$$80. \lim_{\theta \rightarrow 0} \frac{e^\theta - e^{-\theta} - 2\theta}{\theta - \sin \theta}$$

$$81. \lim_{t \rightarrow 0} \left(\frac{1}{2-2\cos t} - \frac{1}{t^2} \right)$$

$$82. \lim_{h \rightarrow 0} \frac{(\sin h)/h - \cos h}{h^2}$$

$$83. \lim_{z \rightarrow 0} \frac{1 - \cos^2 z}{\ln(1-z) + \sin z}$$

$$84. \lim_{y \rightarrow 0} \frac{y^2}{\cos y - \cosh y}$$

Theory and Examples

85. Use a series representation of $\sin 3x$ to find values of r and s for which

$$\lim_{x \rightarrow 0} \left(\frac{\sin 3x}{x^3} + \frac{r}{x^2} + s \right) = 0.$$

T 86. Compare the accuracies of the approximations $\sin x \approx x$ and $\sin x \approx 6x/(6+x^2)$ by comparing the graphs of $f(x) = \sin x - x$ and $g(x) = \sin x - (6x/(6+x^2))$. Describe what you find.

87. Find the radius of convergence of the series

$$\sum_{n=1}^{\infty} \frac{2 \cdot 5 \cdot 8 \cdots (3n-1)}{2 \cdot 4 \cdot 6 \cdots (2n)} x^n.$$

88. Find the radius of convergence of the series

$$\sum_{n=1}^{\infty} \frac{3 \cdot 5 \cdot 7 \cdots (2n+1)}{4 \cdot 9 \cdot 14 \cdots (5n-1)} (x-1)^n.$$

89. Find a closed-form formula for the n th partial sum of the series $\sum_{n=2}^{\infty} \ln(1 - (1/n^2))$ and use it to determine the convergence or divergence of the series.

90. Evaluate $\sum_{k=2}^{\infty} (1/(k^2 - 1))$ by finding the limits as $n \rightarrow \infty$ of the series' n th partial sum.

91. a. Find the interval of convergence of the series

$$y = 1 + \frac{1}{6}x^3 + \frac{1}{180}x^6 + \cdots \\ + \frac{1 \cdot 4 \cdot 7 \cdots (3n-2)}{(3n)!} x^{3n} + \cdots.$$

b. Show that the function defined by the series satisfies a differential equation of the form

$$\frac{d^2y}{dx^2} = x^a y + b,$$

and find the values of the constants a and b .

92. a. Find the Maclaurin series for the function $x^2/(1+x)$.

b. Does the series converge at $x = 1$? Explain.

93. If $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ are convergent series of nonnegative numbers, can anything be said about $\sum_{n=1}^{\infty} a_n b_n$? Give reasons for your answer.

94. If $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ are divergent series of nonnegative numbers, can anything be said about $\sum_{n=1}^{\infty} a_n b_n$? Give reasons for your answer.

95. Prove that the sequence $\{x_n\}$ and the series $\sum_{k=1}^{\infty} (x_{k+1} - x_k)$ both converge or both diverge.

96. Prove that $\sum_{n=1}^{\infty} (a_n/(1+a_n))$ converges if $a_n > 0$ for all n and $\sum_{n=1}^{\infty} a_n$ converges.

97. Suppose that $a_1, a_2, a_3, \dots, a_n$ are positive numbers satisfying the following conditions:

i) $a_1 \geq a_2 \geq a_3 \geq \cdots$;

ii) the series $a_2 + a_4 + a_8 + a_{16} + \cdots$ diverges.

Show that the series

$$\frac{a_1}{1} + \frac{a_2}{2} + \frac{a_3}{3} + \cdots$$

diverges.

98. Use the result in Exercise 97 to show that

$$1 + \sum_{n=2}^{\infty} \frac{1}{n \ln n}$$

diverges.

99. Show that if $a_n > 0$ and $\sum_{n=1}^{\infty} a_n$ converges, then $\sum_{n=1}^{\infty} \frac{\sqrt{a_n}}{n}$ converges.

100. Determine whether $\sum_{n=1}^{\infty} b_n$ converges or diverges.

a. $b_1 = 1, b_{n+1} = (-1)^n \frac{n+1}{3n+2} b_n$

b. $b_1 = 3, b_{n+1} = \frac{n}{\ln n} b_n$

101. Assume that $b_n > 0$ and $\sum_{n=1}^{\infty} b_n$ converges. What, if anything, can be said about the following series?

a. $\sum_{n=1}^{\infty} \tan(b_n)$

b. $\sum_{n=1}^{\infty} \ln(1 + b_n)$

c. $\sum_{n=1}^{\infty} \ln(2 + b_n)$

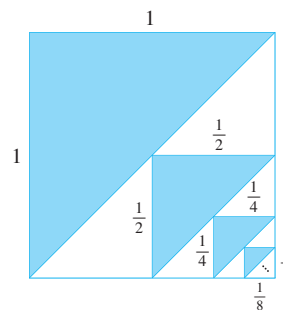

102. Consider the convergent series $\sum_{n=1}^{\infty} \frac{(-1)^n}{e^n + e^{cn}}$, where c is a constant.

What should c be so that the first 10 terms of the series estimate the sum of the entire series with an error of less than 0.00001?

103. Assume that the following sequence has a limit L . Find the value of L .

$$4^{1/3}, (4(4^{1/3}))^{1/3}, (4(4(4^{1/3}))^{1/3})^{1/3}, (4(4(4(4^{1/3}))^{1/3})^{1/3})^{1/3}, \dots$$

104. Consider the infinite sequence of shaded right triangles in the accompanying diagram. Compute the total area of the triangles.

CHAPTER 9 Additional and Advanced Exercises

Determining Convergence of Series

Which of the series $\sum_{n=1}^{\infty} a_n$ defined by the formulas in Exercises 1–4 converge, and which diverge? Give reasons for your answers.

1. $\sum_{n=1}^{\infty} \frac{1}{(3n-2)^{n+(1/2)}}$

2. $\sum_{n=1}^{\infty} \frac{(\tan^{-1} n)^2}{n^2 + 1}$

3. $\sum_{n=1}^{\infty} (-1)^n \tanh n$

4. $\sum_{n=2}^{\infty} \frac{\log_n(n!)}{n^3}$

Which of the series $\sum_{n=1}^{\infty} a_n$ defined by the formulas in Exercises 5–8 converge, and which diverge? Give reasons for your answers.

5. $a_1 = 1, a_{n+1} = \frac{n(n+1)}{(n+2)(n+3)} a_n$

(Hint: Write out several terms, see which factors cancel, and then generalize.)

6. $a_1 = a_2 = 7, a_{n+1} = \frac{n}{(n-1)(n+1)} a_n$ if $n \geq 2$

7. $a_1 = a_2 = 1, a_{n+1} = \frac{1}{1+a_n}$ if $n \geq 2$

8. $a_n = 1/3^n$ if n is odd, $a_n = n/3^n$ if n is even

Choosing Centers for Taylor Series

Taylor's formula

$$f(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \dots + \frac{f^{(n)}(a)}{n!}(x-a)^n + \frac{f^{(n+1)}(c)}{(n+1)!}(x-a)^{n+1}$$

expresses the value of f at x in terms of the values of f and its derivatives at $x = a$. In numerical computations, we therefore need a to be a

point where we know the values of f and its derivatives. We also need a to be close enough to the values of f in which we are interested to make $(x-a)^{n+1}$ so small we can neglect the remainder.

In Exercises 9–14, what Taylor series would you choose to represent the function near the given value of x ? (There may be more than one good answer.) Write out the first four nonzero terms of the series you choose.

9. $\cos x$ near $x = 1$ 10. $\sin x$ near $x = 6.3$

11. e^x near $x = 0.4$ 12. $\ln x$ near $x = 1.3$

13. $\cos x$ near $x = 69$ 14. $\arctan x$ near $x = 2$

Theory and Examples

15. Let a and b be constants with $0 < a < b$. Does the sequence $\{(a^n + b^n)^{1/n}\}$ converge? If it does converge, what is the limit?

16. Find the sum of the infinite series

$$1 + \frac{2}{10} + \frac{3}{10^2} + \frac{7}{10^3} + \frac{2}{10^4} + \frac{3}{10^5} + \frac{7}{10^6} + \frac{2}{10^7} + \frac{3}{10^8} + \frac{7}{10^9} + \dots$$

17. Evaluate

$$\sum_{n=0}^{\infty} \int_n^{n+1} \frac{1}{1+x^2} dx.$$

18. Find all values of x for which

$$\sum_{n=1}^{\infty} \frac{nx^n}{(n+1)(2x+1)^n}$$

converges absolutely.

T 19. a. Does the value of

$$\lim_{n \rightarrow \infty} \left(1 - \frac{\cos(a/n)}{n} \right)^n, \quad a \text{ constant,}$$

appear to depend on the value of a ? If so, how?

b. Does the value of

$$\lim_{n \rightarrow \infty} \left(1 - \frac{\cos(a/n)}{bn} \right)^n, \quad a \text{ and } b \text{ constant, } b \neq 0,$$

appear to depend on the value of b ? If so, how?

c. Use calculus to confirm your findings in parts (a) and (b).

20. Show that if $\sum_{n=1}^{\infty} a_n$ converges, then

$$\sum_{n=1}^{\infty} \left(\frac{1 + \sin a_n}{2} \right)^n$$

converges.

21. Find a value for the constant b that will make the radius of convergence of the power series

$$\sum_{n=2}^{\infty} \frac{b^n x^n}{\ln n}$$

equal to 5.

22. How do you know that the functions $\sin x$, $\ln x$, and e^x are not polynomials? Give reasons for your answer.

23. Find the value of a for which the limit

$$\lim_{x \rightarrow 0} \frac{\sin(ax) - \sin x - x}{x^3}$$

is finite, and evaluate the limit.

24. Find values of a and b for which

$$\lim_{x \rightarrow 0} \frac{\cos(ax) - b}{2x^2} = -1.$$

25. **Raabe's (or Gauss's) Test** The following test, which we state without proof, is an extension of the Ratio Test.

Raabe's Test: If $\sum_{n=1}^{\infty} u_n$ is a series of positive constants and there exist constants C , K , and N such that

$$\frac{u_n}{u_{n+1}} = 1 + \frac{C}{n} + \frac{f(n)}{n^2},$$

where $|f(n)| < K$ for $n \geq N$, then $\sum_{n=1}^{\infty} u_n$ converges if $C > 1$ and diverges if $C \leq 1$.

Show that the results of Raabe's Test agree with what you know about the series $\sum_{n=1}^{\infty} (1/n^2)$ and $\sum_{n=1}^{\infty} (1/n)$.

26. (Continuation of Exercise 25.) Suppose that the terms of $\sum_{n=1}^{\infty} u_n$ are defined recursively by the formulas

$$u_1 = 1, \quad u_{n+1} = \frac{(2n-1)^2}{(2n)(2n+1)} u_n.$$

Apply Raabe's Test to determine whether the series converges.

27. Suppose that $\sum_{n=1}^{\infty} a_n$ converges, $a_n \neq 1$, and $a_n > 0$ for all n .

a. Show that $\sum_{n=1}^{\infty} a_n^2$ converges.

b. Does $\sum_{n=1}^{\infty} a_n/(1-a_n)$ converge? Explain.

28. (Continuation of Exercise 27.) If $\sum_{n=1}^{\infty} a_n$ converges, and if $0 < a_n < 1$ for all n , show that $\sum_{n=1}^{\infty} \ln(1-a_n)$ converges.

(Hint: First show that $|\ln(1-a_n)| \leq a_n/(1-a_n)$.)

29. **Nicole Oresme's Theorem** Prove Nicole Oresme's Theorem:

$$1 + \frac{1}{2} \cdot 2 + \frac{1}{4} \cdot 3 + \cdots + \frac{n}{2^{n-1}} + \cdots = 4.$$

(Hint: Differentiate both sides of the equation $1/(1-x) = 1 + \sum_{n=1}^{\infty} x^n$.)

30. a. Find a power series representation of $\frac{e^x - 1}{x}$.

b. By differentiating the series in part (a) term by term, show

$$\text{that } \sum_{n=1}^{\infty} \frac{n}{(n+1)!} = 1.$$

31. a. Find a power series representation of e^{-x^2} .

b. By differentiating the series in part (a) twice term-by-term,

$$\text{show that } \sum_{n=1}^{\infty} (-1)^{n+1} \frac{2n+1}{2^n n!} = 1.$$

32. a. Show that

$$\sum_{n=1}^{\infty} \frac{n(n+1)}{x^n} = \frac{2x^2}{(x-1)^3}$$

for $|x| > 1$ by differentiating the identity

$$\sum_{n=1}^{\infty} x^{n+1} = \frac{x^2}{1-x}$$

twice, multiplying the result by x , and then replacing x by $1/x$.

b. Use part (a) to find the real solution greater than 1 of the equation

$$x = \sum_{n=1}^{\infty} \frac{n(n+1)}{x^n}.$$

33. **Quality control**

a. Differentiate the series

$$\frac{1}{1-x} = 1 + x + x^2 + \cdots + x^n + \cdots$$

to obtain a series for $1/(1-x)^2$.

b. In one throw of two dice, the probability of getting a roll of 7 is $p = 1/6$. If you throw the dice repeatedly, the probability that a 7 will appear for the first time at the n th throw is $q^{n-1}p$, where $q = 1 - p = 5/6$. The expected number of throws until a 7 first appears is $\sum_{n=1}^{\infty} nq^{n-1}p$. Find the sum of this series.

c. As an engineer applying statistical control to an industrial operation, you inspect items taken at random from the assembly line. You classify each sampled item as either "good" or "bad." If the probability of an item's being good is p and of an item's being bad is $q = 1 - p$, the probability that the first bad item found is the n th one inspected is $p^{n-1}q$. The average number inspected up to and including the first bad item found is $\sum_{n=1}^{\infty} np^{n-1}q$. Evaluate this sum, assuming $0 < p < 1$.

34. **Expected value** Suppose that a random variable X may assume the values $1, 2, 3, \dots$, with probabilities p_1, p_2, p_3, \dots , where p_k is the probability that X equals k ($k = 1, 2, 3, \dots$). Suppose also that $p_k \geq 0$ and that $\sum_{k=1}^{\infty} p_k = 1$. The **expected value** of X ,

denoted by $E(X)$, is the number $\sum_{k=1}^{\infty} kp_k$, provided the series converges. In each of the following cases, show that $\sum_{k=1}^{\infty} p_k = 1$ and find $E(X)$ if it exists. (Hint: See Exercise 33.)

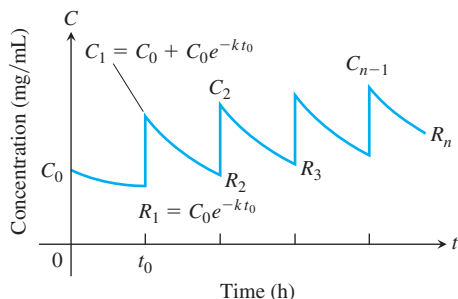

a. $p_k = 2^{-k}$ b. $p_k = \frac{5^{k-1}}{6^k}$

c. $p_k = \frac{1}{k(k+1)} = \frac{1}{k} - \frac{1}{k+1}$

- T 35. Safe and effective dosage** The concentration in the blood resulting from a single dose of a drug normally decreases with time as the drug is eliminated from the body. Doses may therefore need to be repeated periodically to keep the concentration from dropping below some particular level. One model for the effect of repeated doses gives the residual concentration just before the $(n+1)$ st dose as

$$R_n = C_0 e^{-kt_0} + C_0 e^{-2kt_0} + \cdots + C_0 e^{-nkt_0},$$

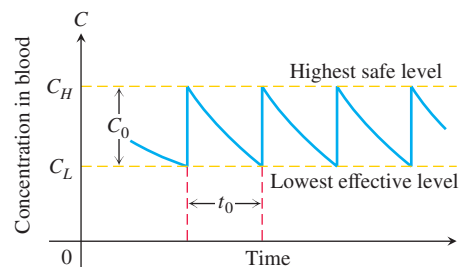

where C_0 = the change in concentration achievable by a single dose (mg/mL), k = the *elimination constant* (h^{-1}), and t_0 = time between doses (h). See the accompanying figure.

- Write R_n in closed form as a single fraction, and find $R = \lim_{n \rightarrow \infty} R_n$.
 - Calculate R_1 and R_{10} for $C_0 = 1 \text{ mg/mL}$, $k = 0.1 \text{ h}^{-1}$, and $t_0 = 10 \text{ h}$. How good an estimate of R is R_{10} ?
 - If $k = 0.01 \text{ h}^{-1}$ and $t_0 = 10 \text{ h}$, find the smallest n such that $R_n > (1/2)R$. Use $C_0 = 1 \text{ mg/mL}$.
- (Source: *Prescribing Safe and Effective Dosage*, B. Horelick and S. Koont, COMAP, Inc., Lexington, MA.)

- 36. Time between drug doses** (Continuation of Exercise 35.) If a drug is known to be ineffective below a concentration C_L and harmful above some higher concentration C_H , we need to find values of C_0 and t_0 that will produce a concentration that is safe (not above C_H) but effective (not below C_L). See the accompanying figure. We therefore want to find values for C_0 and t_0 for which

$$R = C_L \text{ and } C_0 + R = C_H.$$

Thus $C_0 = C_H - C_L$. When these values are substituted in the equation for R obtained in part (a) of Exercise 35, the resulting equation simplifies to

$$t_0 = \frac{1}{k} \ln \frac{C_H}{C_L}.$$

To reach an effective level rapidly, one might administer a “loading” dose that would produce a concentration of C_H mg/mL. This could be followed every t_0 hours by a dose that raises the concentration by $C_0 = C_H - C_L$ mg/mL.

- Verify the preceding equation for t_0 .
- If $k = 0.05 \text{ h}^{-1}$ and the highest safe concentration is e times the lowest effective concentration, find the length of time between doses that will ensure safe and effective concentrations.
- Given $C_H = 2 \text{ mg/mL}$, $C_L = 0.5 \text{ mg/mL}$, and $k = 0.02 \text{ h}^{-1}$, determine a scheme for administering the drug.
- Suppose that $k = 0.2 \text{ h}^{-1}$ and that the smallest effective concentration is 0.03 mg/mL . A single dose that produces a concentration of 0.1 mg/mL is administered. About how long will the drug remain effective?

CHAPTER 9 Technology Application Projects

Mathematica/Maple Projects

Projects can be found within MyLab Math.

• Bouncing Ball

The model predicts the height of a bouncing ball, and the time until it stops bouncing.

• Taylor Polynomial Approximations of a Function

A graphical animation shows the convergence of the Taylor polynomials to functions having derivatives of all orders over an interval in their domains.

10

Parametric Equations and Polar Coordinates

OVERVIEW In this chapter we study new ways to describe curves in the plane. Instead of considering a curve as the graph of a function or equation, we think of it as the path of a moving particle whose position is changing over time. Then each of the x - and y -coordinates of the particle's position becomes a function of a third variable t . We can also change the way in which points in the plane themselves are described by using *polar coordinates* rather than the rectangular or Cartesian system. Both of these new tools are useful for describing motion, like that of planets and satellites, or projectiles moving in the plane or in space.

10.1 Parametrizations of Plane Curves

Parametric Equations

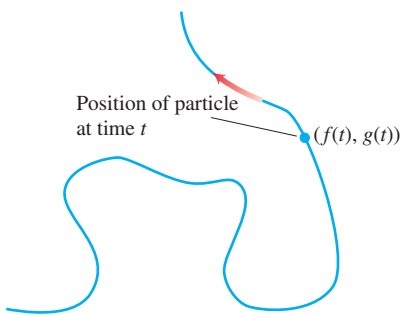

FIGURE 10.1 The curve or path traced by a particle moving in the xy -plane is not always the graph of a function or single equation.

Figure 10.1 shows the path of a moving particle in the xy -plane. Notice that the path fails the vertical line test, so it cannot be described as the graph of a function of the variable x . However, we can describe the path by a pair of equations, $x = f(t)$ and $y = g(t)$, where f and g are continuous functions. In the study of motion, t usually denotes time. Equations like these can describe more general curves than those described by a single function, and they provide not only the graph of the path traced out but also the location of the particle $(x, y) = (f(t), g(t))$ at any time t .

DEFINITION If x and y are given as functions

$$x = f(t), \quad y = g(t)$$

over an interval I of t -values, then the set of points $(x, y) = (f(t), g(t))$ defined by these equations is a **parametric curve**. The equations are **parametric equations** for the curve.

The variable t is a **parameter** for the curve, and its domain I is the **parameter interval**. If I is a closed interval, $a \leq t \leq b$, the point $(f(a), g(a))$ is the **initial point** of the curve and $(f(b), g(b))$ is the **terminal point**. When we give parametric equations and a parameter interval for a curve, we say that we have **parametrized** the curve. The equations and interval together constitute a **parametrization** of the curve. A given curve can be represented by different sets of parametric equations. (See Exercises 29 and 30.)

EXAMPLE 1 Sketch the curve defined by the parametric equations

$$x = \sin \frac{\pi t}{2}, \quad y = t, \quad 0 \leq t \leq 6.$$

Solution We make a table of values (Table 10.1), plot the points (x, y) , and draw a smooth curve through them (Figure 10.2). If we think of the curve as the path of a moving particle, the particle starts at time $t = 0$ at the initial point $(0, 0)$ and then moves upward in a wavy path until at time $t = 6$ it reaches the terminal point $(0, 6)$. The direction of motion is shown by the arrows in Figure 10.2.

