours (SPI-B) which 'provides behavioural science advice aimed at anticipating and helping people adhere to interventions that are recommended by medical or epidemiological experts'. That means manipulating public perception and behaviour to do whatever government tells them to do. It's disgusting and if they really want the public to be 'safe' this lot should all be under lock and key. According to the government website SPI-B consists of

'behavioural scientists, health and social psychologists, anthropologists and historians' and advises the Whitty-Vallance-led Scientific Advisory Group for Emergencies (SAGE) which in turn advises the government on 'the science' (it doesn't) and 'Covid' policy. When politicians say they are being guided by 'the science' this is the rabble in each country they are talking about and that 'science' is dominated by behaviour manipulators to enforce government fascism through public compliance. The Behaviour Insight Team is headed by psychologist David Solomon Halpern, a visiting professor at King's College London, and connects with a national and global web of other civilian and military organisations as the Cult moves towards its goal of fusing them into one fascistic whole in every country through its 'Fusion Doctrine'. The behaviour manipulation network involves, but is not confined to, the Foreign Office; National Security Council; government communications headquarters (GCHQ); MI5; MI6; the Cabinet Office-based Media Monitoring Unit; and the Rapid Response Unit which 'monitors digital trends to spot emerging issues; including misinformation and disinformation; and identifies the best way to respond'.

There is also the 77th Brigade of the UK military which operates like the notorious Israeli military's Unit 8200 in manipulating information and discussion on the Internet by posing as members of the public to promote the narrative and discredit those who challenge it. Here we have the military seeking to manipulate *domestic* public opinion while the Nazis in government are fine with that. Conservative Member of Parliament Tobias Ellwood, an advocate of lockdown and control through 'vaccine passports', is a Lieutenant Colonel reservist in the 77th Brigade which connects with the military operation jHub, the 'innovation centre' for the Ministry of Defence and Strategic Command. jHub has also been involved with the civilian National Health Service (NHS) in 'symptom tracing' the population. The NHS is a key part of this mind control network and produced a document in December, 2020, explaining to staff how to use psychological manipulation with different groups and ages to get them to have the DNA-manipulating 'Covid vaccine'

that's designed to cumulatively rewrite human genetics. The document, called 'Optimising Vaccination Roll Out – Do's and Dont's for all messaging, documents and "communications" in the widest sense', was published by NHS England and the NHS Improvement *Behaviour Change Unit* in partnership with Public Health England and Warwick Business School. I hear the mantra about 'save the NHS' and 'protect the NHS' when we need to scrap the NHS and start again. The current version is far too corrupt, far too anti-human and totally compromised by Cult operatives and their assets. UK government broadcast media censor Ofcom will connect into this web – as will the BBC with its tremendous Ofcom influence – to control what the public see and hear and dictate mass perception. Nuremberg trials must include personnel from all these organisations.

The fear factor

The 'Covid' hoax has led to the creation of the UK Cabinet Office-connected Joint Biosecurity Centre (JBC) which is officially described as providing 'expert advice on pandemics' using its independent [all Cult operations are 'independent'] analytical function to provide real-time analysis about infection outbreaks to identify and respond to outbreaks of Covid-19'. Another role is to advise the government on a response to spikes in infections – 'for example by closing schools or workplaces in local areas where infection levels have risen'. Put another way, promoting the Cult agenda. The Joint Biosecurity Centre is modelled on the Joint Terrorism Analysis Centre which analyses intelligence to set 'terrorism threat levels' and here again you see the fusion of civilian and military operations and intelligence that has led to military intelligence producing documents about 'vaccine hesitancy' and how it can be combated. Domestic civilian matters and opinions should not be the business of the military. The Joint Biosecurity Centre is headed by Tom Hurd, director general of the Office for Security and Counter-Terrorism from the establishment-to-its-fingertips Hurd family. His father is former Foreign Secretary Douglas Hurd. How coincidental that Tom

Hurd went to the elite Eton College and Oxford University with Boris Johnson. Imperial College with its ridiculous computer modeller Neil Ferguson will connect with this gigantic web that will itself interconnect with similar set-ups in other major and not so major countries. Compared with this Cult network the politicians, be they Boris Johnson, Donald Trump or Joe Biden, are bit-part players 'following the science'. The network of psychologists was on the 'Covid' case from the start with the aim of generating maximum fear of the 'virus' to ensure compliance by the population. A government behavioural science group known as SPI-B produced a paper in March, 2020, for discussion by the main government science advisory group known as SAGE. It was headed 'Options for increasing adherence to social distancing measures' and it said the following in a section headed 'Persuasion':

- A substantial number of people still do not feel sufficiently personally threatened; it could be that they are reassured by the low death rate in their demographic group, although levels of concern may be rising. Having a good understanding of the risk has been found to be positively associated with adoption of COVID-19 social distancing measures in Hong Kong.

- The perceived level of personal threat needs to be increased among those who are complacent, using hard-hitting evaluation of options for increasing social distancing emotional messaging. To be effective this must also empower people by making clear the actions they can take to reduce the threat.

- Responsibility to others: There seems to be insufficient understanding of, or feelings of responsibility about, people's role in transmitting the infection to others … Messaging about actions need to be framed positively in terms of protecting oneself and the community, and increase confidence that they will be effective.

- Some people will be more persuaded by appeals to play by the rules, some by duty to the community, and some to personal risk.

> All these different approaches are needed. The messaging also needs to take account of the realities of different people's lives. Messaging needs to take account of the different motivational levers and circumstances of different people.

All this could be achieved the SPI-B psychologists said by *using the media to increase the sense of personal threat* which translates as terrify the shit out of the population, including children, so they all do what we want. That's not happened has it? Those excuses for 'journalists' who wouldn't know journalism if it bit them on the arse (the great majority) have played their crucial part in serving this Cult-government Psyop to enslave their own kids and grandkids. How they live with themselves I have no idea. The psychological war has been underpinned by constant government 'Covid' propaganda in almost every television and radio ad break, plus the Internet and print media, which has pounded out the fear with taxpayers footing the bill for their own programming. The result has been people terrified of a 'virus' that doesn't exist or one with a tiny fatality rate even if you believe it does. People walk down the street and around the shops wearing face-nappies damaging their health and psychology while others report those who refuse to be that naïve to the police who turn up in their own face-nappies. I had a cameraman come to my flat and he was so frightened of 'Covid' he came in wearing a mask and refused to shake my hand in case he caught something. He had – naïveitis – and the thought that he worked in the mainstream media was both depressing and made his behaviour perfectly explainable. The fear which has gripped the minds of so many and frozen them into compliance has been carefully cultivated by these psychologists who are really psychopaths. If lives get destroyed and a lot of young people commit suicide it shows our plan is working. SPI-B then turned to compulsion on the public to comply. 'With adequate preparation, rapid change can be achieved', it said. Some countries had introduced mandatory self-isolation on a wide scale without evidence of major public unrest and a large majority of the UK's population appeared to be supportive of more coercive measures with 64 percent of adults saying they would

support putting London under a lockdown (watch the 'polls' which are designed to make people believe that public opinion is in favour or against whatever the subject in hand).

For 'aggressive protective measures' to be effective, the SPI-B paper said, special attention should be devoted to those population groups that are more at risk. Translated from the Orwellian this means making the rest of population feel guilty for not protecting the 'vulnerable' such as old people which the Cult and its agencies were about to kill on an industrial scale with lockdown, lack of treatment and the Gates 'vaccine'. Psychopath psychologists sold their guilt-trip so comprehensively that Los Angeles County Supervisor Hilda Solis reported that children were apologising (from a distance) to their parents and grandparents for bringing 'Covid' into their homes and getting them sick. '… These apologies are just some of the last words that loved ones will ever hear as they die alone,' she said. Gut-wrenchingly Solis then used this childhood tragedy to tell children to stay at home and 'keep your loved ones alive'. Imagine heaping such potentially life-long guilt on a kid when it has absolutely nothing to do with them. These people are deeply disturbed and the psychologists behind this even more so.

Uncivil war – divide and rule

Professional mind-controllers at SPI-B wanted the media to increase a sense of responsibility to others (do as you're told) and promote 'positive messaging' for those actions while in contrast to invoke 'social disapproval' by the unquestioning, obedient, community of anyone with a mind of their own. Again the compliant Goebbels-like media obliged. This is an old, old, trick employed by tyrannies the world over throughout human history. You get the target population to keep the target population in line – *your* line. SPI-B said this could 'play an important role in preventing anti-social behaviour or discouraging failure to enact pro-social behaviour'. For 'anti-social' in the Orwellian parlance of SPI-B see any behaviour that government doesn't approve. SPI-B recommendations said that 'social disapproval' should be accompanied by clear messaging and

promotion of strong collective identity – hence the government and celebrity mantra of 'we're all in this together'. Sure we are. The mind doctors have such contempt for their targets that they think some clueless comedian, actor or singer telling them to do what the government wants will be enough to win them over. We have had UK comedian Lenny Henry, actor Michael Caine and singer Elton John wheeled out to serve the propagandists by urging people to have the DNA-manipulating 'Covid' non-'vaccine'. The role of Henry and fellow black celebrities in seeking to coax a 'vaccine' reluctant black community into doing the government's will was especially stomach-turning. An emotion-manipulating script and carefully edited video featuring these black 'celebs' was such an insult to the intelligence of black people and where's the self-respect of those involved selling their souls to a fascist government agenda? Henry said he heard black people's 'legitimate worries and concerns', but people must 'trust the facts' when they were doing exactly that by not having the 'vaccine'. They had to include the obligatory reference to Black Lives Matter with the line … 'Don't let coronavirus cost even more black lives – because we matter'. My god, it was pathetic. 'I know the vaccine is safe and what it does.' How? 'I'm a comedian and it says so in my script.'

SPI-B said social disapproval needed to be carefully managed to avoid victimisation, scapegoating and misdirected criticism, but they knew that their 'recommendations' would lead to exactly that and the media were specifically used to stir-up the divide-and-conquer hostility. Those who conform like good little baa, baas, are praised while those who have seen through the tidal wave of lies are 'Covidiots'. The awake have been abused by the fast asleep for not conforming to fascism and impositions that the awake know are designed to endanger their health, dehumanise them, and tear asunder the very fabric of human society. We have had the curtain-twitchers and morons reporting neighbours and others to the face-nappied police for breaking 'Covid rules' with fascist police delighting in posting links and phone numbers where this could be done. The Cult cannot impose its will without a compliant police

and military or a compliant population willing to play their part in enslaving themselves and their kids. The words of a pastor in Nazi Germany are so appropriate today:

First they came for the socialists and I did not speak out because I was not a socialist.

Then they came for the trade unionists and I did not speak out because I was not a trade unionist.

Then they came for the Jews and I did not speak out because I was not a Jew.

Then they came for me and there was no one left to speak for me.

Those who don't learn from history are destined to repeat it and so many are.

'Covid' rules: Rewiring the mind

With the background laid out to this gigantic national and global web of psychological manipulation we can put 'Covid' rules into a clear and sinister perspective. Forget the claims about protecting health. 'Covid' rules are about dismantling the human mind, breaking the human spirit, destroying self-respect, and then putting Humpty Dumpty together again as a servile, submissive slave. Social isolation through lockdown and distancing have devastating effects on the human psyche as the psychological psychopaths well know and that's the real reason for them. Humans need contact with each other, discourse, closeness and touch, or they eventually, and literarily, go crazy. Masks, which I will address at some length, fundamentally add to the effects of isolation and the Cult agenda to dehumanise and de-individualise the population. To do this while knowing – in fact *seeking* – this outcome is the very epitome of evil and psychologists involved in this *are* the epitome of evil. They must like all the rest of the Cult demons and their assets stand trial for crimes against humanity on a scale that defies the imagination. Psychopaths in uniform use isolation to break enemy troops and agents and make them subservient and submissive to tell what they know. The technique is rightly considered a form of torture and

torture is most certainly what has been imposed on the human population.

Clinically-insane American psychologist Harry Harlow became famous for his isolation experiments in the 1950s in which he separated baby monkeys from their mothers and imprisoned them for months on end in a metal container or 'pit of despair'. They soon began to show mental distress and depression as any idiot could have predicted. Harlow put other monkeys in steel chambers for three, six or twelve months while denying them any contact with animals or humans. He said that the effects of total social isolation for six months were 'so devastating and debilitating that we had assumed initially that twelve months of isolation would not produce any additional decrement'; but twelve months of isolation 'almost obliterated the animals socially'. This is what the Cult and its psychopaths are doing to you and your children. Even monkeys in partial isolation in which they were not allowed to form relationships with other monkeys became 'aggressive and hostile, not only to others, but also towards their own bodies'. We have seen this in the young as a consequence of lockdown. UK government psychopaths launched a public relations campaign telling people not to hug each other even after they received the 'Covid-19 vaccine' which we were told with more lies would allow a return to 'normal life'. A government source told *The Telegraph*: 'It will be along the lines that it is great that you have been vaccinated, but if you are going to visit your family and hug your grandchildren there is a chance you are going to infect people you love.' The source was apparently speaking from a secure psychiatric facility. Janet Lord, director of Birmingham University's Institute of Inflammation and Ageing, said that parents and grandparents should avoid hugging their children. Well, how can I put it, Ms Lord? Fuck off. Yep, that'll do.

Destroying the kids – where are the parents?

Observe what has happened to people enslaved and isolated by lockdown as suicide and self-harm has soared worldwide,

particularly among the young denied the freedom to associate with their friends. A study of 49,000 people in English-speaking countries concluded that almost half of young adults are at clinical risk of mental health disorders. A national survey in America of 1,000 currently enrolled high school and college students found that 5 percent reported attempting suicide during the pandemic. Data from the US CDC's National Syndromic Surveillance Program from January 1st to October 17th, 2020, revealed a *31 percent* increase in mental health issues among adolescents aged 12 to 17 compared with 2019. The CDC reported that America in general suffered the biggest drop in life expectancy since World War Two as it fell by a year in the first half of 2020 as a result of 'deaths of despair' – overdoses and suicides. Deaths of despair have leapt by more than 20 percent during lockdown and include the highest number of fatal overdoses ever recorded in a single year – 81,000. Internet addiction is another consequence of being isolated at home which lowers interest in physical activities as kids fall into inertia and what's the point? Children and young people are losing hope and giving up on life, sometimes literally. A 14-year-old boy killed himself in Maryland because he had 'given up' when his school district didn't reopen; an 11-year-old boy shot himself during a zoom class; a teenager in Maine succumbed to the isolation of the 'pandemic' when he ended his life after experiencing a disrupted senior year at school. Children as young as nine have taken their life and all these stories can be repeated around the world. Careers are being destroyed before they start and that includes those in sport in which promising youngsters have not been able to take part. The plan of the psycho-psychologists is working all right. Researchers at Cambridge University found that lockdowns cause significant harm to children's mental health. Their study was published in the *Archives of Disease in Childhood*, and followed 168 children aged between 7 and 11. The researchers concluded:

> During the UK lockdown, children's depression symptoms have increased substantially, relative to before lockdown. The scale of this effect has direct relevance for the continuation of different elements of lockdown policy, such as complete or partial school closures …

… Specifically, we observed a statistically significant increase in ratings of depression, with a medium-to-large effect size. Our findings emphasise the need to incorporate the potential impact of lockdown on child mental health in planning the ongoing response to the global pandemic and the recovery from it.

Not a chance when the Cult's psycho-psychologists were getting exactly what they wanted. The UK's Royal College of Paediatrics and Child Health has urged parents to look for signs of eating disorders in children and young people after a three to four fold increase. Specialists say the 'pandemic' is a major reason behind the rise. You don't say. The College said isolation from friends during school closures, exam cancellations, loss of extra-curricular activities like sport, and an increased use of social media were all contributory factors along with fears about the virus (psycho-psychologists again), family finances, and students being forced to quarantine. Doctors said young people were becoming severely ill by the time they were seen with 'Covid' regulations reducing face-to-face consultations. Nor is it only the young that have been devastated by the psychopaths. Like all bullies and cowards the Cult is targeting the young, elderly, weak and infirm. A typical story was told by a British lady called Lynn Parker who was not allowed to visit her husband in 2020 for the last ten and half months of his life 'when he needed me most' between March 20th and when he died on December 19th. This vacates the criminal and enters the territory of evil. The emotional impact on the immune system alone is immense as are the number of people of all ages worldwide who have died as a result of Cult-demanded, Gates-demanded, lockdowns.

Isolation is torture

The experience of imposing solitary confinement on millions of prisoners around the world has shown how a large percentage become 'actively psychotic and/or acutely suicidal'. Social isolation has been found to trigger 'a specific psychiatric syndrome, characterized by hallucinations; panic attacks; overt paranoia; diminished impulse control; hypersensitivity to external stimuli; and difficulties with thinking, concentration and memory'. Juan Mendez,

a United Nations rapporteur (investigator), said that isolation is a form of torture. Research has shown that even after isolation prisoners find it far more difficult to make social connections and I remember chatting to a shop assistant after one lockdown who told me that when her young son met another child again he had no idea how to act or what to do. Hannah Flanagan, Director of Emergency Services at Journey Mental Health Center in Dane County, Wisconsin, said: 'The specificity about Covid social distancing and isolation that we've come across as contributing factors to the suicides are really new to us this year.' But they are not new to those that devised them. They are getting the effect they want as the population is psychologically dismantled to be rebuilt in a totally different way. Children and the young are particularly targeted. They will be the adults when the full-on fascist AI-controlled technocracy is planned to be imposed and they are being prepared to meekly submit. At the same time older people who still have a memory of what life was like before – and how fascist the new normal really is – are being deleted. You are going to see efforts to turn the young against the old to support this geriatric genocide. Hannah Flanagan said the big increase in suicide in her county proved that social isolation is not only harmful, but deadly. Studies have shown that isolation from others is one of the main risk factors in suicide and even more so with women. Warnings that lockdown could create a 'perfect storm' for suicide were ignored. After all this was one of the *reasons* for lockdown. Suicide, however, is only the most extreme of isolation consequences. There are many others. Dr Dhruv Khullar, assistant professor of healthcare policy at Weill Cornell Medical College, said in a *New York Times* article in 2016 long before the fake 'pandemic':

> A wave of new research suggests social separation is bad for us. Individuals with less social connection have disrupted sleep patterns, altered immune systems, more inflammation and higher levels of stress hormones. One recent study found that isolation increases the risk of heart disease by 29 percent and stroke by 32 percent. Another analysis that pooled data from 70 studies and 3.4 million people found that socially isolated individuals had a 30 percent higher risk of dying in the next seven years, and that this effect was largest in middle age.

Loneliness can accelerate cognitive decline in older adults, and isolated individuals are twice as likely to die prematurely as those with more robust social interactions. These effects start early: Socially isolated children have significantly poorer health 20 years later, even after controlling for other factors. All told, loneliness is as important a risk factor for early death as obesity and smoking.

There you have proof from that one article alone four years before 2020 that those who have enforced lockdown, social distancing and isolation knew what the effect would be and that is even more so with professional psychologists that have been driving the policy across the globe. We can go back even further to the years 2000 and 2003 and the start of a major study on the effects of isolation on health by Dr Janine Gronewold and Professor Dirk M. Hermann at the University Hospital in Essen, Germany, who analysed data on 4,316 people with an average age of 59 who were recruited for the long-term research project. They found that socially isolated people are more than 40 percent more likely to have a heart attack, stroke, or other major cardiovascular event and nearly 50 percent more likely to die from any cause. Given the financial Armageddon unleashed by lockdown we should note that the study found a relationship between increased cardiovascular risk and lack of financial support. After excluding other factors social isolation was still connected to a 44 percent increased risk of cardiovascular problems and a 47 percent increased risk of death by any cause. Lack of financial support was associated with a 30 percent increase in the risk of cardiovascular health events. Dr Gronewold said it had been known for some time that feeling lonely or lacking contact with close friends and family can have an impact on physical health and the study had shown that having strong social relationships is of high importance for heart health. Gronewold said they didn't understand yet why people who are socially isolated have such poor health outcomes, but this was obviously a worrying finding, particularly during these times of prolonged social distancing. Well, it can be explained on many levels. You only have to identify the point in the body where people feel loneliness and missing people they are parted from – it's in the centre of the chest where they feel the ache of loneliness and the ache of missing people. 'My heart aches for

you' … 'My heart aches for some company.' I will explain this more in the chapter Escaping Wetiko, but when you realise that the body is the mind – they are expressions of each other – the reason why state of the mind dictates state of the body becomes clear.

American psychologist Ranjit Powar was highlighting the effects of lockdown isolation as early as April, 2020. She said humans have evolved to be social creatures and are wired to live in interactive groups. Being isolated from family, friends and colleagues could be unbalancing and traumatic for most people and could result in short or even long-term psychological and physical health problems. An increase in levels of anxiety, aggression, depression, forgetfulness and hallucinations were possible psychological effects of isolation. 'Mental conditions may be precipitated for those with underlying pre-existing susceptibilities and show up in many others without any pre-condition.' Powar said personal relationships helped us cope with stress and if we lost this outlet for letting off steam the result can be a big emotional void which, for an average person, was difficult to deal with. 'Just a few days of isolation can cause increased levels of anxiety and depression' – so what the hell has been the effect on the global population of *18 months* of this at the time of writing? Powar said: 'Add to it the looming threat of a dreadful disease being repeatedly hammered in through the media and you have a recipe for many shades of mental and physical distress.' For those with a house and a garden it is easy to forget that billions have had to endure lockdown isolation in tiny overcrowded flats and apartments with nowhere to go outside. The psychological and physical consequences of this are unimaginable and with lunatic and abusive partners and parents the consequences have led to tremendous increases in domestic and child abuse and alcoholism as people seek to shut out the horror. Ranjit Powar said:

> Staying in a confined space with family is not all a rosy picture for everyone. It can be extremely oppressive and claustrophobic for large low-income families huddled together in small single-room houses. Children here are not lucky enough to have many board/electronic games or books to keep them occupied.

Add to it the deep insecurity of running out of funds for food and basic necessities. On the other hand, there are people with dysfunctional family dynamics, such as domineering, abusive or alcoholic partners, siblings or parents which makes staying home a period of trial. Incidence of suicide and physical abuse against women has shown a worldwide increase. Heightened anxiety and depression also affect a person's immune system, making them more susceptible to illness.

To think that Powar's article was published on April 11th, 2020.

Six-feet fantasy

Social (unsocial) distancing demanded that people stay six feet or two metres apart. UK government advisor Robert Dingwall from the New and Emerging Respiratory Virus Threats Advisory Group said in a radio interview that the two-metre rule was 'conjured up out of nowhere' and was not based on science. No, it was not based on *medical* science, but it didn't come out of nowhere. The distance related to *psychological* science. Six feet/two metres was adopted in many countries and we were told by people like the criminal Anthony Fauci and his ilk that it was founded on science. Many schools could not reopen because they did not have the space for six-feet distancing. Then in March, 2021, after a year of six-feet 'science', a study published in the *Journal of Infectious Diseases* involving more than 500,000 students and almost 100,000 staff over 16 weeks revealed no significant difference in 'Covid' cases between six feet and three feet and Fauci changed his tune. Now three feet was okay. There is no difference between six feet and three *inches* when there is no 'virus' and they got away with six feet for psychological reasons for as long as they could. I hear journalists and others talk about 'unintended consequences' of lockdown. They are not *unintended* at all; they have been coldly-calculated for a specific outcome of human control and that's why super-psychopaths like Gates have called for them so vehemently. Super-psychopath psychologists have demanded them and psychopathic or clueless, spineless, politicians have gone along with them by 'following the science'. But it's not science at all. 'Science' is not what is; it's only what people can be manipulated to believe it is. The whole 'Covid' catastrophe is

founded on mind control. Three word or three statement mantras issued by the UK government are a well-known mind control technique and so we've had 'Stay home/protect the NHS/save lives', 'Stay alert/control the virus/save lives' and 'hands/face/space'. One of the most vocal proponents of extreme 'Covid' rules in the UK has been Professor Susan Michie, a member of the British Communist Party, who is not a medical professional. Michie is the director of the Centre for Behaviour Change at University College London. She is a *behavioural psychologist* and another filthy rich 'Marxist' who praised China's draconian lockdown. She was known by fellow students at Oxford University as 'Stalin's nanny' for her extreme Marxism. Michie is an influential member of the UK government's Scientific Advisory Group for Emergencies (SAGE) and behavioural manipulation groups which have dominated 'Covid' policy. She is a consultant adviser to the World Health Organization on 'Covid-19' and behaviour. Why the hell are lockdowns anything to do with her when they are claimed to be about health? Why does a behavioural psychologist from a group charged with changing the behaviour of the public want lockdown, human isolation and mandatory masks? Does that question really need an answer? Michie *absolutely* has to explain herself before a Nuremberg court when humanity takes back its world again and even more so when you see the consequences of masks that she demands are compulsory. This is a Michie classic:

> The benefits of getting primary school children to wear masks is that regardless of what little degree of transmission is occurring in those age groups it could help normalise the practice. Young children wearing masks may be more likely to get their families to accept masks.

Those words alone should carry a prison sentence when you ponder on the callous disregard for children involved and what a statement it makes about the mind and motivations of Susan Michie. What a lovely lady and what she said there encapsulates the mentality of the psychopaths behind the 'Covid' horror. Let us compare what Michie said with a countrywide study in Germany published at researchsquare.com involving 25,000 school children and 17,854 health complaints submitted by parents. Researchers

found that masks are harming children physically, psychologically, and behaviourally with 24 health issues associated with mask wearing. They include: shortness of breath (29.7%); dizziness (26.4%); increased headaches (53%); difficulty concentrating (50%); drowsiness or fatigue (37%); and malaise (42%). Nearly a third of children experienced more sleep issues than before and a quarter developed new fears. Researchers found health issues and other impairments in 68 percent of masked children covering their faces for an average of 4.5 hours a day. Hundreds of those taking part experienced accelerated respiration, tightness in the chest, weakness, and short-term impairment of consciousness. A reminder of what Michie said again:

> The benefits of getting primary school children to wear masks is that regardless of what little degree of transmission is occurring in those age groups it could help normalise the practice. Young children wearing masks may be more likely to get their families to accept masks.

Psychopaths in government and psychology now have children and young people – plus all the adults – wearing masks for hours on end while clueless teachers impose the will of the psychopaths on the young they should be protecting. What the hell are parents doing?

Cult lab rats

We have some schools already imposing on students microchipped buzzers that activate when they get 'too close' to their pals in the way they do with lab rats. How apt. To the Cult and its brain-dead servants our children *are* lab rats being conditioned to be unquestioning, dehumanised slaves for the rest of their lives. Children and young people are being weaned and frightened away from the most natural human instincts including closeness and touch. I have tracked in the books over the years how schools were banning pupils from greeting each other with a hug and the whole Cult-induced Me Too movement has terrified men and boys from a relaxed and natural interaction with female friends and work colleagues to the point where many men try never to be in a room

alone with a woman that's not their partner. Airhead celebrities have as always played their virtue-signalling part in making this happen with their gross exaggeration. For every monster like Harvey Weinstein there are at least tens of thousands of men that don't treat women like that; but everyone must be branded the same and policy changed for them as well as the monster. I am going to be using the word 'dehumanise' many times in this chapter because that is what the Cult is seeking to do and it goes very deep as we shall see. Don't let them kid you that social distancing is planned to end one day. That's not the idea. We are seeing more governments and companies funding and producing wearable gadgets to keep people apart and they would not be doing that if this was meant to be short-term. A tech start-up company backed by GCHQ, the British Intelligence and military surveillance headquarters, has created a social distancing wrist sensor that alerts people when they get too close to others. The CIA has also supported tech companies developing similar devices. The wearable sensor was developed by Tended, one of a number of start-up companies supported by GCHQ (see the CIA and DARPA). The device can be worn on the wrist or as a tag on the waistband and will vibrate whenever someone wearing the device breaches social distancing and gets anywhere near natural human contact. The company had a lucky break in that it was developing a distancing sensor when the 'Covid' hoax arrived which immediately provided a potentially enormous market. How fortunate. The government in big-time Cult-controlled Ontario in Canada is investing $2.5 million in wearable contact tracing technology that 'will alert users if they may have been exposed to the Covid-19 in the workplace and will beep or vibrate if they are within six feet of another person'. Facedrive Inc., the technology company behind this, was founded in 2016 with funding from the Ontario Together Fund and obviously they, too, had a prophet on the board of directors. The human surveillance and control technology is called TraceSCAN and would be worn by the human cyborgs in places such as airports, workplaces, construction sites, care homes and … *schools*.

I emphasise schools with children and young people the prime targets. You know what is planned for society as a whole if you keep your eyes on the schools. They have always been places where the state program the next generation of slaves to be its compliant worker-ants – or Woker-ants these days; but in the mist of the 'Covid' madness they have been transformed into mind laboratories on a scale never seen before. Teachers and head teachers are just as programmed as the kids – often more so. Children are kept apart from human interaction by walk lanes, classroom distancing, staggered meal times, masks, and the rolling-out of buzzer systems. Schools are now physically laid out as a laboratory maze for lab-rats. Lunatics at a school in Anchorage, Alaska, who should be prosecuted for child abuse, took away desks and forced children to kneel (know your place) on a mat for five hours a day while wearing a mask and using their chairs as a desk. How this was supposed to impact on a 'virus' only these clinically insane people can tell you and even then it would be clap-trap. The school banned recess (interaction), art classes (creativity), and physical exercise (getting body and mind moving out of inertia). Everyone behind this outrage should be in jail or better still a mental institution. The behavioural manipulators are all for this dystopian approach to schools. Professor Susan Michie, the mind-doctor and British Communist Party member, said it was wrong to say that schools were safe. They had to be made so by 'distancing', masks and ventilation (sitting all day in the cold). I must ask this lady round for dinner on a night I know I am going to be out and not back for weeks. She probably wouldn't be able to make it, anyway, with all the visits to her own psychologist she must have block-booked.

Masking identity

I know how shocking it must be for you that a behaviour manipulator like Michie wants everyone to wear masks which have long been a feature of mind-control programs like the infamous MKUltra in the United States, but, there we are. We live and learn. I spent many years from 1996 to right across the millennium

researching mind control in detail on both sides of the Atlantic and elsewhere. I met a large number of mind-control survivors and many had been held captive in body and mind by MKUltra. MK stands for mind-control, but employs the German spelling in deference to the Nazis spirited out of Germany at the end of World War Two by Operation Paperclip in which the US authorities, with help from the Vatican, transported Nazi mind-controllers and engineers to America to continue their work. Many of them were behind the creation of NASA and they included Nazi scientist and SS officer Wernher von Braun who swapped designing V-2 rockets to bombard London with designing the Saturn V rockets that powered the NASA moon programme's Apollo craft. I think I may have mentioned that the Cult has no borders. Among Paperclip escapees was Josef Mengele, the Angel of Death in the Nazi concentration camps where he conducted mind and genetic experiments on children often using twins to provide a control twin to measure the impact of his 'work' on the other. If you want to observe the Cult mentality in all its extremes of evil then look into the life of Mengele. I have met many people who suffered mercilessly under Mengele in the United States where he operated under the name Dr Greene and became a stalwart of MKUltra programming and torture. Among his locations was the underground facility in the Mojave Desert in California called the China Lake Naval Weapons Station which is almost entirely below the surface. My books *The Biggest Secret*, *Children of the Matrix* and *The Perception Deception* have the detailed background to MKUltra.

The best-known MKUltra survivor is American Cathy O'Brien. I first met her and her late partner Mark Phillips at a conference in Colorado in 1996. Mark helped her escape and deprogram from decades of captivity in an offshoot of MKUltra known as Project Monarch in which 'sex slaves' were provided for the rich and famous including Father George Bush, Dick Cheney and the Clintons. Read Cathy and Mark's book *Trance-Formation of America* and if you are new to this you will be shocked to the core. I read it in 1996 shortly before, with the usual synchronicity of my life, I found

myself given a book table at the conference right next to hers. MKUltra never ended despite being very publicly exposed (only a small part of it) in the 1970s and continues in other guises. I am still in touch with Cathy. She contacted me during 2020 after masks became compulsory in many countries to tell me how they were used as part of MKUltra programming. I had been observing 'Covid regulations' and the relationship between authority and public for months. I saw techniques that I knew were employed on individuals in MKUltra being used on the global population. I had read many books and manuals on mind control including one called *Silent Weapons for Quiet Wars* which came to light in the 1980s and was a guide on how to perceptually program on a mass scale. 'Silent Weapons' refers to mind-control. I remembered a line from the manual as governments, medical authorities and law enforcement agencies have so obviously talked to – or rather at – the adult population since the 'Covid' hoax began as if they are children. The document said:

> If a person is spoken to by a T.V. advertiser as if he were a twelve-year-old, then, due to suggestibility, he will, with a certain probability, respond or react to that suggestion with the uncritical response of a twelve-year-old and will reach in to his economic reservoir and deliver its energy to buy that product on impulse when he passes it in the store.

That's why authority has spoken to adults like children since all this began.

Why did Michael Jackson wear masks?