TABLE 10.1 Values of $x = \sin \frac{\pi t}{2}$ and $y = t$ for selected values of t .

6	0	6

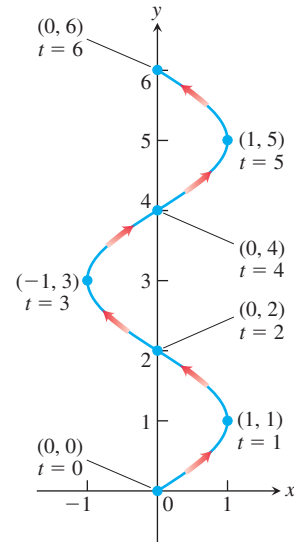

FIGURE 10.2 The curve given by the parametric equations $x = \sin \frac{\pi t}{2}$ and $y = t$ (Example 1).

EXAMPLE 2 Sketch the curve defined by the parametric equations

$$x = t^2, \quad y = t + 1, \quad -\infty < t < \infty.$$

Solution We make a table of values (Table 10.2), plot the points (x, y) , and draw a smooth curve through them (Figure 10.3). We think of the curve as the path that a particle moves along the curve in the direction of the arrows. Although the time intervals in the table are equal, the consecutive points plotted along the curve are not at equal arc length distances. The reason for this is that the particle slows down as it gets nearer to the y -axis along the lower branch of the curve as t increases, and then speeds up after reaching the y -axis at $(0, 1)$ and moving along the upper branch. Since the interval of values for t is all real numbers, there is no initial point or terminal point for the curve.

TABLE 10.2 Values of $x = t^2$ and $y = t + 1$ for selected values of t .

t	x	y
-3	9	-2
-2	4	-1
-1	1	0
0	0	1
1	1	2
2	4	3
3	9	4

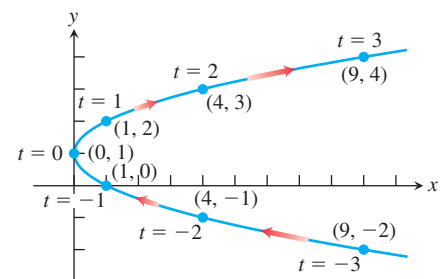

FIGURE 10.3 The curve given by the parametric equations $x = t^2$ and $y = t + 1$ (Example 2).

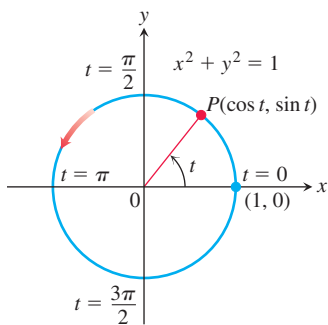

FIGURE 10.4 The equations $x = \cos t$ and $y = \sin t$ describe motion on the circle $x^2 + y^2 = 1$. The arrow shows the direction of increasing t (Example 3).

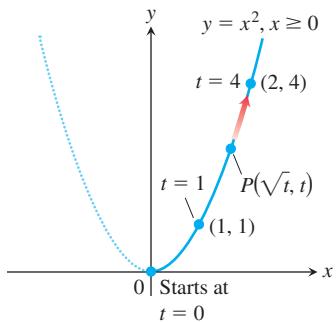

FIGURE 10.5 The equations $x = \sqrt{t}$ and $y = t$ and the interval $t \geq 0$ describe the path of a particle that traces the right-hand half of the parabola $y = x^2$ (Example 4).

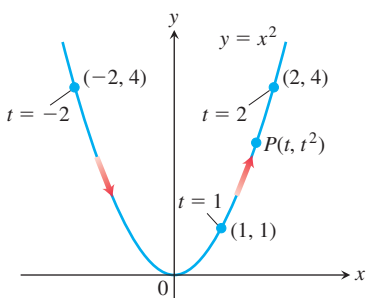

FIGURE 10.6 The path defined by $x = t$, $y = t^2$, $-\infty < t < \infty$ is the entire parabola $y = x^2$ (Example 5).

For this example we can use algebraic manipulation to eliminate the parameter t and obtain an algebraic equation for the curve in terms of x and y alone. We solve $y = t + 1$ for t and substitute the resulting equation $t = y - 1$ into the equation for x , which yields

$$x = t^2 = (y - 1)^2 = y^2 - 2y + 1.$$

The equation $x = y^2 - 2y + 1$ represents a parabola, as displayed in Figure 10.3. It is sometimes quite difficult, or even impossible, to eliminate the parameter from a pair of parametric equations, as we did here. ■

EXAMPLE 3 Graph the parametric curves

- (a) $x = \cos t$, $y = \sin t$, $0 \leq t \leq 2\pi$.
 (b) $x = a \cos t$, $y = a \sin t$, $0 \leq t \leq 2\pi$.

Solution

- (a) Since $x^2 + y^2 = \cos^2 t + \sin^2 t = 1$, the parametric curve lies along the unit circle $x^2 + y^2 = 1$. As t increases from 0 to 2π , the point $(x, y) = (\cos t, \sin t)$ starts at $(1, 0)$ and traces the entire circle once counterclockwise (Figure 10.4).
 (b) For $x = a \cos t$, $y = a \sin t$, we have $x^2 + y^2 = a^2 \cos^2 t + a^2 \sin^2 t = a^2$. The parametrization describes a motion that begins at the point $(a, 0)$ and traverses the circle $x^2 + y^2 = a^2$ once counterclockwise, returning to $(a, 0)$ at $t = 2\pi$. The graph is a circle centered at the origin with radius $r = |a|$ and coordinate points $(a \cos t, a \sin t)$. ■

EXAMPLE 4 The position $P(x, y)$ of a particle moving in the xy -plane is given by the equations and parameter interval

$$x = \sqrt{t}, \quad y = t, \quad t \geq 0.$$

Identify the path traced by the particle and describe the motion.

Solution We try to identify the path by eliminating t between the equations $x = \sqrt{t}$ and $y = t$, which might produce a recognizable algebraic relation between x and y . We find that

$$y = t = (\sqrt{t})^2 = x^2.$$

Thus, the particle's position coordinates satisfy the equation $y = x^2$, so the particle moves along the parabola $y = x^2$.

It would be a mistake, however, to conclude that the particle's path is the entire parabola $y = x^2$; it is only half the parabola. The particle's x -coordinate is never negative. The particle starts at $(0, 0)$ when $t = 0$ and rises into the first quadrant as t increases (Figure 10.5). The parameter interval is $[0, \infty)$, and there is no terminal point. ■

The graph of any function $y = f(x)$ can always be given a **natural parametrization** $x = t$ and $y = f(t)$. The domain of the parameter in this case is the same as the domain of the function f .

EXAMPLE 5 A parametrization of the graph of the function $f(x) = x^2$ is given by

$$x = t, \quad y = f(t) = t^2, \quad -\infty < t < \infty.$$

When $t \geq 0$, this parametrization gives the same path in the xy -plane as we had in Example 4. However, since the parameter t here can now also be negative, we obtain the left-hand part of the parabola as well; that is, we have the entire parabolic curve. For this parametrization, there is no starting point and no terminal point (Figure 10.6). ■

Notice that a parametrization also specifies *when* a particle moving along the curve is *located* at a specific point along the curve. In Example 4, the point $(2, 4)$ is reached when $t = 4$; in Example 5, it is reached “earlier” when $t = 2$. You can see the implications of this aspect of parametrizations when considering the possibility of two objects coming into collision: they have to be at the exact same location point $P(x, y)$ for some (possibly different) values of their respective parameters. We will say more about this aspect of parametrizations when we study motion in Chapter 12.

EXAMPLE 6 Find a parametrization for the line through the point (a, b) having slope m .

Solution A Cartesian equation of the line is $y - b = m(x - a)$. If we define the parameter t by $t = x - a$, we find that $x = a + t$ and $y - b = mt$. That is,

$$x = a + t, \quad y = b + mt, \quad -\infty < t < \infty$$

parametrizes the line. This parametrization differs from the one we would obtain by the natural parametrization in Example 5 when $t = x$. However, both parametrizations describe the same line. ■

TABLE 10.3 Values of $x = t + (1/t)$ and $y = t - (1/t)$ for selected values of t .

t	$1/t$	x	y
0.1	10.0	10.1	-9.9
0.2	5.0	5.2	-4.8
0.4	2.5	2.9	-2.1
1.0	1.0	2.0	0.0
2.0	0.5	2.5	1.5
5.0	0.2	5.2	4.8
10.0	0.1	10.1	9.9

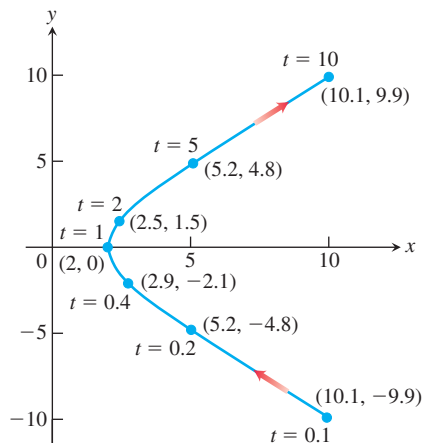

FIGURE 10.7 The curve for $x = t + (1/t)$, $y = t - (1/t)$, $t > 0$ in Example 7. (The part shown is for $0.1 \leq t \leq 10$.)

EXAMPLE 7 Sketch and identify the path traced by the point $P(x, y)$ if

$$x = t + \frac{1}{t}, \quad y = t - \frac{1}{t}, \quad t > 0.$$

Solution We make a brief table of values in Table 10.3, plot the points, and draw a smooth curve through them, as we did in Example 1. Next we eliminate the parameter t from the equations. The procedure is more complicated than in Example 2. Taking the difference between x and y as given by the parametric equations, we find that

$$x - y = \left(t + \frac{1}{t}\right) - \left(t - \frac{1}{t}\right) = \frac{2}{t}.$$

If we add the two parametric equations, we get

$$x + y = \left(t + \frac{1}{t}\right) + \left(t - \frac{1}{t}\right) = 2t.$$

We can then eliminate the parameter t by multiplying these last equations together:

$$(x - y)(x + y) = \left(\frac{2}{t}\right)(2t) = 4.$$

Expanding the expression on the left-hand side, we obtain a standard equation for a hyperbola (Section 10.6):

$$x^2 - y^2 = 4. \quad (1)$$

Thus the coordinates of all the points $P(x, y)$ described by the parametric equations satisfy Equation (1). However, Equation (1) does not require that the x -coordinate be positive. So there are points (x, y) on the hyperbola that do not satisfy the parametric equation $x = t + (1/t)$, $t > 0$. In fact, the parametric equations do not yield any points on the left branch of the hyperbola given by Equation (1), points where the x -coordinate would be negative. For small positive values of t , the path lies in the fourth quadrant and rises into the first quadrant as t increases, crossing the x -axis when $t = 1$ (see Figure 10.7). The parameter domain is $(0, \infty)$ and there is no starting point or terminal point for the path. ■

Examples 4, 5, and 6 illustrate that a given curve, or portion of it, can be represented by different parametrizations. In the case of Example 7, we can also represent the right-hand branch of the hyperbola by the parametrization

$$x = \sqrt{4 + t^2}, \quad y = t, \quad -\infty < t < \infty,$$

which is obtained by solving Equation (1) for $x \geq 0$ and letting y be the parameter. Still another parametrization for the right-hand branch of the hyperbola given by Equation (1) is

$$x = 2 \sec t, \quad y = 2 \tan t, \quad -\frac{\pi}{2} < t < \frac{\pi}{2}.$$

This parametrization follows from the trigonometric identity $\sec^2 t - \tan^2 t = 1$, because

$$x^2 - y^2 = 4 \sec^2 t - 4 \tan^2 t = 4(\sec^2 t - \tan^2 t) = 4.$$

As t runs between $-\pi/2$ and $\pi/2$, $x = \sec t$ remains positive and $y = \tan t$ runs between $-\infty$ and ∞ , so P traverses the hyperbola's right-hand branch. It comes in along the branch's lower half as $t \rightarrow 0^-$, reaches $(2, 0)$ at $t = 0$, and moves out into the first quadrant as t increases steadily toward $\pi/2$. This is the same branch of the hyperbola shown in Figure 10.7.

Cycloids

The problem with a pendulum clock whose bob swings in a circular arc is that the frequency of the swing depends on the amplitude of the swing. The wider the swing, the longer it takes the bob to return to center (its lowest position).

This does not happen if the bob can be made to swing in a curve called a *cycloid*. In 1673, Christiaan Huygens designed a pendulum clock whose bob would swing in a cycloid, a curve we define in Example 8. He hung the bob from a fine wire constrained by guards that caused it to draw up as it swung away from center (Figure 10.8). We describe the path parametrically in the next example.

EXAMPLE 8 A wheel of radius a rolls along a horizontal straight line. Find parametric equations for the path traced by a point P on the wheel's circumference. The path is called a **cycloid**.

Solution We take the line to be the x -axis, mark a point P on the wheel, start the wheel with P at the origin, and roll the wheel to the right. As parameter, we use the angle t through which the wheel turns, measured in radians. Figure 10.9 shows the wheel a short while later when its base lies at units from the origin. The wheel's center C lies at (at, a) and the coordinates of P are

$$x = at + a \cos \theta, \quad y = a + a \sin \theta.$$

To express θ in terms of t , we observe that $t + \theta = 3\pi/2$ in the figure, so that

$$\theta = \frac{3\pi}{2} - t.$$

This makes

$$\cos \theta = \cos\left(\frac{3\pi}{2} - t\right) = -\sin t, \quad \sin \theta = \sin\left(\frac{3\pi}{2} - t\right) = -\cos t.$$

The equations we seek are

$$x = at - a \sin t, \quad y = a - a \cos t.$$

These are usually written with the a factored out:

$$x = a(t - \sin t), \quad y = a(1 - \cos t). \quad (2)$$

Figure 10.10 shows the first arch of the cycloid and part of the next. ■

HISTORICAL BIOGRAPHY

Christiaan Huygens

(1629–1695)

Huygens was born in the Hague, Netherlands. He studied mathematics at the University of Leiden. Huygens was a follower of Descartes. He published his important geometrical results in *Theoremata de quadratura hyperboles, ellipses et circuli* and *De circuli magnitudine inventa* (1654). Later, he considered the subject of probability and published *Tractatus de ratiociniis in aleae ludo* (1657).

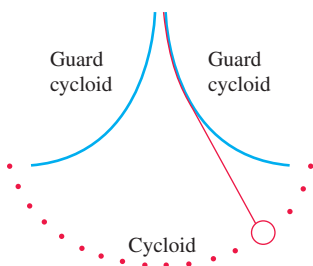

FIGURE 10.8 In Huygens' pendulum clock, the bob swings in a cycloid, so the frequency is independent of the amplitude.

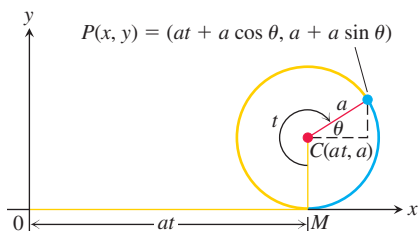

FIGURE 10.9 The position of $P(x, y)$ on the rolling wheel at angle t (Example 8).

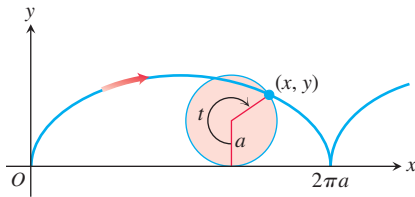

FIGURE 10.10 The cycloid curve $x = a(t - \sin t)$, $y = a(1 - \cos t)$, for $t \geq 0$.

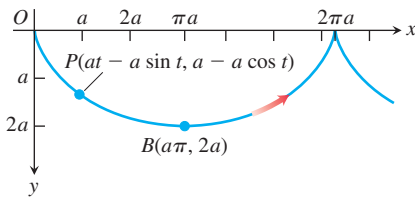

FIGURE 10.11 When Figure 10.10 is turned upside down, the y -axis points downward, indicating the direction of the gravitational force. Equations (2) still describe the curve parametrically.

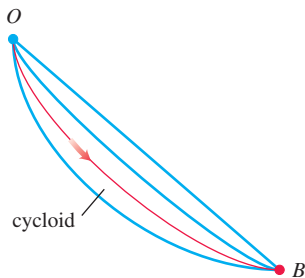

FIGURE 10.12 The cycloid is the unique curve that minimizes the time it takes for a frictionless bead to slide from point O to point B .

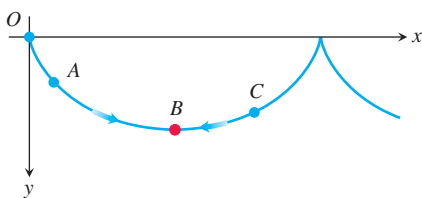

FIGURE 10.13 Beads released simultaneously on the upside-down cycloid at O , A , and C will reach B at the same time.

Brachistochrones and Tautochrones

If we turn Figure 10.10 upside down, Equations (2) still apply and the resulting curve (Figure 10.11) has two interesting physical properties. The first relates to the origin O and the point B at the bottom of the first arch. Among all smooth curves joining these points, the cycloid is the curve along which a frictionless bead, subject only to the force of gravity, will slide from O to B the fastest. This makes the cycloid a **brachistochrone** (“brah-kiss-toe-krone”), or shortest-time curve for these points. The second property is that even if you start the bead partway down the curve toward B , it will still take the bead the same amount of time to reach B . This makes the cycloid a **tautochrone** (“tauw-toe-krone”), or same-time curve for O and B .

Are there any other brachistochrones joining O and B , or is the cycloid the only one? We can formulate this as a mathematical question in the following way. At the start, the kinetic energy of the bead is zero since its velocity (speed) is zero. The work done by gravity in moving the bead from $(0, 0)$ to any other point (x, y) in the plane is mgy , and this must equal the change in kinetic energy. (See Exercise 25 in Section 6.5.) That is,

$$mgy = \frac{1}{2}mv^2 - \frac{1}{2}m(0)^2.$$

Thus, the speed of the bead when it reaches (x, y) has to be $v = \sqrt{2gy}$. That is,

$$\frac{ds}{dT} = \sqrt{2gy} \quad \text{\textit{ds is the arc length differential along the bead's path, and T represents time.}}$$

or

$$dT = \frac{ds}{\sqrt{2gy}} = \frac{\sqrt{1 + (dy/dx)^2} dx}{\sqrt{2gy}}. \quad (3)$$

The time T_f it takes the bead to slide along a particular path $y = f(x)$ from O to $B(a\pi, 2a)$ is

$$T_f = \int_{x=0}^{x=a\pi} \sqrt{\frac{1 + (dy/dx)^2}{2gy}} dx. \quad (4)$$

What curves $y = f(x)$, if any, minimize the value of this integral?

At first sight, we might guess that the straight line joining O and B would give the shortest time, but perhaps not. There might be some advantage in having the bead fall vertically at first to build up its speed faster. With a higher speed, the bead could travel a longer path and still reach B first. Indeed, this is the right idea. The solution, from a branch of mathematics known as the *calculus of variations*, is that the original cycloid from O to B is the one and only brachistochrone for O and B (Figure 10.12).

In the next section we show how to find the arc length differential ds for a parametrized curve. Once we know how to find ds , we can calculate the time given by the right-hand side of Equation (4) for the cycloid. This calculation gives the amount of time it takes a frictionless bead to slide down the cycloid to B after it is released from rest at O . The time turns out to be equal to $\pi\sqrt{a/g}$, where a is the radius of the wheel defining the particular cycloid. Moreover, if we start the bead at some lower point on the cycloid, corresponding to a parameter value $t_0 > 0$, we can integrate the parametric form of $ds/\sqrt{2gy}$ in Equation (3) over the interval $[t_0, \pi]$ to find the time it takes the bead to reach the point B . That calculation results in the same time $T = \pi\sqrt{a/g}$. It takes the bead the same amount of time to reach B no matter where it starts, which makes the cycloid a tautochrone. Beads starting simultaneously from O , A , and C in Figure 10.13, for instance, will all reach B at exactly the same time. This is the reason why Huygens' pendulum clock in Figure 10.8 is independent of the amplitude of the swing.