Every aspect of the 'Covid' narrative has mind-control as its central theme. Cathy O'Brien wrote an article for davidicke.com about the connection between masks and mind control. Her daughter Kelly who I first met in the 1990s was born while Cathy was still held captive in MKUltra. Kelly was forced to wear a mask as part of her programming from the age of *two* to dehumanise her, target her sense of individuality and reduce the amount of oxygen her brain and body received. *Bingo*. This is the real reason for compulsory

masks, why they have been enforced en masse, and why they seek to increase the number they demand you wear. First one, then two, with one disgraceful alleged 'doctor' recommending four which is nothing less than a death sentence. Where and how often they must be worn is being expanded for the purpose of mass mind control and damaging respiratory health which they can call 'Covid-19'. Canada's government headed by the man-child Justin Trudeau, says it's fine for children of two and older to wear masks. An insane 'study' in Italy involving just 47 children concluded there was no problem for babies as young as *four months* wearing them. Even after people were 'vaccinated' they were still told to wear masks by the criminal that is Anthony Fauci. Cathy wrote that mandating masks is allowing the authorities literally to control the air we breathe which is what was done in MKUltra. You might recall how the singer Michael Jackson wore masks and there is a reason for that. He was subjected to MKUltra mind control through Project Monarch and his psyche was scrambled by these simpletons. Cathy wrote:

In MKUltra Project Monarch mind control, Michael Jackson had to wear a mask to silence his voice so he could not reach out for help. Remember how he developed that whisper voice when he wasn't singing? Masks control the mind from the outside in, like the redefining of words is doing. By controlling what we can and cannot say for fear of being labeled racist or beaten, for example, it ultimately controls thought that drives our words and ultimately actions (or lack thereof).

Likewise, a mask muffles our speech so that we are not heard, which controls voice … words … mind. This is Mind Control. Masks are an obvious mind control device, and I am disturbed so many people are complying on a global scale. Masks depersonalize while making a person feel as though they have no voice. It is a barrier to others. People who would never choose to comply but are forced to wear a mask in order to keep their job, and ultimately their family fed, are compromised. They often feel shame and are subdued. People have stopped talking with each other while media controls the narrative.

The 'no voice' theme has often become literal with train passengers told not to speak to each other in case they pass on the 'virus', singing banned for the same reason and bonkers California officials telling people riding roller coasters that they cannot shout and scream. Cathy said she heard every day from healed MKUltra survivors who cannot wear a mask without flashing back on ways

their breathing was controlled – 'from ball gags and penises to water boarding'. She said that through the years when she saw images of people in China wearing masks 'due to pollution' that it was really to control their oxygen levels. 'I knew it was as much of a population control mechanism of depersonalisation as are burkas', she said. Masks are another Chinese communist/fascist method of control that has been swept across the West as the West becomes China at lightning speed since we entered 2020.

Mask-19

There are other reasons for mandatory masks and these include destroying respiratory health to call it 'Covid-19' and stunting brain development of children and the young. Dr Margarite Griesz-Brisson MD, PhD, is a Consultant Neurologist and Neurophysiologist and the Founder and Medical Director of the London Neurology and Pain Clinic. Her CV goes down the street and round the corner. She is clearly someone who cares about people and won't parrot the propaganda. Griesz-Brisson has a PhD in pharmacology, with special interest in neurotoxicology, environmental medicine, neuroregeneration and neuroplasticity (the way the brain can change in the light of information received). She went public in October, 2020, with a passionate warning about the effects of mask-wearing laws:

> The reinhalation of our exhaled air will without a doubt create oxygen deficiency and a flooding of carbon dioxide. We know that the human brain is very sensitive to oxygen deprivation. There are nerve cells for example in the hippocampus that can't be longer than 3 minutes without oxygen – they cannot survive. The acute warning symptoms are headaches, drowsiness, dizziness, issues in concentration, slowing down of reaction time – reactions of the cognitive system.

Oh, I know, let's tell bus, truck and taxi drivers to wear them and people working machinery. How about pilots, doctors and police? Griesz-Brisson makes the important point that while the symptoms she mentions may fade as the body readjusts this does not alter the fact that people continue to operate in oxygen deficit with long list of

potential consequences. She said it was well known that neurodegenerative diseases take years or decades to develop. 'If today you forget your phone number, the breakdown in your brain would have already started 20 or 30 years ago.' She said degenerative processes in your brain are getting amplified as your oxygen deprivation continues through wearing a mask. Nerve cells in the brain are unable to divide themselves normally in these circumstances and lost nerve cells will no longer be regenerated. 'What is gone is gone.' Now consider that people like shop workers and *schoolchildren* are wearing masks for hours every day. What in the name of sanity is going to be happening to them? 'I do not wear a mask, I need my brain to think', Griesz-Brisson said, 'I want to have a clear head when I deal with my patients and not be in a carbon dioxide-induced anaesthesia'. If you are told to wear a mask anywhere ask the organisation, police, store, whatever, for their risk assessment on the dangers and negative effects on mind and body of enforcing mask-wearing. They won't have one because it has never been done not even by government. All of them must be subject to class-action lawsuits as the consequences come to light. They don't do mask risk assessments for an obvious reason. They know what the conclusions would be and independent scientific studies that *have* been done tell a horror story of consequences.

'Masks are criminal'

Dr Griesz-Brisson said that for children and adolescents, masks are an absolute no-no. They had an extremely active and adaptive immune system and their brain was incredibly active with so much to learn. 'The child's brain, or the youth's brain, is thirsting for oxygen.' The more metabolically active an organ was, the more oxygen it required; and in children and adolescents every organ was metabolically active. Griesz-Brisson said that to deprive a child's or adolescent's brain of oxygen, or to restrict it in any way, was not only dangerous to their health, it was absolutely criminal. 'Oxygen deficiency inhibits the development of the brain, and the damage that has taken place as a result CANNOT be reversed.' Mind

manipulators of MKUltra put masks on two-year-olds they wanted to neurologically rewire and you can see why. Griesz-Brisson said a child needs the brain to learn and the brain needs oxygen to function. 'We don't need a clinical study for that. This is simple, indisputable physiology.' Consciously and purposely induced oxygen deficiency was an absolutely deliberate health hazard, and an absolute medical contraindication which means that 'this drug, this therapy, this method or measure should not be used, and is not allowed to be used'. To coerce an entire population to use an absolute medical contraindication by force, she said, there had to be definite and serious reasons and the reasons must be presented to competent interdisciplinary and independent bodies to be verified and authorised. She had this warning of the consequences that were coming if mask wearing continued:

When, in ten years, dementia is going to increase exponentially, and the younger generations couldn't reach their god-given potential, it won't help to say 'we didn't need the masks'. I know how damaging oxygen deprivation is for the brain, cardiologists know how damaging it is for the heart, pulmonologists know how damaging it is for the lungs. Oxygen deprivation damages every single organ. Where are our health departments, our health insurance, our medical associations? It would have been their duty to be vehemently against the lockdown and to stop it and stop it from the very beginning.

Why do the medical boards issue punishments to doctors who give people exemptions? Does the person or the doctor seriously have to prove that oxygen deprivation harms people? What kind of medicine are our doctors and medical associations representing? Who is responsible for this crime? The ones who want to enforce it? The ones who let it happen and play along, or the ones who don't prevent it?

All of the organisations and people she mentions there either answer directly to the Cult or do whatever hierarchical levels above them tell them to do. The outcome of both is the same. 'It's not about masks, it's not about viruses, it's certainly not about your health', Griesz-Brisson said. 'It is about much, much more. I am not participating. I am not afraid.' They were taking our air to breathe and there was no unfounded medical exemption from face masks. Oxygen deprivation was dangerous for every single brain. It had to be the free decision of every human being whether they want to

wear a mask that was absolutely ineffective to protect themselves from a virus. She ended by rightly identifying where the responsibility lies for all this:

> The imperative of the hour is personal responsibility. We are responsible for what we think, not the media. We are responsible for what we do, not our superiors. We are responsible for our health, not the World Health Organization. And we are responsible for what happens in our country, not the government.

Halle-bloody-lujah.

But surgeons wear masks, right?

Independent studies of mask-wearing have produced a long list of reports detailing mental, emotional and physical dangers. What a definition of insanity to see police officers imposing mask-wearing on the public which will cumulatively damage their health while the police themselves wear masks that will cumulatively damage *their* health. It's utter madness and both public and police do this because 'the government says so' – yes a government of brain-donor idiots like UK Health Secretary Matt Hancock reading the 'follow the science' scripts of psychopathic, lunatic psychologists. The response you get from Stockholm syndrome sufferers defending the very authorities that are destroying them and their families is that 'surgeons wear masks'. This is considered the game, set and match that they must work and don't cause oxygen deficit. Well, actually, scientific studies have shown that they *do* and oxygen levels are monitored in operating theatres to compensate. Surgeons wear masks to stop spittle and such like dropping into open wounds – not to stop 'viral particles' which are so miniscule they can only be seen through an electron microscope. Holes in the masks are significantly bigger than 'viral particles' and if you sneeze or cough they will breach the mask. I watched an incredibly disingenuous 'experiment' that claimed to prove that masks work in catching 'virus' material from the mouth and nose. They did this with a slow motion camera and the mask did block big stuff which stayed inside the mask and

against the face to be breathed in or cause infections on the face as we have seen with many children. 'Viral particles', however, would never have been picked up by the camera as they came through the mask when they are far too small to be seen. The 'experiment' was therefore disingenuous *and* useless.

Studies have concluded that wearing masks in operating theatres (and thus elsewhere) make no difference to preventing infection while the opposite is true with toxic shite building up in the mask and this had led to an explosion in tooth decay and gum disease dubbed by dentists 'mask mouth'. You might have seen the Internet video of a furious American doctor urging people to take off their masks after a four-year-old patient had been rushed to hospital the night before and nearly died with a lung infection that doctors sourced to mask wearing. A study in the journal *Cancer Discovery* found that inhalation of harmful microbes can contribute to advanced stage lung cancer in adults and long-term use of masks can help breed dangerous pathogens. Microbiologists have said frequent mask wearing creates a moist environment in which microbes can grow and proliferate before entering the lungs. The Canadian Agency for Drugs and Technologies in Health, or CADTH, a Canadian national organisation that provides research and analysis to healthcare decision-makers, said this as long ago as 2013 in a report entitled 'Use of Surgical Masks in the Operating Room: A Review of the Clinical Effectiveness and Guidelines'. It said:

- No evidence was found to support the use of surgical face masks to reduce the frequency of surgical site infections
- No evidence was found on the effectiveness of wearing surgical face masks to protect staff from infectious material in the operating room.
- Guidelines recommend the use of surgical face masks by staff in the operating room to protect both operating room staff and patients (despite the lack of evidence).

We were told that the world could go back to 'normal' with the arrival of the 'vaccines'. When they came, fraudulent as they are, the story changed as I knew that it would. We are in the midst of transforming 'normal', not going back to it. Mary Ramsay, head of immunisation at Public Health England, echoed the words of US criminal Anthony Fauci who said masks and other regulations must stay no matter if people are vaccinated. The Fauci idiot continued to wear two masks – different colours so both could be clearly seen – after he *claimed* to have been vaccinated. Senator Rand Paul told Fauci in one exchange that his double-masks were 'theatre' and he was right. It's all theatre. Mary Ramsay back-tracked on the vaccine-return-to-normal theme when she said the public may need to wear masks and social-distance for years despite the jabs. 'People have got used to those lower-level restrictions now, and [they] can live with them', she said telling us what the idea has been all along. 'The vaccine does not give you a pass, even if you have had it, you must continue to follow all the guidelines' said a Public Health England statement which reneged on what we had been told before and made having the 'vaccine' irrelevant to 'normality' even by the official story. Spain's fascist government trumped everyone by passing a law mandating the wearing of masks on the beach and even when swimming in the sea. The move would have devastated what's left of the Spanish tourist industry, posed potential breathing dangers to swimmers and had Northern European sunbathers walking around with their forehead brown and the rest of their face white as a sheet. The ruling was so crazy that it had to be retracted after pressure from public and tourist industry, but it confirmed where the Cult wants to go with masks and how clinically insane authority has become. The determination to make masks permanent and hide the serious dangers to body and mind can be seen in the censorship of scientist Professor Denis Rancourt by Bill Gates-funded academic publishing website ResearchGate over his papers exposing the dangers and uselessness of masks. Rancourt said:

ResearchGate today has permanently locked my account, which I have had since 2015. Their reasons graphically show the nature of their attack against democracy, and their corruption of

science … By their obscene non-logic, a scientific review of science articles reporting on harms caused by face masks has a 'potential to cause harm'. No criticism of the psychological device (face masks) is tolerated, if the said criticism shows potential to influence public policy.

This is what happens in a fascist world.

Where are the 'greens' (again)?

Other dangers of wearing masks especially regularly relate to the inhalation of minute plastic fibres into the lungs and the deluge of discarded masks in the environment and oceans. Estimates predicted that more than 1.5 billion disposable masks will end up in the world's oceans every year polluting the water with tons of plastic and endangering marine wildlife. Studies project that humans are using 129 billion face masks each month worldwide – about three million a minute. Most are disposable and made from plastic, non-biodegradable microfibers that break down into smaller plastic particles that become widespread in ecosystems. They are littering cities, clogging sewage channels and turning up in bodies of water. I have written in other books about the immense amounts of microplastics from endless sources now being absorbed into the body. Rolf Halden, director of the Arizona State University (ASU) Biodesign Center for Environmental Health Engineering, was the senior researcher in a 2020 study that analysed 47 human tissue samples and found microplastics in all of them. 'We have detected these chemicals of plastics in every single organ that we have investigated', he said. I wrote in *The Answer* about the world being deluged with microplastics. A study by the Worldwide Fund for Nature (WWF) found that people are consuming on average every week some 2,000 tiny pieces of plastic mostly through water and also through marine life and the air. Every year humans are ingesting enough microplastics to fill a heaped dinner plate and in a life-time of 79 years it is enough to fill two large waste bins. Marco Lambertini, WWF International director general said: 'Not only are plastics polluting our oceans and waterways and killing marine life – it's in all of us and we can't escape consuming plastics,' American

geologists found tiny plastic fibres, beads and shards in rainwater samples collected from the remote slopes of the Rocky Mountain National Park near Denver, Colorado. Their report was headed: 'It is raining plastic.' Rachel Adams, senior lecturer in Biomedical Science at Cardiff Metropolitan University, said that among health consequences are internal inflammation and immune responses to a 'foreign body'. She further pointed out that microplastics become carriers of toxins including mercury, pesticides and dioxins (a known cause of cancer and reproductive and developmental problems). These toxins accumulate in the fatty tissues once they enter the body through microplastics. Now this is being compounded massively by people putting plastic on their face and throwing it away.

Workers exposed to polypropylene plastic fibres known as 'flock' have developed 'flock worker's lung' from inhaling small pieces of the flock fibres which can damage lung tissue, reduce breathing capacity and exacerbate other respiratory problems. *Now* … commonly used surgical masks have three layers of melt-blown textiles made of … polypropylene. We have billions of people putting these microplastics against their mouth, nose and face for hours at a time day after day in the form of masks. How does anyone think that will work out? I mean – what could possibly go wrong? We posted a number of scientific studies on this at davidicke.com, but when I went back to them as I was writing this book the links to the science research website where they were hosted were dead. Anything that challenges the official narrative in any way is either censored or vilified. The official narrative is so unsupportable by the evidence that only deleting the truth can protect it. A study by Chinese scientists still survived – with the usual twist which it why it was still active, I guess. Yes, they found that virtually all the masks they tested increased the daily intake of microplastic fibres, but people should still wear them because the danger from the 'virus' was worse said the crazy 'team' from the Institute of Hydrobiology in Wuhan. Scientists first discovered microplastics in lung tissue of some patients who died of lung cancer

in the 1990s. Subsequent studies have confirmed the potential health damage with the plastic degrading slowly and remaining in the lungs to accumulate in volume. Wuhan researchers used a machine simulating human breathing to establish that masks shed up to nearly 4,000 microplastic fibres in a month with reused masks producing more. Scientists said some masks are laced with toxic chemicals and a variety of compounds seriously restricted for both health and environmental reasons. They include cobalt (used in blue dye) and formaldehyde known to cause watery eyes, burning sensations in the eyes, nose, and throat, plus coughing, wheezing and nausea. No – that must be 'Covid-19'.

Mask 'worms'

There is another and potentially even more sinister content of masks. Mostly new masks of different makes filmed under a microscope around the world have been found to contain strange black fibres or 'worms' that appear to move or 'crawl' by themselves and react to heat and water. The nearest I have seen to them are the self-replicating fibres that are pulled out through the skin of those suffering from Morgellons disease which has been connected to the phenomena of 'chemtrails' which I will bring into the story later on. Morgellons fibres continue to grow outside the body and have a form of artificial intelligence. Black 'worm' fibres in masks have that kind of feel to them and there is a nanotechnology technique called 'worm micelles' which carry and release drugs or anything else you want to deliver to the body. For sure the suppression of humanity by mind altering drugs is the Cult agenda big time and the more excuses they can find to gain access to the body the more opportunities there are to make that happen whether through 'vaccines' or masks pushed against the mouth and nose for hours on end.

So let us summarise the pros and cons of masks:

Against masks: Breathing in your own carbon dioxide; depriving the body and brain of sufficient oxygen; build-up of toxins in the mask that can be breathed into the lungs and cause rashes on the face and 'mask-mouth'; breathing microplastic fibres and toxic chemicals into the lungs; dehumanisation and deleting individualisation by literally making people faceless; destroying human emotional interaction through facial expression and deleting parental connection with their babies which look for guidance to their facial expression.

For masks: They don't protect you from a 'virus' that doesn't exist and even if it did 'viral' particles are so minute they are smaller than the holes in the mask.

Governments, police, supermarkets, businesses, transport companies, and all the rest who seek to impose masks have done no risk assessment on their consequences for health and psychology and are now open to group lawsuits when the impact becomes clear with a cumulative epidemic of respiratory and other disease. Authorities will try to exploit these effects and hide the real cause by dubbing them 'Covid-19'. Can you imagine setting out to force the population to wear health-destroying masks without doing any assessment of the risks? It is criminal and it is evil, but then how many people targeted in this way, who see their children told to wear them all day at school, have asked for a risk assessment? Billions can't be imposed upon by the few unless the billions allow it. Oh, yes, with just a tinge of irony, 85 percent of all masks made worldwide come from *China*.

Wash your hands in toxic shite

'Covid' rules include the use of toxic sanitisers and again the health consequences of constantly applying toxins to be absorbed through the skin is obvious to any level of Renegade Mind. America's Food and Drug Administration (FDA) said that sanitisers are drugs and issued a warning about 75 dangerous brands which contain

methanol used in antifreeze and can cause death, kidney damage and blindness. The FDA circulated the following warning even for those brands that it claims to be safe:

> Store hand sanitizer out of the reach of pets and children, and children should use it only with adult supervision. Do not drink hand sanitizer. This is particularly important for young children, especially toddlers, who may be attracted by the pleasant smell or brightly colored bottles of hand sanitizer.
>
> Drinking even a small amount of hand sanitizer can cause alcohol poisoning in children. (However, there is no need to be concerned if your children eat with or lick their hands after using hand sanitizer.) During this coronavirus pandemic, poison control centers have had an increase in calls about accidental ingestion of hand sanitizer, so it is important that adults monitor young children's use.
>
> Do not allow pets to swallow hand sanitizer. If you think your pet has eaten something potentially dangerous, call your veterinarian or a pet poison control center right away. Hand sanitizer is flammable and should be stored away from heat and flames. When using hand sanitizer, rub your hands until they feel completely dry before performing activities that may involve heat, sparks, static electricity, or open flames.

There you go, perfectly safe, then, and that's without even a mention of the toxins absorbed through the skin. Come on kids – sanitise your hands everywhere you go. It will save you from the 'virus'. Put all these elements together of the 'Covid' normal and see how much health and psychology is being cumulatively damaged, even devastated, to 'protect your health'. Makes sense, right? They are only imposing these things because they care, right? *Right?*

Submitting to insanity

Psychological reframing of the population goes very deep and is done in many less obvious ways. I hear people say how contradictory and crazy 'Covid' rules are and how they are ever changing. This is explained away by dismissing those involved as idiots. It is a big mistake. The Cult is delighted if its cold calculation is perceived as incompetence and idiocy when it is anything but. Oh, yes, there are idiots within the system – lots of them – but they are *administering* the Cult agenda, mostly unknowingly. They are not deciding and dictating it. The bulwark against tyranny is self-

respect, always has been, always will be. It is self-respect that has broken every tyranny in history. By its very nature self-respect will not bow to oppression and its perpetrators. There is so little self-respect that it's always the few that overturn dictators. Many may eventually follow, but the few with the iron spines (self-respect) kick it off and generate the momentum. The Cult targets self-respect in the knowledge that once this has gone only submission remains. Crazy, contradictory, ever-changing 'Covid' rules are systematically applied by psychologists to delete self-respect. They *want* you to see that the rules make no sense. It is one thing to decide to do something when *you* have made the choice based on evidence and logic. You still retain your self-respect. It is quite another when you can see what you are being told to do is insane, ridiculous and makes no sense, and *yet you still do it*. Your self-respect is extinguished and this has been happening as ever more obviously stupid and nonsensical things have been demanded and the great majority have complied even when they can see they are stupid and nonsensical.

People walk around in face-nappies knowing they are damaging their health and make no difference to a 'virus'. They do it in fear of not doing it. I know it's daft, but I'll do it anyway. When that happens something dies inside of you and submissive reframing has begun. Next there's a need to hide from yourself that you have conceded your self-respect and you convince yourself that you have not really submitted to fear and intimidation. You begin to believe that you are complying with craziness because it's the right thing to do. When first you concede your self-respect of 2+2 = 4 to 2+2 = 5 you *know* you are compromising your self-respect. Gradually to avoid facing that fact you begin to *believe* that 2+2=5. You have been reframed and I have been watching this process happening in the human psyche on an industrial scale. The Cult is working to break your spirit and one of its major tools in that war is humiliation. I read how former American soldier Bradley Manning (later Chelsea Manning after a sex-change) was treated after being jailed for supplying WikiLeaks with documents exposing the enormity of

government and elite mendacity. Manning was isolated in solitary confinement for eight months, put under 24-hour surveillance, forced to hand over clothing before going to bed, and stand naked for every roll call. This is systematic humiliation. The introduction of anal swab 'Covid' tests in China has been done for the same reason to delete self-respect and induce compliant submission. Anal swabs are mandatory for incoming passengers in parts of China and American diplomats have said they were forced to undergo the indignity which would have been calculated humiliation by the Cult-owned Chinese government that has America in its sights.

Government-people: An abusive relationship

Spirit-breaking psychological techniques include giving people hope and apparent respite from tyranny only to take it away again. This happened in the UK during Christmas, 2020, when the psycho-psychologists and their political lackeys announced an easing of restrictions over the holiday only to reimpose them almost immediately on the basis of yet another lie. There is a big psychological difference between getting used to oppression and being given hope of relief only to have that dashed. Psychologists know this and we have seen the technique used repeatedly. Then there is traumatising people before you introduce more extreme regulations that require compliance. A perfect case was the announcement by the dark and sinister Whitty and Vallance in the UK that 'new data' predicted that 4,000 could die every day over the winter of 2020/2021 if we did not lockdown again. I think they call it lying and after traumatising people with that claim out came Jackboot Johnson the next day with new curbs on human freedom. Psychologists know that a frightened and traumatised mind becomes suggestable to submission and behaviour reframing. Underpinning all this has been to make people fearful and suspicious of each other and see themselves as a potential danger to others. In league with deleted self-respect you have the perfect psychological recipe for self-loathing. The relationship between authority and public is now demonstrably the same as that of

subservience to an abusive partner. These are signs of an abusive relationship explained by psychologist Leslie Becker-Phelps:

Psychological and emotional abuse: Undermining a partner's self-worth with verbal attacks, name-calling, and belittling. Humiliating the partner in public, unjustly accusing them of having an affair, or interrogating them about their every behavior. Keeping partner confused or off balance by saying they were just kidding or blaming the partner for 'making' them act this way … Feigning in public that they care while turning against them in private. This leads to victims frequently feeling confused, incompetent, unworthy, hopeless, and chronically self-doubting. [Apply these techniques to how governments have treated the population since New Year, 2020, and the parallels are obvious.]

Physical abuse: The abuser might physically harm their partner in a range of ways, such as grabbing, hitting, punching, or shoving them. They might throw objects at them or harm them with a weapon. [Observe the physical harm imposed by masks, lockdown, and so on.]

Threats and intimidation: One way abusers keep their partners in line is by instilling fear. They might be verbally threatening, or give threatening looks or gestures. Abusers often make it known that they are tracking their partner's every move. They might destroy their partner's possessions, threaten to harm them, or threaten to harm their family members. Not surprisingly, victims of this abuse often feel anxiety, fear, and panic. [No words necessary.]

Isolation: Abusers often limit their partner's activities, forbidding them to talk or interact with friends or family. They might limit access to a car or even turn off their phone. All of this might be done by physically holding them against their will, but is often accomplished through psychological abuse and intimidation. The more isolated a person feels, the fewer resources they have to help gain perspective on their situation and to escape from it. [No words necessary.]

Economic abuse: Abusers often make their partners beholden to them for money by controlling access to funds of any kind. They might prevent their partner from getting a job or withhold access to money they earn from a job. This creates financial dependency that makes leaving the relationship very difficult. [See destruction of livelihoods and the proposed meagre 'guaranteed income' so long as you do whatever you are told.]

Using children: An abuser might disparage their partner's parenting skills, tell their children lies about their partner, threaten to take custody of their children, or threaten to harm their children. These tactics instil fear and often elicit compliance. [See reframed social service mafia and how children are being mercilessly abused by the state over 'Covid' while their parents look on too frightened to do anything.]

A further recurring trait in an abusive relationship is the abused blaming themselves for their abuse and making excuses for the abuser. We have the public blaming each other for lockdown abuse by government and many making excuses for the government while attacking those who challenge the government. How often we have heard authorities say that rules are being imposed or reimposed only because people have refused to 'behave' and follow the rules. We don't want to do it – it's *you*.

Renegade Minds are an antidote to all of these things. They will never concede their self-respect no matter what the circumstances. Even when apparent humiliation is heaped upon them they laugh in its face and reflect back the humiliation on the abuser where it belongs. Renegade Minds will never wear masks they know are only imposed to humiliate, suppress and damage both physically and psychologically. Consequences will take care of themselves and they will never break their spirit or cause them to concede to tyranny. UK newspaper columnist Peter Hitchens was one of the few in the mainstream media to speak out against lockdowns and forced vaccinations. He then announced he had taken the jab. He wanted to see family members abroad and he believed vaccine passports were inevitable even though they had not yet been introduced. Hitchens

has a questioning and critical mind, but not a Renegade one. If he had no amount of pressure would have made him concede. Hitchens excused his action by saying that the battle has been lost. Renegade Minds never accept defeat when freedom is at stake and even if they are the last one standing the self-respect of not submitting to tyranny is more important than any outcome or any consequence.

That's why Renegade Minds are the only minds that ever changed anything worth changing.

CHAPTER EIGHT

'Reframing' insanity

Insanity is relative. It depends on who has who locked in what cage
Ray Bradbury

'Reframing' a mind means simply to change its perception and behaviour. This can be done subconsciously to such an extent that subjects have no idea they have been 'reframed' while to any observer changes in behaviour and attitudes are obvious.

Human society is being reframed on a ginormous scale since the start of 2020 and here we have the reason why psychologists rather than doctors have been calling the shots. Ask most people who have succumbed to 'Covid' reframing if they have changed and most will say 'no'; but they *have* and fundamentally. The Cult's long-game has been preparing for these times since way back and crucial to that has been to prepare both population and officialdom mentally and emotionally. To use the mind-control parlance they had to reframe the population with a mentality that would submit to fascism and reframe those in government and law enforcement to impose fascism or at least go along with it. The result has been the fact-deleted mindlessness of 'Wokeness' and officialdom that has either enthusiastically or unquestioningly imposed global tyranny demanded by reframed politicians on behalf of psychopathic and deeply evil cultists. 'Cognitive reframing' identifies and challenges the way someone sees the world in the form of situations, experiences and emotions and then restructures those perceptions to view the same set of circumstances in a different way. This can have

benefits if the attitudes are personally destructive while on the other side it has the potential for individual and collective mind control which the subject has no idea has even happened.

Cognitive therapy was developed in the 1960s by Aaron T. Beck who was born in Rhode Island in 1921 as the son of Jewish immigrants from the Ukraine. He became interested in the techniques as a treatment for depression. Beck's daughter Judith S. Beck is prominent in the same field and they founded the Beck Institute for Cognitive Behavior Therapy in Philadelphia in 1994. Cognitive reframing, however, began to be used worldwide by those with a very dark agenda. The Cult reframes politicians to change their attitudes and actions until they are completely at odds with what they once appeared to stand for. The same has been happening to government administrators at all levels, law enforcement, military and the human population. Cultists love mind control for two main reasons: It allows them to control what people think, do and say to secure agenda advancement and, by definition, it calms their legendary insecurity and fear of the unexpected. I have studied mind control since the time I travelled America in 1996. I may have been talking to next to no one in terms of an audience in those years, but my goodness did I gather a phenomenal amount of information and knowledge about so many things including the techniques of mind control. I have described this in detail in other books going back to *The Biggest Secret* in 1998. I met a very large number of people recovering from MKUltra and its offshoots and successors and I began to see how these same techniques were being used on the population in general. This was never more obvious than since the 'Covid' hoax began.

Reframing the enforcers

I have observed over the last two decades and more the very clear transformation in the dynamic between the police, officialdom and the public. I tracked this in the books as the relationship mutated from one of serving the public to seeing them as almost the enemy and certainly a lower caste. There has always been a class divide

based on income and always been some psychopathic, corrupt, and big-I-am police officers. This was different. Wholesale change was unfolding in the collective dynamic; it was less about money and far more about position and perceived power. An us-and-them was emerging. Noses were lifted skyward by government administration and law enforcement and their attitude to the public they were *supposed* to be serving changed to one of increasing contempt, superiority and control. The transformation was so clear and widespread that it had to be planned. Collective attitudes and dynamics do not change naturally and organically that quickly on that scale. I then came across an organisation in Britain called Common Purpose created in the late 1980s by Julia Middleton who would work in the office of Deputy Prime Minister John Prescott during the long and disastrous premiership of war criminal Tony Blair. When Blair speaks the Cult is speaking and the man should have been in jail a long time ago. Common Purpose proclaims itself to be one of the biggest 'leadership development' organisations in the world while functioning as a *charity* with all the financial benefits which come from that. It hosts 'leadership development' courses and programmes all over the world and claims to have 'brought together' what it calls 'leaders' from more than 100 countries on six continents. The modus operandi of Common Purpose can be compared with the work of the UK government's reframing network that includes the Behavioural Insights Team 'nudge unit' and 'Covid' reframing specialists at SPI-B. WikiLeaks described Common Purpose long ago as 'a hidden virus in our government and schools' which is unknown to the general public: 'It recruits and trains "leaders" to be loyal to the directives of Common Purpose and the EU, instead of to their own departments, which they then undermine or subvert, the NHS [National Health Service] being an example.' This is a vital point to understand the 'Covid' hoax. The NHS, and its equivalent around the world, has been utterly reframed in terms of administrators and much of the medical personnel with the transformation underpinned by recruitment policies. The outcome has been the criminal and psychopathic behaviour of the

NHS over 'Covid' and we have seen the same in every other major country. WikiLeaks said Common Purpose trainees are 'learning to rule without regard to democracy' and to usher in a police state (current events explained). Common Purpose operated like a 'glue' and had members in the NHS, BBC, police, legal profession, church, many of Britain's 7,000 quangos, local councils, the Civil Service, government ministries and Parliament, and controlled many RDA's (Regional Development Agencies). Here we have one answer for how and why British institutions and their like in other countries have changed so negatively in relation to the public. This further explains how and why the beyond-disgraceful reframed BBC has become a propaganda arm of 'Covid' fascism. They are all part of a network pursuing the same goal.

By 2019 Common Purpose was quoting a figure of 85,000 'leaders' that had attended its programmes. These 'students' of all ages are known as Common Purpose 'graduates' and they consist of government, state and local government officials and administrators, police chiefs and officers, and a whole range of others operating within the national, local and global establishment. Cressida Dick, Commissioner of the London Metropolitan Police, is the Common Purpose graduate who was the 'Gold Commander' that oversaw what can only be described as the murder of Brazilian electrician Jean Charles de Menezes in 2005. He was held down by psychopathic police and shot seven times in the head by a psychopathic lunatic after being mistaken for a terrorist when he was just a bloke going about his day. Dick authorised officers to pursue and keep surveillance on de Menezes and ordered that he be stopped from entering the underground train system. Police psychopaths took her at her word clearly. She was 'disciplined' for this outrage by being *promoted* – eventually to the top of the 'Met' police where she has been a disaster. Many Chief Constables controlling the police in different parts of the UK are and have been Common Purpose graduates. I have heard the 'graduate' network described as a sort of Mafia or secret society operating within the fabric of government at all levels pursuing a collective policy

ingrained at Common Purpose training events. Founder Julia Middleton herself has said:

> Locally and internationally, Common Purpose graduates will be 'lighting small fires' to create change in their organisations and communities … The Common Purpose effect is best illustrated by the many stories of small changes brought about by leaders, who themselves have changed.

A Common Purpose mission statement declared:

> Common Purpose aims to improve the way society works by expanding the vision, decision-making ability and influence of all kinds of leaders. The organisation runs a variety of educational programmes for leaders of all ages, backgrounds and sectors, in order to provide them with the inspirational, information and opportunities they need to change the world.