EXERCISES 10.1

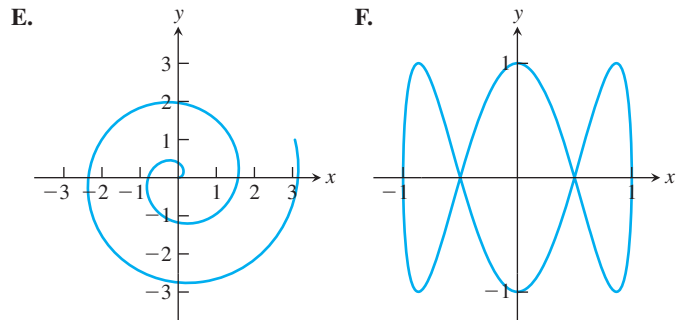

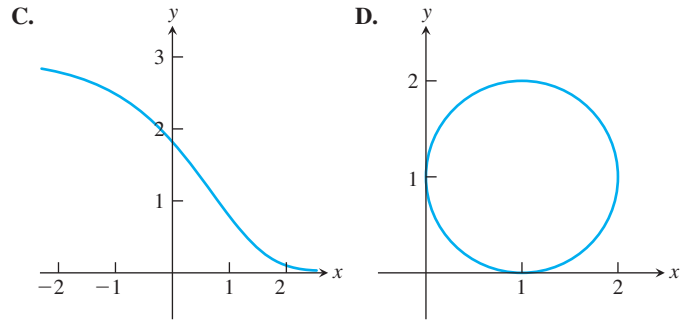

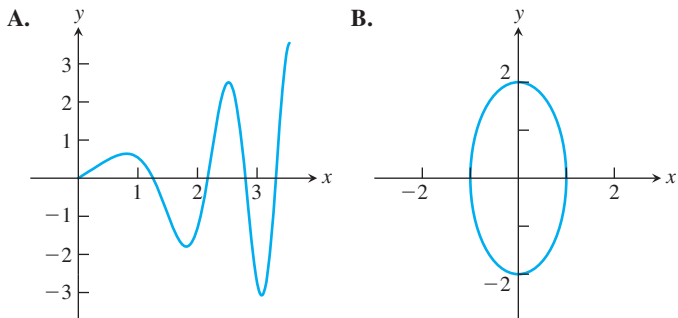

Finding Cartesian from Parametric Equations

Exercises 1–18 give parametric equations and parameter intervals for the motion of a particle in the xy -plane. Identify the particle's path by finding a Cartesian equation for it. Graph the Cartesian equation. (The graphs will vary with the equation used.) Indicate the portion of the graph traced by the particle and the direction of motion.

- $x = 3t$, $y = 9t^2$, $-\infty < t < \infty$
- $x = -\sqrt{t}$, $y = t$, $t \geq 0$
- $x = 2t - 5$, $y = 4t - 7$, $-\infty < t < \infty$
- $x = 3 - 3t$, $y = 2t$, $0 \leq t \leq 1$
- $x = \cos 2t$, $y = \sin 2t$, $0 \leq t \leq \pi$
- $x = \cos(\pi - t)$, $y = \sin(\pi - t)$, $0 \leq t \leq \pi$
- $x = 4 \cos t$, $y = 2 \sin t$, $0 \leq t \leq 2\pi$
- $x = 4 \sin t$, $y = 5 \cos t$, $0 \leq t \leq 2\pi$
- $x = \sin t$, $y = \cos 2t$, $-\frac{\pi}{2} \leq t \leq \frac{\pi}{2}$
- $x = 1 + \sin t$, $y = \cos t - 2$, $0 \leq t \leq \pi$
- $x = t^2$, $y = t^6 - 2t^4$, $-\infty < t < \infty$
- $x = \frac{t}{t-1}$, $y = \frac{t-2}{t+1}$, $-1 < t < 1$
- $x = t$, $y = \sqrt{1-t^2}$, $-1 \leq t \leq 0$
- $x = \sqrt{t+1}$, $y = \sqrt{t}$, $t \geq 0$
- $x = \sec^2 t - 1$, $y = \tan t$, $-\pi/2 < t < \pi/2$
- $x = -\sec t$, $y = \tan t$, $-\pi/2 < t < \pi/2$
- $x = -\cosh t$, $y = \sinh t$, $-\infty < t < \infty$
- $x = 2 \sinh t$, $y = 2 \cosh t$, $-\infty < t < \infty$

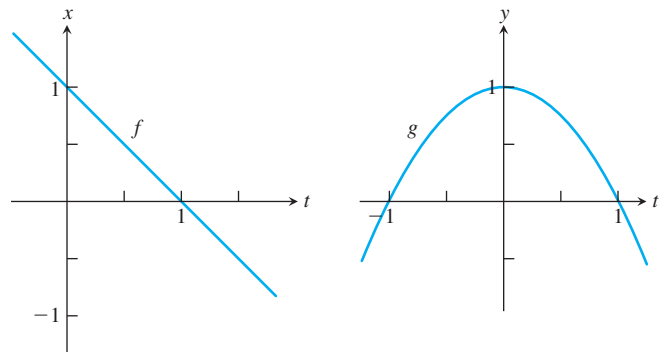

In Exercises 19–24, match the parametric equations with the parametric curves labeled A through F.

- $x = 1 - \sin t$, $y = 1 + \cos t$
- $x = \cos t$, $y = 2 \sin t$
- $x = \frac{1}{4}t \cos t$, $y = \frac{1}{4}t \sin t$
- $x = \sqrt{t}$, $y = \sqrt{t} \cos t$
- $x = \ln t$, $y = 3e^{-t/2}$
- $x = \cos t$, $y = \sin 3t$

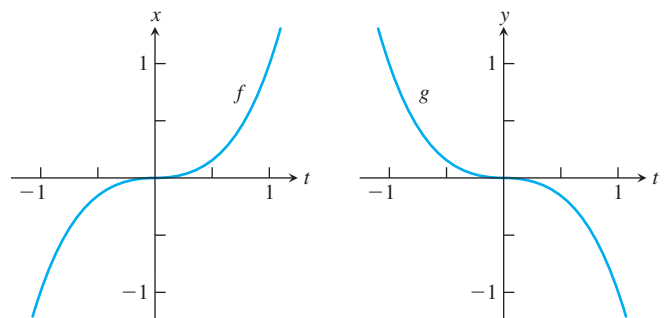

In Exercises 25–28, use the given graphs of $x = f(t)$ and $y = g(t)$ to sketch the corresponding parametric curve in the xy -plane.

Finding Parametric Equations

29. Find parametric equations and a parameter interval for the motion of a particle that starts at $(a, 0)$ and traces the circle $x^2 + y^2 = a^2$

- once clockwise.
- once counterclockwise.
- twice clockwise.
- twice counterclockwise.

(There are many ways to do these, so your answers may not be the same as the ones at the back of the text.)

30. Find parametric equations and a parameter interval for the motion of a particle that starts at $(a, 0)$ and traces the ellipse $(x^2/a^2) + (y^2/b^2) = 1$

- once clockwise.
- once counterclockwise.
- twice clockwise.
- twice counterclockwise.

(As in Exercise 29, there are many correct answers.)

In Exercises 31–36, find a parametrization for the curve.

- the line segment with endpoints $(-1, -3)$ and $(4, 1)$
- the line segment with endpoints $(-1, 3)$ and $(3, -2)$
- the lower half of the parabola $x - 1 = y^2$
- the left half of the parabola $y = x^2 + 2x$
- the ray (half line) with initial point $(2, 3)$ that passes through the point $(-1, -1)$
- the ray (half line) with initial point $(-1, 2)$ that passes through the point $(0, 0)$

37. Find parametric equations and a parameter interval for the motion of a particle starting at the point $(2, 0)$ and tracing the top half of the circle $x^2 + y^2 = 4$ four times.

38. Find parametric equations and a parameter interval for the motion of a particle that moves along the graph of $y = x^2$ in the following way: Beginning at $(0, 0)$ it moves to $(3, 9)$, and then it travels back and forth from $(3, 9)$ to $(-3, 9)$ infinitely many times.

39. Find parametric equations for the semicircle

$$x^2 + y^2 = a^2, \quad y > 0,$$

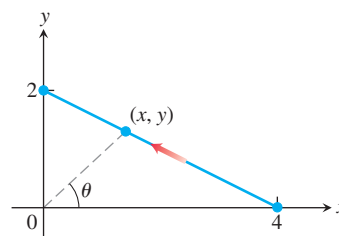

using as parameter the slope $t = dy/dx$ of the tangent line to the curve at (x, y) .

40. Find parametric equations for the circle

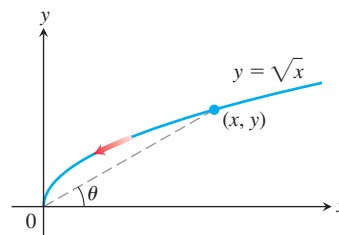

$$x^2 + y^2 = a^2,$$

using as parameter the arc length s measured counterclockwise from the point $(a, 0)$ to the point (x, y) .

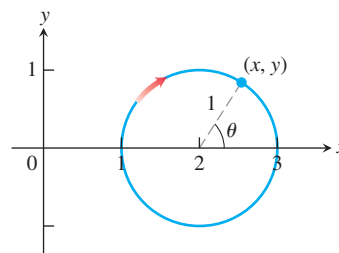

41. Find a parametrization for the line segment joining points $(0, 2)$ and $(4, 0)$ using the angle θ in the accompanying figure as the parameter.

42. Find a parametrization for the curve $y = \sqrt{x}$ with terminal point $(0, 0)$ using the angle θ in the accompanying figure as the parameter.

43. Find a parametrization for the circle $(x - 2)^2 + y^2 = 1$ starting at $(1, 0)$ and moving clockwise once around the circle, using the central angle θ in the accompanying figure as the parameter.

57. a. Epicycloid

$$x = 9 \cos t - \cos 9t, \quad y = 9 \sin t - \sin 9t, \quad 0 \leq t \leq 2\pi$$

b. Hypocycloid

$$x = 8 \cos t + 2 \cos 4t, \quad y = 8 \sin t - 2 \sin 4t, \quad 0 \leq t \leq 2\pi$$

c. Hypotrochoid

$$x = \cos t + 5 \cos 3t, \quad y = 6 \cos t - 5 \sin 3t, \quad 0 \leq t \leq 2\pi$$

$$\mathbf{58. a.} \quad x = 6 \cos t + 5 \cos 3t, \quad y = 6 \sin t - 5 \sin 3t, \quad 0 \leq t \leq 2\pi$$

$$\mathbf{b.} \quad x = 6 \cos 2t + 5 \cos 6t, \quad y = 6 \sin 2t - 5 \sin 6t, \quad 0 \leq t \leq \pi$$

$$\mathbf{c.} \quad x = 6 \cos t + 5 \cos 3t, \quad y = 6 \sin 2t - 5 \sin 3t, \quad 0 \leq t \leq 2\pi$$

$$\mathbf{d.} \quad x = 6 \cos 2t + 5 \cos 6t, \quad y = 6 \sin 4t - 5 \sin 6t, \quad 0 \leq t \leq \pi$$

10.2 Calculus with Parametric Curves

In this section we use calculus to study parametric curves. Specifically, we find slopes, lengths, and areas associated with parametrized curves.

Tangent Lines and Areas

A parametrized curve $x = f(t)$ and $y = g(t)$ is **differentiable** at t if f and g are each differentiable at t . At a point on a differentiable parametrized curve where y is also a differentiable function of x , the derivatives dy/dt , dx/dt , and dy/dx are related by the Chain Rule:

$$\frac{dy}{dt} = \frac{dy}{dx} \cdot \frac{dx}{dt}$$

If $dx/dt \neq 0$, we may divide both sides of this equation by dx/dt to solve for dy/dx .

Parametric Formula for dy/dx

If all three derivatives exist and $dx/dt \neq 0$, then

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} \quad (1)$$

If parametric equations define y as a twice-differentiable function of x , we can apply Equation (1) to the function $dy/dx = y'$ to calculate d^2y/dx^2 as a function of t :

$$\frac{d^2y}{dx^2} = \frac{d}{dx}(y') = \frac{dy'/dt}{dx/dt} \quad \text{Eq. (1) with } y' \text{ in place of } y$$

Parametric Formula for d^2y/dx^2

If the equations $x = f(t)$, $y = g(t)$ define y as a twice-differentiable function of x , then at any point where $dx/dt \neq 0$ and $y' = dy/dx$,

$$\frac{d^2y}{dx^2} = \frac{dy'/dt}{dx/dt} \quad (2)$$

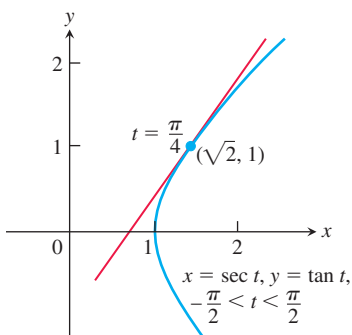

FIGURE 10.14 The curve in Example 1 is the right-hand branch of the hyperbola $x^2 - y^2 = 1$.

EXAMPLE 1 Find the tangent line to the curve

$$x = \sec t, \quad y = \tan t, \quad -\frac{\pi}{2} < t < \frac{\pi}{2},$$

at the point $(\sqrt{2}, 1)$, where $t = \pi/4$ (Figure 10.14).

Solution The slope of the curve at t is

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{\sec^2 t}{\sec t \tan t} = \frac{\sec t}{\tan t} \quad \text{Eq. (1)}$$

Setting t equal to $\pi/4$ gives

$$\left. \frac{dy}{dx} \right|_{t=\pi/4} = \frac{\sec(\pi/4)}{\tan(\pi/4)} = \frac{\sqrt{2}}{1} = \sqrt{2}.$$

The tangent line is

$$\begin{aligned} y - 1 &= \sqrt{2}(x - \sqrt{2}) \\ y &= \sqrt{2}x - 2 + 1 \\ y &= \sqrt{2}x - 1. \end{aligned}$$

Finding d^2y/dx^2 in Terms of t

1. Express $y' = dy/dx$ in terms of t .
2. Find dy'/dt .
3. Divide dy'/dt by dx/dt .

EXAMPLE 2 Find d^2y/dx^2 as a function of t if $x = t - t^2$ and $y = t - t^3$.

Solution

1. Express $y' = dy/dx$ in terms of t .

$$y' = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{1 - 3t^2}{1 - 2t}$$

2. Differentiate y' with respect to t .

$$\frac{dy'}{dt} = \frac{d}{dt} \left(\frac{1 - 3t^2}{1 - 2t} \right) = \frac{2 - 6t + 6t^2}{(1 - 2t)^2} \quad \text{Derivative Quotient Rule}$$

3. Divide dy'/dt by dx/dt .

$$\frac{d^2y}{dx^2} = \frac{dy'/dt}{dx/dt} = \frac{(2 - 6t + 6t^2)/(1 - 2t)^2}{1 - 2t} = \frac{2 - 6t + 6t^2}{(1 - 2t)^3} \quad \text{Eq. (2)}$$

EXAMPLE 3 Find the area enclosed by the astroid (Figure 10.15)

$$x = \cos^3 t, \quad y = \sin^3 t, \quad 0 \leq t \leq 2\pi.$$

Solution By symmetry, the enclosed area is four times the area beneath the curve in the first quadrant where $0 \leq t \leq \pi/2$. We can apply the definite integral formula for area studied in Chapter 5, using substitution to express the curve and differential dx in terms of the parameter t . Thus,

$$\begin{aligned} A &= 4 \int_0^1 y \, dx && \text{Four times area under } y \\ & && \text{from } x = 0 \text{ to } x = 1 \\ &= 4 \int_{\pi/2}^0 (\sin^3 t)(-3 \cos^2 t \sin t) \, dt && \cos^3 \pi/2 = 0, \cos^3 0 = 1 \\ &= 4 \int_0^{\pi/2} (\sin^3 t)(3 \cos^2 t \sin t) \, dt && \text{Substitution for } y \text{ and } dx \\ &= 12 \int_0^{\pi/2} \left(\frac{1 - \cos 2t}{2} \right)^2 \left(\frac{1 + \cos 2t}{2} \right) dt && \sin^4 t = \left(\frac{1 - \cos 2t}{2} \right)^2 \\ &= \frac{3}{2} \int_0^{\pi/2} (1 - 2 \cos 2t + \cos^2 2t)(1 + \cos 2t) \, dt && \text{Expand squared term.} \\ &= \frac{3}{2} \int_0^{\pi/2} (1 - \cos 2t - \cos^2 2t + \cos^3 2t) \, dt && \text{Multiply terms.} \\ &= \frac{3}{2} \left[\int_0^{\pi/2} (1 - \cos 2t) \, dt - \int_0^{\pi/2} \cos^2 2t \, dt + \int_0^{\pi/2} \cos^3 2t \, dt \right] \\ &= \frac{3}{2} \left[\left(t - \frac{1}{2} \sin 2t \right) - \frac{1}{2} \left(t + \frac{1}{4} \sin 4t \right) + \frac{1}{2} \left(\sin 2t - \frac{1}{3} \sin^3 2t \right) \right]_{\pi/2}^0 && \text{As in Section 8.3,} \\ & && \text{Example 3} \\ &= \frac{3}{2} \left[\left(\frac{\pi}{2} - 0 - 0 - 0 \right) - \frac{1}{2} \left(\frac{\pi}{2} + 0 - 0 - 0 \right) + \frac{1}{2} (0 - 0 - 0 + 0) \right] && \text{Evaluate.} \\ &= \frac{3\pi}{8}. \end{aligned}$$

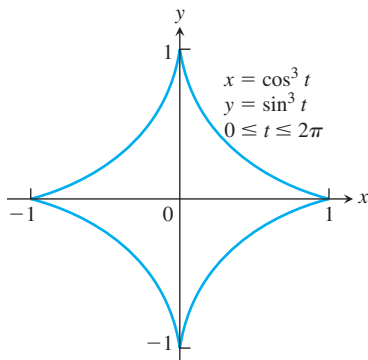

FIGURE 10.15 The astroid in Example 3.

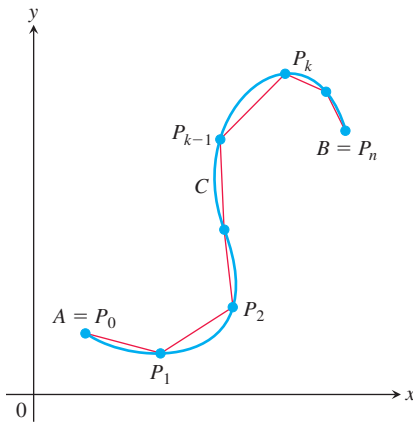

FIGURE 10.16 The length of the smooth curve C from A to B is approximated by the sum of the lengths of the polygonal path (straight-line segments) starting at $A = P_0$, then to P_1 , and so on, ending at $B = P_n$.

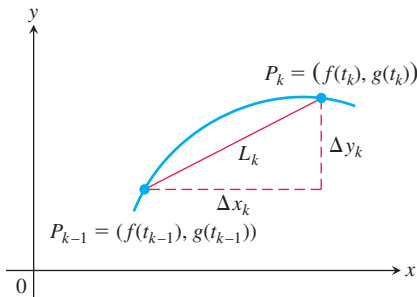

FIGURE 10.17 The arc $P_{k-1}P_k$ is approximated by the straight-line segment shown here, which has length $L_k = \sqrt{(\Delta x_k)^2 + (\Delta y_k)^2}$.

Length of a Parametrically Defined Curve

Let C be a curve given parametrically by the equations

$$x = f(t) \quad \text{and} \quad y = g(t), \quad a \leq t \leq b.$$

We assume the functions f and g are **continuously differentiable** (meaning they have continuous first derivatives) on the interval $[a, b]$. We also assume that the derivatives $f'(t)$ and $g'(t)$ are not simultaneously zero, which prevents the curve C from having any corners or cusps. Such a curve is called a **smooth curve**. We subdivide the path (or arc) AB into n pieces at points $A = P_0, P_1, P_2, \dots, P_n = B$ (Figure 10.16). These points correspond to a partition of the interval $[a, b]$ by $a = t_0 < t_1 < t_2 < \dots < t_n = b$, where $P_k = (f(t_k), g(t_k))$. Join successive points of this subdivision by straight-line segments (Figure 10.16). A representative line segment has length

$$L_k = \sqrt{(\Delta x_k)^2 + (\Delta y_k)^2} \\ = \sqrt{[f(t_k) - f(t_{k-1})]^2 + [g(t_k) - g(t_{k-1})]^2}$$

(see Figure 10.17). If Δt_k is small, the length L_k is approximately the length of arc $P_{k-1}P_k$. By the Mean Value Theorem, there are numbers t_k^* and t_k^{**} in $[t_{k-1}, t_k]$ such that

$$\Delta x_k = f(t_k) - f(t_{k-1}) = f'(t_k^*) \Delta t_k, \\ \Delta y_k = g(t_k) - g(t_{k-1}) = g'(t_k^{**}) \Delta t_k.$$

Assuming the path from A to B is traversed exactly once as t increases from $t = a$ to $t = b$, with no doubling back or retracing, an approximation to the (yet to be defined) “length” of the curve AB is the sum of all the lengths L_k :

$$\sum_{k=1}^n L_k = \sum_{k=1}^n \sqrt{(\Delta x_k)^2 + (\Delta y_k)^2} \\ = \sum_{k=1}^n \sqrt{[f'(t_k^*)]^2 + [g'(t_k^{**})]^2} \Delta t_k.$$

Although this last sum on the right is not exactly a Riemann sum (because f' and g' are evaluated at different points), it can be shown that its limit, as the norm of the partition tends to zero and the number of segments $n \rightarrow \infty$, is the definite integral

$$\lim_{\|P\| \rightarrow 0} \sum_{k=1}^n \sqrt{[f'(t_k^*)]^2 + [g'(t_k^{**})]^2} \Delta t_k = \int_a^b \sqrt{[f'(t)]^2 + [g'(t)]^2} dt.$$

Therefore, it is reasonable to define the length of the curve from A to B to be this integral.