Yes, but into what? Since 2020 the answer has become clear.

NLP and the Delphi technique

Common Purpose would seem to be a perfect name or would common programming be better? One of the foundation methods of reaching 'consensus' (group think) is by setting the agenda theme and then encouraging, cajoling or pressuring everyone to agree a 'consensus' in line with the core theme promoted by Common Purpose. The methodology involves the 'Delphi technique', or an adaption of it, in which opinions are expressed that are summarised by a 'facilitator or change agent' at each stage. Participants are 'encouraged' to modify their views in the light of what others have said. Stage by stage the former individual opinions are merged into group consensus which just happens to be what Common Purpose wants them to believe. A key part of this is to marginalise anyone refusing to concede to group think and turn the group against them to apply pressure to conform. We are seeing this very technique used on the general population to make 'Covid' group-thinkers hostile to those who have seen through the bullshit. People can be reframed by using perception manipulation methods such as Neuro-Linguistic Programming (NLP) in which you change perception with the use of

carefully constructed language. An NLP website described the technique this way:

> … A method of influencing brain behaviour (the 'neuro' part of the phrase) through the use of language (the 'linguistic' part) and other types of communication to enable a person to 'recode' the way the brain responds to stimuli (that's the 'programming') and manifest new and better behaviours. Neuro-Linguistic Programming often incorporates hypnosis and self-hypnosis to help achieve the change (or 'programming') that is wanted.

British alternative media operation UKColumn has done very detailed research into Common Purpose over a long period. I quoted co-founder and former naval officer Brian Gerrish in my book *Remember Who You Are*, published in 2011, as saying the following years before current times:

> It is interesting that many of the mothers who have had children taken by the State speak of the Social Services people being icily cool, emotionless and, as two ladies said in slightly different words, '… like little robots'. We know that NLP is cumulative, so people can be given small imperceptible doses of NLP in a course here, another in a few months, next year etc. In this way, major changes are accrued in their personality, but the day by day change is almost unnoticeable.

In these and other ways 'graduates' have had their perceptions uniformly reframed and they return to their roles in the institutions of government, law enforcement, legal profession, military, 'education', the UK National Health Service and the whole swathe of the establishment structure to pursue a common agenda preparing for the 'post-industrial', 'post-democratic' society. I say 'preparing' but we are now there. 'Post-industrial' is code for the Great Reset and 'post-democratic' is 'Covid' fascism. UKColumn has spoken to partners of those who have attended Common Purpose 'training'. They have described how personalities and attitudes of 'graduates' changed very noticeably for the worse by the time they had completed the course. They had been 'reframed' and told they are the 'leaders' – the special ones – who know better than the population. There has also been the very demonstrable recruitment of psychopaths and narcissists into government administration at all

levels and law enforcement. If you want psychopathy hire psychopaths and you get a simple cause and effect. If you want administrators, police officers and 'leaders' to perceive the public as lesser beings who don't matter then employ narcissists. These personalities are identified using 'psychometrics' that identifies knowledge, abilities, attitudes and personality traits, mostly through carefully-designed questionnaires and tests. As this policy has passed through the decades we have had power-crazy, power-trippers appointed into law enforcement, security and government administration in preparation for current times and the dynamic between public and law enforcement/officialdom has been transformed. UKColumn's Brian Gerrish said of the narcissistic personality:

> Their love of themselves and power automatically means that they will crush others who get in their way. I received a major piece of the puzzle when a friend pointed out that when they made public officials re-apply for their own jobs several years ago they were also required to do psychometric tests. This was undoubtedly the start of the screening process to get 'their' sort of people in post.

How obvious that has been since 2020 although it was clear what was happening long before if people paid attention to the changing public-establishment dynamic.

Change agents

At the centre of events in 'Covid' Britain is the National Health Service (NHS) which has behaved disgracefully in slavishly following the Cult agenda. The NHS management structure is awash with Common Purpose graduates or 'change agents' working to a common cause. Helen Bevan, a Chief of Service Transformation at the NHS Institute for Innovation and Improvement, co-authored a document called 'Towards a million change agents, a review of the social movements literature: implications for large scale change in the NHS'. The document compared a project management approach to that of change and social movements where 'people change

themselves and each other – peer to peer'. Two definitions given for a 'social movement' were:

A group of people who consciously attempt to build a radically new social order; involves people of a broad range of social backgrounds; and deploys politically confrontational and socially disruptive tactics – Cyrus Zirakzadeh 1997

Collective challenges, based on common purposes and social solidarities, in sustained interaction with elites, opponents, and authorities – Sidney Tarrow 1994

Helen Bevan wrote another NHS document in which she defined 'framing' as 'the process by which leaders construct, articulate and put across their message in a powerful and compelling way in order to win people to their cause and call them to action'. I think I could come up with another definition that would be rather more accurate. The National Health Service and institutions of Britain and the wider world have been taken over by reframed 'change agents' and that includes everything from the United Nations to national governments, local councils and social services which have been kidnapping children from loving parents on an extraordinary and gathering scale on the road to the end of parenthood altogether. Children from loving homes are stolen and kidnapped by the state and put into the 'care' (inversion) of the local authority through council homes, foster parents and forced adoption. At the same time children are allowed to be abused without response while many are under council 'care'. UKColumn highlighted the Common Purpose connection between South Yorkshire Police and Rotherham council officers in the case of the scandal in that area of the sexual exploitation of children to which the authorities turned not one blind eye, but both:

We were alarmed to discover that the Chief Executive, the Strategic Director of Children and Young People's Services, the Manager for the Local Strategic Partnership, the Community Cohesion Manager, the Cabinet Member for Cohesion, the Chief Constable and his predecessor had all attended Leadership training courses provided by the pseudo-charity Common Purpose.

Once 'change agents' have secured positions of hire and fire within any organisation things start to move very quickly. Personnel are then hired and fired on the basis of whether they will work towards the agenda the change agent represents. If they do they are rapidly promoted even though they may be incompetent. Those more qualified and skilled who are pre-Common Purpose 'old school' see their careers stall and even disappear. This has been happening for decades in every institution of state, police, 'health' and social services and all of them have been transformed as a result in their attitudes to their jobs and the public. Medical professions, including nursing, which were once vocations for the caring now employ many cold, callous and couldn't give a shit personality types. The UKColumn investigation concluded:

By blurring the boundaries between people, professions, public and private sectors, responsibility and accountability, Common Purpose encourages 'graduates' to believe that as new selected leaders, they can work together, outside of the established political and social structures, to achieve a paradigm shift or CHANGE – so called 'Leading Beyond Authority'. In doing so, the allegiance of the individual becomes 'reframed' on CP colleagues and their NETWORK.

Reframing the Face-Nappies

Nowhere has this process been more obvious than in the police where recruitment of psychopaths and development of unquestioning mind-controlled group-thinkers have transformed law enforcement into a politically-correct 'Woke' joke and a travesty of what should be public service. Today they wear their face-nappies like good little gofers and enforce 'Covid' rules which are fascism under another name. Alongside the specifically-recruited psychopaths we have software minds incapable of free thought. Brian Gerrish again:

An example is the policeman who would not get on a bike for a press photo because he had not done the cycling proficiency course. Normal people say this is political correctness gone mad. Nothing could be further from the truth. The policeman has been reframed, and in his reality it is perfect common sense not to get on the bike 'because he hasn't done the cycling course'.

Another example of this is where the police would not rescue a boy from a pond until they had taken advice from above on the 'risk assessment'. A normal person would have arrived, perhaps thought of the risk for a moment, and dived in. To the police now 'reframed', they followed 'normal' procedure.

There are shocking cases of reframed ambulance crews doing the same. Sheer unthinking stupidity of London Face-Nappies headed by Common Purpose graduate Cressida Dick can be seen in their behaviour at a vigil in March, 2021, for a murdered woman, Sarah Everard. A police officer had been charged with the crime. Anyone with a brain would have left the vigil alone in the circumstances. Instead they 'manhandled' women to stop them breaking 'Covid rules' to betray classic reframing. Minds in the thrall of perception control have no capacity for seeing a situation on its merits and acting accordingly. 'Rules is rules' is their only mind-set. My father used to say that rules and regulations are for the guidance of the intelligent and the blind obedience of the idiot. Most of the intelligent, decent, coppers have gone leaving only the other kind and a few old school for whom the job must be a daily nightmare. The combination of psychopaths and rule-book software minds has been clearly on public display in the 'Covid' era with automaton robots in uniform imposing fascistic 'Covid' regulations on the population without any personal initiative or judging situations on their merits. There are thousands of examples around the world, but I'll make my point with the infamous Derbyshire police in the English East Midlands – the ones who think pouring dye into beauty spots and using drones to track people walking in the countryside away from anyone is called 'policing'. To them there are rules decreed by the government which they have to enforce and in their bewildered state a group gathering in a closed space and someone walking alone in the countryside are the same thing. It is beyond idiocy and enters the realm of clinical insanity.

Police officers in Derbyshire said they were 'horrified' – *horrified* – to find 15 to 20 'irresponsible' kids playing a football match at a closed leisure centre 'in breach of coronavirus restrictions'. When they saw the police the kids ran away leaving their belongings behind and the reframed men and women of Derbyshire police were seeking to establish their identities with a view to fining their parents. The most natural thing for youngsters to do – kicking a ball about – is turned into a criminal activity and enforced by the moronic software programs of Derbyshire police. You find the same mentality in every country. These barely conscious 'horrified' officers said they had to take action because 'we need to ensure these rules are being followed' and 'it is of the utmost importance that you ensure your children are following the rules and regulations for Covid-19'. Had any of them done ten seconds of research to see if this parroting of their masters' script could be supported by any evidence? Nope. Reframed people don't think – others think for them and that's the whole idea of reframing. I have seen police officers one after the other repeating without question word for word what officialdom tells them just as I have seen great swathes of the public doing the same. Ask either for 'their' opinion and out spews what they have been told to think by the official narrative. Police and public may seem to be in different groups, but their mentality is the same. Most people do whatever they are told in fear not doing so or because they believe what officialdom tells them; almost the entirety of the police do what they are told for the same reason. Ultimately it's the tiny inner core of the global Cult that's telling both what to do.

So Derbyshire police were 'horrified'. Oh, really? Why did they think those kids were playing football? It was to relieve the psychological consequences of lockdown and being denied human contact with their friends and interaction, touch and discourse vital to human psychological health. Being denied this month after month has dismantled the psyche of many children and young people as depression and suicide have exploded. Were Derbyshire police *horrified by that*? Are you kidding? Reframed people don't have those

mental and emotional processes that can see how the impact on the psychological health of youngsters is far more dangerous than any 'virus' even if you take the mendacious official figures to be true. The reframed are told (programmed) how to act and so they do. The Derbyshire Chief Constable in the first period of lockdown when the black dye and drones nonsense was going on was Peter Goodman. He was the man who severed the connection between his force and the Derbyshire Constabulary *Male Voice* Choir when he decided that it was not inclusive enough to allow women to join. The fact it was a male voice choir making a particular sound produced by male voices seemed to elude a guy who terrifyingly ran policing in Derbyshire. He retired weeks after his force was condemned as disgraceful by former Supreme Court Justice Jonathan Sumption for their behaviour over extreme lockdown impositions. Goodman was replaced by his deputy Rachel Swann who was in charge when her officers were 'horrified'. The police statement over the boys committing the hanging-offence of playing football included the line about the youngsters being 'irresponsible in the times we are all living through' missing the point that the real relevance of the 'times we are all living through' is the imposition of fascism enforced by psychopaths and reframed minds of police officers playing such a vital part in establishing the fascist tyranny that their own children and grandchildren will have to live in their entire lives. As a definition of insanity that is hard to beat although it might be run close by imposing masks on people that can have a serious effect on their health while wearing a face nappy all day themselves. Once again public and police do it for the same reason – the authorities tell them to and who are they to have the self-respect to say no?

Wokers in uniform

How reframed do you have to be to arrest a *six-year-old* and take him to court for *picking a flower* while waiting for a bus? Brain dead police and officialdom did just that in North Carolina where criminal proceedings happen regularly for children under nine. Attorney Julie Boyer gave the six-year-old crayons and a colouring book

during the 'flower' hearing while the 'adults' decided his fate. County Chief District Court Judge Jay Corpening asked: 'Should a child that believes in Santa Claus, the Easter Bunny and the tooth fairy be making life-altering decisions?' Well, of course not, but common sense has no meaning when you have a common purpose and a reframed mind. Treating children in this way, and police operating in American schools, is all part of the psychological preparation for children to accept a police state as normal all their adult lives. The same goes for all the cameras and biometric tracking technology in schools. Police training is focused on reframing them as snowflake Wokers and this is happening in the military. Pentagon top brass said that 'training sessions on extremism' were needed for troops who asked why they were so focused on the Capitol Building riot when Black Lives Matter riots were ignored. What's the difference between them some apparently and rightly asked. Actually, there is a difference. Five people died in the Capitol riot, only one through violence, and that was a police officer shooting an unarmed protestor. BLM riots killed at least 25 people and cost billions. Asking the question prompted the psychopaths and reframed minds that run the Pentagon to say that more 'education' (programming) was needed. Troop training is all based on psychological programming to make them fodder for the Cult – 'Military men are just dumb, stupid animals to be used as pawns in foreign policy' as Cult-to-his-DNA former Secretary of State Henry Kissinger famously said. Governments see the police in similar terms and it's time for those among them who can see this to defend the people and stop being enforcers of the Cult agenda upon the people.

The US military, like the country itself, is being targeted for destruction through a long list of Woke impositions. Cult-owned gaga 'President' Biden signed an executive order when he took office to allow taxpayer money to pay for transgender surgery for active military personnel and veterans. Are you a man soldier? No, I'm a LGBTQIA+ with a hint of Skoliosexual and Spectrasexual. Oh, good man. Bad choice of words you bigot. The Pentagon announced in March, 2021, the appointment of the first 'diversity and inclusion

officer' for US Special Forces. Richard Torres-Estrada arrived with the publication of a 'D&I Strategic Plan which will guide the enterprise-wide effort to institutionalize and sustain D&I'. If you think a Special Forces 'Strategic Plan' should have something to do with defending America you haven't been paying attention. Defending Woke is now the military's new role. Torres-Estrada has posted images comparing Donald Trump with Adolf Hitler and we can expect no bias from him as a representative of the supposedly non-political Pentagon. Cable news host Tucker Carlson said: 'The Pentagon is now the Yale faculty lounge but with cruise missiles.' Meanwhile Secretary of Defense Lloyd Austin, a board member of weapons-maker Raytheon with stock and compensation interests in October, 2020, worth $1.4 million, said he was purging the military of the 'enemy within' – anyone who isn't Woke and supports Donald Trump. Austin refers to his targets as 'racist extremists' while in true Woke fashion being himself a racist extremist. Pentagon documents pledge to 'eradicate, eliminate and conquer all forms of racism, sexism and homophobia'. The definitions of these are decided by 'diversity and inclusion committees' peopled by those who see racism, sexism and homophobia in every situation and opinion. Woke (the Cult) is dismantling the US military and purging testosterone as China expands its military and gives its troops 'masculinity training'. How do we think that is going to end when this is all Cult coordinated? The US military, like the British military, is controlled by Woke and spineless top brass who just go along with it out of personal career interests.

'Woke' means fast asleep

Mind control and perception manipulation techniques used on individuals to create group-think have been unleashed on the global population in general. As a result many have no capacity to see the obvious fascist agenda being installed all around them or what 'Covid' is really all about. Their brains are firewalled like a computer system not to process certain concepts, thoughts and realisations that are bad for the Cult. The young are most targeted as the adults they

will be when the whole fascist global state is planned to be fully implemented. They need to be prepared for total compliance to eliminate all pushback from entire generations. The Cult has been pouring billions into taking complete control of 'education' from schools to universities via its operatives and corporations and not least Bill Gates as always. The plan has been to transform 'education' institutions into programming centres for the mentality of 'Woke'. James McConnell, professor of psychology at the University of Michigan, wrote in *Psychology Today* in 1970:

> The day has come when we can combine sensory deprivation with drugs, hypnosis, and astute manipulation of reward and punishment, to gain almost absolute control over an individual's behaviour. It should then be possible to achieve a very rapid and highly effective type of brainwashing that would allow us to make dramatic changes in a person's behaviour and personality ...
>
> … We should reshape society so that we all would be trained from birth to want to do what society wants us to do. We have the techniques to do it... no-one owns his own personality you acquired, and there's no reason to believe you should have the right to refuse to acquire a new personality if your old one is anti-social.

This was the potential for mass brainwashing in 1970 and the mentality there displayed captures the arrogant psychopathy that drives it forward. I emphasise that not all young people have succumbed to Woke programming and those that haven't are incredibly impressive people given that today's young are the most perceptually-targeted generations in history with all the technology now involved. Vast swathes of the young generations, however, have fallen into the spell – and that's what it is – of Woke. The Woke mentality and perceptual program is founded on *inversion* and you will appreciate later why that is so significant. Everything with Woke is inverted and the opposite of what it is claimed to be. Woke was a term used in African-American culture from the 1900s and referred to an awareness of social and racial justice. This is not the meaning of the modern version or 'New Woke' as I call it in *The Answer*. Oh, no, Woke today means something very different no matter how much Wokers may seek to hide that and insist Old Woke and New

Woke are the same. See if you find any 'awareness of social justice' here in the modern variety:

- Woke demands 'inclusivity' while excluding anyone with a different opinion and calls for mass censorship to silence other views.

- Woke claims to stand against oppression when imposing oppression is the foundation of all that it does. It is the driver of political correctness which is nothing more than a Cult invention to manipulate the population to silence itself.

- Woke believes itself to be 'liberal' while pursuing a global society that can only be described as fascist (see 'anti-fascist' fascist Antifa).

- Woke calls for 'social justice' while spreading injustice wherever it goes against the common 'enemy' which can be easily identified as a differing view.

- Woke is supposed to be a metaphor for 'awake' when it is solid-gold asleep and deep in a Cult-induced coma that meets the criteria for 'off with the fairies'.

I state these points as obvious facts if people only care to look. I don't do this with a sense of condemnation. We need to appreciate that the onslaught of perceptual programming on the young has been incessant and merciless. I can understand why so many have been reframed, or, given their youth, framed from the start to see the world as the Cult demands. The Cult has had access to their minds day after day in its 'education' system for their entire formative years. Perception is formed from information received and the Cult-created system is a life-long download of information delivered to elicit a particular perception, thus behaviour. The more this has expanded into still new extremes in recent decades and ever-increasing censorship has deleted other opinions and information why wouldn't that lead to a perceptual reframing on a mass scale? I

have described already cradle-to-grave programming and in more recent times the targeting of young minds from birth to adulthood has entered the stratosphere. This has taken the form of skewing what is 'taught' to fit the Cult agenda and the omnipresent techniques of group-think to isolate non-believers and pressure them into line. There has always been a tendency to follow the herd, but we really are in a new world now in relation to that. We have parents who can see the 'Covid' hoax told by their children not to stop them wearing masks at school, being 'Covid' tested or having the 'vaccine' in fear of the peer-pressure consequences of being different. What is 'peer-pressure' if not pressure to conform to group-think? Renegade Minds never group-think and always retain a set of perceptions that are unique to them. Group-think is always underpinned by consequences for not group-thinking. Abuse now aimed at those refusing DNA-manipulating 'Covid vaccines' are a potent example of this. The biggest pressure to conform comes from the very group which is itself being manipulated. 'I am programmed to be part of a hive mind and so you must be.'

Woke control structures in 'education' now apply to every mainstream organisation. Those at the top of the 'education' hierarchy (the Cult) decide the policy. This is imposed on governments through the Cult network; governments impose it on schools, colleges and universities; their leadership impose the policy on teachers and academics and they impose it on children and students. At any level where there is resistance, perhaps from a teacher or university lecturer, they are targeted by the authorities and often fired. Students themselves regularly demand the dismissal of academics (increasingly few) at odds with the narrative that the students have been programmed to believe in. It is quite a thought that students who are being targeted by the Cult become so consumed by programmed group-think that they launch protests and demand the removal of those who are trying to push back against those targeting the students. Such is the scale of perceptual inversion. We see this with 'Covid' programming as the Cult imposes the rules via psycho-psychologists and governments on

shops, transport companies and businesses which impose them on their staff who impose them on their customers who pressure Pushbackers to conform to the will of the Cult which is in the process of destroying them and their families. Scan all aspects of society and you will see the same sequence every time.

Fact free Woke and hijacking the 'left'

There is no more potent example of this than 'Woke', a mentality only made possible by the deletion of factual evidence by an 'education' system seeking to produce an ever more uniform society. Why would you bother with facts when you don't know any? Deletion of credible history both in volume and type is highly relevant. Orwell said: 'Who controls the past controls the future: who controls the present controls the past.' They who control the perception of the past control the perception of the future and they who control the present control the perception of the past through the writing and deleting of history. Why would you oppose the imposition of Marxism in the name of Wokeism when you don't know that Marxism cost at least 100 million lives in the 20th century alone? Watch videos and read reports in which Woker generations are asked basic historical questions – it's mind-blowing. A survey of 2,000 people found that six percent of millennials (born approximately early1980s to early 2000s) believed the Second World War (1939-1945) broke out with the assassination of President Kennedy (in 1963) and one in ten thought Margaret Thatcher was British Prime Minister at the time. She was in office between 1979 and 1990. We are in a post-fact society. Provable facts are no defence against the fascism of political correctness or Silicon Valley censorship. Facts don't matter anymore as we have witnessed with the 'Covid' hoax. Sacrificing uniqueness to the Woke group-think religion is all you are required to do and that means thinking for yourself is the biggest Woke no, no. All religions are an expression of group-think and censorship and Woke is just another religion with an orthodoxy defended by group-think and censorship. Burned at

the stake becomes burned on Twitter which leads back eventually to burned at the stake as Woke humanity regresses to ages past.

The biggest Woke inversion of all is its creators and funders. I grew up in a traditional left of centre political household on a council estate in Leicester in the 1950s and 60s – you know, the left that challenged the power of wealth-hoarding elites and threats to freedom of speech and opinion. In those days students went on marches defending freedom of speech while today's Wokers march for its deletion. What on earth could have happened? Those very elites (collectively the Cult) that we opposed in my youth and early life have funded into existence the antithesis of that former left and hijacked the 'brand' while inverting everything it ever stood for. We have a mentality that calls itself 'liberal' and 'progressive' while acting like fascists. Cult billionaires and their corporations have funded themselves into control of 'education' to ensure that Woke programming is unceasing throughout the formative years of children and young people and that non-Wokers are isolated (that word again) whether they be students, teachers or college professors. The Cult has funded into existence the now colossal global network of Woke organisations that have spawned and promoted all the 'causes' on the Cult wish-list for global transformation and turned Wokers into demanders of them. Does anyone really think it's a coincidence that the Cult agenda for humanity is a carbon (sorry) copy of the societal transformations desired by Woke?? These are only some of them:

Political correctness: The means by which the Cult deletes all public debates that it knows it cannot win if we had the free-flow of information and evidence.

Human-caused 'climate change': The means by which the Cult seeks to transform society into a globally-controlled dictatorship imposing its will over the fine detail of everyone's lives 'to save the planet' which doesn't actually need saving.

Transgender obsession: Preparing collective perception to accept the 'new human' which would not have genders because it would be created technologically and not through procreation. I'll have much more on this in Human 2.0.

Race obsession: The means by which the Cult seeks to divide and rule the population by triggering racial division through the perception that society is more racist than ever when the opposite is the case. Is it perfect in that regard? No. But to compare today with the racism of apartheid and segregation brought to an end by the civil rights movement in the 1960s is to insult the memory of that movement and inspirations like Martin Luther King. Why is the 'anti-racism' industry (which it is) so dominated by privileged white people?

White supremacy: This is a label used by privileged white people to demonise poor and deprived white people pushing back on tyranny to marginalise and destroy them. White people are being especially targeted as the dominant race by number within Western society which the Cult seeks to transform in its image. If you want to change a society you must weaken and undermine its biggest group and once you have done that by using the other groups you next turn on them to do the same … 'Then they came for the Jews and I was not a Jew so I did nothing.'

Mass migration: The mass movement of people from the Middle East, Africa and Asia into Europe, from the south into the United States and from Asia into Australia are another way the Cult seeks to dilute the racial, cultural and political influence of white people on Western society. White people ask why their governments appear to be working against them while being politically and culturally biased towards incoming cultures. Well, here's your answer. In the same way sexually 'straight' people, men and women, ask why the

authorities are biased against them in favour of other sexualities. The answer is the same – that's the way the Cult wants it to be for very sinister motives.

These are all central parts of the Cult agenda and central parts of the Woke agenda and Woke was created and continues to be funded to an immense degree by Cult billionaires and corporations. If anyone begins to say 'coincidence' the syllables should stick in their throat.

Billionaire 'social justice warriors'

Joe Biden is a 100 percent-owned asset of the Cult and the Wokers' man in the White House whenever he can remember his name and for however long he lasts with his rapidly diminishing cognitive function. Even walking up the steps of an aircraft without falling on his arse would appear to be a challenge. He's not an empty-shell puppet or anything. From the minute Biden took office (or the Cult did) he began his executive orders promoting the Woke wish-list. You will see the Woke agenda imposed ever more severely because it's really the *Cult* agenda. Woke organisations and activist networks spawned by the Cult are funded to the extreme so long as they promote what the Cult wants to happen. Woke is funded to promote 'social justice' by billionaires who become billionaires by destroying social justice. The social justice mantra is only a cover for dismantling social justice and funded by billionaires that couldn't give a damn about social justice. Everything makes sense when you see that. One of Woke's premier funders is Cult billionaire financier George Soros who said: 'I am basically there to make money, I cannot and do not look at the social consequences of what I do.' This is the same Soros who has given more than $32 billion to his Open Society Foundations global Woke network and funded Black Lives Matter, mass immigration into Europe and the United States, transgender activism, climate change activism, political correctness and groups targeting 'white supremacy' in the form of privileged white thugs that dominate Antifa. What a scam it all is and when

you are dealing with the unquestioning fact-free zone of Woke scamming them is child's play. All you need to pull it off in all these organisations are a few in-the-know agents of the Cult and an army of naïve, reframed, uninformed, narcissistic, know-nothings convinced of their own self-righteousness, self-purity and virtue.

Soros and fellow billionaires and billionaire corporations have poured hundreds of millions into Black Lives Matter and connected groups and promoted them to a global audience. None of this is motivated by caring about black people. These are the billionaires that have controlled and exploited a system that leaves millions of black people in abject poverty and deprivation which they do absolutely nothing to address. The same Cult networks funding BLM were behind the *slave trade!* Black Lives Matter hijacked a phrase that few would challenge and they have turned this laudable concept into a political weapon to divide society. You know that BLM is a fraud when it claims that *All* Lives Matter, the most inclusive statement of all, is 'racist'. BLM and its Cult masters don't want to end racism. To them it's a means to an end to control all of humanity never mind the colour, creed, culture or background. What has destroying the nuclear family got to do with ending racism? Nothing – but that is one of the goals of BLM and also happens to be a goal of the Cult as I have been exposing in my books for decades. Stealing children from loving parents and giving schools ever more power to override parents is part of that same agenda. BLM is a Marxist organisation and why would that not be the case when the Cult created Marxism *and* BLM? Patrisse Cullors, a BLM co-founder, said in a 2015 video that she and her fellow organisers, including co-founder Alicia Garza, are 'trained Marxists'. The lady known after marriage as Patrisse Khan-Cullors bought a $1.4 million home in 2021 in one of the whitest areas of California with a black population of just 1.6 per cent and has so far bought *four* high-end homes for a total of $3.2 million. How very Marxist. There must be a bit of spare in the BLM coffers, however, when Cult corporations and billionaires have handed over the best part of $100 million. Many black people can see that Black Lives Matter is not

working for them, but against them, and this is still more confirmation. Black journalist Jason Whitlock, who had his account suspended by Twitter for simply linking to the story about the 'Marxist's' home buying spree, said that BLM leaders are 'making millions of dollars off the backs of these dead black men who they wouldn't spit on if they were on fire and alive'.

Black Lies Matter

Cult assets and agencies came together to promote BLM in the wake of the death of career criminal George Floyd who had been jailed a number of times including for forcing his way into the home of a black woman with others in a raid in which a gun was pointed at her stomach. Floyd was filmed being held in a Minneapolis street in 2020 with the knee of a police officer on his neck and he subsequently died. It was an appalling thing for the officer to do, but the same technique has been used by police on peaceful protestors of lockdown without any outcry from the Woke brigade. As unquestioning supporters of the Cult agenda Wokers have supported lockdown and all the 'Covid' claptrap while attacking anyone standing up to the tyranny imposed in its name. Court documents would later include details of an autopsy on Floyd by County Medical Examiner Dr Andrew Baker who concluded that Floyd had taken a fatal level of the drug fentanyl. None of this mattered to fact-free, question-free, Woke. Floyd's death was followed by worldwide protests against police brutality amid calls to defund the police. Throwing babies out with the bathwater is a Woke speciality. In the wake of the murder of British woman Sarah Everard a Green Party member of the House of Lords, Baroness Jones of Moulescoomb (Nincompoopia would have been better), called for a 6pm curfew for all men. This would be in breach of the Geneva Conventions on war crimes which ban collective punishment, but that would never have crossed the black and white Woke mind of Baroness Nincompoopia who would have been far too convinced of her own self-righteousness to compute such details. Many American cities did defund the police in the face of Floyd riots

and after $15 million was deleted from the police budget in Washington DC under useless Woke mayor Muriel Bowser car-jacking alone rose by 300 percent and within six months the US capital recorded its highest murder rate in 15 years. The same happened in Chicago and other cities in line with the Cult/Soros plan to bring fear to streets and neighbourhoods by reducing the police, releasing violent criminals and not prosecuting crime. This is the mob-rule agenda that I have warned in the books was coming for so long. Shootings in the area of Minneapolis where Floyd was arrested increased by 2,500 percent compared with the year before. Defunding the police over George Floyd has led to a big increase in dead people with many of them black. Police protection for politicians making these decisions stayed the same or increased as you would expect from professional hypocrites. The Cult doesn't actually want to abolish the police. It wants to abolish local control over the police and hand it to federal government as the psychopaths advance the Hunger Games Society. Many George Floyd protests turned into violent riots with black stores and businesses destroyed by fire and looting across America fuelled by Black Lives Matter. Woke doesn't do irony. If you want civil rights you must loot the liquor store and the supermarket and make off with a smart TV. It's the only way.

It's not a race war – it's a class war

Black people are patronised by privileged blacks and whites alike and told they are victims of white supremacy. I find it extraordinary to watch privileged blacks supporting the very system and bloodline networks behind the slave trade and parroting the same Cult-serving manipulative crap of their privileged white, often billionaire, associates. It is indeed not a race war but a class war and colour is just a diversion. Black Senator Cory Booker and black Congresswoman Maxine Waters, more residents of Nincompoopia, personify this. Once you tell people they are victims of someone else you devalue both their own responsibility for their plight and the power they have to impact on their reality and experience. Instead

we have: 'You are only in your situation because of whitey – turn on them and everything will change.' It won't change. Nothing changes in our lives unless *we* change it. Crucial to that is never seeing yourself as a victim and always as the creator of your reality. Life is a simple sequence of choice and consequence. Make different choices and you create different consequences. *You* have to make those choices – not Black Lives Matter, the Woke Mafia and anyone else that seeks to dictate your life. Who are they these Wokers, an emotional and psychological road traffic accident, to tell you what to do? Personal empowerment is the last thing the Cult and its Black Lives Matter want black people or anyone else to have. They claim to be defending the underdog while *creating* and perpetuating the underdog. The Cult's worst nightmare is human unity and if they are going to keep blacks, whites and every other race under economic servitude and control then the focus must be diverted from what they have in common to what they can be manipulated to believe divides them. Blacks have to be told that their poverty and plight is the fault of the white bloke living on the street in the same poverty and with the same plight they are experiencing. The difference is that your plight black people is due to him, a white supremacist with 'white privilege' living on the street. Don't unite as one human family against your mutual oppressors and suppressors – fight the oppressor with the white face who is as financially deprived as you are. The Cult knows that as its 'Covid' agenda moves into still new levels of extremism people are going to respond and it has been spreading the seeds of disunity everywhere to stop a united response to the evil that targets *all of us*.

Racist attacks on 'whiteness' are getting ever more outrageous and especially through the American Democratic Party which has an appalling history for anti-black racism. Barack Obama, Joe Biden, Hillary Clinton and Nancy Pelosi all eulogised about Senator Robert Byrd at his funeral in 2010 after a nearly 60-year career in Congress. Byrd was a brutal Ku Klux Klan racist and a violent abuser of Cathy O'Brien in MKUltra. He said he would never fight in the military 'with a negro by my side' and 'rather I should die a thousand times,

and see Old Glory trampled in the dirt never to rise again, than to see this beloved land of ours become degraded by race mongrels, a throwback to the blackest specimen from the wilds'. Biden called Byrd a 'very close friend and mentor'. These 'Woke' hypocrites are not anti-racist they are anti-poor and anti-people not of their perceived class. Here is an illustration of the scale of anti-white racism to which we have now descended. Seriously Woke and moronic *New York Times* contributor Damon Young described whiteness as a 'virus' that 'like other viruses will not die until there are no bodies left for it to infect'. He went on: '… the only way to stop it is to locate it, isolate it, extract it, and kill it.' Young can say that as a black man with no consequences when a white man saying the same in reverse would be facing a jail sentence. *That's* racism. We had super-Woke numbskull senators Tammy Duckworth and Mazie Hirono saying they would object to future Biden Cabinet appointments if he did not nominate more Asian Americans and Pacific Islanders. Never mind the ability of the candidate what do they look like? Duckworth said: 'I will vote for racial minorities and I will vote for LGBTQ, but anyone else I'm not voting for.' Appointing people on the grounds of race is illegal, but that was not a problem for this ludicrous pair. They were on-message and that's a free pass in any situation.

Critical race racism

White children are told at school they are intrinsically racist as they are taught the divisive 'critical race theory'. This claims that the law and legal institutions are inherently racist and that race is a socially constructed concept used by white people to further their economic and political interests at the expense of people of colour. White is a 'virus' as we've seen. Racial inequality results from 'social, economic, and legal differences that white people create between races to maintain white interests which leads to poverty and criminality in minority communities'. I must tell that to the white guy sleeping on the street. The principal of East Side Community School in New York sent white parents a manifesto that called on

them to become 'white traitors' and advocate for full 'white abolition'. These people are teaching your kids when they urgently need a psychiatrist. The 'school' included a chart with 'eight white identities' that ranged from 'white supremacist' to 'white abolition' and defined the behaviour white people must follow to end 'the regime of whiteness'. Woke blacks and their privileged white associates are acting exactly like the slave owners of old and Ku Klux Klan racists like Robert Byrd. They are too full of their own self-purity to see that, but it's true. Racism is not a body type; it's a state of mind that can manifest through any colour, creed or culture.

Another racial fraud is *'equity'*. Not equality of treatment and opportunity – equity. It's a term spun as equality when it means something very different. Equality in its true sense is a raising up while 'equity' is a race to the bottom. Everyone in the same level of poverty is 'equity'. Keep everyone down – that's equity. The Cult doesn't want anyone in the human family to be empowered and BLM leaders, like all these 'anti-racist' organisations, continue their privileged, pampered existence by perpetuating the perception of gathering racism. When is the last time you heard an 'anti-racist' or 'anti-Semitism' organisation say that acts of racism and discrimination have *fallen?* It's not in the interests of their fund-raising and power to influence and the same goes for the professional soccer anti-racism operation, Kick It Out. Two things confirmed that the Black Lives Matter riots in the summer of 2020 were Cult creations. One was that while anti-lockdown protests were condemned in this same period for 'transmitting 'Covid' the authorities supported mass gatherings of Black Lives Matter supporters. I even saw self-deluding people claiming to be doctors say the two types of protest were not the same. No – the non-existent 'Covid' was in favour of lockdowns and attacked those that protested against them while 'Covid' supported Black Lives Matter and kept well away from its protests. The whole thing was a joke and as lockdown protestors were arrested, often brutally, by reframed Face-Nappies we had the grotesque sight of police officers taking the knee to Black Lives Matter, a Cult-funded Marxist

organisation that supports violent riots and wants to destroy the nuclear family and white people.

He's not white? Shucks!

Woke obsession with race was on display again when ten people were shot dead in Boulder, Colorado, in March, 2021. Cult-owned Woke TV channels like CNN said the shooter appeared to be a white man and Wokers were on Twitter condemning 'violent white men' with the usual mantras. Then the shooter's name was released as Ahmad Al Aliwi Alissa, an anti-Trump Arab-American, and the sigh of disappointment could be heard five miles away. Never mind that ten people were dead and what that meant for their families. Race baiting was all that mattered to these sick Cult-serving people like Barack Obama who exploited the deaths to further divide America on racial grounds which is his job for the Cult. This is the man that 'racist' white Americans made the first black president of the United States and then gave him a second term. Not-very-bright Obama has become filthy rich on the back of that and today appears to have a big influence on the Biden administration. Even so he's still a downtrodden black man and a victim of white supremacy. This disingenuous fraud reveals the contempt he has for black people when he puts on a Deep South Alabama accent whenever he talks to them, no, *at* them.

Another BLM red flag was how the now fully-Woke (fully-Cult) and fully-virtue-signalled professional soccer authorities had their teams taking the knee before every match in support of Marxist Black Lives Matter. Soccer authorities and clubs displayed 'Black Lives Matter' on the players' shirts and flashed the name on electronic billboards around the pitch. Any fans that condemned what is a Freemasonic taking-the-knee ritual were widely condemned as you would expect from the Woke virtue-signallers of professional sport and the now fully-Woke media. We have reverse racism in which you are banned from criticising any race or culture except for white people for whom anything goes – say what you like, no problem. What has this got to do with racial harmony and

equality? We've had black supremacists from Black Lives Matter telling white people to fall to their knees in the street and apologise for their white supremacy. Black supremacists acting like white supremacist slave owners of the past couldn't breach their self-obsessed, race-obsessed sense of self-purity. Joe Biden appointed a race-obsessed black supremacist Kristen Clarke to head the Justice Department Civil Rights Division. Clarke claimed that blacks are endowed with 'greater mental, physical and spiritual abilities' than whites. If anyone reversed that statement they would be vilified. Clarke is on-message so no problem. She's never seen a black-white situation in which the black figure is anything but a virtuous victim and she heads the Civil Rights Division which should treat everyone the same or it isn't civil rights. Another perception of the Renegade Mind: If something or someone is part of the Cult agenda they will be supported by Woke governments and media no matter what. If they're not, they will be condemned and censored. It really is that simple and so racist Clarke prospers despite (make that because of) her racism.

The end of culture

Biden's administration is full of such racial, cultural and economic bias as the Cult requires the human family to be divided into warring factions. We are now seeing racially-segregated graduations and everything, but everything, is defined through the lens of perceived 'racism. We have 'racist' mathematics, 'racist' food and even 'racist' *plants*. World famous Kew Gardens in London said it was changing labels on plants and flowers to tell its pre-'Covid' more than two million visitors a year how racist they are. Kew director Richard Deverell said this was part of an effort to 'move quickly to decolonise collections' after they were approached by one Ajay Chhabra 'an actor with an insight into how sugar cane was linked to slavery'. They are *plants* you idiots. 'Decolonisation' in the Woke manual really means colonisation of society with its mentality and by extension colonisation by the Cult. We are witnessing a new Chinese-style 'Cultural Revolution' so essential to the success of all

Marxist takeovers. Our cultural past and traditions have to be swept away to allow a new culture to be built-back-better. Woke targeting of long-standing Western cultural pillars including historical monuments and cancelling of historical figures is what happened in the Mao revolution in China which 'purged remnants of capitalist and traditional elements from Chinese society' and installed Maoism as the dominant ideology'. For China see the Western world today and for 'dominant ideology' see Woke. Better still see Marxism or Maoism. The 'Covid' hoax has specifically sought to destroy the arts and all elements of Western culture from people meeting in a pub or restaurant to closing theatres, music venues, sports stadiums, places of worship and even banning *singing*. Destruction of Western society is also why criticism of any religion is banned except for Christianity which again is the dominant religion as white is the numerically-dominant race. Christianity may be fading rapidly, but its history and traditions are weaved through the fabric of Western society. Delete the pillars and other structures will follow until the whole thing collapses. I am not a Christian defending that religion when I say that. I have no religion. It's just a fact. To this end Christianity has itself been turned Woke to usher its own downfall and its ranks are awash with 'change agents' – knowing and unknowing – at every level including Pope Francis (*definitely* knowing) and the clueless Archbishop of Canterbury Justin Welby (possibly not, but who can be sure?). Woke seeks to coordinate attacks on Western culture, traditions, and ways of life through 'intersectionality' defined as 'the complex, cumulative way in which the effects of multiple forms of discrimination (such as racism, sexism, and classism) combine, overlap, or intersect especially in the experiences of marginalised individuals or groups'. Wade through the Orwellian Woke-speak and this means coordinating disparate groups in a common cause to overthrow freedom and liberal values.

The entire structure of public institutions has been infested with Woke – government at all levels, political parties, police, military, schools, universities, advertising, media and trade unions. This abomination has been achieved through the Cult web by appointing

Wokers to positions of power and battering non-Wokers into line through intimidation, isolation and threats to their job. Many have been fired in the wake of the empathy-deleted, vicious hostility of 'social justice' Wokers and the desire of gutless, spineless employers to virtue-signal their Wokeness. Corporations are filled with Wokers today, most notably those in Silicon Valley. Ironically at the top they are not Woke at all. They are only exploiting the mentality their Cult masters have created and funded to censor and enslave while the Wokers cheer them on until it's their turn. Thus the Woke 'liberal left' is an inversion of the traditional liberal left. Campaigning for justice on the grounds of power and wealth distribution has been replaced by campaigning for identity politics. The genuine traditional left would never have taken money from today's billionaire abusers of fairness and justice and nor would the billionaires have wanted to fund that genuine left. It would not have been in their interests to do so. The division of opinion in those days was between the haves and have nots. This all changed with Cult manipulated and funded identity politics. The division of opinion today is between Wokers and non-Wokers and not income brackets. Cult corporations and their billionaires may have taken wealth disparity to cataclysmic levels of injustice, but as long as they speak the language of Woke, hand out the dosh to the Woke network and censor the enemy they are 'one of us'. Billionaires who don't give a damn about injustice are laughing at them till their bellies hurt. Wokers are not even close to self-aware enough to see that. The transformed 'left' dynamic means that Wokers who drone on about 'social justice' are funded by billionaires that have destroyed social justice the world over. It's *why* they are billionaires.

The climate con

Nothing encapsulates what I have said more comprehensively than the hoax of human-caused global warming. I have detailed in my books over the years how Cult operatives and organisations were the pump-primers from the start of the climate con. A purpose-built vehicle for this is the Club of Rome established by the Cult in 1968

with the Rockefellers and Rothschilds centrally involved all along. Their gofer frontman Maurice Strong, a Canadian oil millionaire, hosted the Earth Summit in Rio de Janeiro, Brazil, in 1992 where the global 'green movement' really expanded in earnest under the guiding hand of the Cult. The Earth Summit established Agenda 21 through the Cult-created-and-owned United Nations to use the illusion of human-caused climate change to justify the transformation of global society to save the world from climate disaster. It is a No-Problem-Reaction-Solution sold through governments, media, schools and universities as whole generations have been terrified into believing that the world was going to end in their lifetimes unless what old people had inflicted upon them was stopped by a complete restructuring of how everything is done. Chill, kids, it's all a hoax. Such restructuring is precisely what the Cult agenda demands (purely by coincidence of course). Today this has been given the codename of the Great Reset which is only an updated term for Agenda 21 and its associated Agenda 2030. The latter, too, is administered through the UN and was voted into being by the General Assembly in 2015. Both 21 and 2030 seek centralised control of all resources and food right down to the raindrops falling on your own land. These are some of the demands of Agenda 21 established in 1992. See if you recognise this society emerging today:

- End national sovereignty
- State planning and management of all land resources, ecosystems, deserts, forests, mountains, oceans and fresh water; agriculture; rural development; biotechnology; and ensuring *'equity'*
- The state to 'define the role' of business and financial resources
- Abolition of private property
- 'Restructuring' the family unit (see BLM)
- Children raised by the state
- People told what their job will be
- Major restrictions on movement
- Creation of 'human settlement zones'

- Mass resettlement as people are forced to vacate land where they live
- Dumbing down education
- Mass global depopulation in pursuit of all the above

The United Nations was created as a Trojan horse for world government. With the climate con of critical importance to promoting that outcome you would expect the UN to be involved. Oh, it's involved all right. The UN is promoting Agenda 21 and Agenda 2030 justified by 'climate change' while also driving the climate hoax through its Intergovernmental Panel on Climate Change (IPCC), one of the world's most corrupt organisations. The IPCC has been lying ferociously and constantly since the day it opened its doors with the global media hanging unquestioningly on its every mendacious word. The Green movement is entirely Woke and has long lost its original environmental focus since it was co-opted by the Cult. An obsession with 'global warming' has deleted its values and scrambled its head. I experienced a small example of what I mean on a beautiful country walk that I have enjoyed several times a week for many years. The path merged into the fields and forests and you felt at one with the natural world. Then a 'Green' organisation, the Hampshire and Isle of Wight Wildlife Trust, took over part of the land and proceeded to cut down a large number of trees, including mature ones, to install a horrible big, bright steel 'this-is-ours-stay-out' fence that destroyed the whole atmosphere of this beautiful place. No one with a feel for nature would do that. Day after day I walked to the sound of chainsaws and a magnificent mature weeping willow tree that I so admired was cut down at the base of the trunk. When I challenged a Woke young girl in a green shirt (of course) about this vandalism she replied: 'It's a weeping willow – it will grow back.' This is what people are paying for when they donate to the Hampshire and Isle of Wight Wildlife Trust and many other 'green' organisations today. It is not the environmental movement that I knew and instead has become a support-system – as with Extinction Rebellion – for a very dark agenda.

Private jets for climate justice

The Cult-owned, Gates-funded, World Economic Forum and its founder Klaus Schwab were behind the emergence of Greta Thunberg to harness the young behind the climate agenda and she was invited to speak to the world at … the UN. Schwab published a book, *Covid-19: The Great Reset* in 2020 in which he used the 'Covid' hoax and the climate hoax to lay out a new society straight out of Agenda 21 and Agenda 2030. Bill Gates followed in early 2021 when he took time out from destroying the world to produce a book in his name about the way to save it. Gates flies across the world in private jets and admitted that 'I probably have one of the highest greenhouse gas footprints of anyone on the planet … my personal flying alone is gigantic.' He has also bid for the planet's biggest private jet operator. Other climate change saviours who fly in private jets include John Kerry, the US Special Presidential Envoy for Climate, and actor Leonardo DiCaprio, a 'UN Messenger of Peace with special focus on climate change'. These people are so full of bullshit they could corner the market in manure. We mustn't be sceptical, though, because the Gates book, *How to Avoid a Climate Disaster: The Solutions We Have and the Breakthroughs We Need*, is a genuine attempt to protect the world and not an obvious pile of excrement attributed to a mega-psychopath aimed at selling his masters' plans for humanity. The Gates book and the other shite-pile by Klaus Schwab could have been written by the same person and may well have been. Both use 'climate change' and 'Covid' as the excuses for their new society and by coincidence the Cult's World Economic Forum and Bill and Melinda Gates Foundation promote the climate hoax and hosted Event 201 which pre-empted with a 'simulation' the very 'coronavirus' hoax that would be simulated for real on humanity within weeks. The British 'royal' family is promoting the 'Reset' as you would expect through Prince 'climate change caused the war in Syria' Charles and his hapless son Prince William who said that we must 'reset our relationship with nature and our trajectory as a species' to avoid a climate disaster. Amazing how many promotors of the 'Covid' and 'climate change' control

systems are connected to Gates and the World Economic Forum. A 'study' in early 2021 claimed that carbon dioxide emissions must fall by the equivalent of a global lockdown roughly every two years for the next decade to save the planet. The 'study' appeared in the same period that the Schwab mob claimed in a video that lockdowns destroying the lives of billions are good because they make the earth 'quieter' with less 'ambient noise'. They took down the video amid a public backlash for such arrogant, empathy-deleted stupidity You see, however, where they are going with this. Corinne Le Quéré, a professor at the Tyndall Centre for Climate Change Research, University of East Anglia, was lead author of the climate lockdown study, and she writes for … the World Economic Forum. Gates calls in 'his' book for changing 'every aspect of the economy' (long-time Cult agenda) and for humans to eat synthetic 'meat' (predicted in my books) while cows and other farm animals are eliminated. Australian TV host and commentator Alan Jones described what carbon emission targets would mean for farm animals in Australia alone if emissions were reduced as demanded by 35 percent by 2030 and zero by 2050:

Well, let's take agriculture, the total emissions from agriculture are about 75 million tonnes of carbon dioxide, equivalent. Now reduce that by 35 percent and you have to come down to 50 million tonnes, I've done the maths. So if you take for example 1.5 million cows, you're going to have to reduce the herd by 525,000 [by] 2030, nine years, that's 58,000 cows a year. The beef herd's 30 million, reduce that by 35 percent, that's 10.5 million, which means 1.2 million cattle have to go every year between now and 2030. This is insanity!

There are 75 million sheep. Reduce that by 35 percent, that's 26 million sheep, that's almost 3 million a year. So under the Paris Agreement over 30 million beasts. dairy cows, cattle, pigs and sheep would go. More than 8,000 every minute of every hour for the next decade, do these people know what they're talking about?

Clearly they don't at the level of campaigners, politicians and administrators. The Cult *does* know; that's the outcome it wants. We are faced with not just a war on humanity. Animals and the natural world are being targeted and I have been saying since the 'Covid' hoax began that the plan eventually was to claim that the 'deadly virus' is able to jump from animals, including farm animals and

domestic pets, to humans. Just before this book went into production came this story: 'Russia registers world's first Covid-19 vaccine for cats & dogs as makers of Sputnik V warn pets & farm animals could spread virus'. The report said 'top scientists warned that the deadly pathogen could soon begin spreading through homes and farms' and 'the next stage is the infection of farm and domestic animals'. Know the outcome and you'll see the journey. Think what that would mean for animals and keep your eye on a term called zoonosis or zoonotic diseases which transmit between animals and humans. The Cult wants to break the connection between animals and people as it does between people and people. Farm animals fit with the Cult agenda to transform food from natural to synthetic.

The gas of life is killing us

There can be few greater examples of Cult inversion than the condemnation of carbon dioxide as a dangerous pollutant when it is the gas of life. Without it the natural world would be dead and so we would all be dead. We breathe in oxygen and breathe out carbon dioxide while plants produce oxygen and absorb carbon dioxide. It is a perfect symbiotic relationship that the Cult wants to dismantle for reasons I will come to in the final two chapters. Gates, Schwab, other Cult operatives and mindless repeaters, want the world to be 'carbon neutral' by at least 2050 and the earlier the better. 'Zero carbon' is the cry echoed by lunatics calling for 'Zero Covid' when we already have it. These carbon emission targets will deindustrialise the world in accordance with Cult plans – the post-industrial, post-democratic society – and with so-called renewables like solar and wind not coming even close to meeting human energy needs blackouts and cold are inevitable. Texans got the picture in the winter of 2021 when a snow storm stopped wind turbines and solar panels from working and the lights went down along with water which relies on electricity for its supply system. Gates wants everything to be powered by electricity to ensure that his masters have the kill switch to stop all human activity, movement, cooking, water and warmth any time they like. The climate lie is so

stupendously inverted that it claims we must urgently reduce carbon dioxide when we *don't have enough*.

Co2 in the atmosphere is a little above 400 parts per million when the optimum for plant growth is 2,000 ppm and when it falls anywhere near 150 ppm the natural world starts to die and so do we. It fell to as low as 280 ppm in an 1880 measurement in Hawaii and rose to 413 ppm in 2019 with industrialisation which is why the planet has become *greener* in the industrial period. How insane then that psychopathic madman Gates is not satisfied only with blocking the rise of Co2. He's funding technology to suck it out of the atmosphere. The reason why will become clear. The industrial era is not destroying the world through Co2 and has instead turned around a potentially disastrous ongoing fall in Co2. Greenpeace co-founder and scientist Patrick Moore walked away from Greenpeace in 1986 and has exposed the green movement for fear-mongering and lies. He said that 500 million years ago there was *17 times* more Co2 in the atmosphere than we have today and levels have been falling for hundreds of millions of years. In the last 150 million years Co2 levels in Earth's atmosphere had reduced by *90 percent*. Moore said that by the time humanity began to unlock carbon dioxide from fossil fuels we were at '38 seconds to midnight' and in that sense: 'Humans are [the Earth's] salvation.' Moore made the point that only half the Co2 emitted by fossil fuels stays in the atmosphere and we should remember that all pollution pouring from chimneys that we are told is carbon dioxide is in fact nothing of the kind. It's pollution. Carbon dioxide is an invisible gas.

William Happer, Professor of Physics at Princeton University and long-time government adviser on climate, has emphasised the Co2 deficiency for maximum growth and food production. Greenhouse growers don't add carbon dioxide for a bit of fun. He said that most of the warming in the last 100 years, after the earth emerged from the super-cold period of the 'Little Ice Age' into a natural warming cycle, was over by 1940. Happer said that a peak year for warming in 1988 can be explained by a 'monster El Nino' which is a natural and cyclical warming of the Pacific that has nothing to do with 'climate

change'. He said the effect of Co2 could be compared to painting a wall with red paint in that once two or three coats have been applied it didn't matter how much more you slapped on because the wall will not get much redder. Almost all the effect of the rise in Co2 has already happened, he said, and the volume in the atmosphere would now have to *double* to increase temperature by a single degree. Climate hoaxers know this and they have invented the most ridiculously complicated series of 'feedback' loops to try to overcome this rather devastating fact. You hear puppet Greta going on cluelessly about feedback loops and this is why.

The Sun affects temperature? No you *climate denier*

Some other nonsense to contemplate: Climate graphs show that rises in temperature do not follow rises in Co2 – *it's the other way round* with a lag between the two of some 800 years. If we go back 800 years from present time we hit the Medieval Warm Period when temperatures were higher than now without any industrialisation and this was followed by the Little Ice Age when temperatures plummeted. The world was still emerging from these centuries of serious cold when many climate records began which makes the ever-repeated line of the 'hottest year since records began' meaningless when you are not comparing like with like. The coldest period of the Little Ice Age corresponded with the lowest period of sunspot activity when the Sun was at its least active. Proper scientists will not be at all surprised by this when it confirms the obvious fact that earth temperature is affected by the scale of Sun activity and the energetic power that it subsequently emits; but when is the last time you heard a climate hoaxer talking about the Sun as a source of earth temperature?? Everything has to be focussed on Co2 which makes up just 0.117 percent of so-called greenhouse gases and only a fraction of even that is generated by human activity. The rest is natural. More than *90 percent* of those greenhouse gases are water vapour and clouds (Fig 9). Ban moisture I say. Have you noticed that the climate hoaxers no longer use the polar bear as their promotion image? That's because far from becoming extinct polar

bear communities are stable or thriving. Joe Bastardi, American meteorologist, weather forecaster and outspoken critic of the climate lie, documents in his book *The Climate Chronicles* how weather patterns and events claimed to be evidence of climate change have been happening since long before industrialisation: 'What happened before naturally is happening again, as is to be expected given the cyclical nature of the climate due to the design of the planet.' If you read the detailed background to the climate hoax in my other books you will shake your head and wonder how anyone could believe the crap which has spawned a multi-trillion dollar industry based on absolute garbage (see HIV causes AIDs and Sars-Cov-2 causes 'Covid-19'). Climate and 'Covid' have much in common given they have the same source. They both have the contradictory *everything* factor in which everything is explained by reference to them. It's hot – 'it's climate change'. It's cold – 'it's climate change'. I got a sniffle – 'it's Covid'. I haven't got a sniffle – 'it's Covid'. Not having a sniffle has to be a symptom of 'Covid'. Everything is and not having a sniffle is especially dangerous if you are a slow walker. For sheer audacity I offer you a Cambridge University 'study' that actually linked 'Covid' to 'climate change'. It had to happen eventually. They concluded that climate change played a role in 'Covid-19' spreading from animals to humans because … wait for it … I kid you not … *the two groups were forced closer together as populations grow*. Er, that's it. The whole foundation on which this depended was that 'Bats are the likely zoonotic origin of SARS-CoV-1 and SARS-CoV-2'. Well, they are not. They are nothing to do with it. Apart from bats not being the origin and therefore 'climate change' effects on bats being irrelevant I am in awe of their academic insight. Where would we be without them? Not where we are that's for sure.

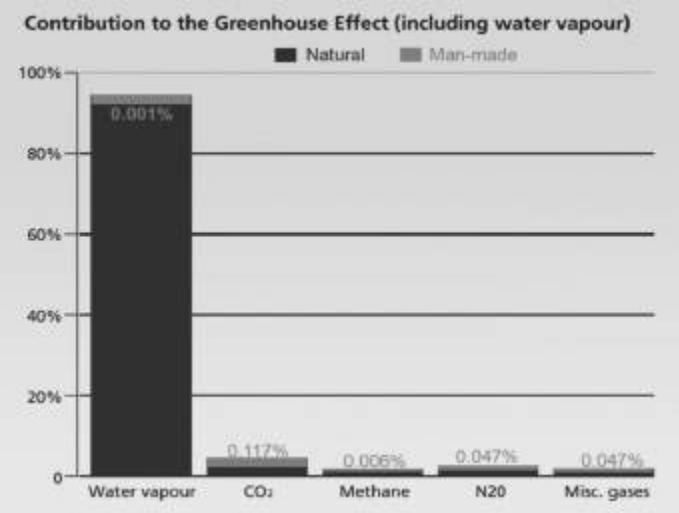

Figure 9: The idea that the gas of life is disastrously changing the climate is an insult to brain cell activity.

One other point about the weather is that climate modification is now well advanced and not every major weather event is natural – or earthquake come to that. I cover this subject at some length in other books. China is openly planning a rapid expansion of its weather modification programme which includes changing the climate in an area more than one and a half times the size of India. China used weather manipulation to ensure clear skies during the 2008 Olympics in Beijing. I have quoted from US military documents detailing how to employ weather manipulation as a weapon of war and they did that in the 1960s and 70s during the conflict in Vietnam with Operation Popeye manipulating monsoon rains for military purposes. Why would there be international treaties on weather modification if it wasn't possible? Of course it is. Weather is energetic information and it can be changed.

How was the climate hoax pulled off? See 'Covid'

If you can get billions to believe in a 'virus' that doesn't exist you can get them to believe in human-caused climate change that doesn't exist. Both are being used by the Cult to transform global society in the way it has long planned. Both hoaxes have been achieved in pretty much the same way. First you declare a lie is a fact. There's a

'virus' you call SARS-Cov-2 or humans are warming the planet with their behaviour. Next this becomes, via Cult networks, the foundation of government, academic and science policy and belief. Those who parrot the mantra are given big grants to produce research that confirms the narrative is true and ever more 'symptoms' are added to make the 'virus'/'climate change' sound even more scary. Scientists and researchers who challenge the narrative have their grants withdrawn and their careers destroyed. The media promote the lie as the unquestionable truth and censor those with an alternative view or evidence. A great percentage of the population believe what they are told as the lie becomes an everybody-knows-that and the believing-masses turn on those with a mind of their own. The technique has been used endlessly throughout human history. Wokers are the biggest promotors of the climate lie *and* 'Covid' fascism because their minds are owned by the Cult; their sense of self-righteous self-purity knows no bounds; and they exist in a bubble of reality in which facts are irrelevant and only get in the way of looking without seeing.

Running through all of this like veins in a blue cheese is control of information, which means control of perception, which means control of behaviour, which collectively means control of human society. The Cult owns the global media and Silicon Valley fascists for the simple reason that it *has* to. Without control of information it can't control perception and through that human society. Examine every facet of the Cult agenda and you will see that anything supporting its introduction is never censored while anything pushing back is always censored. I say again: Psychopaths that know why they are doing this must go before Nuremberg trials and those that follow their orders must trot along behind them into the same dock. 'I was just following orders' didn't work the first time and it must not work now. Nuremberg trials must be held all over the world before public juries for politicians, government officials, police, compliant doctors, scientists and virologists, and all Cult operatives such as Gates, Tedros, Fauci, Vallance, Whitty, Ferguson, Zuckerberg, Wojcicki, Brin, Page, Dorsey, the whole damn lot of

them – including, no *especially*, the psychopath psychologists. Without them and the brainless, gutless excuses for journalists that have repeated their lies, none of this could be happening. Nobody can be allowed to escape justice for the psychological and economic Armageddon they are all responsible for visiting upon the human race.

As for the compliant, unquestioning, swathes of humanity, and the self-obsessed, all-knowing ignorance of the Wokers … don't start me. God help their kids. God help their grandkids. God *help them*.

CHAPTER NINE

We must have it? So what is it?

Well I won't back down. No, I won't back down. You can stand me up at the Gates of Hell. But I won't back down
Tom Petty

I will now focus on the genetically-manipulating 'Covid vaccines' which do not meet this official definition of a vaccine by the US Centers for Disease Control (CDC): 'A product that stimulates a person's immune system to produce immunity to a specific disease, protecting the person from that disease.' On that basis 'Covid vaccines' are not a vaccine in that the makers don't even claim they stop infection or transmission.

They are instead part of a multi-levelled conspiracy to change the nature of the human body and what it means to be 'human' and to depopulate an enormous swathe of humanity. What I shall call Human 1.0 is on the cusp of becoming Human 2.0 and for very sinister reasons. Before I get to the 'Covid vaccine' in detail here's some background to vaccines in general. Government regulators do not test vaccines – the makers do – and the makers control which data is revealed and which isn't. Children in America are given 50 vaccine doses by age six and 69 by age 19 and the effect of the whole combined schedule has never been tested. Autoimmune diseases when the immune system attacks its own body have soared in the mass vaccine era and so has disease in general in children and the young. Why wouldn't this be the case when vaccines target the *immune system?* The US government gave Big Pharma drug

companies immunity from prosecution for vaccine death and injury in the 1986 National Childhood Vaccine Injury Act (NCVIA) and since then the government (taxpayer) has been funding compensation for the consequences of Big Pharma vaccines. The criminal and satanic drug giants can't lose and the vaccine schedule has increased dramatically since 1986 for this reason. There is no incentive to make vaccines safe and a big incentive to make money by introducing ever more. Even against a ridiculously high bar to prove vaccine liability, and with the government controlling the hearing in which it is being challenged for compensation, the vaccine court has so far paid out more than $4 billion. These are the vaccines we are told are safe and psychopaths like Zuckerberg censor posts saying otherwise. The immunity law was even justified by a ruling that vaccines by their nature were 'unavoidably unsafe'.

Check out the ingredients of vaccines and you will be shocked if you are new to this. *They put that in children's bodies?? What??* Try aluminium, a brain toxin connected to dementia, aborted foetal tissue and formaldehyde which is used to embalm corpses. World-renowned aluminium expert Christopher Exley had his research into the health effect of aluminium in vaccines shut down by Keele University in the UK when it began taking funding from the Bill and Melinda Gates Foundation. Research when diseases 'eradicated' by vaccines began to decline and you will find the fall began long *before* the vaccine was introduced. Sometimes the fall even plateaued after the vaccine. Diseases like scarlet fever for which there was no vaccine declined in the same way because of environmental and other factors. A perfect case in point is the polio vaccine. Polio began when lead arsenate was first sprayed as an insecticide and residues remained in food products. Spraying started in 1892 and the first US polio epidemic came in Vermont in 1894. The simple answer was to stop spraying, but Rockefeller-created Big Pharma had a better idea. Polio was decreed to be caused by the *poliovirus* which 'spreads from person to person and can infect a person's spinal cord'. Lead arsenate was replaced by the lethal DDT which had the same effect of causing paralysis by damaging the brain and central nervous

system. Polio plummeted when DDT was reduced and then banned, but the vaccine is still given the credit for something it didn't do. Today by far the biggest cause of polio is the vaccines promoted by Bill Gates. Vaccine justice campaigner Robert Kennedy Jr, son of assassinated (by the Cult) US Attorney General Robert Kennedy, wrote:

> In 2017, the World Health Organization (WHO) reluctantly admitted that the global explosion in polio is predominantly vaccine strain. The most frightening epidemics in Congo, Afghanistan, and the Philippines, are all linked to vaccines. In fact, by 2018, 70% of global polio cases were vaccine strain.

Vaccines make fortunes for Cult-owned Gates and Big Pharma while undermining the health and immune systems of the population. We had a glimpse of the mentality behind the Big Pharma cartel with a report on WION (World is One News), an international English language TV station based in India, which exposed the extraordinary behaviour of US drug company Pfizer over its 'Covid vaccine'. The WION report told how Pfizer had made fantastic demands of Argentina, Brazil and other countries in return for its 'vaccine'. These included immunity from prosecution, even for Pfizer negligence, government insurance to protect Pfizer from law suits and handing over as collateral sovereign assets of the country to include Argentina's bank reserves, military bases and embassy buildings. Pfizer demanded the same of Brazil in the form of waiving sovereignty of its assets abroad; exempting Pfizer from Brazilian laws; and giving Pfizer immunity from all civil liability. This is a 'vaccine' developed with government funding. Big Pharma is evil incarnate as a creation of the Cult and all must be handed tickets to Nuremberg.