DEFINITION If a curve C is defined parametrically by $x = f(t)$ and $y = g(t)$, $a \leq t \leq b$, where f' and g' are continuous and not simultaneously zero on $[a, b]$, and if C is traversed exactly once as t increases from $t = a$ to $t = b$, then **the length of C** is the definite integral

$$L = \int_a^b \sqrt{[f'(t)]^2 + [g'(t)]^2} dt.$$

If $x = f(t)$ and $y = g(t)$, then using the Leibniz notation we can write the formula for arc length this way:

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt. \quad (3)$$

A smooth curve C does not come to a stop and reverse its direction of motion over the time interval $[a, b]$ since $(f')^2 + (g')^2 > 0$ throughout the interval. At a point where a curve stops and then doubles back on itself, either the curve fails to be differentiable or both derivatives must simultaneously equal zero. We will examine this phenomenon in Chapter 12, where we study tangent vectors to curves.

If there are two different parametrizations for a curve C whose length we want to find, it does not matter which one we use. However, the parametrization we choose must meet the conditions stated in the definition of the length of C (see Exercise 41 for an example).

EXAMPLE 4 Using the definition, find the length of the circle of radius r defined parametrically by

$$x = r \cos t \quad \text{and} \quad y = r \sin t, \quad 0 \leq t \leq 2\pi.$$

Solution As t varies from 0 to 2π , the circle is traversed exactly once, so the circumference is

$$L = \int_0^{2\pi} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt.$$

We find

$$\frac{dx}{dt} = -r \sin t, \quad \frac{dy}{dt} = r \cos t$$

and

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = r^2(\sin^2 t + \cos^2 t) = r^2.$$

Therefore, the total arc length is

$$L = \int_0^{2\pi} \sqrt{r^2} dt = r \left[t \right]_0^{2\pi} = 2\pi r. \quad \blacksquare$$

EXAMPLE 5 Find the length of the astroid (Figure 10.15)

$$x = \cos^3 t, \quad y = \sin^3 t, \quad 0 \leq t \leq 2\pi.$$

Solution Because of the curve's symmetry with respect to the coordinate axes, its length is four times the length of the first-quadrant portion. We have

$$\begin{aligned} x &= \cos^3 t, & y &= \sin^3 t \\ \left(\frac{dx}{dt}\right)^2 &= [3 \cos^2 t (-\sin t)]^2 = 9 \cos^4 t \sin^2 t \\ \left(\frac{dy}{dt}\right)^2 &= [3 \sin^2 t (\cos t)]^2 = 9 \sin^4 t \cos^2 t \\ \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} &= \sqrt{9 \cos^2 t \sin^2 t (\underbrace{\cos^2 t + \sin^2 t}_1)} \\ &= \sqrt{9 \cos^2 t \sin^2 t} \\ &= 3 |\cos t \sin t| \quad \text{because } \cos t \sin t \geq 0 \text{ for } 0 \leq t \leq \pi/2 \\ &= 3 \cos t \sin t. \end{aligned}$$

Therefore,

$$\begin{aligned} \text{Length of first-quadrant portion} &= \int_0^{\pi/2} 3 \cos t \sin t \, dt \\ &= \frac{3}{2} \int_0^{\pi/2} \sin 2t \, dt && \cos t \sin t = (1/2)\sin 2t \\ &= -\frac{3}{4} \cos 2t \Big|_0^{\pi/2} = \frac{3}{2}. \end{aligned}$$

The length of the astroid is four times this: $4(3/2) = 6$. ■

EXAMPLE 6 Find the perimeter of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, where $a > b > 0$.

Solution Parametrically, we represent the ellipse by the equations $x = a \sin t$ and $y = b \cos t$, $0 \leq t \leq 2\pi$. Then

$$\begin{aligned} \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 &= a^2 \cos^2 t + b^2 \sin^2 t \\ &= a^2 - (a^2 - b^2) \sin^2 t \\ &= a^2 [1 - e^2 \sin^2 t]. \end{aligned} \quad \begin{aligned} e &= \sqrt{1 - \frac{b^2}{a^2}} \\ & \text{(eccentricity, not the number 2.71828...)} \end{aligned}$$

From Equation (3), the perimeter is given by

$$P = 4a \int_0^{\pi/2} \sqrt{1 - e^2 \sin^2 t} \, dt.$$

The integral for P is nonelementary and is known as the *complete elliptic integral of the second kind*. We can compute its value to within any degree of accuracy using infinite series in the following way. From the binomial expansion for $\sqrt{1 - x^2}$ in Section 9.10, we have

$$\sqrt{1 - e^2 \sin^2 t} = 1 - \frac{1}{2} e^2 \sin^2 t - \frac{1}{2 \cdot 4} e^4 \sin^4 t - \dots \quad |e \sin t| \leq e < 1$$

Then, to each term in this last expression, we apply the integral Formula 157 (at the back of the text) for $\int_0^{\pi/2} \sin^n t \, dt$ when n is even, which yields the perimeter

$$\begin{aligned} P &= 4a \int_0^{\pi/2} \sqrt{1 - e^2 \sin^2 t} \, dt \\ &= 4a \left[\frac{\pi}{2} - \left(\frac{1}{2} e^2\right) \left(\frac{1}{2} \cdot \frac{\pi}{2}\right) - \left(\frac{1}{2 \cdot 4} e^4\right) \left(\frac{1 \cdot 3}{2 \cdot 4} \cdot \frac{\pi}{2}\right) - \left(\frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} e^6\right) \left(\frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} \cdot \frac{\pi}{2}\right) - \dots \right] \\ &= 2\pi a \left[1 - \left(\frac{1}{2}\right)^2 e^2 - \left(\frac{1 \cdot 3}{2 \cdot 4}\right)^2 \frac{e^4}{3} - \left(\frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\right)^2 \frac{e^6}{5} - \dots \right]. \end{aligned}$$

Since $e < 1$, the series on the right-hand side converges by comparison with the geometric series $\sum_{n=1}^{\infty} (e^2)^n$. We do not have an explicit value for P , but we can estimate it as closely as we like by summing finitely many terms from the infinite series. ■

Length of a Curve $y = f(x)$

We will show that the length formula in Section 6.3 is a special case of Equation (3). Given a continuously differentiable function $y = f(x)$, $a \leq x \leq b$, we can assign $x = t$ as a parameter. The graph of the function f is then the curve C defined parametrically by

$$x = t \quad \text{and} \quad y = f(t), \quad a \leq t \leq b,$$

which is a special case of what we have considered in this chapter. We have

$$\frac{dx}{dt} = 1 \quad \text{and} \quad \frac{dy}{dt} = f'(t).$$

From Equation (1),

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = f'(t),$$

giving

$$\begin{aligned} \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 &= 1 + [f'(t)]^2 \\ &= 1 + [f'(x)]^2. \quad t = x \end{aligned}$$

Substitution into Equation (3) gives exactly the arc length formula for the graph of $y = f(x)$ that we found in Section 6.3.

The Arc Length Differential

As in Section 6.3, we define the arc length function for a parametrically defined curve $x = f(t)$ and $y = g(t)$, $a \leq t \leq b$, by

$$s(t) = \int_a^t \sqrt{[f'(z)]^2 + [g'(z)]^2} dz.$$

Then, by the Fundamental Theorem of Calculus,

$$\frac{ds}{dt} = \sqrt{[f'(t)]^2 + [g'(t)]^2} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}.$$

The differential of arc length is

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt. \quad (4)$$

Equation (4) is often abbreviated as

$$ds = \sqrt{dx^2 + dy^2}.$$

Just as in Section 6.3, we can integrate the differential ds between appropriate limits to find the total length of a curve.

Here's an example where we use the arc length differential to find the centroid of an arc.

EXAMPLE 7 Find the centroid of the first-quadrant arc of the astroid in Example 5.

Solution We take the curve's density to be $\delta = 1$ and calculate the curve's mass and moments about the coordinate axes as we did in Section 6.6.

The distribution of mass is symmetric about the line $y = x$, so $\bar{x} = \bar{y}$. A typical segment of the curve (Figure 10.18) has mass

$$dm = 1 \cdot ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt = 3 \cos t \sin t dt. \quad \text{From Example 5}$$

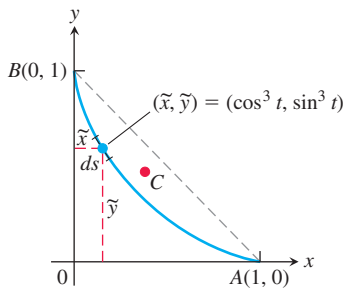

FIGURE 10.18 The centroid C of the astroid arc in Example 7.

The curve's mass is

$$M = \int_0^{\pi/2} dm = \int_0^{\pi/2} 3 \cos t \sin t \, dt = \frac{3}{2}. \quad \text{Again from Example 5}$$

The curve's moment about the x -axis is

$$\begin{aligned} M_x &= \int \tilde{y} \, dm = \int_0^{\pi/2} \sin^3 t \cdot 3 \cos t \sin t \, dt \\ &= 3 \int_0^{\pi/2} \sin^4 t \cos t \, dt = 3 \cdot \left. \frac{\sin^5 t}{5} \right|_0^{\pi/2} = \frac{3}{5}. \end{aligned}$$

It follows that

$$\bar{y} = \frac{M_x}{M} = \frac{3/5}{3/2} = \frac{2}{5}.$$

The centroid is the point $(2/5, 2/5)$. ■

EXAMPLE 8 Find the time T_c it takes for a frictionless bead to slide along the cycloid $x = a(t - \sin t)$, $y = a(1 - \cos t)$ from $t = 0$ to $t = \pi$ (see Figure 10.13).

Solution From Equation (3) in Section 10.1, we want to find the time

$$T_c = \int_{t=0}^{t=\pi} \frac{ds}{\sqrt{2gy}}.$$

We need to express ds parametrically in terms of the parameter t . For the cycloid, $dx/dt = a(1 - \cos t)$ and $dy/dt = a \sin t$, so

$$\begin{aligned} ds &= \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} \, dt \\ &= \sqrt{a^2(1 - 2\cos t + \cos^2 t + \sin^2 t)} \, dt \\ &= \sqrt{a^2(2 - 2\cos t)} \, dt. \end{aligned}$$

Substituting for ds and y in the integrand, it follows that

$$\begin{aligned} T_c &= \int_0^\pi \sqrt{\frac{a^2(2 - 2\cos t)}{2ga(1 - \cos t)}} \, dt \quad y = a(1 - \cos t) \\ &= \int_0^\pi \sqrt{\frac{a}{g}} \, dt = \pi \sqrt{\frac{a}{g}}. \end{aligned}$$

This is the amount of time it takes the frictionless bead to slide down the cycloid to B after it is released from rest at O (see Figure 10.13). ■

Areas of Surfaces of Revolution

In Section 6.4 we found integral formulas for the area of a surface when a curve is revolved about a coordinate axis. Specifically, we found that the surface area is $S = \int 2\pi y \, ds$ for revolution about the x -axis, and $S = \int 2\pi x \, ds$ for revolution about the y -axis. If the curve is parametrized by the equations $x = f(t)$ and $y = g(t)$, $a \leq t \leq b$, where f and g are continuously differentiable and $(f')^2 + (g')^2 > 0$ on $[a, b]$, then the arc length differential ds is given by Equation (4). This observation leads to the following formulas for area of surfaces of revolution for smooth parametrized curves.

Area of Surface of Revolution for Parametrized Curves

If a smooth curve $x = f(t)$, $y = g(t)$, $a \leq t \leq b$, is traversed exactly once as t increases from a to b , then the areas of the surfaces generated by revolving the curve about the coordinate axes are as follows.

1. Revolution about the x -axis ($y \geq 0$):

$$S = \int_a^b 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \quad (5)$$

2. Revolution about the y -axis ($x \geq 0$):

$$S = \int_a^b 2\pi x \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \quad (6)$$

As with length, we can calculate surface area from any convenient parametrization that meets the stated criteria.

EXAMPLE 9 The standard parametrization of the circle of radius 1 centered at the point $(0, 1)$ in the xy -plane is

$$x = \cos t, \quad y = 1 + \sin t, \quad 0 \leq t \leq 2\pi.$$

Use this parametrization to find the area of the surface swept out by revolving the circle about the x -axis (Figure 10.19).

Solution We evaluate the formula

$$\begin{aligned} S &= \int_a^b 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt \\ &= \int_0^{2\pi} 2\pi(1 + \sin t) \sqrt{\underbrace{(-\sin t)^2 + (\cos t)^2}_1} dt \\ &= 2\pi \int_0^{2\pi} (1 + \sin t) dt \\ &= 2\pi \left[t - \cos t \right]_0^{2\pi} = 4\pi^2. \end{aligned}$$

Eq. (5) for revolution about the x -axis; $y = 1 + \sin t \geq 0$

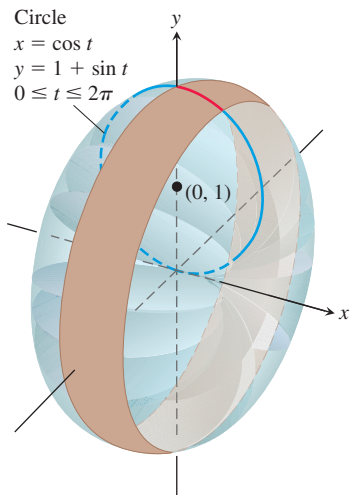

FIGURE 10.19 In Example 9 we calculate the area of the surface of revolution swept out by this parametrized curve.

EXERCISES 10.2**Tangent Lines to Parametrized Curves**

In Exercises 1–14, find an equation for the line tangent to the curve at the point defined by the given value of t . Also, find the value of d^2y/dx^2 at this point.

1. $x = 2 \cos t$, $y = 2 \sin t$, $t = \pi/4$

2. $x = \sin 2\pi t$, $y = \cos 2\pi t$, $t = -1/6$

3. $x = 4 \sin t$, $y = 2 \cos t$, $t = \pi/4$

4. $x = \cos t$, $y = \sqrt{3} \cos t$, $t = 2\pi/3$

5. $x = t$, $y = \sqrt{t}$, $t = 1/4$

6. $x = \sec^2 t - 1$, $y = \tan t$, $t = -\pi/4$

7. $x = \sec t$, $y = \tan t$, $t = \pi/6$

8. $x = -\sqrt{t+1}$, $y = \sqrt{3t}$, $t = 3$

9. $x = 2t^2 + 3$, $y = t^4$, $t = -1$

10. $x = 1/t$, $y = -2 + \ln t$, $t = 1$

11. $x = t - \sin t$, $y = 1 - \cos t$, $t = \pi/3$

12. $x = \cos t, y = 1 + \sin t, t = \pi/2$

13. $x = \frac{1}{t+1}, y = \frac{t}{t-1}, t = 2$

14. $x = t + e^t, y = 1 - e^t, t = 0$

Implicitly Defined Parametrizations

Assuming that the equations in Exercises 15–20 define x and y implicitly as differentiable functions $x = f(t), y = g(t)$, find the slope of the curve $x = f(t), y = g(t)$ at the given value of t .

15. $x^3 + 2t^2 = 9, 2y^3 - 3t^2 = 4, t = 2$

16. $x = \sqrt{5 - \sqrt{t}}, y(t-1) = \sqrt{t}, t = 4$

17. $x + 2x^{3/2} = t^2 + t, y\sqrt{t+1} + 2t\sqrt{y} = 4, t = 0$

18. $x \sin t + 2x = t, t \sin t - 2t = y, t = \pi$

19. $x = t^3 + t, y + 2t^3 = 2x + t^2, t = 1$

20. $t = \ln(x-t), y = te^t, t = 0$

Area

21. Find the area under one arch of the cycloid

$$x = a(t - \sin t), y = a(1 - \cos t).$$

22. Find the area enclosed by the y -axis and the curve

$$x = t - t^2, y = 1 + e^{-t}.$$

23. Find the area enclosed by the ellipse

$$x = a \cos t, y = b \sin t, 0 \leq t \leq 2\pi.$$

24. Find the area under $y = x^3$ over $[0, 1]$ using the following parametrizations.

a. $x = t^2, y = t^6$ b. $x = t^3, y = t^9$

Lengths of Curves

Find the lengths of the curves in Exercises 25–30.

25. $x = \cos t, y = t + \sin t, 0 \leq t \leq \pi$

26. $x = t^3, y = 3t^2/2, 0 \leq t \leq \sqrt{3}$

27. $x = t^2/2, y = (2t+1)^{3/2}/3, 0 \leq t \leq 4$

28. $x = (2t+3)^{3/2}/3, y = t + t^2/2, 0 \leq t \leq 3$

29. $x = 8 \cos t + 8t \sin t$ 30. $x = \ln(\sec t + \tan t) - \sin t$

$$y = 8 \sin t - 8t \cos t, \quad y = \cos t, 0 \leq t \leq \pi/3$$

$$0 \leq t \leq \pi/2$$

Surface Area

Find the areas of the surfaces generated by revolving the curves in Exercises 31–34 about the indicated axes.

31. $x = \cos t, y = 2 + \sin t, 0 \leq t \leq 2\pi$; x -axis

32. $x = (2/3)t^{3/2}, y = 2\sqrt{t}, 0 \leq t \leq \sqrt{3}$; y -axis

33. $x = t + \sqrt{2}, y = (t^2/2) + \sqrt{2}t, -\sqrt{2} \leq t \leq \sqrt{2}$; y -axis

34. $x = \ln(\sec t + \tan t) - \sin t, y = \cos t, 0 \leq t \leq \pi/3$; x -axis

35. **A cone frustum** The line segment joining the points $(0, 1)$ and $(2, 2)$ is revolved about the x -axis to generate a frustum of a cone. Find the surface area of the frustum using the parametrization $x = 2t, y = t + 1, 0 \leq t \leq 1$. Check your result with the geometry formula: Area = $\pi(r_1 + r_2)(\text{slant height})$.

36. **A cone** The line segment joining the origin to the point (h, r) is revolved about the x -axis to generate a cone of height h and base radius r . Find the cone's surface area with the parametric equations $x = ht, y = rt, 0 \leq t \leq 1$. Check your result with the geometry formula: Area = $\pi r(\text{slant height})$.

Centroids

37. Find the coordinates of the centroid of the curve

$$x = \cos t + t \sin t, y = \sin t - t \cos t, 0 \leq t \leq \pi/2.$$

38. Find the coordinates of the centroid of the curve

$$x = e^t \cos t, y = e^t \sin t, 0 \leq t \leq \pi.$$

39. Find the coordinates of the centroid of the curve

$$x = \cos t, y = t + \sin t, 0 \leq t \leq \pi.$$

T 40. Most centroid calculations for curves are done with a calculator or computer that has an integral evaluation program. As a case in point, find, to the nearest hundredth, the coordinates of the centroid of the curve

$$x = t^3, y = 3t^2/2, 0 \leq t \leq \sqrt{3}.$$

Theory and Examples

41. **Length is independent of parametrization** To illustrate the fact that the numbers we get for length do not depend on the way we parametrize our curves (except for the mild restrictions preventing doubling back mentioned earlier), calculate the length of the semicircle $y = \sqrt{1 - x^2}$ with these two different parametrizations:

a. $x = \cos 2t, y = \sin 2t, 0 \leq t \leq \pi/2.$

b. $x = \sin \pi t, y = \cos \pi t, -1/2 \leq t \leq 1/2.$

42. a. Show that the Cartesian formula

$$L = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

for the length of the curve $x = g(y), c \leq y \leq d$ (Section 6.3, Equation 4), is a special case of the parametric length formula

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt.$$

Use this result to find the length of each curve.

b. $x = y^{3/2}, 0 \leq y \leq 4/3$

c. $x = \frac{3}{2}y^{2/3}, 0 \leq y \leq 1$

43. The curve with parametric equations

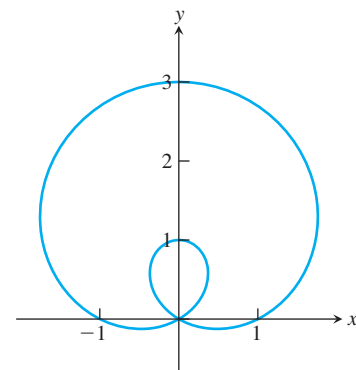

$$x = (1 + 2 \sin \theta) \cos \theta, y = (1 + 2 \sin \theta) \sin \theta$$

is called a *limaçon* and is shown in the accompanying figure. Find the points (x, y) and the slopes of the tangent lines at these points for

a. $\theta = 0.$

b. $\theta = \pi/2.$

c. $\theta = 4\pi/3.$

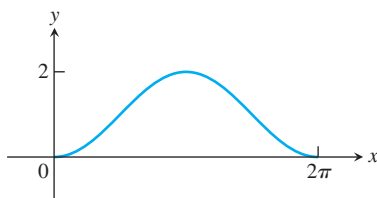

44. The curve with parametric equations

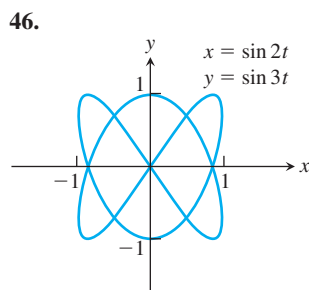

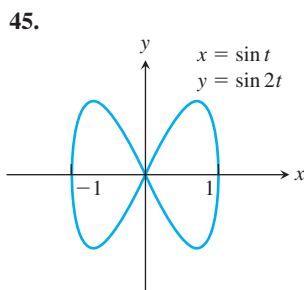

$$x = t, \quad y = 1 - \cos t, \quad 0 \leq t \leq 2\pi$$

is called a *sinusoid* and is shown in the accompanying figure. Find the point (x, y) where the slope of the tangent line is

- a. largest. b. smallest.