Phantom 'vaccine' for a phantom 'disease'

I'll expose the 'Covid vaccine' fraud and then go on to the wider background of why the Cult has set out to 'vaccinate' every man, woman and child on the planet for an alleged 'new disease' with a survival rate of 99.77 percent (or more) even by the grotesquely-

manipulated figures of the World Health Organization and Johns Hopkins University. The 'infection' to 'death' ratio is 0.23 to 0.15 percent according to Stanford epidemiologist Dr John Ioannidis and while estimates vary the danger remains tiny. I say that if the truth be told the fake infection to fake death ratio is zero. Never mind all the evidence I have presented here and in *The Answer* that there is no 'virus' let us just focus for a moment on that death-rate figure of say 0.23 percent. The figure includes all those worldwide who have tested positive with a test not testing for the 'virus' and then died within 28 days or even longer of any other cause – *any other cause*. Now subtract all those illusory 'Covid' deaths on the global data sheets from the 0.23 percent. What do you think you would be left with? *Zero*. A vaccination has never been successfully developed for a so-called coronavirus. They have all failed at the animal testing stage when they caused hypersensitivity to what they were claiming to protect against and made the impact of a disease far worse. Cult-owned vaccine corporations got around that problem this time by bypassing animal trials, going straight to humans and making the length of the 'trials' before the public rollout as short as they could get away with. Normally it takes five to ten years or more to develop vaccines that still cause demonstrable harm to many people and that's without including the long-term effects that are never officially connected to the vaccination. 'Covid' non-vaccines have been officially produced and approved in a matter of months from a standing start and part of the reason is that (a) they were developed before the 'Covid' hoax began and (b) they are based on computer programs and not natural sources. Official non-trials were so short that government agencies gave *emergency*, not full, approval. 'Trials' were not even completed and full approval cannot be secured until they are. Public 'Covid vaccination' is actually a *continuation of the trial*. Drug company 'trials' are not scheduled to end until 2023 by which time a lot of people are going to be dead. Data on which government agencies gave this emergency approval was supplied by the Big Pharma corporations themselves in the form of Pfizer/BioNTech, AstraZeneca, Moderna, Johnson & Johnson, and

others, and this is the case with all vaccines. By its very nature *emergency* approval means drug companies do not have to prove that the 'vaccine' is 'safe and effective'. How could they with trials way short of complete? Government regulators only have to *believe* that they *could* be safe and effective. It is criminal manipulation to get products in circulation with no testing worth the name. Agencies giving that approval are infested with Big Pharma-connected place-people and they act in the interests of Big Pharma (the Cult) and not the public about whom they do not give a damn.

More human lab rats

'Covid vaccines' produced in record time by Pfizer/BioNTech and Moderna employ a technique *never approved before for use on humans*. They are known as mRNA 'vaccines' and inject a synthetic version of 'viral' mRNA or 'messenger RNA'. The key is in the term 'messenger'. The body works, or doesn't, on the basis of information messaging. Communications are constantly passing between and within the genetic system and the brain. Change those messages and you change the state of the body and even its very nature and you can change psychology and behaviour by the way the brain processes information. I think you are going to see significant changes in personality and perception of many people who have had the 'Covid vaccine' synthetic potions. Insider Aldous Huxley predicted the following in 1961 and mRNA 'vaccines' can be included in the term 'pharmacological methods':

> There will be, in the next generation or so, a pharmacological method of making people love their servitude, and producing dictatorship without tears, so to speak, producing a kind of painless concentration camp for entire societies, so that people will in fact have their own liberties taken away from them, but rather enjoy it, because they will be distracted from any desire to rebel by propaganda or brainwashing, or brainwashing enhanced by pharmacological methods. And this seems to be the final revolution.

Apologists claim that mRNA synthetic 'vaccines' don't change the DNA genetic blueprint because RNA does not affect DNA only the other way round. This is so disingenuous. A process called 'reverse

transcription' can convert RNA into DNA and be integrated into DNA in the cell nucleus. This was highlighted in December, 2020, by scientists at Harvard and Massachusetts Institute of Technology (MIT). Geneticists report that more than 40 percent of mammalian genomes results from reverse transcription. On the most basic level if messaging changes then that sequence must lead to changes in DNA which is receiving and transmitting those communications. How can introducing synthetic material into cells not change the cells where DNA is located? The process is known as transfection which is defined as 'a technique to insert foreign nucleic acid (DNA or RNA) into a cell, typically with the intention of altering the properties of the cell'. Researchers at the Sloan Kettering Institute in New York found that changes in messenger RNA can deactivate tumour-suppressing proteins and thereby promote cancer. This is what happens when you mess with messaging. 'Covid vaccine' maker Moderna was founded in 2010 by Canadian stem cell biologist Derrick J. Rossi after his breakthrough discovery in the field of transforming and reprogramming stem cells. These are neutral cells that can be programmed to become any cell including sperm cells. Moderna was therefore founded on the principle of genetic manipulation and has never produced any vaccine or drug before its genetically-manipulating synthetic 'Covid' shite. Look at the name – Mode-RNA or Modify-RNA. Another important point is that the US Supreme Court has ruled that genetically-modified DNA, or complementary DNA (cDNA) synthesized in the laboratory from messenger RNA, can be patented and owned. These psychopaths are doing this to the human body.

Cells replicate synthetic mRNA in the 'Covid vaccines' and in theory the body is tricked into making antigens which trigger antibodies to target the 'virus spike proteins' which as Dr Tom Cowan said have *never been seen*. Cut the crap and these 'vaccines' deliver *self-replicating* synthetic material to the cells with the effect of changing human DNA. The more of them you have the more that process is compounded while synthetic material is all the time self-replicating. 'Vaccine'-maker Moderna describes mRNA as 'like

software for the cell' and so they are messing with the body's software. What happens when you change the software in a computer? Everything changes. For this reason the Cult is preparing a production line of mRNA 'Covid vaccines' and a long list of excuses to use them as with all the 'variants' of a 'virus' never shown to exist. The plan is further to transfer the mRNA technique to other vaccines mostly given to children and young people. The cumulative consequences will be a transformation of human DNA through a constant infusion of synthetic genetic material which will kill many and change the rest. Now consider that governments that have given emergency approval for a vaccine that's not a vaccine; never been approved for humans before; had no testing worth the name; and the makers have been given immunity from prosecution for any deaths or adverse effects suffered by the public. The UK government awarded *permanent legal indemnity* to itself and its employees for harm done when a patient is being treated for 'Covid-19' or 'suspected Covid-19'. That is quite a thought when these are possible 'side-effects' from the 'vaccine' (they are not 'side', they are effects) listed by the US Food and Drug Administration:

Guillain-Barre syndrome; acute disseminated encephalomyelitis; transverse myelitis; encephalitis; myelitis; encephalomyelitis; meningoencephalitis; meningitis; encephalopathy; convulsions; seizures; stroke; narcolepsy; cataplexy; anaphylaxis; acute myocardial infarction (heart attack); myocarditis; pericarditis; autoimmune disease; death; implications for pregnancy, and birth outcomes; other acute demyelinating diseases; non anaphylactic allergy reactions; thrombocytopenia ; disseminated intravascular coagulation; venous thromboembolism; arthritis; arthralgia; joint pain; Kawasaki disease; multisystem inflammatory syndrome in children; vaccine enhanced disease. The latter is the way the 'vaccine' has the potential to make diseases far worse than they would otherwise be.

UK doctor and freedom campaigner Vernon Coleman described the conditions in this list as 'all unpleasant, most of them very serious, and you can't get more serious than death'. The thought that anyone at all has had the 'vaccine' in these circumstances is testament to the potential that humanity has for clueless, unquestioning, stupidity and for many that programmed stupidity has already been terminal.

An insider speaks

Dr Michael Yeadon is a former Vice President, head of research and Chief Scientific Adviser at vaccine giant Pfizer. Yeadon worked on the inside of Big Pharma, but that did not stop him becoming a vocal critic of 'Covid vaccines' and their potential for multiple harms, including infertility in women. By the spring of 2021 he went much further and even used the no, no, term 'conspiracy'. When you begin to see what is going on it is impossible not to do so. Yeadon spoke out in an interview with freedom campaigner James Delingpole and I mentioned earlier how he said that no one had samples of 'the virus'. He explained that the mRNA technique originated in the anti-cancer field and ways to turn on and off certain genes which could be advantageous if you wanted to stop cancer growing out of control. 'That's the origin of them. They are a very unusual application, really.' Yeadon said that treating a cancer patient with an aggressive procedure might be understandable if the alternative was dying, but it was quite another thing to use the same technique as a public health measure. Most people involved wouldn't catch the infectious agent you were vaccinating against and if they did they probably wouldn't die:

> If you are really using it as a public health measure you really want to as close as you can get to zero sides-effects … I find it odd that they chose techniques that were really cutting their teeth in the field of oncology and I'm worried that in using gene-based vaccines that have to be injected in the body and spread around the body, get taken up into some cells, and the regulators haven't quite told us which cells they get taken up into … you are going to be generating a wide range of responses … with multiple steps each of which could go well or badly.

I doubt the Cult intends it to go well. Yeadon said that you can put any gene you like into the body through the 'vaccine'. 'You can certainly give them a gene that would do them some harm if you wanted.' I was intrigued when he said that when used in the cancer field the technique could turn genes on and off. I explore this process in *The Answer* and with different genes having different functions you could create mayhem – physically and psychologically – if you turned the wrong ones on and the right ones off. I read reports of an experiment by researchers at the University of Washington's school of computer science and engineering in which they encoded DNA to infect computers. The body is itself a biological computer and if human DNA can inflict damage on a computer why can't the computer via synthetic material mess with the human body? It can. The Washington research team said it was possible to insert malicious malware into 'physical DNA strands' and corrupt the computer system of a gene sequencing machine as it 'reads gene letters and stores them as binary digits 0 and 1'. They concluded that hackers could one day use blood or spit samples to access computer systems and obtain sensitive data from police forensics labs or infect genome files. It is at this level of digital interaction that synthetic 'vaccines' need to be seen to get the full picture and that will become very clear later on. Michael Yeadon said it made no sense to give the 'vaccine' to younger people who were in no danger from the 'virus'. What was the benefit? It was all downside with potential effects:

> The fact that my government in what I thought was a civilised, rational country, is raining [the 'vaccine'] on people in their 30s and 40s, even my children in their 20s, they're getting letters and phone calls, I know this is not right and any of you doctors who are vaccinating you know it's not right, too. They are not at risk. They are not at risk from the disease, so you are now hoping that the side-effects are so rare that you get away with it. You don't give new technology … that you don't understand to 100 percent of the population.

Blood clot problems with the AstraZeneca 'vaccine' have been affecting younger people to emphasise the downside risks with no benefit. AstraZeneca's version, produced with Oxford University, does not use mRNA, but still gets its toxic cocktail inside cells where

it targets DNA. The Johnson & Johnson 'vaccine' which uses a similar technique has also produced blood clot effects to such an extent that the United States paused its use at one point. They are all 'gene therapy' (cell modification) procedures and not 'vaccines'. The truth is that once the content of these injections enter cells we have no idea what the effect will be. People can speculate and some can give very educated opinions and that's good. In the end, though, only the makers know what their potions are designed to do and even they won't know every last consequence. Michael Yeadon was scathing about doctors doing what they knew to be wrong. 'Everyone's mute', he said. Doctors in the NHS must know this was not right, coming into work and injecting people. 'I don't know how they sleep at night. I know I couldn't do it. I know that if I were in that position I'd have to quit.' He said he knew enough about toxicology to know this was not a good risk-benefit. Yeadon had spoken to seven or eight university professors and all except two would not speak out publicly. Their universities had a policy that no one said anything that countered the government and its medical advisors. They were afraid of losing their government grants. This is how intimidation has been used to silence the truth at every level of the system. I say silence, but these people could still speak out if they made that choice. Yeadon called them 'moral cowards' – 'This is about your children and grandchildren's lives and you have just buggered off and left it.'

'Variant' nonsense

Some of his most powerful comments related to the alleged 'variants' being used to instil more fear, justify more lockdowns, and introduce more 'vaccines'. He said government claims about 'variants' were nonsense. He had checked the alleged variant 'codes' and they were 99.7 percent identical to the 'original'. This was the human identity difference equivalent to putting a baseball cap on and off or wearing it the other way round. A 0.3 percent difference would make it impossible for that 'variant' to escape immunity from the 'original'. This made no sense of having new 'vaccines' for

'variants'. He said there would have to be at least a *30 percent* difference for that to be justified and even then he believed the immune system would still recognise what it was. Gates-funded 'variant modeller' and 'vaccine'-pusher John Edmunds might care to comment. Yeadon said drug companies were making new versions of the 'vaccine' as a 'top up' for 'variants'. Worse than that, he said, the 'regulators' around the world like the MHRA in the UK had got together and agreed that because 'vaccines' for 'variants' were so similar to the first 'vaccines' *they did not have to do safety studies*. How transparently sinister that is. This is when Yeadon said: 'There is a conspiracy here.' There was no need for another vaccine for 'variants' and yet we were told that there was and the country had shut its borders because of them. 'They are going into hundreds of millions of arms without passing 'go' or any regulator. Why did they do that? Why did they pick this method of making the vaccine?'

The reason had to be something bigger than that it seemed and 'it's not protection against the virus'. It's was a far bigger project that meant politicians and advisers were willing to do things and not do things that knowingly resulted in avoidable deaths – 'that's already happened when you think about lockdown and deprivation of health care for a year.' He spoke of people prepared to do something that results in the avoidable death of their fellow human beings and it not bother them. This is the penny-drop I have been working to get across for more than 30 years – the level of pure evil we are dealing with. Yeadon said his friends and associates could not believe there could be that much evil, but he reminded them of Stalin, Pol Pot and Hitler and of what Stalin had said: 'One death is a tragedy. A million? A statistic.' He could not think of a benign explanation for why you need top-up vaccines 'which I'm sure you don't' and for the regulators 'to just get out of the way and wave them through'. Why would the regulators do that when they were still wrestling with the dangers of the 'parent' vaccine? He was clearly shocked by what he had seen since the 'Covid' hoax began and now he was thinking the previously unthinkable:

If you wanted to depopulate a significant proportion of the world and to do it in a way that doesn't involve destruction of the environment with nuclear weapons, poisoning everyone with anthrax or something like that, and you wanted plausible deniability while you had a multi-year infectious disease crisis, I actually don't think you could come up with a better plan of work than seems to be in front of me. I can't say that's what they are going to do, but I can't think of a benign explanation why they are doing it.

He said he never thought that they would get rid of 99 percent of humans, but now he wondered. 'If you wanted to that this would be a hell of a way to do it – it would be unstoppable folks.' Yeadon had concluded that those who submitted to the 'vaccine' would be allowed to have some kind of normal life (but for how long?) while screws were tightened to coerce and mandate the last few percent. 'I think they'll put the rest of them in a prison camp. I wish I was wrong, but I don't think I am.' Other points he made included: There were no coronavirus vaccines then suddenly they all come along at the same time; we have no idea of the long term affect with trials so short; coercing or forcing people to have medical procedures is against the Nuremberg Code instigated when the Nazis did just that; people should at least delay having the 'vaccine'; a quick Internet search confirms that masks don't reduce respiratory viral transmission and 'the government knows that'; they have smashed civil society and they know that, too; two dozen peer-reviewed studies show no connection between lockdown and reducing deaths; he knew from personal friends the elite were still flying around and going on holiday while the public were locked down; the elite were not having the 'vaccines'. He was also asked if 'vaccines' could be made to target difference races. He said he didn't know, but the document by the Project for the New American Century in September, 2000, said developing 'advanced forms of biological warfare that can target *specific genotypes* may transform biological warfare from the realm of terror to a politically useful tool.' Oh, they're evil all right. Of that we can be *absolutely* sure.

Another cull of old people

We have seen from the CDC definition that the mRNA 'Covid vaccine' is not a vaccine and nor are the others that *claim* to reduce 'severity of symptoms' in *some* people, but not protect from infection or transmission. What about all the lies about returning to 'normal' if people were 'vaccinated'? If they are not claimed to stop infection and transmission of the alleged 'virus', how does anything change? This was all lies to manipulate people to take the jabs and we are seeing that now with masks and distancing still required for the 'vaccinated'. How did they think that elderly people with fragile health and immune responses were going to be affected by infusing their cells with synthetic material and other toxic substances? They *knew* that in the short and long term it would be devastating and fatal as the culling of the old that began with the first lockdowns was continued with the 'vaccine'. Death rates in care homes soared immediately residents began to be 'vaccinated' – infused with synthetic material. Brave and committed whistleblower nurses put their careers at risk by exposing this truth while the rest kept their heads down and their mouths shut to put their careers before those they are supposed to care for. A long-time American Certified Nursing Assistant who gave his name as James posted a video in which he described emotionally what happened in his care home when vaccination began. He said that during 2020 very few residents were sick with 'Covid' and no one died during the entire year; but shortly after the Pfizer mRNA injections 14 people died within two weeks and many others were near death. 'They're dropping like flies', he said. Residents who walked on their own before the shot could no longer and they had lost their ability to conduct an intelligent conversation. The home's management said the sudden deaths were caused by a 'super-spreader' of 'Covid-19'. Then how come, James asked, that residents who refused to take the injections were not sick? It was a case of inject the elderly with mRNA synthetic potions and blame their illness and death that followed on the 'virus'. James described what was happening in care homes as 'the greatest crime of genocide this country has ever seen'. Remember the NHS staff nurse from earlier who used the same

word ‘genocide’ for what was happening with the ‘vaccines’ and that it was an ‘act of human annihilation’. A UK care home whistleblower told a similar story to James about the effect of the ‘vaccine’ in deaths and ‘outbreaks’ of illness dubbed ‘Covid’ after getting the jab. She told how her care home management and staff had zealously imposed government regulations and no one was allowed to even question the official narrative let alone speak out against it. She said the NHS was even worse. Again we see the results of reframing. A worker at a local care home where I live said they had not had a single case of ‘Covid’ there for almost a year and when the residents were ‘vaccinated’ they had 19 positive cases in two weeks with eight dying.

It’s not the ‘vaccine’ – honest

The obvious cause and effect was being ignored by the media and most of the public. Australia’s health minister Greg Hunt (a former head of strategy at the World Economic Forum) was admitted to hospital after he had the ‘vaccine’. He was suffering according to reports from the skin infection ‘cellulitis’ and it must have been a severe case to have warranted days in hospital. Immediately the authorities said this was nothing to do with the ‘vaccine’ when an effect of some vaccines is a ‘cellulitis-like reaction’. We had families of perfectly healthy old people who died after the ‘vaccine’ saying that if only they had been given the ‘vaccine’ earlier they would still be alive. As a numbskull rating that is off the chart. A father of four ‘died of Covid’ at aged 48 when he was taken ill two days after having the ‘vaccine’. The man, a health administrator, had been ‘shielding during the pandemic’ and had ‘not really left the house’ until he went for the ‘vaccine’. Having the ‘vaccine’ and then falling ill and dying does not seem to have qualified as a possible cause and effect and ‘Covid-19’ went on his death certificate. His family said they had no idea how he ‘caught the virus’. A family member said: ‘Tragically, it could be that going for a vaccination ultimately led to him catching Covid …The sad truth is that they are never going to know where it came from.’ The family warned people to remember

that the virus still existed and was 'very real'. So was their stupidity. Nurses and doctors who had the first round of the 'vaccine' were collapsing, dying and ending up in a hospital bed while they or their grieving relatives were saying they'd still have the 'vaccine' again despite what happened. I kid you not. You mean if your husband returned from the dead he'd have the same 'vaccine' again that killed him??

Doctors at the VCU Medical Center in Richmond, Virginia, said the Johnson & Johnson 'vaccine' was to blame for a man's skin peeling off. Patient Richard Terrell said: 'It all just happened so fast. My skin peeled off. It's still coming off on my hands now.' He said it was stinging, burning and itching and when he bent his arms and legs it was very painful with 'the skin swollen and rubbing against itself'. Pfizer/BioNTech and Moderna vaccines use mRNA to change the cell while the Johnson & Johnson version uses DNA in a process similar to AstraZeneca's technique. Johnson & Johnson and AstraZeneca have both had their 'vaccines' paused by many countries after causing serious blood problems. Terrell's doctor Fnu Nutan said he could have died if he hadn't got medical attention. It sounds terrible so what did Nutan and Terrell say about the 'vaccine' now? Oh, they still recommend that people have it. A nurse in a hospital bed 40 minutes after the vaccination and unable to swallow due to throat swelling was told by a doctor that he lost mobility in his arm for 36 hours following the vaccination. What did he say to the ailing nurse? 'Good for you for getting the vaccination.' We are dealing with a serious form of cognitive dissonance madness in both public and medical staff. There is a remarkable correlation between those having the 'vaccine' and trumpeting the fact and suffering bad happenings shortly afterwards. Witold Rogiewicz, a Polish doctor, made a video of his 'vaccination' and ridiculed those who were questioning its safety and the intentions of Bill Gates: 'Vaccinate yourself to protect yourself, your loved ones, friends and also patients. And to mention quickly I have info for anti-vaxxers and anti-Coviders if you want to contact Bill Gates you can do this through me.' He further ridiculed the dangers of 5G. Days later he

was dead, but naturally the vaccination wasn't mentioned in the verdict of 'heart attack'.

Lies, lies and more lies

So many members of the human race have slipped into extreme states of insanity and unfortunately they include reframed doctors and nursing staff. Having a 'vaccine' and dying within minutes or hours is not considered a valid connection while death from any cause within 28 days or longer of a positive test with a test not testing for the 'virus' means 'Covid-19' goes on the death certificate. How could that 'vaccine'-death connection not have been made except by calculated deceit? US figures in the initial rollout period to February 12th, 2020, revealed that a third of the deaths reported to the CDC after 'Covid vaccines' happened within 48 hours. Five men in the UK suffered an 'extremely rare' blood clot problem after having the AstraZeneca 'vaccine', but no causal link was established said the Gates-funded Medicines and Healthcare products Regulatory Agency (MHRA) which had given the 'vaccine' emergency approval to be used. Former Pfizer executive Dr Michael Yeadon explained in his interview how the procedures could cause blood coagulation and clots. People who should have been at no risk were dying from blood clots in the brain and he said he had heard from medical doctor friends that people were suffering from skin bleeding and massive headaches. The AstraZeneca 'shot' was stopped by some 20 countries over the blood clotting issue and still the corrupt MHRA, the European Medicines Agency (EMA) and the World Health Organization said that it should continue to be given even though the EMA admitted that it 'still cannot rule out definitively' a link between blood clotting and the 'vaccine'. Later Marco Cavaleri, head of EMA vaccine strategy, said there was indeed a clear link between the 'vaccine' and thrombosis, but they didn't know why. So much for the trials showing the 'vaccine' is safe. Blood clots were affecting younger people who would be under virtually no danger from 'Covid' even if it existed which makes it all the more stupid and sinister.

The British government responded to public alarm by wheeling out June Raine, the terrifyingly weak infant school headmistress sound-alike who heads the UK MHRA drug 'regulator'. The idea that she would stand up to Big Pharma and government pressure is laughable and she told us that all was well in the same way that she did when allowing untested, never-used-on-humans-before, genetically-manipulating 'vaccines' to be exposed to the public in the first place. Mass lying is the new normal of the 'Covid' era. The MHRA later said 30 cases of rare blood clots had by then been connected with the AstraZeneca 'vaccine' (that means a lot more in reality) while stressing that the benefits of the jab in preventing 'Covid-19' outweighed any risks. A more ridiculous and disingenuous statement with callous disregard for human health it is hard to contemplate. Immediately after the mendacious 'all-clears' two hospital workers in Denmark experienced blood clots and cerebral haemorrhaging following the AstraZeneca jab and one died. Top Norwegian health official Pål Andre Holme said the 'vaccine' was the only common factor: 'There is nothing in the patient history of these individuals that can give such a powerful immune response … I am confident that the antibodies that we have found are the cause, and I see no other explanation than it being the vaccine which triggers it.' Strokes, a clot or bleed in the brain, were clearly associated with the 'vaccine' from word of mouth and whistleblower reports. Similar consequences followed with all these 'vaccines' that we were told were so safe and as the numbers grew by the day it was clear we were witnessing human carnage.

Learning the hard way

A woman interviewed by UKColumn told how her husband suffered dramatic health effects after the vaccine when he'd been in good health all his life. He went from being a little unwell to losing all feeling in his legs and experiencing 'excruciating pain'. Misdiagnosis followed twice at Accident and Emergency (an 'allergy' and 'sciatica') before he was admitted to a neurology ward where doctors said his serious condition had been caused by the

'vaccine'. Another seven 'vaccinated' people were apparently being treated on the same ward for similar symptoms. The woman said he had the 'vaccine' because they believed media claims that it was safe. 'I didn't think the government would give out a vaccine that does this to somebody; I believed they would be bringing out a vaccination that would be safe.' What a tragic way to learn that lesson. Another woman posted that her husband was transporting stroke patients to hospital on almost every shift and when he asked them if they had been 'vaccinated' for 'Covid' they all replied 'yes'. One had a 'massive brain bleed' the day after his second dose. She said her husband reported the 'just been vaccinated' information every time to doctors in A and E only for them to ignore it, make no notes and appear annoyed that it was even mentioned. This particular report cannot be verified, but it expresses a common theme that confirms the monumental underreporting of 'vaccine' consequences. Interestingly as the 'vaccines' and their brain blood clot/stroke consequences began to emerge the UK National Health Service began a publicity campaign telling the public what to do in the event of a stroke. A Scottish NHS staff nurse who quit in disgust in March, 2021, said:

I have seen traumatic injuries from the vaccine, they're not getting reported to the yellow card [adverse reaction] scheme, they're treating the symptoms, not asking why, why it's happening. It's just treating the symptoms and when you speak about it you're dismissed like you're crazy, I'm not crazy, I'm not crazy because every other colleague I've spoken to is terrified to speak out, they've had enough.

Videos appeared on the Internet of people uncontrollably shaking after the 'vaccine' with no control over muscles, limbs and even their face. A Scottish mother broke out in a severe rash all over her body almost immediately after she was given the AstraZeneca 'vaccine'. The pictures were horrific. Leigh King, a 41-year-old hairdresser from Lanarkshire said: 'Never in my life was I prepared for what I was about to experience … My skin was so sore and constantly hot … I have never felt pain like this …' But don't you worry, the 'vaccine' is perfectly safe. Then there has been the effect on medical

staff who have been pressured to have the 'vaccine' by psychopathic 'health' authorities and government. A London hospital consultant who gave the name K. Polyakova wrote this to the *British Medical Journal* or *BMJ*:

> I am currently struggling with … the failure to report the reality of the morbidity caused by our current vaccination program within the health service and staff population. The levels of sickness after vaccination is unprecedented and staff are getting very sick and some with neurological symptoms which is having a huge impact on the health service function. Even the young and healthy are off for days, some for weeks, and some requiring medical treatment. Whole teams are being taken out as they went to get vaccinated together.
>
> Mandatory vaccination in this instance is stupid, unethical and irresponsible when it comes to protecting our staff and public health. We are in the voluntary phase of vaccination, and encouraging staff to take an unlicensed product that is impacting on their immediate health … it is clearly stated that these vaccine products do not offer immunity or stop transmission. In which case why are we doing it?

Not to protect health that's for sure. Medical workers are lauded by governments for agenda reasons when they couldn't give a toss about them any more than they can for the population in general. Schools across America faced the same situation as they closed due to the high number of teachers and other staff with bad reactions to the Pfizer/BioNTech, Moderna, and Johnson & Johnson 'Covid vaccines' all of which were linked to death and serious adverse effects. The *BMJ* took down the consultant's comments pretty quickly on the grounds that they were being used to spread 'disinformation'. They were exposing the truth about the 'vaccine' was the real reason. The cover-up is breathtaking.

Hiding the evidence

The scale of the 'vaccine' death cover-up worldwide can be confirmed by comparing official figures with the personal experience of the public. I heard of many people in my community who died immediately or soon after the vaccine that would never appear in the media or even likely on the official totals of 'vaccine' fatalities and adverse reactions when only about ten percent are estimated to be

reported and I have seen some estimates as low as one percent in a Harvard study. In the UK alone by April 29th, 2021, some 757,654 adverse reactions had been officially reported from the Pfizer/BioNTech, Oxford/AstraZeneca and Moderna 'vaccines' with more than a thousand deaths linked to jabs and that means an estimated ten times this number in reality from a ten percent reporting rate percentage. That's seven million adverse reactions and 10,000 potential deaths and a one percent reporting rate would be ten times *those* figures. In 1976 the US government pulled the swine flu vaccine after *53* deaths. The UK data included a combined 10,000 eye disorders from the 'Covid vaccines' with more than 750 suffering visual impairment or blindness and again multiply by the estimated reporting percentages. As 'Covid cases' officially fell hospitals virtually empty during the 'Covid crisis' began to fill up with a range of other problems in the wake of the 'vaccine' rollout. The numbers across America have also been catastrophic. Deaths linked to *all* types of vaccine increased by *6,000 percent* in the first quarter of 2021 compared with 2020. A 39-year-old woman from Ogden, Utah, died four days after receiving a second dose of Moderna's 'Covid vaccine' when her liver, heart and kidneys all failed despite the fact that she had no known medical issues or conditions. Her family sought an autopsy, but Dr Erik Christensen, Utah's chief medical examiner, said proving vaccine injury as a cause of death almost never happened. He could think of only one instance where an autopsy would name a vaccine as the official cause of death and that would be anaphylaxis where someone received a vaccine and died almost instantaneously. 'Short of that, it would be difficult for us to definitively say this is the vaccine,' Christensen said. If that is true this must be added to the estimated ten percent (or far less) reporting rate of vaccine deaths and serious reactions and the conclusion can only be that vaccine deaths and serious reactions – including these 'Covid' potions' – are phenomenally understated in official figures. The same story can be found everywhere. Endless accounts of deaths and serious reactions among the public, medical

and care home staff while official figures did not even begin to reflect this.

Professional script-reader Dr David Williams, a 'top public-health official' in Ontario, Canada, insulted our intelligence by claiming only four serious adverse reactions and no deaths from the more than 380,000 vaccine doses then given. This bore no resemblance to what people knew had happened in their owns circles and we had Dirk Huyer in charge of getting millions vaccinated in Ontario while at the same time he was Chief Coroner for the province investigating causes of death including possible death from the vaccine. An aide said he had stepped back from investigating deaths, but evidence indicated otherwise. Rosemary Frei, who secured a Master of Science degree in molecular biology at the Faculty of Medicine at Canada's University of Calgary before turning to investigative journalism, was one who could see that official figures for 'vaccine' deaths and reactions made no sense. She said that doctors seldom reported adverse events and when people got really sick or died after getting a vaccination they would attribute that to anything except the vaccines. It had been that way for years and anyone who wondered aloud whether the 'Covid vaccines' or other shots cause harm is immediately branded as 'anti-vax' and 'anti-science'. This was 'career-threatening' for health professionals. Then there was the huge pressure to support the push to 'vaccinate' billions in the quickest time possible. Frei said:

> So that's where we're at today. More than half a million vaccine doses have been given to people in Ontario alone. The rush is on to vaccinate all 15 million of us in the province by September. And the mainstream media are screaming for this to be sped up even more. That all adds up to only a very slim likelihood that we're going to be told the truth by officials about how many people are getting sick or dying from the vaccines.

What is true of Ontario is true of everywhere.

They KNEW – and still did it

The authorities knew what was going to happen with multiple deaths and adverse reactions. The UK government's Gates-funded

and Big Pharma-dominated Medicines and Healthcare products Regulatory Agency (MHRA) hired a company to employ AI in compiling the projected reactions to the 'vaccine' that would otherwise be uncountable. The request for applications said: 'The MHRA urgently seeks an Artificial Intelligence (AI) software tool to process the expected high volume of Covid-19 vaccine Adverse Drug Reaction …' This was from the agency, headed by the disingenuous June Raine, that gave the 'vaccines' emergency approval and the company was hired before the first shot was given. 'We are going to kill and maim you – is that okay?' 'Oh, yes, perfectly fine – I'm very grateful, thank you, doctor.' The range of 'Covid vaccine' adverse reactions goes on for page after page in the MHRA criminally underreported 'Yellow Card' system and includes affects to eyes, ears, skin, digestion, blood and so on. Raine's MHRA amazingly claimed that the 'overall safety experience … is so far as expected from the clinical trials'. The death, serious adverse effects, deafness and blindness were *expected?* When did they ever mention that? If these human tragedies were expected then those that gave approval for the use of these 'vaccines' must be guilty of crimes against humanity including murder – a definition of which is 'killing a person with malice aforethought or with recklessness manifesting extreme indifference to the value of human life.' People involved at the MHRA, the CDC in America and their equivalent around the world must go before Nuremberg trials to answer for their callous inhumanity. We are only talking here about the immediate effects of the 'vaccine'. The longer-term impact of the DNA synthetic manipulation is the main reason they are so hysterically desperate to inoculate the entire global population in the shortest possible time.

Africa and the developing world are a major focus for the 'vaccine' depopulation agenda and a mass vaccination sales-pitch is underway thanks to caring people like the Rockefellers and other Cult assets. The Rockefeller Foundation, which pre-empted the 'Covid pandemic' in a document published in 2010 that 'predicted' what happened a decade later, announced an initial $34.95 million grant in February, 2021, 'to ensure more equitable access to Covid-19

testing and vaccines' among other things in Africa in collaboration with '24 organizations, businesses, and government agencies'. The pan-Africa initiative would focus on 10 countries: Burkina Faso, Ethiopia, Ghana, Kenya, Nigeria, Rwanda, South Africa, Tanzania, Uganda, and Zambia'. Rajiv Shah, President of the Rockefeller Foundation and former administrator of CIA-controlled USAID, said that if Africa was not mass-vaccinated (to change the DNA of its people) it was a 'threat to all of humanity' and not fair on Africans. When someone from the Rockefeller Foundation says they want to do something to help poor and deprived people and countries it is time for a belly-laugh. They are doing this out of the goodness of their 'heart' because 'vaccinating' the entire global population is what the 'Covid' hoax set out to achieve. Official 'decolonisation' of Africa by the Cult was merely a prelude to financial colonisation on the road to a return to physical colonisation. The 'vaccine' is vital to that and the sudden and convenient death of the 'Covid' sceptic president of Tanzania can be seen in its true light. A lot of people in Africa are aware that this is another form of colonisation and exploitation and they need to stand their ground.