T The curves in Exercises 45 and 46 are called *Bowditch curves* or *Lissajous figures*. In each case, find the point in the interior of the first quadrant where the tangent line to the curve is horizontal, and find the equations of the two tangent lines at the origin.

- 47.
- Cycloid**

- a. Find the length of one arch of the cycloid

$$x = a(t - \sin t), \quad y = a(1 - \cos t).$$

- b. Find the area of the surface generated by revolving one arch of the cycloid in part (a) about the
- x
- axis for
- $a = 1$
- .

- 48.
- Volume**
- Find the volume swept out by revolving the region bounded by the
- x
- axis and one arch of the cycloid

$$x = t - \sin t, \quad y = 1 - \cos t$$

about the x -axis.

49. Find the volume swept out by revolving the region bounded by the
- x
- axis and the graph of

$$x = 2t, \quad y = t(2 - t)$$

about the x -axis.

50. Find the volume swept out by revolving the region bounded by the
- y
- axis and the graph of

$$x = t(1 - t), \quad y = 1 + t^2$$

about the y -axis.

COMPUTER EXPLORATIONS

In Exercises 51–54, use a CAS to perform the following steps for the given curve over the closed interval.

- Plot the curve together with the polygonal path approximations for $n = 2, 4, 8$ partition points over the interval. (See Figure 10.16.)
- Find the corresponding approximation to the length of the curve by summing the lengths of the line segments.
- Evaluate the length of the curve using an integral. Compare your approximations for $n = 2, 4, 8$ with the actual length given by the integral. How does the actual length compare with the approximations as n increases? Explain your answer.

51. $x = \frac{1}{3}t^3, \quad y = \frac{1}{2}t^2, \quad 0 \leq t \leq 1$

52. $x = 2t^3 - 16t^2 + 25t + 5, \quad y = t^2 + t - 3, \quad 0 \leq t \leq 6$

53. $x = t - \cos t, \quad y = 1 + \sin t, \quad -\pi \leq t \leq \pi$

54. $x = e^t \cos t, \quad y = e^t \sin t, \quad 0 \leq t \leq \pi$

10.3 Polar Coordinates

In this section we study polar coordinates and their relation to Cartesian coordinates. You will see that polar coordinates are very useful for calculating many multiple integrals studied in Chapter 14. They are also useful in describing the paths of planets and satellites.

Definition of Polar Coordinates

To define polar coordinates, we first fix an **origin** O (called the **pole**) and an **initial ray** from O (Figure 10.20). Usually the positive x -axis is chosen as the initial ray. Then each point P can be located by assigning to it a **polar coordinate pair** (r, θ) in which r gives the directed distance from O to P , and θ gives the directed angle from the initial ray to ray OP . So we label the point P as

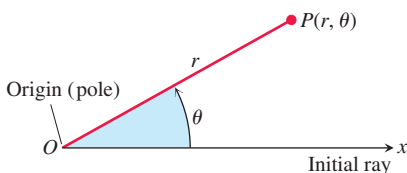

FIGURE 10.20 To define polar coordinates for the plane, we start with an origin, called the pole, and an initial ray.

$$P(r, \theta)$$

Directed distance from O to P Directed angle from initial ray to OP

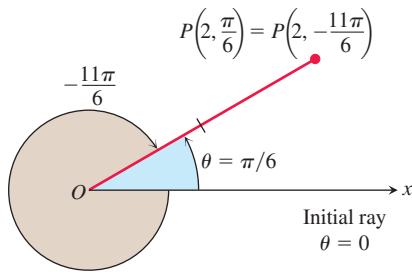

FIGURE 10.21 Polar coordinates are not unique.

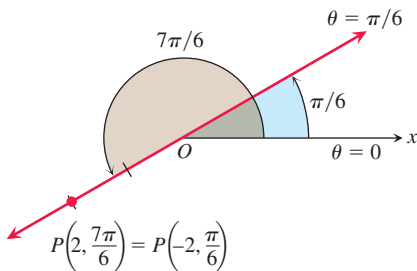

FIGURE 10.22 Polar coordinates can have negative r -values.

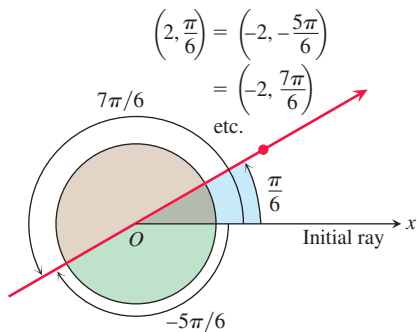

FIGURE 10.23 The point $P(2, \pi/6)$ has infinitely many polar coordinate pairs (Example 1).

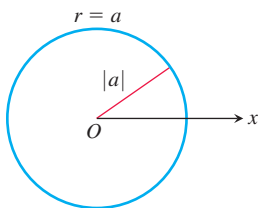

FIGURE 10.24 The polar equation for a circle is $r = a$.

As in trigonometry, θ is positive when measured counterclockwise and negative when measured clockwise. The angle associated with a given point is not unique. A point in the plane has just one pair of Cartesian coordinates, but it has infinitely many pairs of polar coordinates. For instance, the point 2 units from the origin along the ray $\theta = \pi/6$ has polar coordinates $r = 2$, $\theta = \pi/6$. It also has coordinates $r = 2$, $\theta = -11\pi/6$ (Figure 10.21). In some situations we allow r to be negative. That is why we use directed distance in defining $P(r, \theta)$. The point $P(2, 7\pi/6)$ can be reached by turning $7\pi/6$ radians counterclockwise from the initial ray and going forward 2 units (Figure 10.22). It can also be reached by turning $\pi/6$ radians counterclockwise from the initial ray and going *backward* 2 units. So the point also has polar coordinates $r = -2$, $\theta = \pi/6$.

EXAMPLE 1 Find all the polar coordinates of the point $P(2, \pi/6)$.

Solution We sketch the initial ray of the coordinate system, draw the ray from the origin that makes an angle of $\pi/6$ radians with the initial ray, and mark the point $(2, \pi/6)$ (Figure 10.23). We then find the angles for the other coordinate pairs of P in which $r = 2$ and $r = -2$.

For $r = 2$, the complete list of angles is

$$\frac{\pi}{6}, \frac{\pi}{6} \pm 2\pi, \frac{\pi}{6} \pm 4\pi, \frac{\pi}{6} \pm 6\pi, \dots$$

For $r = -2$, the angles are

$$-\frac{5\pi}{6}, -\frac{5\pi}{6} \pm 2\pi, -\frac{5\pi}{6} \pm 4\pi, -\frac{5\pi}{6} \pm 6\pi, \dots$$

The corresponding coordinate pairs of P are

$$\left(2, \frac{\pi}{6} + 2n\pi\right), \quad n = 0, \pm 1, \pm 2, \dots$$

and

$$\left(-2, -\frac{5\pi}{6} + 2n\pi\right), \quad n = 0, \pm 1, \pm 2, \dots$$

When $n = 0$, the formulas give $(2, \pi/6)$ and $(-2, -5\pi/6)$. When $n = 1$, they give $(2, 13\pi/6)$ and $(-2, 7\pi/6)$, and so on. ■

Polar Equations and Graphs

If we hold r fixed at a constant value $r = a \neq 0$, the point $P(r, \theta)$ will lie $|a|$ units from the origin O . As θ varies over any interval of length 2π , P then traces a circle of radius $|a|$ centered at O (Figure 10.24).

If we hold θ fixed at a constant value $\theta = \theta_0$ and let r vary between $-\infty$ and ∞ , the point $P(r, \theta)$ traces the line through O that makes an angle of measure θ_0 with the initial ray. (See Figure 10.22 for an example.)

EXAMPLE 2 A circle or line can have more than one polar equation.

(a) $r = 1$ and $r = -1$ are equations for the circle of radius 1 centered at O .

(b) $\theta = \pi/6$, $\theta = 7\pi/6$, and $\theta = -5\pi/6$ are equations for the line in Figure 10.23. ■

Equations of the form $r = a$ and $\theta = \theta_0$, and inequalities such as $r \leq a$ and $0 \leq \theta \leq \pi$, can be combined to define regions, segments, and rays.

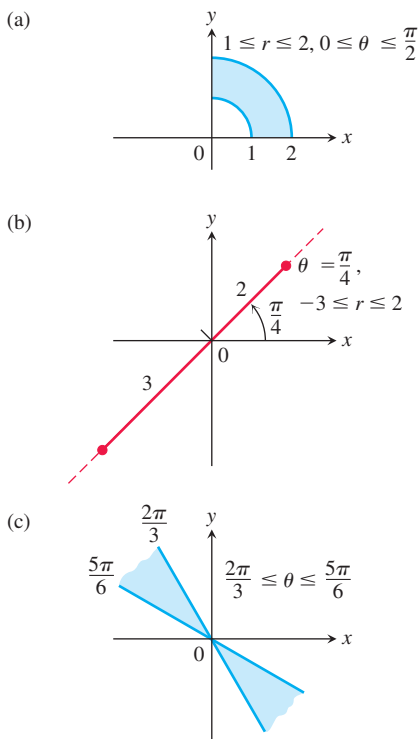

FIGURE 10.25 The graphs of typical inequalities in r and θ (Example 3).

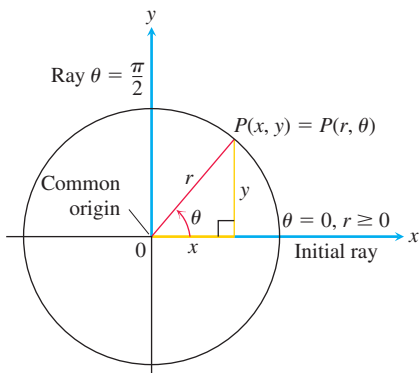

FIGURE 10.26 The usual way to relate polar and Cartesian coordinates.

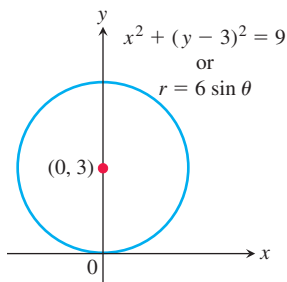

FIGURE 10.27 The circle in Example 5.

EXAMPLE 3 Graph the sets of points whose polar coordinates satisfy the following conditions.

(a) $1 \leq r \leq 2$ and $0 \leq \theta \leq \frac{\pi}{2}$

(b) $-3 \leq r \leq 2$ and $\theta = \frac{\pi}{4}$

(c) $\frac{2\pi}{3} \leq \theta \leq \frac{5\pi}{6}$ (no restriction on r)

Solution The graphs are shown in Figure 10.25. ■

Relating Polar and Cartesian Coordinates

When we use both polar and Cartesian coordinates in a plane, we place the two origins together and let the initial polar ray be the positive x -axis. The ray $\theta = \pi/2$, $r > 0$, becomes the positive y -axis (Figure 10.26). The two coordinate systems are then related by the following equations.

Equations Relating Polar and Cartesian Coordinates

Polar to Cartesian:

$$x = r \cos \theta, \quad y = r \sin \theta$$

Cartesian to Polar:

$$r^2 = x^2 + y^2, \quad \tan \theta = \frac{y}{x}$$

The first two of these equations uniquely determine the Cartesian coordinates x and y given the polar coordinates r and θ . On the other hand, if x and y are given and $(x, y) \neq (0, 0)$, the third equation gives two possible choices for r (a positive and a negative value). For each of these r values, there is a unique $\theta \in [0, 2\pi)$ satisfying the first two equations, each then giving a polar coordinate representation of the Cartesian point (x, y) . The other polar coordinate representations for the point can be determined from these two, as in Example 1.

EXAMPLE 4 Here are some plane curves expressed in terms of both polar coordinate and Cartesian coordinate equations.

Polar equation	Cartesian equivalent
$r \cos \theta = 2$	$x = 2$
$r^2 \cos \theta \sin \theta = 4$	$xy = 4$
$r^2 \cos^2 \theta - r^2 \sin^2 \theta = 1$	$x^2 - y^2 = 1$
$r = 1 + 2r \cos \theta$	$y^2 - 3x^2 - 4x - 1 = 0$
$r = 1 - \cos \theta$	$x^4 + y^4 + 2x^2y^2 + 2x^3 + 2xy^2 - y^2 = 0$

Some curves are more simply expressed with polar coordinates; others are not. ■

EXAMPLE 5 Find a polar equation for the circle $x^2 + (y - 3)^2 = 9$ (Figure 10.27).

Solution We apply the equations relating polar and Cartesian coordinates:

$$\begin{aligned}
 x^2 + (y - 3)^2 &= 9 \\
 x^2 + y^2 - 6y + 9 &= 9 && \text{Expand } (y - 3)^2. \\
 x^2 + y^2 - 6y &= 0 && \text{Cancellation} \\
 r^2 - 6r \sin \theta &= 0 && x^2 + y^2 = r^2, y = r \sin \theta \\
 r = 0 \quad \text{or} \quad r - 6 \sin \theta &= 0 \\
 r &= 6 \sin \theta && \text{Includes both possibilities}
 \end{aligned}$$

EXAMPLE 6 Replace the following polar equations by equivalent Cartesian equations and identify their graphs.

(a) $r \cos \theta = -4$

(b) $r^2 = 4r \cos \theta$

(c) $r = \frac{4}{2 \cos \theta - \sin \theta}$

Solution We use the substitutions $r \cos \theta = x$, $r \sin \theta = y$, and $r^2 = x^2 + y^2$.

(a) $r \cos \theta = -4$

The Cartesian equation: $r \cos \theta = -4$

$$x = -4 \quad \text{Substitute.}$$

The graph: Vertical line through $x = -4$ on the x -axis

(b) $r^2 = 4r \cos \theta$

The Cartesian equation: $r^2 = 4r \cos \theta$

$$x^2 + y^2 = 4x \quad \text{Substitute.}$$

$$x^2 - 4x + y^2 = 0$$

$$x^2 - 4x + 4 + y^2 = 4 \quad \text{Complete the square.}$$

$$(x - 2)^2 + y^2 = 4 \quad \text{Factor.}$$

The graph: Circle, radius 2, center $(h, k) = (2, 0)$

(c) $r = \frac{4}{2 \cos \theta - \sin \theta}$

The Cartesian equation: $r(2 \cos \theta - \sin \theta) = 4$

$$2r \cos \theta - r \sin \theta = 4 \quad \text{Multiply by } r.$$

$$2x - y = 4 \quad \text{Substitute.}$$

$$y = 2x - 4 \quad \text{Solve for } y.$$

The graph: Line, slope $m = 2$, y -intercept $b = -4$

EXERCISES 10.3

Polar Coordinates

1. Which polar coordinate pairs label the same point?

- | | | |
|------------------|-------------------|------------------|
| a. $(3, 0)$ | b. $(-3, 0)$ | c. $(2, 2\pi/3)$ |
| d. $(2, 7\pi/3)$ | e. $(-3, \pi)$ | f. $(2, \pi/3)$ |
| g. $(-3, 2\pi)$ | h. $(-2, -\pi/3)$ | |

2. Which polar coordinate pairs label the same point?

- | | | |
|-------------------------|-------------------|-------------------|
| a. $(-2, \pi/3)$ | b. $(2, -\pi/3)$ | c. (r, θ) |
| d. $(r, \theta + \pi)$ | e. $(-r, \theta)$ | f. $(2, -2\pi/3)$ |
| g. $(-r, \theta + \pi)$ | h. $(-2, 2\pi/3)$ | |

3. Plot the following points, given in polar coordinates. Then find all the polar coordinates of each point.
- a. $(2, \pi/2)$ b. $(2, 0)$
 c. $(-2, \pi/2)$ d. $(-2, 0)$
4. Plot the following points, given in polar coordinates. Then find all the polar coordinates of each point.
- a. $(3, \pi/4)$ b. $(-3, \pi/4)$
 c. $(3, -\pi/4)$ d. $(-3, -\pi/4)$

Polar to Cartesian Coordinates

5. Find the Cartesian coordinates of the points in Exercise 1.
6. Find the Cartesian coordinates of the following points, given in polar coordinates.
- a. $(\sqrt{2}, \pi/4)$ b. $(1, 0)$
 c. $(0, \pi/2)$ d. $(-\sqrt{2}, \pi/4)$
 e. $(-3, 5\pi/6)$ f. $(5, \tan^{-1}(4/3))$
 g. $(-1, 7\pi)$ h. $(2\sqrt{3}, 2\pi/3)$

Cartesian to Polar Coordinates

7. Find the polar coordinates, $0 \leq \theta < 2\pi$ and $r \geq 0$, of the following points given in Cartesian coordinates.
- a. $(1, 1)$ b. $(-3, 0)$
 c. $(\sqrt{3}, -1)$ d. $(-3, 4)$
8. Find the polar coordinates, $-\pi \leq \theta < \pi$ and $r \geq 0$, of the following points given in Cartesian coordinates.
- a. $(-2, -2)$ b. $(0, 3)$
 c. $(-\sqrt{3}, 1)$ d. $(5, -12)$
9. Find the polar coordinates, $0 \leq \theta < 2\pi$ and $r \leq 0$, of the following points given in Cartesian coordinates.
- a. $(3, 3)$ b. $(-1, 0)$
 c. $(-1, \sqrt{3})$ d. $(4, -3)$
10. Find the polar coordinates, $-\pi \leq \theta < \pi$ and $r \leq 0$, of the following points given in Cartesian coordinates.
- a. $(-2, 0)$ b. $(1, 0)$
 c. $(0, -3)$ d. $(\frac{\sqrt{3}}{2}, \frac{1}{2})$

Graphing Sets of Polar Coordinate Points

Graph the sets of points whose polar coordinates satisfy the equations and inequalities in Exercises 11–26.

11. $r = 2$ 12. $0 \leq r \leq 2$
 13. $r \geq 1$ 14. $1 \leq r \leq 2$
 15. $0 \leq \theta \leq \pi/6$, $r \geq 0$ 16. $\theta = 2\pi/3$, $r \leq -2$
 17. $\theta = \pi/3$, $-1 \leq r \leq 3$ 18. $\theta = 11\pi/4$, $r \geq -1$

19. $\theta = \pi/2$, $r \geq 0$ 20. $\theta = \pi/2$, $r \leq 0$
 21. $0 \leq \theta \leq \pi$, $r = 1$ 22. $0 \leq \theta \leq \pi$, $r = -1$
 23. $\pi/4 \leq \theta \leq 3\pi/4$, $0 \leq r \leq 1$
 24. $-\pi/4 \leq \theta \leq \pi/4$, $-1 \leq r \leq 1$
 25. $-\pi/2 \leq \theta \leq \pi/2$, $1 \leq r \leq 2$
 26. $0 \leq \theta \leq \pi/2$, $1 \leq |r| \leq 2$

Polar to Cartesian Equations

Replace the polar equations in Exercises 27–52 with equivalent Cartesian equations. Then describe or identify the graph.

27. $r \cos \theta = 2$ 28. $r \sin \theta = -1$
 29. $r \sin \theta = 0$ 30. $r \cos \theta = 0$
 31. $r = 4 \csc \theta$ 32. $r = -3 \sec \theta$
 33. $r \cos \theta + r \sin \theta = 1$ 34. $r \sin \theta = r \cos \theta$
 35. $r^2 = 1$ 36. $r^2 = 4r \sin \theta$
 37. $r = \frac{5}{\sin \theta - 2 \cos \theta}$ 38. $r^2 \sin 2\theta = 2$
 39. $r = \cot \theta \csc \theta$ 40. $r = 4 \tan \theta \sec \theta$
 41. $r = \csc \theta e^{r \cos \theta}$ 42. $r \sin \theta = \ln r + \ln \cos \theta$
 43. $r^2 + 2r^2 \cos \theta \sin \theta = 1$ 44. $\cos^2 \theta = \sin^2 \theta$
 45. $r^2 = -4r \cos \theta$ 46. $r^2 = -6r \sin \theta$
 47. $r = 8 \sin \theta$ 48. $r = 3 \cos \theta$
 49. $r = 2 \cos \theta + 2 \sin \theta$ 50. $r = 2 \cos \theta - \sin \theta$
 51. $r \sin\left(\theta + \frac{\pi}{6}\right) = 2$ 52. $r \sin\left(\frac{2\pi}{3} - \theta\right) = 5$

Cartesian to Polar Equations

Replace the Cartesian equations in Exercises 53–66 with equivalent polar equations.

53. $x = 7$ 54. $y = 1$ 55. $x = y$
 56. $x - y = 3$ 57. $x^2 + y^2 = 4$ 58. $x^2 - y^2 = 1$
 59. $\frac{x^2}{9} + \frac{y^2}{4} = 1$ 60. $xy = 2$
 61. $y^2 = 4x$ 62. $x^2 + xy + y^2 = 1$
 63. $x^2 + (y - 2)^2 = 4$ 64. $(x - 5)^2 + y^2 = 25$
 65. $(x - 3)^2 + (y + 1)^2 = 4$ 66. $(x + 2)^2 + (y - 5)^2 = 16$
67. Find all polar coordinates of the origin.

68. Vertical and horizontal lines

- a. Show that every vertical line in the xy -plane has a polar equation of the form $r = a \sec \theta$.
- b. Find the analogous polar equation for horizontal lines in the xy -plane.

10.4 Graphing Polar Coordinate Equations

It is often helpful to graph an equation expressed in polar coordinates in the Cartesian xy -plane. This section describes some techniques for graphing these equations using symmetries and tangent lines to the graph.

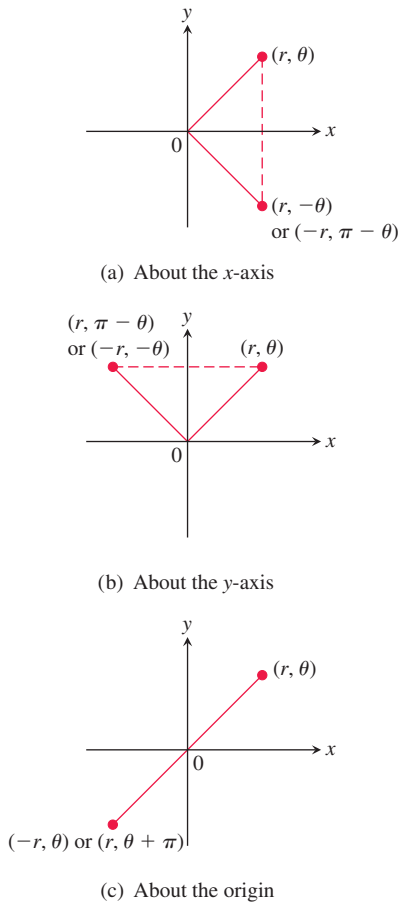

FIGURE 10.28 Three tests for symmetry in polar coordinates.

Symmetry

The following list shows how to test for three standard types of symmetries when using polar coordinates. These symmetries are illustrated in Figure 10.28.

Symmetry Tests for Polar Graphs in the Cartesian xy -Plane

1. *Symmetry about the x-axis:* If the point (r, θ) lies on the graph, then the point $(r, -\theta)$ or $(-r, \pi - \theta)$ lies on the graph (Figure 10.28a).
2. *Symmetry about the y-axis:* If the point (r, θ) lies on the graph, then the point $(r, \pi - \theta)$ or $(-r, -\theta)$ lies on the graph (Figure 10.28b).
3. *Symmetry about the origin:* If the point (r, θ) lies on the graph, then the point $(-r, \theta)$ or $(r, \theta + \pi)$ lies on the graph (Figure 10.28c).

Slope

The slope of a polar curve $r = f(\theta)$ in the xy -plane is dy/dx , but this is **not** given by the formula $r' = df/d\theta$. To see why, think of the graph of f as the graph of the parametric equations

$$x = r \cos \theta = f(\theta) \cos \theta, \quad y = r \sin \theta = f(\theta) \sin \theta.$$

If f is a differentiable function of θ , then so are x and y , and when $dx/d\theta \neq 0$, we can calculate dy/dx from the parametric formula

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} \quad \text{Section 10.2, Eq. (1) with } t = \theta$$

$$= \frac{\frac{d}{d\theta}(f(\theta) \sin \theta)}{\frac{d}{d\theta}(f(\theta) \cos \theta)} \quad \text{Substitute}$$

$$= \frac{\frac{df}{d\theta} \sin \theta + f(\theta) \cos \theta}{\frac{df}{d\theta} \cos \theta - f(\theta) \sin \theta} \quad \text{Product Rule for derivatives}$$

Therefore, we see that dy/dx is not the same as $df/d\theta$.

Slope of the Curve $r = f(\theta)$ in the Cartesian xy -Plane

$$\left. \frac{dy}{dx} \right|_{(r, \theta)} = \frac{f'(\theta) \sin \theta + f(\theta) \cos \theta}{f'(\theta) \cos \theta - f(\theta) \sin \theta}, \quad (1)$$

provided $dx/d\theta \neq 0$ at (r, θ) .

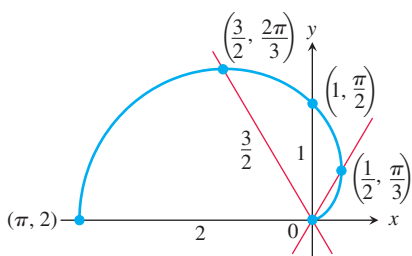

If the curve $r = f(\theta)$ passes through the origin at $\theta = \theta_0$, then $f(\theta_0) = 0$, and the slope equation gives

$$\left. \frac{dy}{dx} \right|_{(0, \theta_0)} = \frac{f'(\theta_0) \sin \theta_0}{f'(\theta_0) \cos \theta_0} = \tan \theta_0.$$

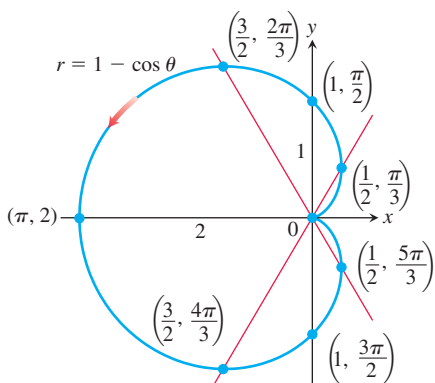

That is, the slope at $(0, \theta_0)$ is $\tan \theta_0$. The reason we say ‘‘slope at $(0, \theta_0)$ ’’ and not just ‘‘slope at the origin’’ is that a polar curve may pass through the origin (or any point) more than once, with different slopes at different θ -values. This is not the case in our first example, however.

θ	$r = 1 - \cos \theta$
0	0
$\frac{\pi}{3}$	$\frac{1}{2}$
$\frac{\pi}{2}$	1
$\frac{2\pi}{3}$	$\frac{3}{2}$
π	2

(a)

(b)

(c)

FIGURE 10.29 The steps in graphing the cardioid $r = 1 - \cos \theta$ (Example 1). The arrow shows the direction of increasing θ .

EXAMPLE 1 Graph the curve $r = 1 - \cos \theta$ in the Cartesian xy -plane.

Solution The curve is symmetric about the x -axis because

$$\begin{aligned} (r, \theta) \text{ on the graph} &\Rightarrow r = 1 - \cos \theta \\ &\Rightarrow r = 1 - \cos(-\theta) && \cos \theta = \cos(-\theta) \\ &\Rightarrow (r, -\theta) \text{ on the graph.} \end{aligned}$$

As θ increases from 0 to π , $\cos \theta$ decreases from 1 to -1 , and $r = 1 - \cos \theta$ increases from a minimum value of 0 to a maximum value of 2. As θ continues on from π to 2π , $\cos \theta$ increases from -1 back to 1, and r decreases from 2 back to 0. The curve starts to repeat when $\theta = 2\pi$ because the cosine has period 2π .

The curve leaves the origin with slope $\tan(0) = 0$ and returns to the origin with slope $\tan(2\pi) = 0$.

We make a table of values from $\theta = 0$ to $\theta = \pi$, plot the points, draw a smooth curve through them with a horizontal tangent line at the origin, and reflect the curve across the x -axis to complete the graph (Figure 10.29). The curve is called a *cardioid* because of its heart shape. ■

EXAMPLE 2 Graph the curve $r^2 = 4 \cos \theta$ in the Cartesian xy -plane.

Solution The equation $r^2 = 4 \cos \theta$ requires $\cos \theta \geq 0$, so we get the entire graph by running θ from $-\pi/2$ to $\pi/2$. The curve is symmetric about the x -axis because

$$\begin{aligned} (r, \theta) \text{ on the graph} &\Rightarrow r^2 = 4 \cos \theta \\ &\Rightarrow r^2 = 4 \cos(-\theta) && \cos \theta = \cos(-\theta) \\ &\Rightarrow (r, -\theta) \text{ on the graph.} \end{aligned}$$

The curve is also symmetric about the origin because

$$\begin{aligned} (r, \theta) \text{ on the graph} &\Rightarrow r^2 = 4 \cos \theta \\ &\Rightarrow (-r)^2 = 4 \cos \theta \\ &\Rightarrow (-r, \theta) \text{ on the graph.} \end{aligned}$$

Together, these two symmetries imply symmetry about the y -axis.

The curve passes through the origin when $\theta = -\pi/2$ and $\theta = \pi/2$. It has a vertical tangent line both times because $\tan \theta$ is infinite.

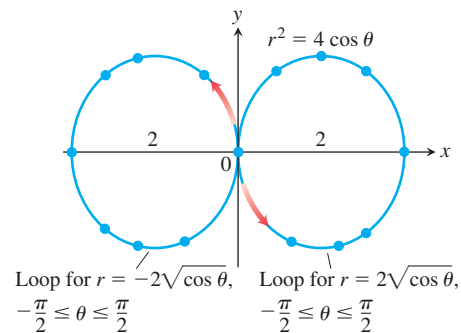

For each value of θ in the interval between $-\pi/2$ and $\pi/2$, the formula $r^2 = 4 \cos \theta$ gives two values of r :

$$r = \pm 2\sqrt{\cos \theta}.$$

We make a short table of values, plot the corresponding points, and use information about symmetry and tangent lines to guide us in connecting the points with a smooth curve (Figure 10.30).

θ	$\cos \theta$	$r = \pm 2\sqrt{\cos \theta}$
0	1	± 2
$\pm \frac{\pi}{6}$	$\frac{\sqrt{3}}{2}$	$\approx \pm 1.9$
$\pm \frac{\pi}{4}$	$\frac{1}{\sqrt{2}}$	$\approx \pm 1.7$
$\pm \frac{\pi}{3}$	$\frac{1}{2}$	$\approx \pm 1.4$
$\pm \frac{\pi}{2}$	0	0

(a)

(b)

FIGURE 10.30 The graph of $r^2 = 4 \cos \theta$. The arrows show the direction of increasing θ . The values of r in the table are rounded (Example 2). ■

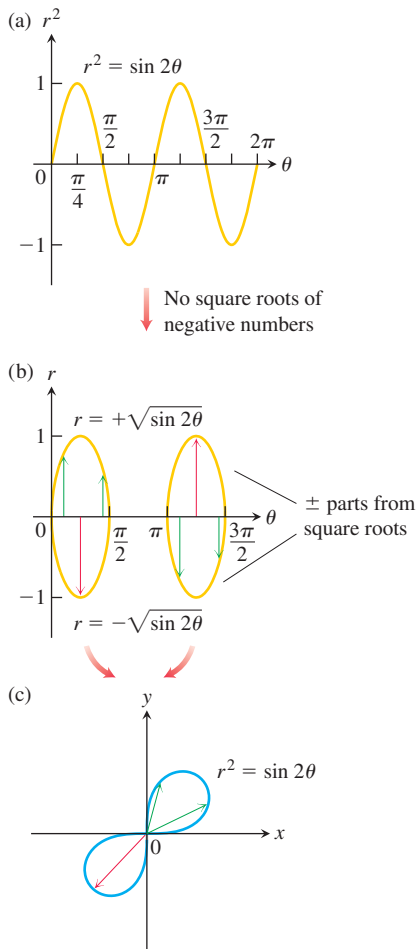

FIGURE 10.31 To plot $r = f(\theta)$ in the Cartesian $r\theta$ -plane in (b), we first plot $r^2 = \sin 2\theta$ in the $r^2\theta$ -plane in (a) and then ignore the values of θ for which $\sin 2\theta$ is negative. The radii from the sketch in (b) cover the polar graph of the lemniscate in (c) twice (Example 3).

Converting a Graph from the $r\theta$ -Plane to the xy -Plane

One way to graph a polar equation $r = f(\theta)$ in the xy -plane is to make a table of (r, θ) -values, plot the corresponding points there, and connect them in order of increasing θ . This can work well if enough points have been plotted to reveal all the loops and dimples in the graph. Another method of graphing follows.

1. First graph the function $r = f(\theta)$ in the Cartesian $r\theta$ -plane.
2. Then use that Cartesian graph as a “table” and guide to sketch the polar coordinate graph in the xy -plane.

This method is sometimes better than simple point plotting because the first Cartesian graph shows at a glance where r is positive, where negative, and where nonexistent, as well as where r is increasing and where it is decreasing. Here is an example.

EXAMPLE 3 Graph the lemniscate curve $r^2 = \sin 2\theta$ in the Cartesian xy -plane.

Solution For this example it will be easier to first plot r^2 , instead of r , as a function of θ in the Cartesian $r^2\theta$ -plane (see Figure 10.31a). We pass from there to the graph of $r = \pm\sqrt{\sin 2\theta}$ in the $r\theta$ -plane (Figure 10.31b), and then draw the polar graph (Figure 10.31c). The graph in Figure 10.31b “covers” the final polar graph in Figure 10.31c twice. We could have managed with either loop alone, with the two upper halves, or with the two lower halves. The double covering does no harm, however, and we actually learn a little more about the behavior of the function this way. ■

USING TECHNOLOGY Graphing Polar Curves Parametrically

For complicated polar curves, we may need to use a graphing calculator or computer to graph the curve. If the device does not plot polar graphs directly, we can convert $r = f(\theta)$ into parametric form using the equations

$$x = r \cos \theta = f(\theta) \cos \theta, \quad y = r \sin \theta = f(\theta) \sin \theta.$$

Then we use the device to draw a parametrized curve in the Cartesian xy -plane.

EXERCISES 10.4

Symmetries and Polar Graphs

Identify the symmetries of the curves in Exercises 1–12. Then sketch the curves in the xy -plane.

1. $r = 1 + \cos \theta$
2. $r = 2 - 2 \cos \theta$
3. $r = 1 - \sin \theta$
4. $r = 1 + \sin \theta$
5. $r = 2 + \sin \theta$
6. $r = 1 + 2 \sin \theta$
7. $r = \sin(\theta/2)$
8. $r = \cos(\theta/2)$
9. $r^2 = \cos \theta$
10. $r^2 = \sin \theta$
11. $r^2 = -\sin \theta$
12. $r^2 = -\cos \theta$

Graph the lemniscates in Exercises 13–16. What symmetries do these curves have?

13. $r^2 = 4 \cos 2\theta$
14. $r^2 = 4 \sin 2\theta$
15. $r^2 = -\sin 2\theta$
16. $r^2 = -\cos 2\theta$

Slopes of Polar Curves in the xy -Plane

Find the slopes of the curves in Exercises 17–20 at the given points. Sketch the curves along with their tangent lines at these points.

17. **Cardioid** $r = -1 + \cos \theta$; $\theta = \pm\pi/2$
18. **Cardioid** $r = -1 + \sin \theta$; $\theta = 0, \pi$
19. **Four-leaved rose** $r = \sin 2\theta$; $\theta = \pm\pi/4, \pm3\pi/4$
20. **Four-leaved rose** $r = \cos 2\theta$; $\theta = 0, \pm\pi/2, \pi$

Concavity of Polar Curves in the xy -Plane

Equation (1) gives the formula for the derivative y' of a polar curve $r = f(\theta)$. The second derivative is $\frac{d^2y}{dx^2} = \frac{dy'/d\theta}{dx/d\theta}$ (see Equation (2) in Section 10.2). Find the slope and concavity of the curves in Exercises 21–24 at the given points.

21. $r = \sin \theta$, $\theta = \pi/6$, $\pi/3$ 22. $r = e^\theta$, $\theta = 0$, π
 23. $r = \theta$, $\theta = 0$, $\pi/2$ 24. $r = 1/\theta$, $\theta = -\pi$, 1

Graphing Limaçons

Graph the limaçons in Exercises 25–28. Limaçon (“lee-ma-sahn”) is Old French for “snail.” You will understand the name when you graph the limaçons in Exercise 25. Equations for limaçons have the form $r = a \pm b \cos \theta$ or $r = a \pm b \sin \theta$. There are four basic shapes.

25. Limaçons with an inner loop

- a. $r = \frac{1}{2} + \cos \theta$ b. $r = \frac{1}{2} + \sin \theta$

26. Cardioids

- a. $r = 1 - \cos \theta$ b. $r = -1 + \sin \theta$

27. Dimpled limaçons

- a. $r = \frac{3}{2} + \cos \theta$ b. $r = \frac{3}{2} - \sin \theta$

28. Oval limaçons

- a. $r = 2 + \cos \theta$ b. $r = -2 + \sin \theta$

Graphing Polar Regions and Curves in the xy -Plane

29. Sketch the region defined by the inequalities $-1 \leq r \leq 2$ and $-\pi/2 \leq \theta \leq \pi/2$.
 30. Sketch the region defined by the inequalities $0 \leq r \leq 2 \sec \theta$ and $-\pi/4 \leq \theta \leq \pi/4$.

In Exercises 31 and 32, sketch the region defined by the inequality.

31. $0 \leq r \leq 2 - 2 \cos \theta$ 32. $0 \leq r^2 \leq \cos \theta$

T 33. Which of the following has the same graph as $r = 1 - \cos \theta$?

- a. $r = -1 - \cos \theta$ b. $r = 1 + \cos \theta$

Confirm your answer with algebra.

T 34. Which of the following has the same graph as $r = \cos 2\theta$?

- a. $r = -\sin(2\theta + \pi/2)$ b. $r = -\cos(\theta/2)$

Confirm your answer with algebra.

T 35. **A rose within a rose** Graph the equation $r = 1 - 2 \sin 3\theta$.

T 36. **The nephroid of Freeth** Graph the nephroid of Freeth:

$$r = 1 + 2 \sin \frac{\theta}{2}.$$

T 37. **Roses** Graph the roses $r = \cos m\theta$ for $m = 1/3, 2, 3$, and 7 .

T 38. **Spirals** Polar coordinates are just the thing for defining spirals. Graph the following spirals.

- a. $r = \theta$
 b. $r = -\theta$
 c. A logarithmic spiral: $r = e^{\theta/10}$
 d. A hyperbolic spiral: $r = 8/\theta$
 e. An equilateral hyperbola: $r = \pm 10/\sqrt{\theta}$
 (Use different colors for the two branches.)

T 39. Graph the equation $r = \sin(\frac{8}{7}\theta)$ for $0 \leq \theta \leq 14\pi$.

T 40. Graph the equation

$$r = \sin^2(2.3\theta) + \cos^4(2.3\theta)$$

for $0 \leq \theta \leq 10\pi$.

10.5 Areas and Lengths in Polar Coordinates

This section shows how to calculate areas of plane regions and lengths of curves in polar coordinates.

Area in the Plane

The region OTS in Figure 10.32 is bounded by the rays $\theta = \alpha$ and $\theta = \beta$ and the curve $r = f(\theta)$. We approximate the region with n nonoverlapping fan-shaped circular sectors based on a partition P of angle TOS . The typical sector has radius $r_k = f(\theta_k)$ and central angle of radian measure $\Delta\theta_k$. Its area is $\Delta\theta_k/2\pi$ times the area of a circle of radius r_k , or

$$A_k = \frac{1}{2} r_k^2 \Delta\theta_k = \frac{1}{2} (f(\theta_k))^2 \Delta\theta_k.$$

The area of region OTS is approximately

$$\sum_{k=1}^n A_k = \sum_{k=1}^n \frac{1}{2} (f(\theta_k))^2 \Delta\theta_k.$$

If f is continuous, we expect the approximations to improve as the norm of the partition P goes to zero, where the norm of P is the largest value of $\Delta\theta_k$. We are therefore led to the following formula for the region's area.

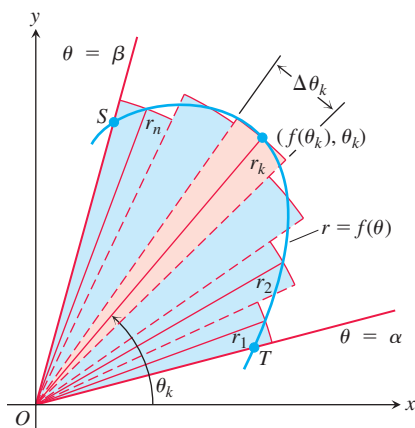

FIGURE 10.32 To derive a formula for the area of region OTS , we approximate the region with fan-shaped circular sectors.

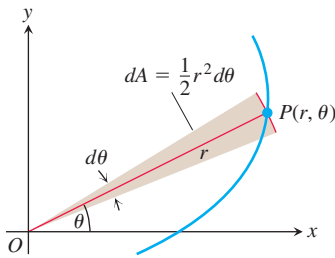

FIGURE 10.33 The area differential dA for the curve $r = f(\theta)$.

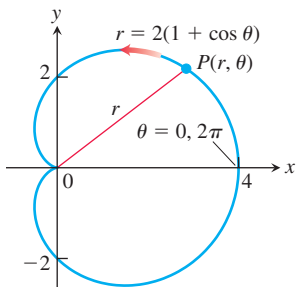

FIGURE 10.34 The cardioid in Example 1.

$$A = \lim_{\|P\| \rightarrow 0} \sum_{k=1}^n \frac{1}{2} (f(\theta_k))^2 \Delta\theta_k = \int_{\alpha}^{\beta} \frac{1}{2} (f(\theta))^2 d\theta.$$

Area of the Fan-Shaped Region Between the Origin and the Curve
 $r = f(\theta)$ when $\alpha \leq \theta \leq \beta$, $r \geq 0$, and $\beta - \alpha \leq 2\pi$

$$A = \int_{\alpha}^{\beta} \frac{1}{2} r^2 d\theta$$

This is the integral of the **area differential** (Figure 10.33)

$$dA = \frac{1}{2} r^2 d\theta = \frac{1}{2} (f(\theta))^2 d\theta.$$

In the area formula above, we assumed that $r \geq 0$ and that the region does not sweep out an angle of more than 2π . This avoids issues with negatively signed areas or with regions that overlap themselves. More general regions can usually be handled by subdividing them into regions of this type if necessary.