The 'vaccine is working' scam

A potential problem for the Cult was that the 'vaccine' is meant to change human DNA and body messaging and not to protect anyone from a 'virus' never shown to exist. The vaccine couldn't work because it was not designed to work and how could they make it *appear* to be working so that more people would have it? This was overcome by lowering the amplification rate of the PCR test to produce fewer 'cases' and therefore fewer 'deaths'. Some of us had been pointing out since March, 2020, that the amplification rate of the test not testing for the 'virus' had been made artificially high to generate positive tests which they could call 'cases' to justify lockdowns. The World Health Organization recommended an absurdly high 45 amplification cycles to ensure the high positives required by the Cult and then remained silent on the issue until January 20th, 2021 – Biden's Inauguration Day. This was when the

'vaccinations' were seriously underway and on that day the WHO recommended after discussions with America's CDC that laboratories *lowered their testing amplification*. Dr David Samadi, a certified urologist and health writer, said the WHO was encouraging all labs to reduce their cycle count for PCR tests. He said the current cycle was much too high and was 'resulting in any particle being declared a positive case'. Even one mainstream news report I saw said this meant the number of 'Covid' infections may have been 'dramatically inflated'. Oh, just a little bit. The CDC in America issued new guidance to laboratories in April, 2021, to use 28 cycles *but only for 'vaccinated' people*. The timing of the CDC/WHO interventions were cynically designed to make it appear the 'vaccines' were responsible for falling cases and deaths when the real reason can be seen in the following examples. New York's state lab, the Wadsworth Center, identified 872 positive tests in July, 2020, based on a threshold of 40 cycles. When the figure was lowered to 35 cycles *43 percent* of the 872 were no longer 'positives'. At 30 cycles the figure was 63 percent. A Massachusetts lab found that between *85 to 90 percent* of people who tested positive in July with a cycle threshold of 40 would be negative at 30 cycles, Ashish Jha, MD, director of the Harvard Global Health Institute, said: 'I'm really shocked that it could be that high … Boy, does it really change the way we need to be thinking about testing.' I'm shocked that I could see the obvious in the spring of 2020, with no medical background, and most medical professionals still haven't worked it out. No, that's not shocking – it's terrifying.

Three weeks after the WHO directive to lower PCR cycles the London *Daily Mail* ran this headline: 'Why ARE Covid cases plummeting? New infections have fallen 45% in the US and 30% globally in the past 3 weeks but experts say vaccine is NOT the main driver because only 8% of Americans and 13% of people worldwide have received their first dose.' They acknowledged that the drop could not be attributed to the 'vaccine', but soon this morphed throughout the media into the 'vaccine' has caused cases and deaths to fall when it was the PCR threshold. In December, 2020, there was

chaos at English Channel ports with truck drivers needing negative 'Covid' tests before they could board a ferry home for Christmas. The government wanted to remove the backlog as fast as possible and they brought in troops to do the 'testing'. Out of 1,600 drivers just *36* tested positive and the rest were given the all clear to cross the Channel. I guess the authorities thought that 36 was the least they could get away with without the unquestioning catching on. The amplification trick which most people believed in the absence of information in the mainstream applied more pressure on those refusing the 'vaccine' to succumb when it 'obviously worked'. The truth was the exact opposite with deaths in care homes soaring with the 'vaccine' and in Israel the term used was 'skyrocket'. A re-analysis of published data from the Israeli Health Ministry led by Dr Hervé Seligmann at the Medicine Emerging Infectious and Tropical Diseases at Aix-Marseille University found that Pfizer's 'Covid vaccine' killed 'about 40 times more [elderly] people than the disease itself would have killed' during a five-week vaccination period and *260 times* more younger people than would have died from the 'virus' even according to the manipulated 'virus' figures. Dr Seligmann and his co-study author, Haim Yativ, declared after reviewing the Israeli 'vaccine' death data: 'This is a new Holocaust.'

Then, in mid-April, 2021, after vast numbers of people worldwide had been 'vaccinated', the story changed with clear coordination. The UK government began to prepare the ground for more future lockdowns when Nuremberg-destined Boris Johnson told yet another whopper. He said that cases had fallen because of *lockdowns* not 'vaccines'. Lockdowns are irrelevant when *there is no 'virus'* and the test and fraudulent death certificates are deciding the number of 'cases' and 'deaths'. Study after study has shown that lockdowns don't work and instead kill and psychologically destroy people. Meanwhile in the United States Anthony Fauci and Rochelle Walensky, the ultra-Zionist head of the CDC, peddled the same line. More lockdown was the answer and not the 'vaccine', a line repeated on cue by the moron that is Canadian Prime Minister Justin Trudeau. Why all the hysteria to get everyone 'vaccinated' if lockdowns and

not 'vaccines' made the difference? None of it makes sense on the face of it. Oh, but it does. The Cult wants lockdowns *and* the 'vaccine' and if the 'vaccine' is allowed to be seen as the total answer lockdowns would no longer be justified when there are still livelihoods to destroy. 'Variants' and renewed upward manipulation of PCR amplification are planned to instigate never-ending lockdown *and* more 'vaccines'.

You *must* have it – we're desperate

Israel, where the Jewish and Arab population are ruled by the Sabbatian Cult, was the front-runner in imposing the DNA-manipulating 'vaccine' on its people to such an extent that Jewish refusers began to liken what was happening to the early years of Nazi Germany. This would seem to be a fantastic claim. Why would a government of Jewish people be acting like the Nazis did? If you realise that the Sabbatian Cult was behind the Nazis and that Sabbatians hate Jews the pieces start to fit and the question of why a 'Jewish' government would treat Jews with such callous disregard for their lives and freedom finds an answer. Those controlling the government of Israel *aren't Jewish* – they're Sabbatian. Israeli lawyer Tamir Turgal was one who made the Nazi comparison in comments to German lawyer Reiner Fuellmich who is leading a class action lawsuit against the psychopaths for crimes against humanity. Turgal described how the Israeli government was vaccinating children and pregnant women on the basis that there was no evidence that this was dangerous when they had no evidence that it *wasn't* dangerous either. They just had no evidence. This was medical experimentation and Turgal said this breached the Nuremberg Code about medical experimentation and procedures requiring informed consent and choice. Think about that. A Nuremberg Code developed because of Nazi experimentation on Jews and others in concentration camps by people like the evil-beyond-belief Josef Mengele is being breached by the *Israeli* government; but when you know that it's a *Sabbatian* government along with its intelligence and military agencies like Mossad, Shin Bet and the Israeli Defense Forces, and that Sabbatians

were the force behind the Nazis, the kaleidoscope comes into focus. What have we come to when Israeli Jews are suing their government for violating the Nuremberg Code by essentially making Israelis subject to a medical experiment using the controversial 'vaccines'? It's a shocker that this has to be done in the light of what happened in Nazi Germany. The Anshe Ha-Emet, or 'People of the Truth', made up of Israeli doctors, lawyers, campaigners and public, have launched a lawsuit with the International Criminal Court. It says:

> When the heads of the Ministry of Health as well as the prime minister presented the vaccine in Israel and began the vaccination of Israeli residents, the vaccinated were not advised, that, in practice, they are taking part in a medical experiment and that their consent is required for this under the Nuremberg Code.

The irony is unbelievable, but easily explained in one word: Sabbatians. The foundation of Israeli 'Covid' apartheid is the 'green pass' or 'green passport' which allows Jews and Arabs who have had the DNA-manipulating 'vaccine' to go about their lives – to work, fly, travel in general, go to shopping malls, bars, restaurants, hotels, concerts, gyms, swimming pools, theatres and sports venues, while non-'vaccinated' are banned from all those places and activities. Israelis have likened the 'green pass' to the yellow stars that Jews in Nazi Germany were forced to wear – the same as the yellow stickers that a branch of UK supermarket chain Morrisons told exempt mask-wears they had to display when shopping. How very sensitive. The Israeli system is blatant South African-style apartheid on the basis of compliance or non-compliance to fascism rather than colour of the skin. How appropriate that the Sabbatian Israeli government was so close to the pre-Mandela apartheid regime in Pretoria. The Sabbatian-instigated 'vaccine passport' in Israel is planned for everywhere. Sabbatians struck a deal with Pfizer that allowed them to lead the way in the percentage of a national population infused with synthetic material and the result was catastrophic. Israeli freedom activist Shai Dannon told me how chairs were appearing on beaches that said 'vaccinated only'. Health Minister Yuli Edelstein said that anyone unwilling or unable to get

the jabs that 'confer immunity' will be 'left behind'. The man's a liar. Not even the makers claim the 'vaccines' confer immunity. When you see those figures of 'vaccine' deaths these psychopaths were saying that you must take the chance the 'vaccine' will kill you or maim you while knowing it will change your DNA or lockdown for you will be permanent. That's fascism. The Israeli parliament passed a law to allow personal information of the non-vaccinated to be shared with local and national authorities for three months. This was claimed by its supporters to be a way to 'encourage' people to be vaccinated. Hadas Ziv from Physicians for Human Rights described this as a 'draconian law which crushed medical ethics and the patient rights'. But that's the idea, the Sabbatians would reply.

Your papers, please

Sabbatian Israel was leading what has been planned all along to be a global 'vaccine pass' called a 'green passport' without which you would remain in permanent lockdown restriction and unable to do anything. This is how badly – *desperately* – the Cult is to get everyone 'vaccinated'. The term and colour 'green' was not by chance and related to the psychology of fusing the perception of the green climate hoax with the 'Covid' hoax and how the 'solution' to both is the same Great Reset. Lying politicians, health officials and psychologists denied there were any plans for mandatory vaccinations or restrictions based on vaccinations, but they knew that was exactly what was meant to happen with governments of all countries reaching agreements to enforce a global system. 'Free' Denmark and 'free' Sweden unveiled digital vaccine certification. Cyprus, Czech Republic, Estonia, Greece, Hungary, Iceland, Italy, Poland, Portugal, Slovakia, and Spain have all committed to a vaccine passport system and the rest including the whole of the EU would follow. The satanic UK government will certainly go this way despite mendacious denials and at the time of writing it is trying to manipulate the public into having the 'vaccine' so they could go abroad on a summer holiday. How would that work without something to prove you had the synthetic toxicity injected into you?

Documents show that the EU's European Commission was moving towards 'vaccine certificates' in 2018 and 2019 before the 'Covid' hoax began. They knew what was coming. Abracadabra – Ursula von der Leyen, the German President of the Commission, announced in March, 2021, an EU 'Digital Green Certificate' – green again – to track the public's 'Covid status'. The passport sting is worldwide and the Far East followed the same pattern with South Korea ruling that only those with 'vaccination' passports – again the *green* pass – would be able to 'return to their daily lives'.

Bill Gates has been preparing for this 'passport' with other Cult operatives for years and beyond the paper version is a Gates-funded 'digital tattoo' to identify who has been vaccinated and who hasn't. The 'tattoo' is reported to include a substance which is externally readable to confirm who has been vaccinated. This is a bio-luminous light-generating enzyme (think fireflies) called … *Luciferase*. Yes, named after the Cult 'god' Lucifer the 'light bringer' of whom more to come. Gates said he funded the readable tattoo to ensure children in the developing world were vaccinated and no one was missed out. He cares so much about poor kids as we know. This was just the cover story to develop a vaccine tagging system for everyone on the planet. Gates has been funding the ID2020 'alliance' to do just that in league with other lovely people at Microsoft, GAVI, the Rockefeller Foundation, Accenture and IDEO.org. He said in interviews in March, 2020, before any 'vaccine' publicly existed, that the world must have a globalised digital certificate to track the 'virus' and who had been vaccinated. Gates knew from the start that the mRNA vaccines were coming and when they would come and that the plan was to tag the 'vaccinated' to marginalise the intelligent and stop them doing anything including travel. Evil just doesn't suffice. Gates was exposed for offering a $10 million bribe to the Nigerian House of Representatives to invoke compulsory 'Covid' vaccination of all Nigerians. Sara Cunial, a member of the Italian Parliament, called Gates a 'vaccine criminal'. She urged the Italian President to hand him over to the International Criminal Court for crimes against

humanity and condemned his plans to 'chip the human race' through ID2020.

You know it's a long-planned agenda when war criminal and Cult gofer Tony Blair is on the case. With the scale of arrogance only someone as dark as Blair can muster he said: 'Vaccination in the end is going to be your route to liberty.' Blair is a disgusting piece of work and he confirms that again. The media has given a lot of coverage to a bloke called Charlie Mullins, founder of London's biggest independent plumbing company, Pimlico Plumbers, who has said he won't employ anyone who has not been vaccinated or have them go to any home where people are not vaccinated. He said that if he had his way no one would be allowed to walk the streets if they have not been vaccinated. Gates was cheering at the time while I was alerting the white coats. The plan is that people will qualify for 'passports' for having the first two doses and then to keep it they will have to have all the follow ups and new ones for invented 'variants' until human genetics is transformed and many are dead who can't adjust to the changes. Hollywood celebrities – the usual propaganda stunt – are promoting something called the WELL Health-Safety Rating to verify that a building or space has 'taken the necessary steps to prioritize the health and safety of their staff, visitors and other stakeholders'. They included Lady Gaga, Jennifer Lopez, Michael B. Jordan, Robert DeNiro, Venus Williams, Wolfgang Puck, Deepak Chopra and 17th Surgeon General Richard Carmona. Yawn. WELL Health-Safety has big connections with China. Parent company Delos is headed by former Goldman Sachs partner Paul Scialla. This is another example – and we will see so many others – of using the excuse of 'health' to dictate the lives and activities of the population. I guess one confirmation of the 'safety' of buildings is that only 'vaccinated' people can go in, right?

Electronic concentration camps

I wrote decades ago about the plans to restrict travel and here we are for those who refuse to bow to tyranny. This can be achieved in one go with air travel if the aviation industry makes a blanket decree.

The ‘vaccine’ and guaranteed income are designed to be part of a global version of China’s social credit system which tracks behaviour 24/7 and awards or deletes ‘credits’ based on whether your behaviour is supported by the state or not. I mean your entire lifestyle – what you do, eat, say, everything. Once your credit score falls below a certain level consequences kick in. In China tens of millions have been denied travel by air and train because of this. All the locations and activities denied to refusers by the ‘vaccine’ passports will be included in one big mass ban on doing almost anything for those that don’t bow their head to government. It’s beyond fascist and a new term is required to describe its extremes – I guess fascist technocracy will have to do. The way the Chinese system of technological – technocratic – control is sweeping the West can be seen in the Los Angeles school system and is planned to be expanded worldwide. Every child is required to have a ‘Covid’-tracking app scanned daily before they can enter the classroom. The so-called Daily Pass tracking system is produced by Gates’ Microsoft which I’m sure will shock you rigid. The pass will be scanned using a barcode (one step from an inside-the-body barcode) and the information will include health checks, ‘Covid’ tests and vaccinations. Entry codes are for one specific building only and access will only be allowed if a student or teacher has a negative test with a test not testing for the ‘virus’, has no symptoms of anything alleged to be related to ‘Covid’ (symptoms from a range of other illness), and has a temperature under 100 degrees. No barcode, no entry, is planned to be the case for everywhere and not only schools.

Kids are being psychologically prepared to accept this as ‘normal’ their whole life which is why what they can impose in schools is so important to the Cult and its gofers. Long-time American freedom campaigner John Whitehead of the Rutherford Institute was not exaggerating when he said: ‘Databit by databit, we are building our own electronic concentration camps.’ Canada under its Cult gofer prime minister Justin Trudeau has taken a major step towards the real thing with people interned against their will if they test positive with a test not testing for the ‘virus’ when they arrive at a Canadian

airport. They are jailed in internment hotels often without food or water for long periods and with many doors failing to lock there have been sexual assaults. The interned are being charged sometimes $2,000 for the privilege of being abused in this way. Trudeau is fully on board with the Cult and says the 'Covid pandemic' has provided an opportunity for a global 'reset' to permanently change Western civilisation. His number two, Deputy Prime Minister Chrystia Freeland, is a trustee of the World Economic Forum and a Rhodes Scholar. The Trudeau family have long been servants of the Cult. See *The Biggest Secret* and Cathy O'Brien's book *Trance-Formation of America* for the horrific background to Trudeau's father Pierre Trudeau another Canadian prime minister. Hide your fascism behind the façade of a heart-on-the-sleeve liberal. It's a well-honed Cult technique.

What can the 'vaccine' *really* do?

We have a 'virus' never shown to exist and 'variants' of the 'virus' that have also never been shown to exist except, like the 'original', as computer-generated fictions. Even if you believe there's a 'virus' the 'case' to 'death' rate is in the region of 0.23 to 0.15 percent and those 'deaths' are concentrated among the very old around the same average age that people die anyway. In response to this lack of threat (in truth none) psychopaths and idiots, knowingly and unknowingly answering to Gates and the Cult, are seeking to 'vaccinate' every man, woman and child on Planet Earth. Clearly the 'vaccine' is not about 'Covid' – none of this ever has been. So what is it all about *really*? Why the desperation to infuse genetically-manipulating synthetic material into everyone through mRNA fraudulent 'vaccines' with the intent of doing this over and over with the excuses of 'variants' and other 'virus' inventions? Dr Sherri Tenpenny, an osteopathic medical doctor in the United States, has made herself an expert on vaccines and their effects as a vehement campaigner against their use. Tenpenny was board certified in emergency medicine, the director of a level two trauma centre for 12 years, and moved to Cleveland in 1996 to start an integrative

medicine practice which has treated patients from all 50 states and some 17 other countries. Weaning people off pharmaceutical drugs is a speciality.

She became interested in the consequences of vaccines after attending a meeting at the National Vaccine Information Center in Washington DC in 2000 where she 'sat through four days of listening to medical doctors and scientists and lawyers and parents of vaccine injured kids' and asked: 'What's going on?' She had never been vaccinated and never got ill while her father was given a list of vaccines to be in the military and was 'sick his entire life'. The experience added to her questions and she began to examine vaccine documents from the Centers for Disease Control (CDC). After reading the first one, the 1998 version of *The General Recommendations of Vaccination*, she thought: 'This is it?' The document was poorly written and bad science and Tenpenny began 20 years of research into vaccines that continues to this day. She began her research into 'Covid vaccines' in March, 2020, and she describes them as 'deadly'. For many, as we have seen, they already have been. Tenpenny said that in the first 30 days of the 'vaccine' rollout in the United States there had been more than 40,000 adverse events reported to the vaccine adverse event database. A document had been delivered to her the day before that was 172 pages long. 'We have over 40,000 adverse events; we have over 3,100 cases of [potentially deadly] anaphylactic shock; we have over 5,000 neurological reactions.' Effects ranged from headaches to numbness, dizziness and vertigo, to losing feeling in hands or feet and paraesthesia which is when limbs 'fall asleep' and people have the sensation of insects crawling underneath their skin. All this happened in the first 30 days and remember that only about *ten percent* (or far less) of adverse reactions and vaccine-related deaths are estimated to be officially reported. Tenpenny said:

So can you think of one single product in any industry, any industry, for as long as products have been made on the planet that within 30 days we have 40,000 people complaining of side effects that not only is still on the market but … we've got paid actors telling us how great

they are for getting their vaccine. We're offering people $500 if they will just get their vaccine and we've got nurses and doctors going; 'I got the vaccine, I got the vaccine'.

Tenpenny said they were not going to be 'happy dancing folks' when they began to suffer Bell's palsy (facial paralysis), neuropathies, cardiac arrhythmias and autoimmune reactions that kill through a blood disorder. 'They're not going to be so happy, happy then, but we're never going to see pictures of those people' she said. Tenpenny described the 'vaccine' as 'a well-designed killing tool'.

No off-switch

Bad as the initial consequences had been Tenpenny said it would be maybe 14 months before we began to see the 'full ravage' of what is going to happen to the 'Covid vaccinated' with full-out consequences taking anything between two years and 20 years to show. You can understand why when you consider that variations of the 'Covid vaccine' use mRNA (messenger RNA) to in theory activate the immune system to produce protective antibodies without using the actual 'virus'. How can they when it's a computer program and they've never isolated what they claim is the 'real thing'? Instead they use *synthetic* mRNA. They are inoculating synthetic material into the body which through a technique known as the Trojan horse is absorbed into cells to change the nature of DNA. Human DNA is changed by an infusion of messenger RNA and with each new 'vaccine' of this type it is changed even more. Say so and you are banned by Cult Internet platforms. The contempt the contemptuous Mark Zuckerberg has for the truth and human health can be seen in an internal Facebook video leaked to the Project Veritas investigative team in which he said of the 'Covid vaccines': '… I share some caution on this because we just don't know the long term side-effects of basically modifying people's DNA and RNA.' At the same time this disgusting man's Facebook was censoring and banning anyone saying exactly the same. He must go before a Nuremberg trial for crimes against humanity when he *knows* that he

is censoring legitimate concerns and denying the right of informed consent on behalf of the Cult that owns him. People have been killed and damaged by the very 'vaccination' technique he cast doubt on himself when they may not have had the 'vaccine' with access to information that he denied them. The plan is to have at least annual 'Covid vaccinations', add others to deal with invented 'variants', and change all other vaccines into the mRNA system. Pfizer executives told shareholders at a virtual Barclays Global Healthcare Conference in March, 2021, that the public may need a third dose of 'Covid vaccine', plus regular yearly boosters and the company planned to hike prices to milk the profits in a 'significant opportunity for our vaccine'. These are the professional liars, cheats and opportunists who are telling you their 'vaccine' is safe. Given this volume of mRNA planned to be infused into the human body and its ability to then replicate we will have a transformation of human genetics from biological to synthetic biological – exactly the long-time Cult plan for reasons we'll see – and many will die. Sherri Tenpenny said of this replication:

> It's like having an on-button but no off-button and that whole mechanism … they actually give it a name and they call it the Trojan horse mechanism, because it allows that [synthetic] virus and that piece of that [synthetic] virus to get inside of your cells, start to replicate and even get inserted into other parts of your DNA as a Trojan-horse.

Ask the overwhelming majority of people who have the 'vaccine' what they know about the contents and what they do and they would reply: 'The government says it will stop me getting the virus.' Governments give that false impression on purpose to increase take-up. You can read Sherri Tenpenny's detailed analysis of the health consequences in her blog at Vaxxter.com, but in summary these are some of them. She highlights the statement by Bill Gates about how human beings can become their own 'vaccine manufacturing machine'. The man is insane. ['Vaccine'-generated] 'antibodies' carry synthetic messenger RNA into the cells and the damage starts, Tenpenny contends, and she says that lungs can be adversely affected through varying degrees of pus and bleeding which

obviously affects breathing and would be dubbed 'Covid-19'. Even more sinister was the impact of 'antibodies' on macrophages, a white blood cell of the immune system. They consist of Type 1 and Type 2 which have very different functions. She said Type 1 are 'hyper-vigilant' white blood cells which 'gobble up' bacteria etc. However, in doing so, this could cause inflammation and in extreme circumstances be fatal. She says these affects are mitigated by Type 2 macrophages which kick in to calm down the system and stop it going rogue. They clear up dead tissue debris and reduce inflammation that the Type 1 'fire crews' have caused. Type 1 kills the infection and Type 2 heals the damage, she says. This is her punchline with regard to 'Covid vaccinations': She says that mRNA 'antibodies' block Type 2 macrophages by attaching to them and deactivating them. This meant that when the Type 1 response was triggered by infection there was nothing to stop that getting out of hand by calming everything down. There's an on-switch, but no off-switch, she says. What follows can be 'over and out, see you when I see you'.

Genetic suicide

Tenpenny also highlights the potential for autoimmune disease – the body attacking itself – which has been associated with vaccines since they first appeared. Infusing a synthetic foreign substance into cells could cause the immune system to react in a panic believing that the body is being overwhelmed by an invader (it is) and the consequences can again be fatal. There is an autoimmune response known as a 'cytokine storm' which I have likened to a homeowner panicked by an intruder and picking up a gun to shoot randomly in all directions before turning the fire on himself. The immune system unleashes a storm of inflammatory response called cytokines to a threat and the body commits hara-kiri. The lesson is that you mess with the body's immune response at your peril and these 'vaccines' seriously – fundamentally – mess with immune response. Tenpenny refers to a consequence called anaphylactic shock which is a severe and highly dangerous allergic reaction when the immune system

floods the body with chemicals. She gives the example of having a bee sting which primes the immune system and makes it sensitive to those chemicals. When people are stung again maybe years later the immune response can be so powerful that it leads to anaphylactic shock. Tenpenny relates this 'shock' with regard to the 'Covid vaccine' to something called polyethylene glycol or PEG. Enormous numbers of people have become sensitive to this over decades of use in a whole range of products and processes including food, drink, skin creams and 'medicine'. Studies have claimed that some 72 percent of people have antibodies triggered by PEG compared with two percent in the 1960s and allergic hypersensitive reactions to this become a gathering cause for concern. Tenpenny points out that the 'mRNA vaccine' is coated in a 'bubble' of polyethylene glycol which has the potential to cause anaphylactic shock through immune sensitivity. Many reports have appeared of people reacting this way after having the 'Covid vaccine'. What do we think is going to happen as humanity has more and more of these 'vaccines'? Tenpenny said: 'All these pictures we have seen with people with these rashes … these weepy rashes, big reactions on their arms and things like that – it's an acute allergic reaction most likely to the polyethylene glycol that you've been previously primed and sensitised to.'

Those who have not studied the conspiracy and its perpetrators at length might think that making the population sensitive to PEG and then putting it in these 'vaccines' is just a coincidence. It is not. It is instead testament to how carefully and coldly-planned current events have been and the scale of the conspiracy we are dealing with. Tenpenny further explains that the 'vaccine' mRNA procedure can breach the blood-brain barrier which protects the brain from toxins and other crap that will cause malfunction. In this case they could make two proteins corrupt brain function to cause Amyotrophic lateral sclerosis (ALS) , a progressive nervous system disease leading to loss of muscle control, and frontal lobe degeneration – Alzheimer's and dementia. Immunologist J. Bart Classon published a paper connecting mRNA 'vaccines' to prion

disease which can lead to Alzheimer's and other forms of neurogenerative disease while others have pointed out the potential to affect the placenta in ways that make women infertile. This will become highly significant in the next chapter when I will discuss other aspects of this non-vaccine that relate to its nanotechnology and transmission from the injected to the uninjected.

Qualified in idiocy

Tenpenny describes how research has confirmed that these 'vaccine'-generated antibodies can interact with a range of other tissues in the body and attack many other organs including the lungs. 'This means that if you have a hundred people standing in front of you that all got this shot they could have a hundred different symptoms.' Anyone really think that Cult gofers like the Queen, Tony Blair, Christopher Whitty, Anthony Fauci, and all the other psychopaths have really had this 'vaccine' in the pictures we've seen? Not a bloody chance. Why don't doctors all tell us about all these dangers and consequences of the 'Covid vaccine'? Why instead do they encourage and pressure patients to have the shot? Don't let's think for a moment that doctors and medical staff can't be stupid, lazy, and psychopathic and that's without the financial incentives to give the jab. Tenpenny again:

> Some people are going to die from the vaccine directly but a large number of people are going to start to get horribly sick and get all kinds of autoimmune diseases 42 days to maybe a year out. What are they going to do, these stupid doctors who say; 'Good for you for getting that vaccine.' What are they going to say; 'Oh, it must be a mutant, we need to give an extra dose of that vaccine.'
>
> Because now the vaccine, instead of one dose or two doses we need three or four because the stupid physicians aren't taking the time to learn anything about it. If I can learn this sitting in my living room reading a 19 page paper and several others so can they. There's nothing special about me, I just take the time to do it.

Remember how Sara Kayat, the NHS and TV doctor, said that the 'Covid vaccine' would '100 percent prevent hospitalisation and death'. Doctors can be idiots like every other profession and they

should not be worshipped as infallible. They are not and far from it. Behind many medical and scientific 'experts' lies an uninformed prat trying to hide themselves from you although in the 'Covid' era many have failed to do so as with UK narrative-repeating 'TV doctor' Hilary Jones. Pushing back against the minority of proper doctors and scientists speaking out against the 'vaccine' has been the entire edifice of the Cult global state in the form of governments, medical systems, corporations, mainstream media, Silicon Valley, and an army of compliant doctors, medical staff and scientists willing to say anything for money and to enhance their careers by promoting the party line. If you do that you are an 'expert' and if you won't you are an 'anti-vaxxer' and 'Covidiot'. The pressure to be 'vaccinated' is incessant. We have even had reports claiming that the 'vaccine' can help cure cancer and Alzheimer's and make the lame walk. I am waiting for the announcement that it can bring you coffee in the morning and cook your tea. Just as the symptoms of 'Covid' seem to increase by the week so have the miracles of the 'vaccine'. American supermarket giant Kroger Co. offered nearly 500,000 employees in 35 states a $100 bonus for having the 'vaccine' while donut chain Krispy Kreme promised 'vaccinated' customers a free glazed donut every day for the rest of 2021. Have your DNA changed and you will get a doughnut although we might not have to give you them for long. Such offers and incentives confirm the desperation.

Perhaps the worse vaccine-stunt of them all was UK 'Health' Secretary Matt-the-prat Hancock on live TV after watching a clip of someone being 'vaccinated' when the roll-out began. Hancock faked tears so badly it was embarrassing. Brain-of-Britain Piers Morgan, the lockdown-supporting, 'vaccine' supporting, 'vaccine' passport-supporting, TV host played along with Hancock – 'You're quite emotional about that' he said in response to acting so atrocious it would have been called out at a school nativity which will presumably today include Mary and Jesus in masks, wise men keeping their camels six feet apart, and shepherds under tent arrest. System-serving Morgan tweeted this: 'Love the idea of covid vaccine passports for everywhere: flights, restaurants, clubs, football, gyms,

shops etc. It's time covid-denying, anti-vaxxer loonies had their bullsh*t bluff called & bar themselves from going anywhere that responsible citizens go.' If only I could aspire to his genius. To think that Morgan, who specialises in shouting over anyone he disagrees with, was lauded as a free speech hero when he lost his job after storming off the set of his live show like a child throwing his dolly out of the pram. If he is a free speech hero we are in real trouble. I have no idea what 'bullsh*t' means, by the way, the * throws me completely.

The Cult is desperate to infuse its synthetic DNA-changing concoction into everyone and has been using every lie, trick and intimidation to do so. The question of '*Why*?' we shall now address.

CHAPTER TEN

Human 2.0

I believe that at the end of the century the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted –
Alan Turing (1912-1954), the 'Father of artificial intelligence'

I have been exposing for decades the plan to transform the human body from a biological to a synthetic-biological state. The new human that I will call Human 2.0 is planned to be connected to artificial intelligence and a global AI 'Smart Grid' that would operate as one global system in which AI would control everything from your fridge to your heating system to your car to your mind. Humans would no longer be 'human', but post-human and sub-human, with their thinking and emotional processes replaced by AI.

What I said sounded crazy and beyond science fiction and I could understand that. To any balanced, rational, mind it *is* crazy. Today, however, that world is becoming reality and it puts the 'Covid vaccine' into its true context. Ray Kurzweil is the ultra-Zionist 'computer scientist, inventor and futurist' and co-founder of the Singularity University. Singularity refers to the merging of humans with machines or 'transhumanism'. Kurzweil has said humanity would be connected to the cyber 'cloud' in the period of the ever-recurring year of 2030:

Our thinking … will be a hybrid of biological and non-biological thinking … humans will be able to extend their limitations and 'think in the cloud' … We're going to put gateways to the

cloud in our brains ... We're going to gradually merge and enhance ourselves ... In my view, that's the nature of being human – we transcend our limitations. As the technology becomes vastly superior to what we are then the small proportion that is still human gets smaller and smaller and smaller until it's just utterly negligible.

They are trying to sell this end-of-humanity-as-we-know-it as the next stage of 'evolution' when we become super-human and 'like the gods'. They are lying to you. Shocked, eh? The population, and again especially the young, have been manipulated into addiction to technologies designed to enslave them for life. First they induced an addiction to smartphones (holdables); next they moved to technology on the body (wearables); and then began the invasion of the body (implantables). I warned way back about the plan for microchipped people and we are now entering that era. We should not be diverted into thinking that this refers only to chips we can see. Most important are the nanochips known as smart dust, neural dust and nanobots which are far too small to be seen by the human eye. Nanotechnology is everywhere, increasingly in food products, and released into the atmosphere by the geoengineering of the skies funded by Bill Gates to 'shut out the Sun' and 'save the planet from global warming'. Gates has been funding a project to spray millions of tonnes of chalk (calcium carbonate) into the stratosphere over Sweden to 'dim the Sun' and cool the Earth. Scientists warned the move could be disastrous for weather systems in ways no one can predict and opposition led to the Swedish space agency announcing that the 'experiment' would not be happening as planned in the summer of 2021; but it shows where the Cult is going with dimming the impact of the Sun and there's an associated plan to change the planet's atmosphere. Who gives psychopath Gates the right to dictate to the entire human race and dismantle planetary systems? The world will not be safe while this man is at large.

The global warming hoax has made the Sun, like the gas of life, something to fear when both are essential to good health and human survival (more inversion). The body transforms sunlight into vital vitamin D through a process involving … *cholesterol*. This is the cholesterol we are also told to fear. We are urged to take Big Pharma

statin drugs to reduce cholesterol and it's all systematic. Reducing cholesterol means reducing vitamin D uptake with all the multiple health problems that will cause. At least if you take statins long term it saves the government from having to pay you a pension. The delivery system to block sunlight is widely referred to as chemtrails although these have a much deeper agenda, too. They appear at first to be contrails or condensation trails streaming from aircraft into cold air at high altitudes. Contrails disperse very quickly while chemtrails do not and spread out across the sky before eventually their content falls to earth. Many times I have watched aircraft cross-cross a clear blue sky releasing chemtrails until it looks like a cloudy day. Chemtrails contain many things harmful to humans and the natural world including toxic heavy metals, aluminium (see Alzheimer's) and nanotechnology. Ray Kurzweil reveals the reason without actually saying so: 'Nanobots will infuse all the matter around us with information. Rocks, trees, everything will become these intelligent creatures.' How do you deliver that? *From the sky*. Self-replicating nanobots would connect everything to the Smart Grid. The phenomenon of Morgellons disease began in the chemtrail era and the correlation has led to it being dubbed the 'chemtrail disease'. Self-replicating fibres appear in the body that can be pulled out through the skin. Morgellons fibres continue to grow outside the body and have a form of artificial intelligence. I cover this at greater length in *Phantom Self*.

'Vaccine' operating system

'Covid vaccines' with their self-replicating synthetic material are also designed to make the connection between humanity and Kurzweil's 'cloud'. American doctor and dedicated campaigner for truth, Carrie Madej, an Internal Medicine Specialist in Georgia with more than 20 years medical experience, has highlighted the nanotechnology aspect of the fake 'vaccines'. She explains how one of the components in at least the Moderna and Pfizer synthetic potions are 'lipid nanoparticles' which are 'like little tiny computer bits' – a 'sci-fi substance' known as nanobots and hydrogel which can be 'triggered

at any moment to deliver its payload' and act as 'biosensors'. The synthetic substance had 'the ability to accumulate data from your body like your breathing, your respiration, thoughts and emotions, all kind of things' and each syringe could carry a *million* nanobots:

This substance because it's like little bits of computers in your body, crazy, but it's true, it can do that, [and] obviously has the ability to act through Wi-Fi. It can receive and transmit energy, messages, frequencies or impulses. That issue has never been addressed by these companies. What does that do to the human?

Just imagine getting this substance in you and it can react to things all around you, the 5G, your smart device, your phones, what is happening with that? What if something is triggering it, too, like an impulse, a frequency? We have something completely foreign in the human body.

Madej said her research revealed that electromagnetic (EMF) frequencies emitted by phones and other devices had increased dramatically in the same period of the 'vaccine' rollout and she was seeing more people with radiation problems as 5G and other electromagnetic technology was expanded and introduced to schools and hospitals. She said she was 'floored with the EMF coming off' the devices she checked. All this makes total sense and syncs with my own work of decades when you think that Moderna refers in documents to its mRNA 'vaccine' as an 'operating system':

Recognizing the broad potential of mRNA science, we set out to create an mRNA technology platform that functions very much like an operating system on a computer. It is designed so that it can plug and play interchangeably with different programs. In our case, the 'program' or 'app' is our mRNA drug – the unique mRNA sequence that codes for a protein …

… Our MRNA Medicines – 'The 'Software Of Life': When we have a concept for a new mRNA medicine and begin research, fundamental components are already in place. Generally, the only thing that changes from one potential mRNA medicine to another is the coding region – the actual genetic code that instructs ribosomes to make protein. Utilizing these instruction sets gives our investigational mRNA medicines a software-like quality. We also have the ability to combine different mRNA sequences encoding for different proteins in a single mRNA investigational medicine.

Who needs a real 'virus' when you can create a computer version to justify infusing your operating system into the entire human race on the road to making living, breathing people into cyborgs? What is missed with the 'vaccines' is the *digital* connection between synthetic material and the body that I highlighted earlier with the study that hacked a computer with human DNA. On one level the body is digital, based on mathematical codes, and I'll have more about that in the next chapter. Those who ridiculously claim that mRNA 'vaccines' are not designed to change human genetics should explain the words of Dr Tal Zaks, chief medical officer at Moderna, in a 2017 TED talk. He said that over the last 30 years 'we've been living this phenomenal digital scientific revolution, and I'm here today to tell you, that we are actually *hacking the software of life*, and that it's changing the way we think about prevention and treatment of disease':

In every cell there's this thing called messenger RNA, or mRNA for short, that transmits the critical information from the DNA in our genes to the protein, which is really the stuff we're all made out of. This is the critical information that determines what the cell will do. So we think about it as an operating system. So if you could change that, if you could introduce a line of code, or change a line of code, it turns out, that has profound implications for everything, from the flu to cancer.

Zaks should more accurately have said that this has profound implications for the human genetic code and the nature of DNA. Communications within the body go both ways and not only one. But, hey, no, the 'Covid vaccine' will not affect your genetics. Cult fact-checkers say so even though the man who helped to develop the mRNA technique says that it does. Zaks said in 2017:

If you think about what it is we're trying to do. We've taken information and our understanding of that information and how that information is transmitted in a cell, and we've taken our understanding of medicine and how to make drugs, and we're fusing the two. We think of it as information therapy.

I have been writing for decades that the body is an information field communicating with itself and the wider world. This is why

radiation which is information can change the information field of body and mind through phenomena like 5G and change their nature and function. 'Information therapy' means to change the body's information field and change the way it operates. DNA is a receiver-transmitter of information and can be mutated by information like mRNA synthetic messaging. Technology to do this has been ready and waiting in the underground bases and other secret projects to be rolled out when the 'Covid' hoax was played. 'Trials' of such short and irrelevant duration were only for public consumption. When they say the 'vaccine' is 'experimental' that is not true. It may appear to be 'experimental' to those who don't know what's going on, but the trials have already been done to ensure the Cult gets the result it desires. Zaks said that it took decades to sequence the human genome, completed in 2003, but now they could do it in a week. By 'they' he means scientists operating in the public domain. In the secret projects they were sequencing the genome in a week long before even 2003.

Deluge of mRNA

Highly significantly the Moderna document says the guiding premise is that if using mRNA as a medicine works for one disease then it should work for many diseases. They were leveraging the flexibility afforded by their platform and the fundamental role mRNA plays in protein synthesis to pursue mRNA medicines for a broad spectrum of diseases. Moderna is confirming what I was saying through 2020 that multiple 'vaccines' were planned for 'Covid' (and later invented 'variants') and that previous vaccines would be converted to the mRNA system to infuse the body with massive amounts of genetically-manipulating synthetic material to secure a transformation to a synthetic-biological state. The 'vaccines' are designed to kill stunning numbers as part of the long-exposed Cult depopulation agenda and transform the rest. Given this is the goal you can appreciate why there is such hysterical demand for every human to be 'vaccinated' for an alleged 'disease' that has an estimated 'infection' to 'death' ratio of 0.23-0.15 percent. As I write

children are being given the 'vaccine' in trials (their parents are a disgrace) and ever-younger people are being offered the vaccine for a 'virus' that even if you believe it exists has virtually zero chance of harming them. Horrific effects of the 'trials' on a 12-year-old girl were revealed by a family member to be serious brain and gastric problems that included a bowel obstruction and the inability to swallow liquids or solids. She was unable to eat or drink without throwing up, had extreme pain in her back, neck and abdomen, and was paralysed from the waist down which stopped her urinating unaided. When the girl was first taken to hospital doctors said it was all in her mind. She was signed up for the 'trial' by her parents for whom no words suffice. None of this 'Covid vaccine' insanity makes any sense unless you see what the 'vaccine' really is – a body-changer. Synthetic biology or 'SynBio' is a fast-emerging and expanding scientific discipline which includes everything from genetic and molecular engineering to electrical and computer engineering. Synthetic biology is defined in these ways:

- A multidisciplinary area of research that seeks to create new biological parts, devices, and systems, or to redesign systems that are already found in nature.

- The use of a mixture of physical engineering and genetic engineering to create new (and therefore synthetic) life forms.

- An emerging field of research that aims to combine the knowledge and methods of biology, engineering and related disciplines in the design of chemically-synthesized DNA to create organisms with novel or enhanced characteristics and traits (synthetic organisms including humans).

We now have synthetic blood, skin, organs and limbs being developed along with synthetic body parts produced by 3D printers. These are all elements of the synthetic human programme and this comment by Kurzweil's co-founder of the Singularity University,

Peter Diamandis, can be seen in a whole new light with the 'Covid' hoax and the sanctions against those that refuse the 'vaccine':

Anybody who is going to be resisting the progress forward [to transhumanism] is going to be resisting evolution and, fundamentally, they will die out. It's not a matter of whether it's good or bad. It's going to happen.

'Resisting evolution'? What absolute bollocks. The arrogance of these people is without limit. His 'it's going to happen' mantra is another way of saying 'resistance is futile' to break the spirit of those pushing back and we must not fall for it. Getting this genetically-transforming 'vaccine' into everyone is crucial to the Cult plan for total control and the desperation to achieve that is clear for anyone to see. Vaccine passports are a major factor in this and they, too, are a form of resistance is futile. It's NOT. The paper funded by the Rockefeller Foundation for the 2013 'health conference' in China said:

We will interact more with artificial intelligence. The use of robotics, bio-engineering to augment human functioning is already well underway and will advance. Re-engineering of humans into potentially separate and unequal forms through genetic engineering or mixed human-robots raises debates on ethics and equality.

A new demography is projected to emerge after 2030 [that year again] of technologies (robotics, genetic engineering, nanotechnology) producing robots, engineered organisms, 'nanobots' and artificial intelligence (AI) that can self-replicate. Debates will grow on the implications of an impending reality of human designed life.

What is happening today is so long planned. The world army enforcing the will of the world government is intended to be a robot army, not a human one. Today's military and its technologically 'enhanced' troops, pilotless planes and driverless vehicles are just stepping stones to that end. Human soldiers are used as Cult fodder and its time they woke up to that and worked for the freedom of the population instead of their own destruction and their family's destruction – the same with the police. Join us and let's sort this out. The phenomenon of enforce my own destruction is widespread in the 'Covid' era with Woker 'luvvies' in the acting and entertainment

industries supporting 'Covid' rules which have destroyed their profession and the same with those among the public who put signs on the doors of their businesses 'closed due to Covid – stay safe' when many will never reopen. It's a form of masochism and most certainly insanity.

Transgender = transhumanism

When something explodes out of nowhere and is suddenly everywhere it is always the Cult agenda and so it is with the tidal wave of claims and demands that have infiltrated every aspect of society under the heading of 'transgenderism'. The term 'trans' is so 'in' and this is the dictionary definition:

A prefix meaning 'across', 'through', occurring … in loanwords from Latin, used in particular for denoting movement or conveyance from place to place (transfer; transmit; transplant) or complete change (transform; transmute), or to form adjectives meaning 'crossing', 'on the other side of', or 'going beyond' the place named (transmontane; transnational; trans-Siberian).

Transgender means to go beyond gender and transhuman means to go beyond human. Both are aspects of the Cult plan to transform the human body to a synthetic state with *no gender*. Human 2.0 is not designed to procreate and would be produced technologically with no need for parents. The new human would mean the end of parents and so men, and increasingly women, are being targeted for the deletion of their rights and status. Parental rights are disappearing at an ever-quickening speed for the same reason. The new human would have no need for men or women when there is no procreation and no gender. Perhaps the transgender movement that appears to be in a permanent state of frenzy might now contemplate on how it is being used. This was never about transgender rights which are only the interim excuse for confusing gender, particularly in the young, on the road to *fusing* gender. Transgender activism is not an end; it is a *means* to an end. We see again the technique of creative destruction in which you destroy the status quo to 'build back better' in the form that you want. The gender status quo had to be

destroyed by persuading the Cult-created Woke mentality to believe that you can have 100 genders or more. A programme for 9 to 12 year olds produced by the Cult-owned BBC promoted the 100 genders narrative. The very idea may be the most monumental nonsense, but it is not what is true that counts, only what you can make people *believe* is true. Once the gender of 2 + 2 = 4 has been dismantled through indoctrination, intimidation and 2 + 2 = 5 then the new no-gender normal can take its place with Human 2.0. Aldous Huxley revealed the plan in his prophetic *Brave New World* in 1932:

> Natural reproduction has been done away with and children are created, decanted', and raised in 'hatcheries and conditioning centres'. From birth, people are genetically designed to fit into one of five castes, which are further split into 'Plus' and 'Minus' members and designed to fulfil predetermined positions within the social and economic strata of the World State.

How could Huxley know this in 1932? For the same reason George Orwell knew about the Big Brother state in 1948, Cult insiders I have quoted knew about it in 1969, and I have known about it since the early 1990s. If you are connected to the Cult or you work your balls off to uncover the plan you can predict the future. The process is simple. If there is a plan for the world and nothing intervenes to stop it then it will happen. Thus if you communicate the plan ahead of time you are perceived to have predicted the future, but you haven't. You have revealed the plan which without intervention will become the human future. The whole reason I have done what I have is to alert enough people to inspire an intervention and maybe at last that time has come with the Cult and its intentions now so obvious to anyone with a brain in working order.

The future is here

Technological wombs that Huxley described to replace parent procreation are already being developed and they are only the projects we know about in the public arena. Israeli scientists told *The Times of Israel* in March, 2021, that they have grown 250-cell embryos

into mouse foetuses with fully formed organs using artificial wombs in a development they say could pave the way for gestating humans outside the womb. Professor Jacob Hanna of the Weizmann Institute of Science said:

> We took mouse embryos from the mother at day five of development, when they are just of 250 cells, and had them in the incubator from day five until day 11, by which point they had grown all their organs.
>
> By day 11 they make their own blood and have a beating heart, a fully developed brain. Anybody would look at them and say, 'this is clearly a mouse foetus with all the characteristics of a mouse.' It's gone from being a ball of cells to being an advanced foetus.

A special liquid is used to nourish embryo cells in a laboratory dish and they float on the liquid to duplicate the first stage of embryonic development. The incubator creates all the right conditions for its development, Hanna said. The liquid gives the embryo 'all the nutrients, hormones and sugars they need' along with a custom-made electronic incubator which controls gas concentration, pressure and temperature. The cutting-edge in the underground bases and other secret locations will be light years ahead of that, however, and this was reported by the London *Guardian* in 2017:

> We are approaching a biotechnological breakthrough. Ectogenesis, the invention of a complete external womb, could completely change the nature of human reproduction. In April this year, researchers at the Children's Hospital of Philadelphia announced their development of an artificial womb.

The article was headed 'Artificial wombs could soon be a reality. What will this mean for women?' What would it mean for children is an even bigger question. No mother to bond with only a machine in preparation for a life of soulless interaction and control in a world governed by machines (see the *Matrix* movies). Now observe the calculated manipulations of the 'Covid' hoax as human interaction and warmth has been curtailed by distancing, isolation and fear with people communicating via machines on a scale never seen before.

These are all dots in the same picture as are all the personal assistants, gadgets and children's toys through which kids and adults communicate with AI as if it is human. The AI 'voice' on Sat-Nav should be included. All these things are psychological preparation for the Cult endgame. Before you can make a physical connection with AI you have to make a psychological connection and that is what people are being conditioned to do with this ever gathering human-AI interaction. Movies and TV programmes depicting the transhuman, robot dystopia relate to a phenomenon known as 'pre-emptive programming' in which the world that is planned is portrayed everywhere in movies, TV and advertising. This is conditioning the conscious and subconscious mind to become familiar with the planned reality to dilute resistance when it happens for real. What would have been a shock such is the change is made less so. We have young children put on the road to transgender transition surgery with puberty blocking drugs at an age when they could never be able to make those life-changing decisions.

Rachel Levine, a professor of paediatrics and psychiatry who believes in treating children this way, became America's highest-ranked openly-transgender official when she was confirmed as US Assistant Secretary at the Department of Health and Human Services after being nominated by Joe Biden (the Cult). Activists and governments press for laws to deny parents a say in their children's transition process so the kids can be isolated and manipulated into agreeing to irreversible medical procedures. A Canadian father Robert Hoogland was denied bail by the Vancouver Supreme Court in 2021 and remained in jail for breaching a court order that he stay silent over his young teenage daughter, a minor, who was being offered life-changing hormone therapy without parental consent. At the age of 12 the girl's 'school counsellor' said she may be transgender, referred her to a doctor and told the school to treat her like a boy. This is another example of state-serving schools imposing ever more control over children's lives while parents have ever less.

Contemptible and extreme child abuse is happening all over the world as the Cult gender-fusion operation goes into warp-speed.

Why the war on men – and now women?

The question about what artificial wombs mean for women should rightly be asked. The answer can be seen in the deletion of women's rights involving sport, changing rooms, toilets and status in favour of people in male bodies claiming to identify as women. I can identify as a mountain climber, but it doesn't mean I can climb a mountain any more than a biological man can be a biological woman. To believe so is a triumph of belief over factual reality which is the very perceptual basis of everything Woke. Women's sport is being destroyed by allowing those with male bodies who say they identify as female to 'compete' with girls and women. Male body 'women' dominate 'women's' competition with their greater muscle mass, bone density, strength and speed. With that disadvantage sport for women loses all meaning. To put this in perspective nearly 300 American high school boys can run faster than the quickest woman sprinter in the world. Women are seeing their previously protected spaces invaded by male bodies simply because they claim to identify as women. That's all they need to do to access all women's spaces and activities under the Biden 'Equality Act' that destroys equality for women with the usual Orwellian Woke inversion. Male sex offenders have already committed rapes in women's prisons after claiming to identify as women to get them transferred. Does this not matter to the Woke 'equality' hypocrites? Not in the least. What matters to Cult manipulators and funders behind transgender activists is to advance gender fusion on the way to the no-gender 'human'. When you are seeking to impose transparent nonsense like this, or the 'Covid' hoax, the only way the nonsense can prevail is through censorship and intimidation of dissenters, deletion of factual information, and programming of the unquestioning, bewildered and naive. You don't have to scan the world for long to see that all these things are happening.

Many women's rights organisations have realised that rights and status which took such a long time to secure are being eroded and that it is systematic. Kara Dansky of the global Women's Human Rights Campaign said that Biden's transgender executive order immediately he took office, subsequent orders, and Equality Act legislation that followed 'seek to erase women and girls in the law as a category'. *Exactly*. I said during the long ago-started war on men (in which many women play a crucial part) that this was going to turn into a war on them. The Cult is phasing out *both* male and female genders. To get away with that they are brought into conflict so they are busy fighting each other while the Cult completes the job with no unity of response. Unity, people, *unity*. We need unity everywhere. Transgender is the only show in town as the big step towards the no-gender human. It's not about rights for transgender people and never has been. Woke political correctness is deleting words relating to genders to the same end. Wokers believe this is to be 'inclusive' when the opposite is true. They are deleting words describing gender because gender *itself* is being deleted by Human 2.0. Terms like 'man', 'woman', 'mother' and 'father' are being deleted in the universities and other institutions to be replaced by the *no*-gender, not trans-gender, 'individuals' and 'guardians'. Women's rights campaigner Maria Keffler of Partners for Ethical Care said: 'Children are being taught from kindergarten upward that some boys have a vagina, some girls have a penis, and that kids can be any gender they want to be.' Do we really believe that suddenly countries all over the world at the same time had the idea of having drag queens go into schools or read transgender stories to very young children in the local library? It's coldly-calculated confusion of gender on the way to the fusion of gender. Suzanne Vierling, a psychologist from Southern California, made another important point:

> Yesterday's slave woman who endured gynecological medical experiments is today's girl-child being butchered in a booming gender-transitioning sector. Ovaries removed, pushing her into menopause and osteoporosis, uncharted territory, and parents' rights and authority decimated.

The erosion of parental rights is a common theme in line with the Cult plans to erase the very concept of parents and 'ovaries removed, pushing her into menopause' means what? Those born female lose the ability to have children – another way to discontinue humanity as we know it.

Eliminating Human 1.0 (before our very eyes)

To pave the way for Human 2.0 you must phase out Human 1.0. This is happening through plummeting sperm counts and making women infertile through an onslaught of chemicals, radiation (including smartphones in pockets of men) and mRNA 'vaccines'. Common agriculture pesticides are also having a devastating impact on human fertility. I have been tracking collapsing sperm counts in the books for a long time and in 2021 came a book by fertility scientist and reproductive epidemiologist Shanna Swan, *Count Down: How Our Modern World Is Threatening Sperm Counts, Altering Male and Female Reproductive Development and Imperiling the Future of the Human Race*. She reports how the global fertility rate dropped by *half* between 1960 and 2016 with America's birth rate 16 percent below where it needs to be to sustain the population. Women are experiencing declining egg quality, more miscarriages, and more couples suffer from infertility. Other findings were an increase in erectile dysfunction, infant boys developing more genital abnormalities, male problems with conception, and plunging levels of the male hormone testosterone which would explain why so many men have lost their backbone and masculinity. This has been very evident during the 'Covid' hoax when women have been prominent among the Pushbackers and big strapping blokes have bowed their heads, covered their faces with a nappy and quietly submitted. Mind control expert Cathy O'Brien also points to how global education introduced the concept of 'we're all winners' in sport and classrooms: 'Competition was defused, and it in turn defused a sense of fighting back.' This is another version of the 'equity' doctrine in which you drive down rather than raise up. What a contrast in Cult-controlled China with its global ambitions

where the government published plans in January, 2021, to 'cultivate masculinity' in boys from kindergarten through to high school in the face of a 'masculinity crisis'. A government adviser said boys would be soon become 'delicate, timid and effeminate' unless action was taken. Don't expect any similar policy in the targeted West. A 2006 study showed that a 65-year-old man in 2002 had testosterone levels *15 percent* lower than a 65-year-old man in 1987 while a 2020 study found a similar story with young adults and adolescents. Men are getting prescriptions for testosterone replacement therapy which causes an even greater drop in sperm count with up to 99 percent seeing sperm counts drop to zero during the treatment. More sperm is defective and malfunctioning with some having two heads or not pursuing an egg.

A class of *synthetic* chemicals known as phthalates are being blamed for the decline. These are found everywhere in plastics, shampoos, cosmetics, furniture, flame retardants, personal care products, pesticides, canned foods and even receipts. Why till receipts? Everyone touches them. Let no one delude themselves that all this is not systematic to advance the long-time agenda for human body transformation. Phthalates mimic hormones and disrupt the hormone balance causing testosterone to fall and genital birth defects in male infants. Animals and fish have been affected in the same way due to phthalates and other toxins in rivers. When fish turn gay or change sex through chemicals in rivers and streams it is a pointer to why there has been such an increase in gay people and the sexually confused. It doesn't matter to me what sexuality people choose to be, but if it's being affected by chemical pollution and consumption then we need to know. Does anyone really think that this is not connected to the transgender agenda, the war on men and the condemnation of male 'toxic masculinity'? You watch this being followed by 'toxic femininity'. It's already happening. When breastfeeding becomes 'chest-feeding', pregnant women become pregnant people along with all the other Woke claptrap you know that the world is going insane and there's a Cult scam in progress. Transgender activists are promoting the Cult agenda while Cult

billionaires support and fund the insanity as they laugh themselves to sleep at the sheer stupidity for which humans must be infamous in galaxies far, far away.

'Covid vaccines' and female infertility

We can now see why the 'vaccine' has been connected to potential infertility in women. Dr Michael Yeadon, former Vice President and Chief Scientific Advisor at Pfizer, and Dr Wolfgang Wodarg in Germany, filed a petition with the European Medicines Agency in December, 2020, urging them to stop trials for the Pfizer/BioNTech shot and all other mRNA trials until further studies had been done. They were particularly concerned about possible effects on fertility with 'vaccine'-produced antibodies attacking the protein Syncytin-1 which is responsible for developing the placenta. The result would be infertility 'of indefinite duration' in women who have the 'vaccine' with the placenta failing to form. Section 10.4.2 of the Pfizer/BioNTech trial protocol says that pregnant women or those who might become so should not have mRNA shots. Section 10.4 warns men taking mRNA shots to 'be abstinent from heterosexual intercourse' and not to donate sperm. The UK government said that it *did not know* if the mRNA procedure had an effect on fertility. *Did not know?* These people have to go to jail. UK government advice did not recommend at the start that pregnant women had the shot and said they should avoid pregnancy for at least two months after 'vaccination'. The 'advice' was later updated to pregnant women should only have the 'vaccine' if the benefits outweighed the risks to mother and foetus. What the hell is that supposed to mean? Then 'spontaneous abortions' began to appear and rapidly increase on the adverse reaction reporting schemes which include only a fraction of adverse reactions. Thousands and ever-growing numbers of 'vaccinated' women are describing changes to their menstrual cycle with heavier blood flow, irregular periods and menstruating again after going through the menopause – all links to reproduction effects. Women are passing blood clots and the lining of their uterus while men report erectile dysfunction and blood effects. Most

significantly of all *un*vaccinated women began to report similar menstrual changes after interaction with *'vaccinated'* people and men and children were also affected with bleeding noses, blood clots and other conditions. 'Shedding' is when vaccinated people can emit the content of a vaccine to affect the unvaccinated, but this is different. 'Vaccinated' people were not shedding a 'live virus' allegedly in 'vaccines' as before because the fake 'Covid vaccines' involve synthetic material and other toxicity. Doctors exposing what is happening prefer the term 'transmission' to shedding. Somehow those that have had the shots are transmitting effects to those that haven't. Dr Carrie Madej said the nano-content of the 'vaccines' can 'act like an antenna' to others around them which fits perfectly with my own conclusions. This 'vaccine' transmission phenomenon was becoming known as the book went into production and I deal with this further in the Postscript.

Vaccine effects on sterility are well known. The World Health Organization was accused in 2014 of sterilising millions of women in Kenya with the evidence confirmed by the content of the vaccines involved. The same WHO behind the 'Covid' hoax admitted its involvement for more than ten years with the vaccine programme. Other countries made similar claims. Charges were lodged by Tanzania, Nicaragua, Mexico, and the Philippines. The Gardasil vaccine claimed to protect against a genital 'virus' known as HPV has also been linked to infertility. Big Pharma and the WHO (same thing) are criminal and satanic entities. Then there's the Bill Gates Foundation which is connected through funding and shared interests with 20 pharmaceutical giants and laboratories. He stands accused of directing the policy of United Nations Children's Fund (UNICEF), vaccine alliance GAVI, and other groupings, to advance the vaccine agenda and silence opposition at great cost to women and children. At the same time Gates wants to reduce the global population. Coincidence?

Great Reset = Smart Grid = new human

The Cult agenda I have been exposing for 30 years is now being openly promoted by Cult assets like Gates and Klaus Schwab of the World Economic Forum under code-terms like the 'Great Reset', 'Build Back Better' and 'a rare but narrow window of opportunity to reflect, reimagine, and reset our world'. What provided this 'rare but narrow window of opportunity'? The 'Covid' hoax did. Who created that? *They* did. My books from not that long ago warned about the planned 'Internet of Things' (IoT) and its implications for human freedom. This was the plan to connect all technology to the Internet and artificial intelligence and today we are way down that road with an estimated 36 billion devices connected to the World Wide Web and that figure is projected to be 76 billion by 2025. I further warned that the Cult planned to go beyond that to the Internet of *Everything* when the human brain was connected via AI to the Internet and Kurzweil's 'cloud'. Now we have Cult operatives like Schwab calling for precisely that under the term 'Internet of Bodies', a fusion of the physical, digital and biological into one centrally-controlled Smart Grid system which the Cult refers to as the 'Fourth Industrial Revolution'. They talk about the 'biological', but they really mean the synthetic-biological which is required to fully integrate the human body and brain into the Smart Grid and artificial intelligence planned to replace the human mind. We have everything being synthetically manipulated including the natural world through GMO and smart dust, the food we eat and the human body itself with synthetic 'vaccines'. I said in *The Answer* that we would see the Cult push for synthetic meat to replace animals and in February, 2021, the so predictable psychopath Bill Gates called for the introduction of synthetic meat to save us all from 'climate change'. The climate hoax just keeps on giving like the 'Covid' hoax. The war on meat by vegan activists is a carbon (oops, sorry) copy of the manipulation of transgender activists. They have no idea (except their inner core) that they are being used to promote and impose the agenda of the Cult or that they are only the *vehicle* and not the *reason*. This is not to say those who choose not to eat meat shouldn't be respected and supported in that right, but there are ulterior motives

for those in power. A *Forbes* article in December, 2019, highlighted the plan so beloved of Schwab and the Cult under the heading: 'What Is The Internet of Bodies? And How Is It Changing Our World?' The article said the human body is the latest data platform (remember 'our vaccine is an operating system'). *Forbes* described the plan very accurately and the words could have come straight out of my books from long before:

The Internet of Bodies (IoB) is an extension of the IoT and basically connects the human body to a network through devices that are ingested, implanted, or connected to the body in some way. Once connected, data can be exchanged, and the body and device can be remotely monitored and controlled.

They were really describing a human hive mind with human perception centrally-dictated via an AI connection as well as allowing people to be 'remotely monitored and controlled'. Everything from a fridge to a human mind could be directed from a central point by these insane psychopaths and 'Covid vaccines' are crucial to this. Forbes explained the process I mentioned earlier of holdable and wearable technology followed by implantable. The article said there were three generations of the Internet of Bodies that include:

- Body external: These are wearable devices such as Apple Watches or Fitbits that can monitor our health.

- Body internal: These include pacemakers, cochlear implants, and digital pills that go inside our bodies to monitor or control various aspects of health.

- Body embedded: The third generation of the Internet of Bodies is embedded technology where technology and the human body are melded together and have a real-time connection to a remote machine.

Forbes noted the development of the Brain Computer Interface (BCI) which merges the brain with an external device for monitoring and controlling in real-time. 'The ultimate goal is to help restore function to individuals with disabilities by using brain signals rather than conventional neuromuscular pathways.' Oh, do fuck off. The goal of brain interface technology is controlling human thought and emotion from the central point in a hive mind serving its masters wishes. Many people are now agreeing to be chipped to open doors without a key. You can recognise them because they'll be wearing a mask, social distancing and lining up for the 'vaccine'. The Cult plans a Great Reset money system after they have completed the demolition of the global economy in which 'money' will be exchanged through communication with body operating systems. Rand Corporation, a Cult-owned think tank, said of the Internet of Bodies or IoB:

> Internet of Bodies technologies fall under the broader IoT umbrella. But as the name suggests, IoB devices introduce an even more intimate interplay between humans and gadgets. IoB devices monitor the human body, collect health metrics and other personal information, and transmit those data over the Internet. Many devices, such as fitness trackers, are already in use … IoB devices … and those in development can track, record, and store users' whereabouts, bodily functions, and what they see, hear, and even think.

Schwab's World Economic Forum, a long-winded way of saying 'fascism' or 'the Cult', has gone full-on with the Internet of Bodies in the 'Covid' era. 'We're entering the era of the Internet of Bodies', it declared, 'collecting our physical data via a range of devices that can be implanted, swallowed or worn'. The result would be a huge amount of health-related data that could improve human wellbeing around the world, and prove crucial in fighting the 'Covid-19 pandemic'. Does anyone think these clowns care about 'human wellbeing' after the death and devastation their pandemic hoax has purposely caused? Schwab and co say we should move forward with the Internet of Bodies because 'Keeping track of symptoms could help us stop the spread of infection, and quickly detect new cases'. How wonderful, but keeping track' is all they are really bothered

about. Researchers were investigating if data gathered from smartwatches and similar devices could be used as viral infection alerts by tracking the user's heart rate and breathing. Schwab said in his 2018 book *Shaping the Future of the Fourth Industrial Revolution*:

> The lines between technologies and beings are becoming blurred and not just by the ability to create lifelike robots or synthetics. Instead it is about the ability of new technologies to literally become part of us. Technologies already influence how we understand ourselves, how we think about each other, and how we determine our realities. As the technologies … give us deeper access to parts of ourselves, we may begin to integrate digital technologies into our bodies.

You can see what the game is. Twenty-four hour control and people – if you could still call them that – would never know when something would go ping and take them out of circulation. It's the most obvious rush to a global fascist dictatorship and the complete submission of humanity and yet still so many are locked away in their Cult-induced perceptual coma and can't see it.