EXAMPLE 1 Find the area of the region in the xy -plane enclosed by the cardioid $r = 2(1 + \cos \theta)$.

Solution We graph the cardioid (Figure 10.34) and determine that the radius OP sweeps out the region exactly once as θ runs from 0 to 2π . The area is therefore

$$\begin{aligned} \int_{\theta=0}^{\theta=2\pi} \frac{1}{2} r^2 d\theta &= \int_0^{2\pi} \frac{1}{2} \cdot 4(1 + \cos \theta)^2 d\theta \\ &= \int_0^{2\pi} 2(1 + 2\cos \theta + \cos^2 \theta) d\theta \\ &= \int_0^{2\pi} \left(2 + 4\cos \theta + 2 \cdot \frac{1 + \cos 2\theta}{2} \right) d\theta \\ &= \int_0^{2\pi} (3 + 4\cos \theta + \cos 2\theta) d\theta \\ &= \left[3\theta + 4\sin \theta + \frac{\sin 2\theta}{2} \right]_0^{2\pi} = 6\pi - 0 = 6\pi. \end{aligned}$$

To find the area of a region like the one in Figure 10.35, which lies between two polar curves $r_1 = r_1(\theta)$ and $r_2 = r_2(\theta)$ from $\theta = \alpha$ to $\theta = \beta$, we subtract the integral of $(1/2)r_1^2 d\theta$ from the integral of $(1/2)r_2^2 d\theta$. This leads to the following formula.

Area of the Region $0 \leq r_1(\theta) \leq r \leq r_2(\theta)$, $\alpha \leq \theta \leq \beta$, and $\beta - \alpha \leq 2\pi$

$$A = \int_{\alpha}^{\beta} \frac{1}{2} r_2^2 d\theta - \int_{\alpha}^{\beta} \frac{1}{2} r_1^2 d\theta = \int_{\alpha}^{\beta} \frac{1}{2} (r_2^2 - r_1^2) d\theta \quad (1)$$

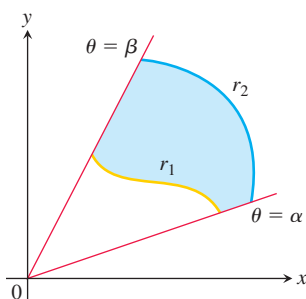

FIGURE 10.35 The area of the shaded region is calculated by subtracting the area of the region between r_1 and the origin from the area of the region between r_2 and the origin.

EXAMPLE 2 Find the area of the region that lies inside the circle $r = 1$ and outside the cardioid $r = 1 - \cos \theta$.

Solution We sketch the region to determine its boundaries and find the limits of integration (Figure 10.36). The outer curve is $r_2 = 1$, the inner curve is $r_1 = 1 - \cos \theta$, and θ runs from $-\pi/2$ to $\pi/2$. The area, from Equation (1), is

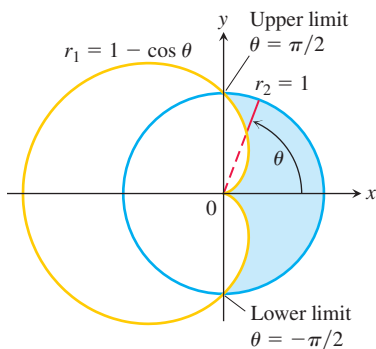

FIGURE 10.36 The region and limits of integration in Example 2.

$$\begin{aligned}
 A &= \int_{-\pi/2}^{\pi/2} \frac{1}{2}(r_2^2 - r_1^2) d\theta && \text{Eq. (1)} \\
 &= 2 \int_0^{\pi/2} \frac{1}{2}(r_2^2 - r_1^2) d\theta && \text{Symmetry} \\
 &= \int_0^{\pi/2} (1 - (1 - 2 \cos \theta + \cos^2 \theta)) d\theta && r_2 = 1 \text{ and } r_1 = 1 - \cos \theta \\
 &= \int_0^{\pi/2} (2 \cos \theta - \cos^2 \theta) d\theta = \int_0^{\pi/2} \left(2 \cos \theta - \frac{1 + \cos 2\theta}{2} \right) d\theta \\
 &= \left[2 \sin \theta - \frac{\theta}{2} - \frac{\sin 2\theta}{4} \right]_0^{\pi/2} = 2 - \frac{\pi}{4}.
 \end{aligned}$$

The fact that we can represent a point in different ways in polar coordinates requires that we take extra care in deciding when a point lies on the graph of a polar equation and in determining the points at which polar graphs intersect. (We needed intersection points in Example 2.) In Cartesian coordinates, we can always find the points where two curves cross by solving their equations simultaneously. In polar coordinates, the story is different. Simultaneous solution may reveal some intersection points without revealing others, so it is sometimes difficult to find all points of intersection of two polar curves. One way to identify all the points of intersection is to graph the equations.

EXAMPLE 3 Find all of the points where the curve $r = 2 \cos(\theta/3)$ intersects the circle of radius $\sqrt{2}$ centered at the origin.

Solution Note that the function $r = 2 \cos(\theta/3)$ takes both positive and negative values. Therefore, when we look for the points where this curve intersects the circle, it is important to take into account that the circle is described both by the equation $r = \sqrt{2}$ and by the equation $r = -\sqrt{2}$.

Solving $2 \cos(\theta/3) = \sqrt{2}$ for θ yields

$$2 \cos(\theta/3) = \sqrt{2}, \quad \cos(\theta/3) = \sqrt{2}/2, \quad \theta/3 = \pi/4, \quad \theta = 3\pi/4.$$

This gives us one point, $(\sqrt{2}, 3\pi/4)$, where the two curves intersect. However, as we can see by looking at the graphs in Figure 10.37, there is a second intersection point. To find the second point, we solve $2 \cos(\theta/3) = -\sqrt{2}$ for θ :

$$2 \cos(\theta/3) = -\sqrt{2}, \quad \cos(\theta/3) = -\sqrt{2}/2, \quad \theta/3 = 3\pi/4, \quad \theta = 9\pi/4.$$

The second intersection point is located at $(-\sqrt{2}, 9\pi/4)$. We can specify this point in polar coordinates using a positive value of r and an angle between 0 and 2π . In polar coordinates, adding multiples of 2π to θ gives a second description of the same point in the plane. Similarly, changing the sign of r , while at the same time adding or subtracting π to or from θ , also gives a description of the same point. So in polar coordinates, $(-\sqrt{2}, 9\pi/4)$ describes the same point in the plane as $(-\sqrt{2}, \pi/4)$ and also as $(\sqrt{2}, 5\pi/4)$. The second intersection point is located at $(\sqrt{2}, 5\pi/4)$.

Length of a Polar Curve

We can obtain a polar coordinate formula for the length of a curve $r = f(\theta)$, $\alpha \leq \theta \leq \beta$, by parametrizing the curve as

$$x = r \cos \theta = f(\theta) \cos \theta, \quad y = r \sin \theta = f(\theta) \sin \theta, \quad \alpha \leq \theta \leq \beta. \quad (2)$$

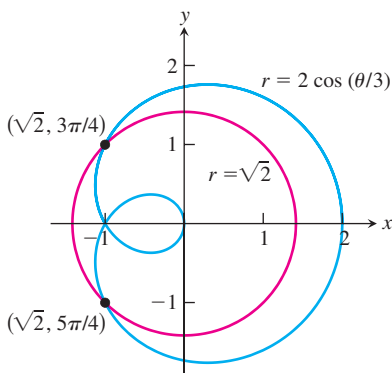

FIGURE 10.37 The curves $r = 2 \cos(\theta/3)$ and $r = \sqrt{2}$ intersect at two points (Example 3).

The parametric length formula, Equation (3) from Section 10.2, then gives the length as

$$L = \int_{\alpha}^{\beta} \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2} d\theta.$$

This equation becomes

$$L = \int_{\alpha}^{\beta} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta$$

when Equations (2) are substituted for x and y (Exercise 29).

Length of a Polar Curve

If $r = f(\theta)$ has a continuous first derivative for $\alpha \leq \theta \leq \beta$, and if the point $P(r, \theta)$ traces the curve $r = f(\theta)$ exactly once as θ runs from α to β , then the length of the curve is

$$L = \int_{\alpha}^{\beta} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta. \quad (3)$$

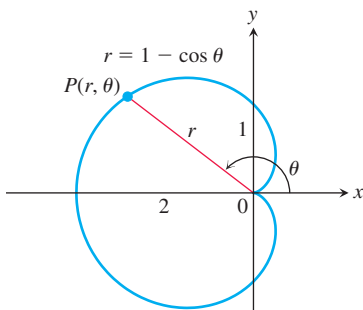

FIGURE 10.38 Calculating the length of a cardioid (Example 4).

EXAMPLE 4 Find the length of the cardioid $r = 1 - \cos \theta$.

Solution We sketch the cardioid to determine the limits of integration (Figure 10.38). The point $P(r, \theta)$ traces the curve once, counterclockwise as θ runs from 0 to 2π , so these are the values we take for α and β .

With

$$r = 1 - \cos \theta, \quad \frac{dr}{d\theta} = \sin \theta,$$

we have

$$\begin{aligned} r^2 + \left(\frac{dr}{d\theta}\right)^2 &= (1 - \cos \theta)^2 + (\sin \theta)^2 \\ &= 1 - 2 \cos \theta + \underbrace{\cos^2 \theta + \sin^2 \theta}_1 = 2 - 2 \cos \theta \end{aligned}$$

and

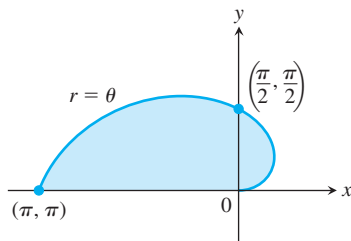

$$\begin{aligned} L &= \int_{\alpha}^{\beta} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta = \int_0^{2\pi} \sqrt{2 - 2 \cos \theta} d\theta \\ &= \int_0^{2\pi} \sqrt{4 \sin^2 \frac{\theta}{2}} d\theta && 1 - \cos \theta = 2 \sin^2(\theta/2) \\ &= \int_0^{2\pi} 2 \left| \sin \frac{\theta}{2} \right| d\theta \\ &= \int_0^{2\pi} 2 \sin \frac{\theta}{2} d\theta && \sin(\theta/2) \geq 0 \text{ for } 0 \leq \theta \leq 2\pi \\ &= \left[-4 \cos \frac{\theta}{2} \right]_0^{2\pi} = 4 + 4 = 8. \end{aligned}$$

EXERCISES 10.5

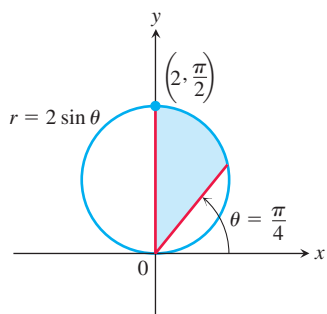

Finding Polar Areas

Find the areas of the regions in Exercises 1–8.

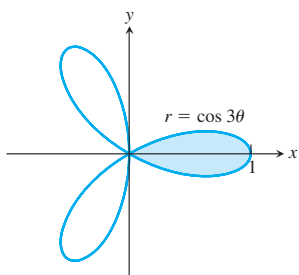

1. Bounded by the spiral
- $r = \theta$
- for
- $0 \leq \theta \leq \pi$

2. Bounded by the circle
- $r = 2 \sin \theta$
- for
- $\pi/4 \leq \theta \leq \pi/2$

3. Inside the oval limaçon $r = 4 + 2 \cos \theta$
 4. Inside the cardioid $r = a(1 + \cos \theta)$, $a > 0$
 5. Inside one leaf of the four-leaved rose $r = \cos 2\theta$
 6. Inside one leaf of the three-leaved rose $r = \cos 3\theta$

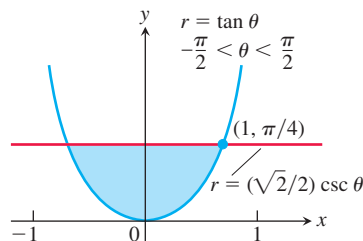

7. Inside one loop of the lemniscate $r^2 = 4 \sin 2\theta$
 8. Inside the six-leaved rose $r^2 = 2 \sin 3\theta$

Find the areas of the regions in Exercises 9–18.

9. Shared by the circles $r = 2 \cos \theta$ and $r = 2 \sin \theta$
 10. Shared by the circles $r = 1$ and $r = 2 \sin \theta$
 11. Shared by the circle $r = 2$ and the cardioid $r = 2(1 - \cos \theta)$
 12. Shared by the cardioids $r = 2(1 + \cos \theta)$ and $r = 2(1 - \cos \theta)$
 13. Inside the lemniscate $r^2 = 6 \cos 2\theta$ and outside the circle $r = \sqrt{3}$
 14. Inside the circle $r = 3a \cos \theta$ and outside the cardioid $r = a(1 + \cos \theta)$, $a > 0$

15. Inside the circle $r = -2 \cos \theta$ and outside the circle $r = 1$
 16. Inside the circle $r = 6$ and above the line $r = 3 \csc \theta$
 17. Inside the circle $r = 4 \cos \theta$ and to the right of the vertical line $r = \sec \theta$
 18. Inside the circle $r = 4 \sin \theta$ and below the horizontal line $r = 3 \csc \theta$
 19. a. Find the area of the shaded region in the accompanying figure.

- b. It looks as if the graph of $r = \tan \theta$, $-\pi/2 < \theta < \pi/2$, could be asymptotic to the lines $x = 1$ and $x = -1$. Is it? Give reasons for your answer.
 20. The area of the region that lies inside the cardioid curve $r = \cos \theta + 1$ and outside the circle $r = \cos \theta$ is not

$$\frac{1}{2} \int_0^{2\pi} [(\cos \theta + 1)^2 - \cos^2 \theta] d\theta = \pi.$$

Why not? What is the area? Give reasons for your answers.

Finding Lengths of Polar Curves

Find the lengths of the curves in Exercises 21–28.

21. The spiral $r = \theta^2$, $0 \leq \theta \leq \sqrt{5}$
 22. The spiral $r = e^\theta/\sqrt{2}$, $0 \leq \theta \leq \pi$
 23. The cardioid $r = 1 + \cos \theta$
 24. The curve $r = a \sin^2(\theta/2)$, $0 \leq \theta \leq \pi$, $a > 0$
 25. The parabolic segment $r = 6/(1 + \cos \theta)$, $0 \leq \theta \leq \pi/2$
 26. The parabolic segment $r = 2/(1 - \cos \theta)$, $\pi/2 \leq \theta \leq \pi$
 27. The curve $r = \cos^3(\theta/3)$, $0 \leq \theta \leq \pi/4$
 28. The curve $r = \sqrt{1 + \sin 2\theta}$, $0 \leq \theta \leq \pi\sqrt{2}$
 29. **The length of the curve $r = f(\theta)$, $\alpha \leq \theta \leq \beta$** Assuming that the necessary derivatives are continuous, show how the substitutions

$$x = f(\theta) \cos \theta, \quad y = f(\theta) \sin \theta$$

(Equations 2 in the text) transform

$$L = \int_{\alpha}^{\beta} \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2} d\theta$$

into

$$L = \int_{\alpha}^{\beta} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} d\theta.$$

30. Circumferences of circles As usual, when faced with a new formula, it is a good idea to try it on familiar objects to be sure it gives results consistent with past experience. Use the length formula in Equation (3) to calculate the circumferences of the following circles ($a > 0$).

- a. $r = a$ b. $r = a \cos \theta$ c. $r = a \sin \theta$

Theory and Examples

31. Average value If f is continuous, the average value of the polar coordinate r over the curve $r = f(\theta)$, $\alpha \leq \theta \leq \beta$, with respect to θ is given by the formula

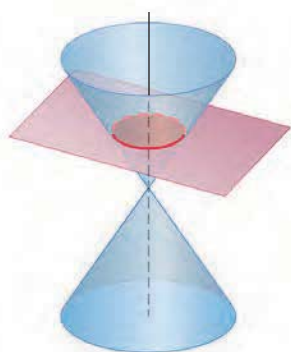

$$r_{\text{av}} = \frac{1}{\beta - \alpha} \int_{\alpha}^{\beta} f(\theta) d\theta.$$

Use this formula to find the average value of r with respect to θ over the following curves ($a > 0$).

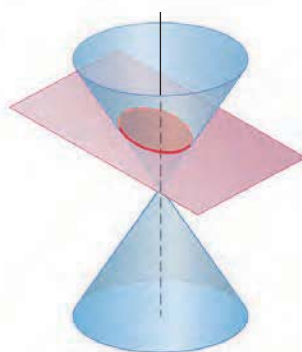

- a. The cardioid $r = a(1 - \cos \theta)$
 b. The circle $r = a$
 c. The circle $r = a \cos \theta$, $-\pi/2 \leq \theta \leq \pi/2$
- 32. $r = f(\theta)$ vs. $r = 2f(\theta)$** Can anything be said about the relative lengths of the curves $r = f(\theta)$, $\alpha \leq \theta \leq \beta$, and $r = 2f(\theta)$, $\alpha \leq \theta \leq \beta$? Give reasons for your answer.

10.6 Conic Sections

In this section we define and review parabolas, ellipses, and hyperbolas geometrically and derive their standard Cartesian equations. These curves are called *conic sections* or *conics* because they are formed by cutting a double cone with a plane (Figure 10.39). This

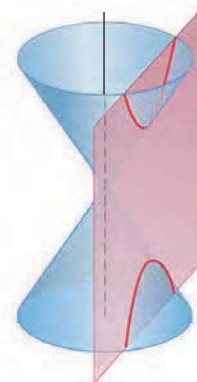

Circle: plane perpendicular to cone axis

Ellipse: plane oblique to cone axis

Parabola: plane parallel to side of cone

Hyperbola: plane parallel to cone axis

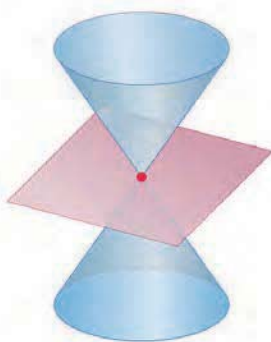

(a)

HISTORICAL BIOGRAPHY

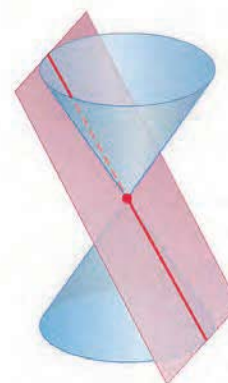

Gregory St. Vincent (1584–1667)

Born in Belgium, St. Vincent studied mathematics at Douai. He made important contributions to the development of calculus, and his books were read by the next generation of mathematicians as they connected ideas and refined the concepts of calculus.

Point: plane through cone vertex only

Single line: plane tangent to cone

Pair of intersecting lines

(b)

FIGURE 10.39 The standard conic sections (a) are the curves in which a plane cuts a *double cone*. Hyperbolas come in two parts, called *branches*. The point and lines obtained by passing the plane through the cone's vertex (b) are *degenerate* conic sections.

EXAMPLE 1 Find the focus and directrix of the parabola $y^2 = 10x$.

Solution We find the value of p in the standard equation $y^2 = 4px$:

$$4p = 10, \quad \text{so} \quad p = \frac{10}{4} = \frac{5}{2}.$$

Then we find the focus and directrix for this value of p :

$$\text{Focus: } (p, 0) = \left(\frac{5}{2}, 0\right)$$

$$\text{Directrix: } x = -p \quad \text{or} \quad x = -\frac{5}{2}. \quad \blacksquare$$

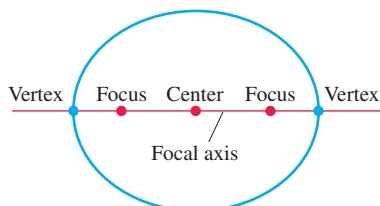

FIGURE 10.42 Points on the focal axis of an ellipse.

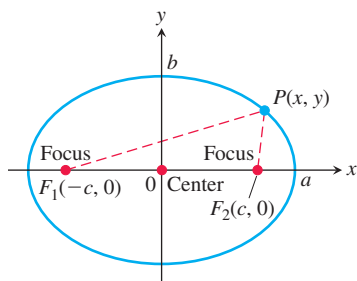

FIGURE 10.43 The ellipse defined by the equation $PF_1 + PF_2 = 2a$ is the graph of the equation $(x^2/a^2) + (y^2/b^2) = 1$, where $b^2 = a^2 - c^2$.

Ellipses

DEFINITIONS An **ellipse** is the set of points in a plane whose distances from two fixed points in the plane have a constant sum. The two fixed points are the foci of the ellipse.

The line through the foci of an ellipse is the ellipse's **focal axis**. The point on the axis halfway between the foci is the **center**. The points where the focal axis and ellipse cross are the ellipse's **vertices** (Figure 10.42).