Smart Grid control centres

The human body is being transformed by the 'vaccines' and in other ways into a synthetic cyborg that can be attached to the global Smart Grid which would be controlled from a central point and other sub-locations of Grid manipulation. Where are these planned to be? Well, China for a start which is one of the Cult's biggest centres of operation. The technological control system and technocratic rule was incubated here to be unleashed across the world after the 'Covid' hoax came out of China in 2020. Another Smart Grid location that will surprise people new to this is Israel. I have exposed in *The Trigger* how Sabbatian technocrats, intelligence and military operatives were behind the horrors of 9/11 and not '19 Arab hijackers' who somehow manifested the ability to pilot big passenger airliners when instructors at puddle-jumping flying schools described some of them as a joke. The 9/11 attacks were made possible through control of civilian and military air computer systems and those of the White House, Pentagon and connected agencies. See *The Trigger* – it

will blow your mind. The controlling and coordinating force were the Sabbatian networks in Israel and the United States which by then had infiltrated the entire US government, military and intelligence system. The real name of the American Deep State is 'Sabbatian State'. Israel is a tiny country of only nine million people, but it is one of the global centres of cyber operations and fast catching Silicon Valley in importance to the Cult. Israel is known as the 'start-up nation' for all the cyber companies spawned there with the Sabbatian specialisation of 'cyber security' that I mentioned earlier which gives those companies access to computer systems of their clients in real time through 'backdoors' written into the coding when security software is downloaded. The Sabbatian centre of cyber operations outside Silicon Valley is the Israeli military Cyber Intelligence Unit, the biggest infrastructure project in Israel's history, headquartered in the desert-city of Beersheba and involving some 20,000 'cyber soldiers'. Here are located a literal army of Internet trolls scanning social media, forums and comment lists for anyone challenging the Cult agenda. The UK military has something similar with its 77th Brigade and associated operations. The Beersheba complex includes research and development centres for other Cult operations such as Intel, Microsoft, IBM, Google, Apple, Hewlett-Packard, Cisco Systems, Facebook and Motorola. Techcrunch.com ran an article about the Beersheba global Internet technology centre headlined 'Israel's desert city of Beersheba is turning into a cybertech oasis':

> The military's massive relocation of its prestigious technology units, the presence of multinational and local companies, a close proximity to Ben Gurion University and generous government subsidies are turning Beersheba into a major global cybertech hub. Beersheba has all of the ingredients of a vibrant security technology ecosystem, including Ben Gurion University with its graduate program in cybersecurity and Cyber Security Research Center, and the presence of companies such as EMC, Deutsche Telekom, PayPal, Oracle, IBM, and Lockheed Martin. It's also the future home of the INCB (Israeli National Cyber Bureau); offers a special income tax incentive for cyber security companies, and was the site for the relocation of the army's intelligence corps units.

Sabbatians have taken over the cyber world through the following process: They scan the schools for likely cyber talent and develop them at Ben Gurion University and their period of conscription in the Israeli Defense Forces when they are stationed at the Beersheba complex. When the cyber talented officially leave the army they are funded to start cyber companies with technology developed by themselves or given to them by the state. Much of this is stolen through backdoors of computer systems around the world with America top of the list. Others are sent off to Silicon Valley to start companies or join the major ones and so we have many major positions filled by apparently 'Jewish' but really Sabbatian operatives. Google, YouTube and Facebook are all run by 'Jewish' CEOs while Twitter is all but run by ultra-Zionist hedge-fund shark Paul Singer. At the centre of the Sabbatian global cyber web is the Israeli army's Unit 8200 which specialises in hacking into computer systems of other countries, inserting viruses, gathering information, instigating malfunction, and even taking control of them from a distance. A long list of Sabbatians involved with 9/11, Silicon Valley and Israeli cyber security companies are operatives of Unit 8200. This is not about Israel. It's about the Cult. Israel is planned to be a Smart Grid hub as with China and what is happening at Beersheba is not for the benefit of Jewish people who are treated disgustingly by the Sabbatian elite that control the country. A glance at the Nuremberg Codes will tell you that.

The story is much bigger than 'Covid', important as that is to where we are being taken. Now, though, it's time to really strap in. There's more … much more …

CHAPTER ELEVEN

Who controls the Cult?

Awake, arise or be forever fall'n
John Milton, *Paradise Lost*

I have exposed this far the level of the Cult conspiracy that operates in the world of the seen and within the global secret society and satanic network which operates in the shadows one step back from the seen. The story, however, goes much deeper than that.

The 'Covid' hoax is major part of the Cult agenda, but only part, and to grasp the biggest picture we have to expand our attention beyond the realm of human sight and into the infinity of possibility that we cannot see. It is from here, ultimately, that humanity is being manipulated into a state of total control by the force which dictates the actions of the Cult. How much of reality can we see? Next to damn all is the answer. We may appear to see all there is to see in the 'space' our eyes survey and observe, but little could be further from the truth. The human 'world' is only a tiny band of frequency that the body's visual and perceptual systems can decode into *perception* of a 'world'. According to mainstream science the electromagnetic spectrum is 0.005 percent of what exists in the Universe (Fig 10). The maximum estimate I have seen is 0.5 percent and either way it's miniscule. I say it is far, far, smaller even than 0.005 percent when you compare reality we see with the totality of reality that we don't. Now get this if you are new to such information: Visible light, the only band of frequency that we can see, is a *fraction* of the 0.005

percent (Fig 11 overleaf). Take this further and realise that our universe is one of infinite universes and that universes are only a fragment of overall reality – *infinite* reality. Then compare that with the almost infinitesimal frequency band of visible light or human sight. You see that humans are as near blind as it is possible to be without actually being so. Artist and filmmaker, Sergio Toporek, said:

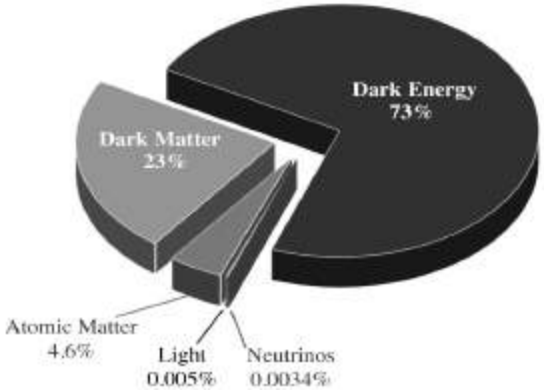

Figure 10: Humans can perceive such a tiny band of visual reality it's laughable.

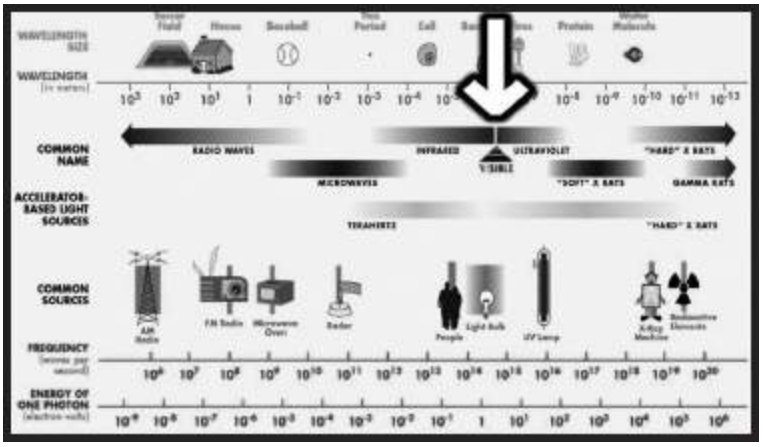

Figure 11: We can see a smear of the 0.005 percent electromagnetic spectrum, but we still know it all. Yep, makes sense.

Consider that you can see less than 1% of the electromagnetic spectrum and hear less than 1% of the acoustic spectrum. 90% of the cells in your body carry their own microbial DNA and are not 'you'. The atoms in your body are 99.9999999999999999% empty space and none of them are the ones you were born with ... Human beings have 46 chromosomes, two less than a potato.

The existence of the rainbow depends on the conical photoreceptors in your eyes; to animals without cones, the rainbow does not exist. So you don't just look at a rainbow, you create it. This is pretty amazing, especially considering that all the beautiful colours you see represent less than 1% of the electromagnetic spectrum.

Suddenly the 'world' of humans looks a very different place. Take into account, too, that Planet Earth when compared with the projected size of this single universe is the equivalent of a billionth of a pinhead. Imagine the ratio that would be when compared to infinite reality. To think that Christianity once insisted that Earth and humanity were the centre of everything. This background is vital if we are going to appreciate the nature of 'human' and how we can be manipulated by an unseen force. To human visual reality virtually *everything* is unseen and yet the prevailing perception within the institutions and so much of the public is that if we can't see it, touch it, hear it, taste it and smell it then it cannot exist. Such perception is indoctrinated and encouraged by the Cult and its agents because it isolates believers in the strictly limited, village-idiot, realm of the five senses where perceptions can be firewalled and information controlled. Most of those perpetuating the 'this-world-is-all-there-is' insanity are themselves indoctrinated into believing the same delusion. While major players and influencers know that official reality is laughable most of those in science, academia and medicine really believe the nonsense they peddle and teach succeeding generations. Those who challenge the orthodoxy are dismissed as nutters and freaks to protect the manufactured illusion from exposure. Observe the dynamic of the 'Covid' hoax and you will see how that takes the same form. The inner-circle psychopaths knows it's a gigantic scam, but almost the entirety of those imposing their fascist rules believe that 'Covid' is all that they're told it is.

Stolen identity

Ask people who they are and they will give you their name, place of birth, location, job, family background and life story. Yet that is not who they are – it is what they are *experiencing*. The difference is *absolutely crucial*. The true 'I', the eternal, infinite 'I', is consciousness,

a state of being aware. Forget 'form'. That is a vehicle for a brief experience. Consciousness does not come *from* the brain, but *through* the brain and even that is more symbolic than literal. We are awareness, pure awareness, and this is what withdraws from the body at what we call 'death' to continue our eternal beingness, *isness*, in other realms of reality within the limitlessness of infinity or the Biblical 'many mansions in my father's house'. Labels of a human life, man, woman, transgender, black, white, brown, nationality, circumstances and income are not who we are. They are what we are – awareness – is *experiencing* in a brief connection with a band of frequency we call 'human'. The labels are not the self; they are, to use the title of one of my books, a *Phantom* Self. I am not David Icke born in Leicester, England, on April 29th, 1952. I am the consciousness *having that experience*. The Cult and its non-human masters seek to convince us through the institutions of 'education', science, medicine, media and government that what we are *experiencing* is who we *are*. It's so easy to control and direct perception locked away in the bewildered illusions of the five senses with no expanded radar. Try, by contrast, doing the same with a humanity aware of its true self and its true power to consciously create its reality and experience. How is it possible to do this? We do it all day every day. If you perceive yourself as 'little me' with no power to impact upon your life and the world then your life experience will reflect that. You will hand the power you don't think you have to authority in all its forms which will use it to control your experience. This, in turn, will appear to confirm your perception of 'little me' in a self-fulfilling feedback loop. But that is what 'little me' really is – a *perception*. We are all 'big-me', infinite me, and the Cult has to make us forget that if its will is to prevail. We are therefore manipulated and pressured into self-identifying with human labels and not the consciousness/awareness *experiencing* those human labels.

The phenomenon of identity politics is a Cult-instigated manipulation technique to sub-divide previous labels into even smaller ones. A United States university employs this list of letters to

describe student identity: LGBTTQQFAGPBDSM or lesbian, gay, bisexual, transgender, transsexual, queer, questioning, flexual, asexual, gender-fuck, polyamorous, bondage/discipline, dominance/submission and sadism/masochism. I'm sure other lists are even longer by now as people feel the need to self-identity the 'I' with the minutiae of race and sexual preference. Wokers programmed by the Cult for generations believe this is about 'inclusivity' when it's really the Cult locking them away into smaller and smaller versions of Phantom Self while firewalling them from the influence of their true self, the infinite, eternal 'I'. You may notice that my philosophy which contends that we are all unique points of attention/awareness within the same infinite whole or Oneness is the ultimate non-racism. The very sense of Oneness makes the judgement of people by their body-type, colour or sexuality utterly ridiculous and confirms that racism has no understanding of reality (including anti-white racism). Yet despite my perception of life Cult agents and fast-asleep Wokers label me racist to discredit my information while they are themselves phenomenally racist and sexist. All they see is race and sexuality and they judge people as good or bad, demons or untouchables, by their race and sexuality. All they see is *Phantom Self* and perceive themselves in terms of Phantom Self. They are pawns and puppets of the Cult agenda to focus attention and self-identity in the five senses and play those identities against each other to divide and rule. Columbia University has introduced segregated graduations in another version of social distancing designed to drive people apart and teach them that different racial and cultural groups have nothing in common with each other. The last thing the Cult wants is unity. Again the pump-primers of this will be Cult operatives in the knowledge of what they are doing, but the rest are just the Phantom Self blind leading the Phantom Self blind. We *do* have something in common – we are all *the same consciousness* having different temporary experiences.

What is this 'human'?

Yes, what *is* 'human'? That is what we are supposed to be, right? I mean 'human'? True, but 'human' is the experience not the 'I'. Break it down to basics and 'human' is the way that information is processed. If we are to experience and interact with this band of frequency we call the 'world' we must have a vehicle that operates within that band of frequency. Our consciousness in its prime form cannot do that; it is way beyond the frequency of the human realm. My consciousness or awareness could not tap these keys and pick up the cup in front of me in the same way that radio station A cannot interact with radio station B when they are on different frequencies. The human body is the means through which we have that interaction. I have long described the body as a biological computer which processes information in a way that allows consciousness to experience this reality. The body is a receiver, transmitter and processor of information in a particular way that we call human. We visually perceive only the world of the five senses in a wakened state – that is the limit of the body's visual decoding system. In truth it's not even visual in the way we experience 'visual reality' as I will come to in a moment. We are 'human' because the body processes the information sources of human into a reality and behaviour system that we *perceive* as human. Why does an elephant act like an elephant and not like a human or a duck? The elephant's biological computer is a different information field and processes information according to that program into a visual and behaviour type we call an elephant. The same applies to everything in our reality. These body information fields are perpetuated through procreation (like making a copy of a software program). The Cult wants to break that cycle and intervene technologically to transform the human information field into one that will change what we call humanity. If it can change the human information field it will change the way that field processes information and change humanity both 'physically' and psychologically. Hence the *messenger* (information) RNA 'vaccines' and so much more that is targeting human genetics by changing the body's information – *messaging* – construct through food, drink, radiation, toxicity and other means.

Reality that we experience is nothing like reality as it really is in the same way that the reality people experience in virtual reality games is not the reality they are really living in. The game is only a decoded source of information that appears to be a reality. Our world is also an information construct – a *simulation* (more later). In its base form our reality is a wavefield of information much the same in theme as Wi-Fi. The five senses decode wavefield information into electrical information which they communicate to the brain to decode into holographic (illusory 'physical') information. Different parts of the brain specialise in decoding different senses and the information is fused into a reality that appears to be outside of us but is really inside the brain and the genetic structure in general (Fig 12 overleaf). DNA is a receiver-transmitter of information and a vital part of this decoding process and the body's connection to other realities. Change DNA and you change the way we decode and connect with reality – see 'Covid vaccines'. Think of computers decoding Wi-Fi. You have information encoded in a radiation field and the computer decodes that information into a very different form on the screen. You can't see the Wi-Fi until its information is made manifest on the screen and the information on the screen is inside the computer and not outside. I have just described how we decode the 'human world'. All five senses decode the waveform 'Wi-Fi' field into electrical signals and the brain (computer) constructs reality inside the brain and not outside – 'You don't just look at a rainbow, you create it'. Sound is a simple example. We don't hear sound until the brain decodes it. Waveform sound waves are picked up by the hearing sense and communicated to the brain in an electrical form to be decoded into the sounds that we hear. Everything we hear is inside the brain along with everything we see, feel, smell and taste. Words and language are waveform fields generated by our vocal chords which pass through this process until they are decoded by the brain into words that we hear. Different languages are different frequency fields or sound waves generated by vocal chords. Late British philosopher Alan Watts said:

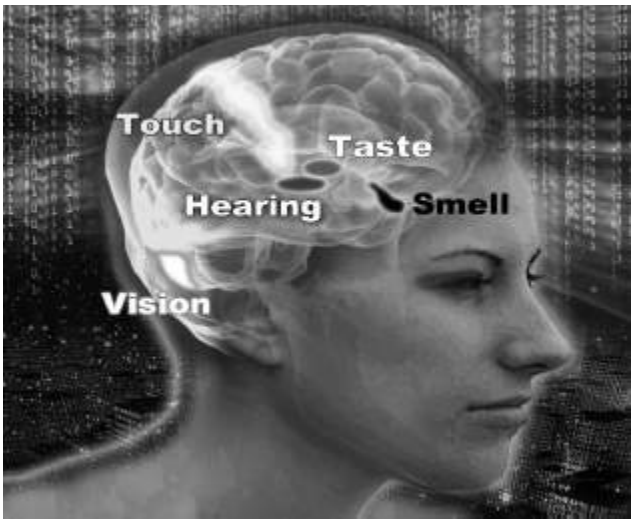

Figure 12: The brain receives information from the five senses and constructs from that our perceived reality.

[Without the brain] the world is devoid of light, heat, weight, solidity, motion, space, time or any other imaginable feature. All these phenomena are interactions, or transactions, of vibrations with a certain arrangement of neurons.

That's exactly what they are and scientist Robert Lanza describes in his book, *Biocentrism*, how we decode electromagnetic waves and energy into visual and 'physical' experience. He uses the example of a flame emitting photons, electromagnetic energy, each pulsing electrically and magnetically:

… these … invisible electromagnetic waves strike a human retina, and if (and only if) the waves happen to measure between 400 and 700 nano meters in length from crest to crest, then their energy is just right to deliver a stimulus to the 8 million cone-shaped cells in the retina.

Each in turn send an electrical pulse to a neighbour neuron, and on up the line this goes, at 250 mph, until it reaches the … occipital lobe of the brain, in the back of the head. There, a cascading complex of neurons fire from the incoming stimuli, and we subjectively perceive this experience as a yellow brightness occurring in a place we have been conditioned to call the 'external world'.

You hear what you decode

If a tree falls or a building collapses they make no noise unless someone is there to decode the energetic waves generated by the disturbance into what we call sound. Does a falling tree make a noise? Only if you hear it – *decode* it. Everything in our reality is a frequency field of information operating within the overall 'Wi-Fi' field that I call The Field. A vibrational disturbance is generated in The Field by the fields of the falling tree or building. These disturbance waves are what we decode into the sound of them falling. If no one is there to do that then neither will make any noise. Reality is created by the observer – *decoder* – and the *perceptions* of the observer affect the decoding process. For this reason different people – different *perceptions* – will perceive the same reality or situation in a different way. What one may perceive as a nightmare another will see as an opportunity. The question of why the Cult is so focused on controlling human perception now answers itself. All experienced reality is the act of decoding and we don't experience Wi-Fi until it is decoded on the computer screen. The sight and sound of an Internet video is encoded in the Wi-Fi all around us, but we don't see or hear it until the computer decodes that information. Taste, smell and touch are all phenomena of the brain as a result of the same process. We don't taste, smell or feel anything except in the brain and there are pain relief techniques that seek to block the signal from the site of discomfort to the brain because if the brain doesn't decode that signal we don't feel pain. Pain is in the brain and only appears to be at the point of impact thanks to the feedback loop between them. We don't see anything until electrical information from the sight senses is decoded in an area at the back of the brain. If that area is damaged we can go blind when our eyes are perfectly okay. So why do we go blind if we damage an eye? We damage the information processing between the waveform visual information and the visual decoding area of the brain. If information doesn't reach the brain in a form it can decode then we can't see the visual reality that it represents. What's more the brain is decoding only a fraction of the information it receives and the rest is absorbed by the

sub-conscious mind. This explanation is from the science magazine, *Wonderpedia*:

> Every second, 11 million sensations crackle along these [brain] pathways ... The brain is confronted with an alarming array of images, sounds and smells which it rigorously filters down until it is left with a manageable list of around 40. Thus 40 sensations per second make up what we perceive as reality.

The 'world' is not what people are told to believe that is it and the inner circles of the Cult *know that*.

Illusory 'physical' reality

We can only see a smear of 0.005 percent of the Universe which is only one of a vast array of universes – 'mansions' – within infinite reality. Even then the brain decodes only 40 pieces of information ('sensations') from a potential *11 million* that we receive every second. Two points strike you from this immediately: The sheer breathtaking stupidity of believing we know anything so rigidly that there's nothing more to know; and the potential for these processes to be manipulated by a malevolent force to control the reality of the population. One thing I can say for sure with no risk of contradiction is that when you can perceive an almost indescribable fraction of infinite reality there is always more to know as in tidal waves of it. Ancient Greek philosopher Socrates was so right when he said that wisdom is to know how little we know. How obviously true that is when you think that we are experiencing a physical world of solidity that is neither physical nor solid and a world of apartness when everything is connected. Cult-controlled 'science' dismisses the so-called 'paranormal' and all phenomena related to that when the 'para'-normal is perfectly normal and explains the alleged 'great mysteries' which dumbfound scientific minds. There is a reason for this. A 'scientific mind' in terms of the mainstream is a material mind, a five-sense mind imprisoned in see it, touch it, hear it, smell it and taste it. Phenomena and happenings that can't be explained that way leave the 'scientific mind' bewildered and the rule is that if they

can't account for why something is happening then it can't, by definition, be happening. I beg to differ. Telepathy is thought waves passing through The Field (think wave disturbance again) to be decoded by someone able to connect with that wavelength (information). For example: You can pick up the thought waves of a friend at any distance and at the very least that will bring them to mind. A few minutes later the friend calls you. 'My god', you say, 'that's incredible – I was just thinking of you.' Ah, but *they* were thinking of *you* before they made the call and that's what you decoded. Native peoples not entrapped in five-sense reality do this so well it became known as the 'bush telegraph'. Those known as psychics and mediums (genuine ones) are doing the same only across dimensions of reality. 'Mind over matter' comes from the fact that matter and mind are the *same*. The state of one influences the state of the other. Indeed one *and* the other are illusions. They are aspects of the same field. Paranormal phenomena are all explainable so why are they still considered 'mysteries' or not happening? Once you go down this road of understanding you begin to expand awareness beyond the five senses and that's the nightmare for the Cult.

Figure 13: Holograms are not solid, but the best ones appear to be.

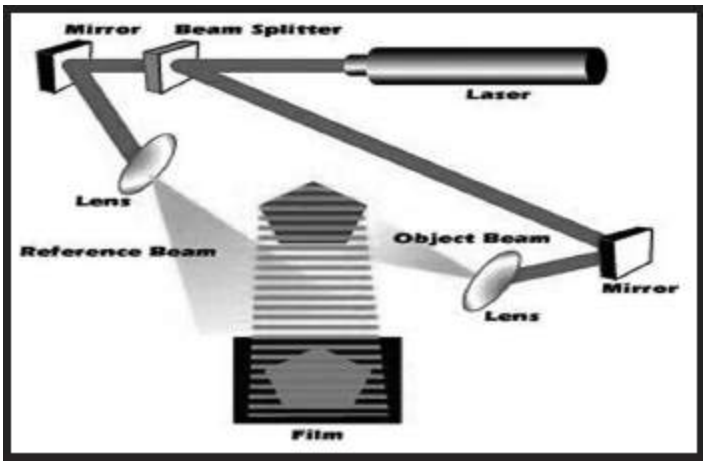

Figure 14: How holograms are created by capturing a waveform version of the subject image.

Holographic 'solidity'

Our reality is not solid, it is holographic. We are now well aware of holograms which are widely used today. Two-dimensional information is decoded into a three-dimensional reality that is not solid although can very much appear to be (Fig 13). Holograms are created with a laser divided into two parts. One goes directly onto a holographic photographic print ('reference beam') and the other takes a waveform image of the subject ('working beam') before being directed onto the print where it 'collides' with the other half of the laser (Fig 14). This creates a *waveform* interference pattern which contains the wavefield information of whatever is being photographed (Fig 15 overleaf). The process can be likened to dropping pebbles in a pond. Waves generated by each one spread out across the water to collide with the others and create a wave representation of where the stones fell and at what speed, weight and distance. A waveform interference pattern of a hologram is akin to the waveform information in The Field which the five senses decode into electrical signals to be decoded by the brain into a holographic illusory 'physical' reality. In the same way when a laser (think human attention) is directed at the waveform interference pattern a three-dimensional version of the subject is projected into apparently 'solid' reality (Fig 16). An amazing trait of holograms reveals more 'paranormal mysteries'. Information of the *whole*

hologram is encoded in waveform in every part of the interference pattern by the way they are created. This means that every *part* of a hologram is a smaller version of the whole. Cut the interference wave-pattern into four and you won't get four parts of the image. You get quarter-sized versions of the *whole* image. The body is a hologram and the same applies. Here we have the basis of acupuncture, reflexology and other forms of healing which identify representations of the whole body in all of the parts, hands, feet, ears, everywhere. Skilled palm readers can do what they do because the information of whole body is encoded in the hand. The concept of as above, so below, comes from this.

Figure 15: A waveform interference pattern that holds the information that transforms into a hologram.

Figure 16: Holographic people including 'Elvis' holographically inserted to sing a duet with Celine Dion.

The question will be asked of why, if solidity is illusory, we can't just walk through walls and each other. The resistance is not solid against solid; it is electromagnetic field against electromagnetic field and we decode this into the *experience* of solid against solid. We should also not underestimate the power of belief to dictate reality. What you believe is impossible *will be*. Your belief impacts on your decoding processes and they won't decode what you think is impossible. What we believe we perceive and what we perceive we experience. 'Can't dos' and 'impossibles' are like a firewall in a computer system that won't put on the screen what the firewall blocks. How vital that is to understanding how human experience has been hijacked. I explain in *The Answer, Everything You Need To Know But Have Never Been Told* and other books a long list of 'mysteries' and 'paranormal' phenomena that are not mysterious and perfectly normal once you realise what reality is and how it works. 'Ghosts' can be seen to pass through 'solid' walls because the walls are not solid and the ghost is a discarnate entity operating on a frequency so different to that of the wall that it's like two radio stations sharing the same space while never interfering with each other. I have seen ghosts do this myself. The apartness of people and objects is also an illusion. Everything is connected by the Field like all sea life is connected by the sea. It's just that within the limits of our visual reality we only 'see' holographic information and not the field of information that connects everything and from which the holographic world is made manifest. If you can only see holographic 'objects' and not the field that connects them they will appear to you as unconnected to each other in the same way that we see the computer while not seeing the Wi-Fi.

What you don't know *can* hurt you

Okay, we return to those 'two worlds' of human society and the Cult with its global network of interconnecting secret societies and satanic groups which manipulate through governments, corporations, media, religions, etc. The fundamental difference between them is *knowledge*. The idea has been to keep humanity

ignorant of the plan for its total enslavement underpinned by a crucial ignorance of reality – who we are and where we are – and how we interact with it. 'Human' should be the interaction between our expanded eternal consciousness and the five-sense body experience. We are meant to be *in* this world in terms of the five senses but not *of* this world in relation to our greater consciousness and perspective. In that state we experience the small picture of the five senses within the wider context of the big picture of awareness beyond the five senses. Put another way the five senses see the dots and expanded awareness connects them into pictures and patterns that give context to the apparently random and unconnected. Without the context of expanded awareness the five senses see only apartness and randomness with apparently no meaning. The Cult and its other-dimensional controllers seek to intervene in the frequency realm where five-sense reality is supposed to connect with expanded reality and to keep the two apart (more on this in the final chapter). When that happens five-sense mental and emotional processes are no longer influenced by expanded awareness, or the True 'I', and instead are driven by the isolated perceptions of the body's decoding systems. They are in the world *and* of it. Here we have the human plight and why humanity with its potential for infinite awareness can be so easily manipulatable and descend into such extremes of stupidity.

Once the Cult isolates five-sense mind from expanded awareness it can then program the mind with perceptions and beliefs by controlling information that the mind receives through the 'education' system of the formative years and the media perceptual bombardment and censorship of an entire lifetime. Limit perception and a sense of the possible through limiting knowledge by limiting and skewing information while censoring and discrediting that which could set people free. As the title of another of my books says *… And The Truth Shall Set You Free*. For this reason the last thing the Cult wants in circulation is the truth about anything – especially the reality of the eternal 'I' – and that's why it is desperate to control information. The Cult knows that information becomes perception

which becomes behaviour which, collectively, becomes human society. Cult-controlled and funded mainstream 'science' denies the existence of an eternal 'I' and seeks to dismiss and trash all evidence to the contrary. Cult-controlled mainstream religion has a version of 'God' that is little more than a system of control and dictatorship that employs threats of damnation in an afterlife to control perceptions and behaviour in the here and now through fear and guilt. Neither is true and it's the 'neither' that the Cult wishes to suppress. This 'neither' is that everything is an expression, a point of attention, within an infinite state of consciousness which is the real meaning of the term 'God'.

Perceptual obsession with the 'physical body' and five-senses means that 'God' becomes personified as a bearded bloke sitting among the clouds or a raging bully who loves us if we do what 'he' wants and condemns us to the fires of hell if we don't. These are no more than a 'spiritual' fairy tales to control and dictate events and behaviour through fear of this 'God' which has bizarrely made 'God-fearing' in religious circles a state to be desired. I would suggest that fearing *anything* is not to be encouraged and celebrated, but rather deleted. You can see why 'God fearing' is so beneficial to the Cult and its religions when *they* decide what 'God' wants and what 'God' demands (the Cult demands) that everyone do. As the great American comedian Bill Hicks said satirising a Christian zealot: 'I think what God meant to say.' How much of this infinite awareness ('God') that we access is decided by how far we choose to expand our perceptions, self-identity and sense of the possible. The scale of self-identity reflects itself in the scale of awareness that we can connect with and are influenced by – how much knowing and insight we have instead of programmed perception. You cannot expand your awareness into the infinity of possibility when you believe that you are little me Peter the postman or Mary in marketing and nothing more. I'll deal with this in the concluding chapter because it's crucial to how we turnaround current events.

Where the Cult came from

When I realised in the early 1990s there was a Cult network behind global events I asked the obvious question: When did it start? I took it back to ancient Rome and Egypt and on to Babylon and Sumer in Mesopotamia, the 'Land Between Two Rivers', in what we now call Iraq. The two rivers are the Tigris and Euphrates and this region is of immense historical and other importance to the Cult, as is the land called Israel only 550 miles away by air. There is much more going with deep esoteric meaning across this whole region. It's not only about 'wars for oil'. Priceless artefacts from Mesopotamia were stolen or destroyed after the American and British invasion of Iraq in 2003 justified by the lies of Boy Bush and Tony Blair (their Cult masters) about non-existent 'weapons of mass destruction'. Mesopotamia was the location of Sumer (about 5,400BC to 1,750BC), and Babylon (about 2,350BC to 539BC). Sabbatians may have become immensely influential in the Cult in modern times but they are part of a network that goes back into the mists of history. Sumer is said by historians to be the 'cradle of civilisation'. I disagree. I say it was the re-start of what we call human civilisation after cataclysmic events symbolised in part as the 'Great Flood' destroyed the world that existed before. These fantastic upheavals that I have been describing in detail in the books since the early1990s appear in accounts and legends of ancient cultures across the world and they are supported by geological and biological evidence. Stone tablets found in Iraq detailing the Sumer period say the cataclysms were caused by non-human 'gods' they call the Anunnaki. These are described in terms of extraterrestrial visitations in which knowledge supplied by the Anunnaki is said to have been the source of at least one of the world's oldest writing systems and developments in astronomy, mathematics and architecture that were way ahead of their time. I have covered this subject at length in *The Biggest Secret* and *Children of the Matrix* and the same basic 'Anunnaki' story can be found in Zulu accounts in South Africa where the late and very great Zulu high shaman Credo Mutwa told me that the Sumerian Anunnaki were known by Zulus as the Chitauri or 'children of the serpent'. See my six-hour video interview with Credo on this subject entitled *The*

Reptilian Agenda recorded at his then home near Johannesburg in 1999 which you can watch on the Ickonic media platform.

The Cult emerged out of Sumer, Babylon and Egypt (and elsewhere) and established the Roman Empire before expanding with the Romans into northern Europe from where many empires were savagely imposed in the form of Cult-controlled societies all over the world. Mass death and destruction was their calling card. The Cult established its centre of operations in Europe and European Empires were Cult empires which allowed it to expand into a global force. Spanish and Portuguese colonialists headed for Central and South America while the British and French targeted North America. Africa was colonised by Britain, France, Belgium, the Netherlands, Portugal, Spain, Italy, and Germany. Some like Britain and France moved in on the Middle East. The British Empire was by far the biggest for a simple reason. By now Britain was the headquarters of the Cult from which it expanded to form Canada, the United States, Australia and New Zealand. The Sun never set on the British Empire such was the scale of its occupation. London remains a global centre for the Cult along with Rome and the Vatican although others have emerged in Israel and China. It is no accident that the 'virus' is alleged to have come out of China while Italy was chosen as the means to terrify the Western population into compliance with 'Covid' fascism. Nor that Israel has led the world in 'Covid' fascism and mass 'vaccination'.

You would think that I would mention the United States here, but while it has been an important means of imposing the Cult's will it is less significant than would appear and is currently in the process of having what power it does have deleted. The Cult in Europe has mostly loaded the guns for the US to fire. America has been controlled from Europe from the start through Cult operatives in Britain and Europe. The American Revolution was an illusion to make it appear that America was governing itself while very different forces were pulling the strings in the form of Cult families such as the Rothschilds through the Rockefellers and other subordinates. The Rockefellers are extremely close to Bill Gates and

established both scalpel and drug 'medicine' and the World Health Organization. They play a major role in the development and circulation of vaccines through the Rockefeller Foundation on which Bill Gates said his Foundation is based. Why wouldn't this be the case when the Rockefellers and Gates are on the same team? Cult infiltration of human society goes way back into what we call history and has been constantly expanding and centralising power with the goal of establishing a global structure to dictate everything. Look how this has been advanced in great leaps with the 'Covid' hoax.

The non-human dimension