If the foci are $F_1(-c, 0)$ and $F_2(c, 0)$ (Figure 10.43), and $PF_1 + PF_2$ is denoted by $2a$, then the coordinates of a point P on the ellipse satisfy the equation

$$\sqrt{(x+c)^2 + y^2} + \sqrt{(x-c)^2 + y^2} = 2a.$$

To simplify this equation, we move the second radical to the right-hand side, square, isolate the remaining radical, and square again, obtaining

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1. \quad (2)$$

Since $PF_1 + PF_2$ is greater than the length F_1F_2 (by the triangle inequality for triangle PF_1F_2), the number $2a$ is greater than $2c$. Accordingly, $a > c$ and the number $a^2 - c^2$ in Equation (2) is positive.

The algebraic steps leading to Equation (2) can be reversed to show that every point P whose coordinates satisfy an equation of this form with $0 < c < a$ also satisfies the equation $PF_1 + PF_2 = 2a$. A point therefore lies on the ellipse if and only if its coordinates satisfy Equation (2).

If we let b denote the positive square root of $a^2 - c^2$,

$$b = \sqrt{a^2 - c^2}, \quad (3)$$

then $a^2 - c^2 = b^2$ and Equation (2) takes the form

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1. \quad (4)$$

Equation (4) reveals that this ellipse is symmetric with respect to the origin and both coordinate axes. It lies inside the rectangle bounded by the lines $x = \pm a$ and $y = \pm b$. It crosses the axes at the points $(\pm a, 0)$ and $(0, \pm b)$. The tangents at these points are perpendicular to the axes because

$$\frac{dy}{dx} = -\frac{b^2x}{a^2y}, \quad \begin{array}{l} \text{Obtained from Eq. (4)} \\ \text{by implicit differentiation} \end{array}$$

which is zero if $x = 0$ and infinite if $y = 0$.

The **major axis** of the ellipse in Equation (4) is the line segment of length $2a$ joining the points $(\pm a, 0)$. The **minor axis** is the line segment of length $2b$ joining the points $(0, \pm b)$. The number a itself is the **semimajor axis**, the number b the **semiminor axis**. The number c , found from Equation (3) as

$$c = \sqrt{a^2 - b^2},$$

is the **center-to-focus distance** of the ellipse. If $a = b$ then the ellipse is a circle.

EXAMPLE 2 The ellipse

$$\frac{x^2}{16} + \frac{y^2}{9} = 1 \quad (5)$$

shown in Figure 10.44 has

$$\text{Semimajor axis: } a = \sqrt{16} = 4, \quad \text{Semiminor axis: } b = \sqrt{9} = 3,$$

$$\text{Center-to-focus distance: } c = \sqrt{16 - 9} = \sqrt{7},$$

$$\text{Foci: } (\pm c, 0) = (\pm\sqrt{7}, 0),$$

$$\text{Vertices: } (\pm a, 0) = (\pm 4, 0),$$

$$\text{Center: } (0, 0).$$

If we interchange x and y in Equation (5), we have the equation

$$\frac{x^2}{9} + \frac{y^2}{16} = 1. \quad (6)$$

The major axis of this ellipse is now vertical instead of horizontal, with the foci and vertices on the y -axis. We can determine which way the major axis runs simply by finding the intercepts of the ellipse with the coordinate axes. The longer of the two axes of the ellipse is the major axis.

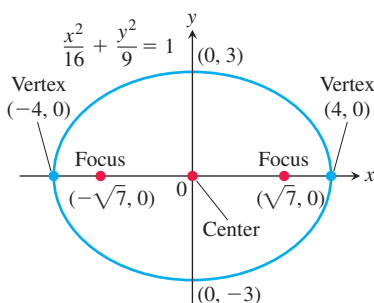

FIGURE 10.44 An ellipse with its major axis horizontal (Example 2).

Standard-Form Equations for Ellipses Centered at the Origin

$$\text{Foci on the } x\text{-axis: } \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad (a > b)$$

$$\text{Center-to-focus distance: } c = \sqrt{a^2 - b^2}$$

$$\text{Foci: } (\pm c, 0)$$

$$\text{Vertices: } (\pm a, 0)$$

$$\text{Foci on the } y\text{-axis: } \frac{x^2}{b^2} + \frac{y^2}{a^2} = 1 \quad (a > b)$$

$$\text{Center-to-focus distance: } c = \sqrt{a^2 - b^2}$$

$$\text{Foci: } (0, \pm c)$$

$$\text{Vertices: } (0, \pm a)$$

In each case, a is the semimajor axis and b is the semiminor axis.

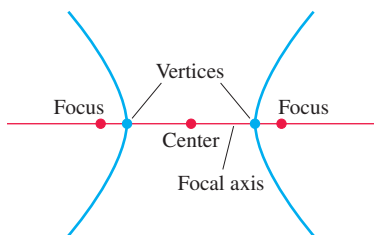

FIGURE 10.45 Points on the focal axis of a hyperbola.

Hyperbolas

DEFINITIONS A **hyperbola** is the set of points in a plane whose distances from two fixed points in the plane have a constant difference. The two fixed points are the foci of the hyperbola.

The line through the foci of a hyperbola is the **focal axis**. The point on the axis halfway between the foci is the hyperbola's **center**. The points where the focal axis and hyperbola cross are the **vertices** (Figure 10.45).

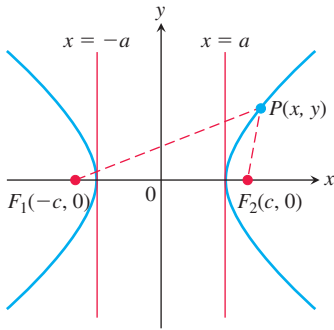

FIGURE 10.46 Hyperbolas have two branches. For points on the right-hand branch of the hyperbola shown here, $PF_1 - PF_2 = 2a$. For points on the left-hand branch, $PF_2 - PF_1 = 2a$. We then let $b = \sqrt{c^2 - a^2}$.

If the foci are $F_1(-c, 0)$ and $F_2(c, 0)$ (Figure 10.46) and the constant difference is $2a$, then a point (x, y) lies on the hyperbola if and only if

$$\sqrt{(x+c)^2 + y^2} - \sqrt{(x-c)^2 + y^2} = \pm 2a. \quad (7)$$

To simplify this equation, we move the second radical to the right-hand side, square, isolate the remaining radical, and square again, obtaining

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1. \quad (8)$$

So far, this looks just like the equation for an ellipse. But now $a^2 - c^2$ is negative because $2a$, being the difference of two sides of triangle PF_1F_2 , is less than $2c$, the third side.

The algebraic steps leading to Equation (8) can be reversed to show that every point P whose coordinates satisfy an equation of this form with $0 < a < c$ also satisfies Equation (7). A point therefore lies on the hyperbola if and only if its coordinates satisfy Equation (8).

If we let b denote the positive square root of $c^2 - a^2$,

$$b = \sqrt{c^2 - a^2}, \quad (9)$$

then $a^2 - c^2 = -b^2$ and Equation (8) takes the compact form

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1. \quad (10)$$

The differences between Equation (10) and the equation for an ellipse (Equation (4)) are the minus sign and the new relation

$$c^2 = a^2 + b^2. \quad \text{From Eq. (9)}$$

Like the ellipse, the hyperbola is symmetric with respect to the origin and coordinate axes. It crosses the x -axis at the points $(\pm a, 0)$. The tangents at these points are vertical because

$$\frac{dy}{dx} = \frac{b^2x}{a^2y} \quad \begin{array}{l} \text{Obtained from Eq. (10) by} \\ \text{implicit differentiation} \end{array}$$

and this is infinite when $y = 0$. The hyperbola has no y -intercepts; in fact, no part of the curve lies between the lines $x = -a$ and $x = a$.

The lines

$$y = \pm \frac{b}{a}x$$

are the two **asymptotes** of the hyperbola defined by Equation (10). The fastest way to find the equations of the asymptotes is to replace the 1 in Equation (10) by 0 and solve the new equation for y :

$$\underbrace{\frac{x^2}{a^2} - \frac{y^2}{b^2}}_{\text{hyperbola}} = 1 \rightarrow \underbrace{\frac{x^2}{a^2} - \frac{y^2}{b^2}}_{0 \text{ for } 1} = 0 \rightarrow \underbrace{y = \pm \frac{b}{a}x}_{\text{asymptotes}}.$$

EXAMPLE 3 The equation

$$\frac{x^2}{4} - \frac{y^2}{5} = 1 \quad (11)$$

is Equation (10) with $a^2 = 4$ and $b^2 = 5$ (Figure 10.47). We have

$$\text{Center-to-focus distance: } c = \sqrt{a^2 + b^2} = \sqrt{4 + 5} = 3,$$

$$\text{Foci: } (\pm c, 0) = (\pm 3, 0), \quad \text{Vertices: } (\pm a, 0) = (\pm 2, 0),$$

$$\text{Center: } (0, 0),$$

$$\text{Asymptotes: } \frac{x^2}{4} - \frac{y^2}{5} = 0 \quad \text{or} \quad y = \pm \frac{\sqrt{5}}{2}x. \quad \blacksquare$$

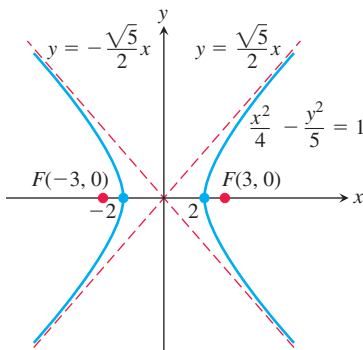

FIGURE 10.47 The hyperbola and its asymptotes in Example 3.

If we interchange x and y in Equation (11), the foci and vertices of the resulting hyperbola will lie along the y -axis. We still find the asymptotes in the same way as before, but now their equations will be $y = \pm 2x/\sqrt{5}$.

Standard-Form Equations for Hyperbolas Centered at the Origin

$$\text{Foci on the } x\text{-axis: } \frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

$$\text{Foci on the } y\text{-axis: } \frac{y^2}{a^2} - \frac{x^2}{b^2} = 1$$

$$\text{Center-to-focus distance: } c = \sqrt{a^2 + b^2}$$

$$\text{Center-to-focus distance: } c = \sqrt{a^2 + b^2}$$

$$\text{Foci: } (\pm c, 0)$$

$$\text{Foci: } (0, \pm c)$$

$$\text{Vertices: } (\pm a, 0)$$

$$\text{Vertices: } (0, \pm a)$$

$$\text{Asymptotes: } \frac{x^2}{a^2} - \frac{y^2}{b^2} = 0 \quad \text{or} \quad y = \pm \frac{b}{a}x$$

$$\text{Asymptotes: } \frac{y^2}{a^2} - \frac{x^2}{b^2} = 0 \quad \text{or} \quad y = \pm \frac{a}{b}x$$

Notice the difference in the asymptote equations (b/a in the first, a/b in the second).

We shift conics using the principles reviewed in Section 1.2, replacing x by $x + h$ and y by $y + k$.

EXAMPLE 4 Show that the equation $x^2 - 4y^2 + 2x + 8y - 7 = 0$ represents a hyperbola. Find its center, asymptotes, and foci.

Solution We reduce the equation to standard form by completing the square in x and y as follows:

$$\begin{aligned} (x^2 + 2x) - 4(y^2 - 2y) &= 7 \\ (x^2 + 2x + 1) - 4(y^2 - 2y + 1) &= 7 + 1 - 4 \\ \frac{(x + 1)^2}{4} - (y - 1)^2 &= 1. \end{aligned}$$

This is the standard form Equation (10) of a hyperbola with x replaced by $x + 1$ and y replaced by $y - 1$. The hyperbola is shifted one unit to the left and one unit upward, and it has center $x + 1 = 0$ and $y - 1 = 0$, or $x = -1$ and $y = 1$. Moreover,

$$a^2 = 4, \quad b^2 = 1, \quad c^2 = a^2 + b^2 = 5,$$

so the asymptotes are the two lines

$$\frac{x + 1}{2} - (y - 1) = 0 \quad \text{and} \quad \frac{x + 1}{2} + (y - 1) = 0,$$

or

$$y - 1 = \pm \frac{1}{2}(x + 1).$$

The shifted foci have coordinates $(-1 \pm \sqrt{5}, 1)$. ■

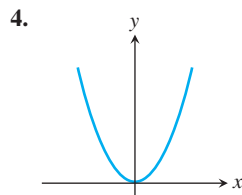

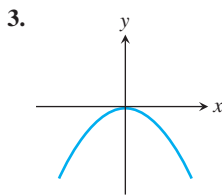

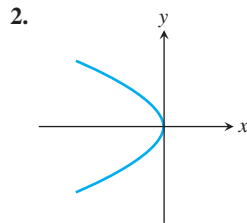

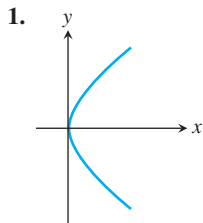

EXERCISES 10.6

Identifying Graphs

Match the parabolas in Exercises 1–4 with the following equations:

$$x^2 = 2y, \quad x^2 = -6y, \quad y^2 = 8x, \quad y^2 = -4x.$$

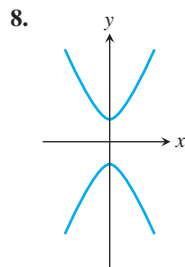

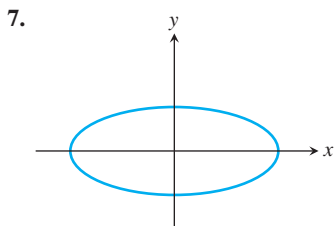

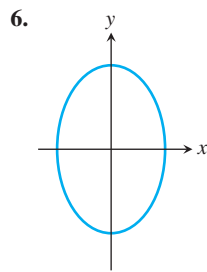

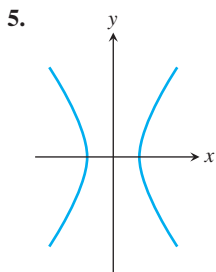

Then find each parabola's focus and directrix.

Match each conic section in Exercises 5–8 with one of these equations:

$$\begin{aligned} \frac{x^2}{4} + \frac{y^2}{9} &= 1, & \frac{x^2}{2} + y^2 &= 1, \\ \frac{y^2}{4} - x^2 &= 1, & \frac{x^2}{4} - \frac{y^2}{9} &= 1. \end{aligned}$$

Then find the conic section's foci and vertices. If the conic section is a hyperbola, find its asymptotes as well.

Parabolas

Exercises 9–16 give equations of parabolas. Find each parabola's focus and directrix. Then sketch the parabola. Include the focus and directrix in your sketch.

9. $y^2 = 12x$ 10. $x^2 = 6y$ 11. $x^2 = -8y$

12. $y^2 = -2x$ 13. $y = 4x^2$ 14. $y = -8x^2$

15. $x = -3y^2$ 16. $x = 2y^2$

Ellipses

Exercises 17–24 give equations for ellipses. Put each equation in standard form. Then sketch the ellipse. Include the foci in your sketch.

17. $16x^2 + 25y^2 = 400$ 18. $7x^2 + 16y^2 = 112$

19. $2x^2 + y^2 = 2$ 20. $2x^2 + y^2 = 4$

21. $3x^2 + 2y^2 = 6$ 22. $9x^2 + 10y^2 = 90$

23. $6x^2 + 9y^2 = 54$ 24. $169x^2 + 25y^2 = 4225$

Exercises 25 and 26 give information about the foci and vertices of ellipses centered at the origin of the xy -plane. In each case, find the ellipse's standard-form equation from the given information.

25. Foci: $(\pm\sqrt{2}, 0)$ Vertices: $(\pm 2, 0)$

26. Foci: $(0, \pm 4)$ Vertices: $(0, \pm 5)$

Hyperbolas

Exercises 27–34 give equations for hyperbolas. Put each equation in standard form and find the hyperbola's asymptotes. Then sketch the hyperbola. Include the asymptotes and foci in your sketch.

27. $x^2 - y^2 = 1$ 28. $9x^2 - 16y^2 = 144$

29. $y^2 - x^2 = 8$ 30. $y^2 - x^2 = 4$

31. $8x^2 - 2y^2 = 16$ 32. $y^2 - 3x^2 = 3$

33. $8y^2 - 2x^2 = 16$ 34. $64x^2 - 36y^2 = 2304$

Exercises 35–38 give information about the foci, vertices, and asymptotes of hyperbolas centered at the origin of the xy -plane. In each case, find the hyperbola's standard-form equation from the information given.

35. Foci: $(0, \pm\sqrt{2})$ 36. Foci: $(\pm 2, 0)$

Asymptotes: $y = \pm x$ Asymptotes: $y = \pm \frac{1}{\sqrt{3}}x$

37. Vertices: $(\pm 3, 0)$ 38. Vertices: $(0, \pm 2)$

Asymptotes: $y = \pm \frac{4}{3}x$ Asymptotes: $y = \pm \frac{1}{2}x$

Shifting Conic Sections

You may wish to review Section 1.2 before solving Exercises 39–56.

39. The parabola $y^2 = 8x$ is shifted down 2 units and right 1 unit to generate the parabola $(y + 2)^2 = 8(x - 1)$.

a. Find the new parabola's vertex, focus, and directrix.

b. Plot the new vertex, focus, and directrix, and sketch in the parabola.

40. The parabola $x^2 = -4y$ is shifted left 1 unit and up 3 units to generate the parabola $(x + 1)^2 = -4(y - 3)$.

a. Find the new parabola's vertex, focus, and directrix.

b. Plot the new vertex, focus, and directrix, and sketch in the parabola.

41. The ellipse $(x^2/16) + (y^2/9) = 1$ is shifted 4 units to the right and 3 units up to generate the ellipse

$$\frac{(x-4)^2}{16} + \frac{(y-3)^2}{9} = 1.$$

- a. Find the foci, vertices, and center of the new ellipse.
 b. Plot the new foci, vertices, and center, and sketch in the new ellipse.
42. The ellipse $(x^2/9) + (y^2/25) = 1$ is shifted 3 units to the left and 2 units down to generate the ellipse

$$\frac{(x+3)^2}{9} + \frac{(y+2)^2}{25} = 1.$$

- a. Find the foci, vertices, and center of the new ellipse.
 b. Plot the new foci, vertices, and center, and sketch in the new ellipse.
43. The hyperbola $(x^2/16) - (y^2/9) = 1$ is shifted 2 units to the right to generate the hyperbola

$$\frac{(x-2)^2}{16} - \frac{y^2}{9} = 1.$$

- a. Find the center, foci, vertices, and asymptotes of the new hyperbola.
 b. Plot the new center, foci, vertices, and asymptotes, and sketch in the hyperbola.
44. The hyperbola $(y^2/4) - (x^2/5) = 1$ is shifted 2 units down to generate the hyperbola

$$\frac{(y+2)^2}{4} - \frac{x^2}{5} = 1.$$

- a. Find the center, foci, vertices, and asymptotes of the new hyperbola.
 b. Plot the new center, foci, vertices, and asymptotes, and sketch in the hyperbola.

Exercises 45–48 give equations for parabolas and tell how many units up or down and to the right or left each parabola is to be shifted. Find an equation for the new parabola, and find the new vertex, focus, and directrix.

45. $y^2 = 4x$, left 2, down 3
 46. $y^2 = -12x$, right 4, up 3
 47. $x^2 = 8y$, right 1, down 7
 48. $x^2 = 6y$, left 3, down 2

Exercises 49–52 give equations for ellipses and tell how many units up or down and to the right or left each ellipse is to be shifted. Find an equation for the new ellipse, and find the new foci, vertices, and center.

49. $\frac{x^2}{6} + \frac{y^2}{9} = 1$, left 2, down 1
 50. $\frac{x^2}{2} + y^2 = 1$, right 3, up 4
 51. $\frac{x^2}{3} + \frac{y^2}{2} = 1$, right 2, up 3
 52. $\frac{x^2}{16} + \frac{y^2}{25} = 1$, left 4, down 5

Exercises 53–56 give equations for hyperbolas and tell how many units up or down and to the right or left each hyperbola is to be shifted. Find an equation for the new hyperbola, and find the new center, foci, vertices, and asymptotes.

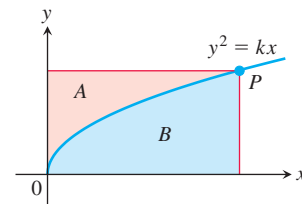

53. $\frac{x^2}{4} - \frac{y^2}{5} = 1$, right 2, up 2
 54. $\frac{x^2}{16} - \frac{y^2}{9} = 1$, left 2, down 1
 55. $y^2 - x^2 = 1$, left 1, down 1
 56. $\frac{y^2}{3} - x^2 = 1$, right 1, up 3

Find the center, foci, vertices, asymptotes, and radius, as appropriate, of the conic sections in Exercises 57–68.

57. $x^2 + 4x + y^2 = 12$
 58. $2x^2 + 2y^2 - 28x + 12y + 114 = 0$
 59. $x^2 + 2x + 4y - 3 = 0$ 60. $y^2 - 4y - 8x - 12 = 0$
 61. $x^2 + 5y^2 + 4x = 1$ 62. $9x^2 + 6y^2 + 36y = 0$
 63. $x^2 + 2y^2 - 2x - 4y = -1$
 64. $4x^2 + y^2 + 8x - 2y = -1$
 65. $x^2 - y^2 - 2x + 4y = 4$ 66. $x^2 - y^2 + 4x - 6y = 6$
 67. $2x^2 - y^2 + 6y = 3$ 68. $y^2 - 4x^2 + 16x = 24$

Theory and Examples

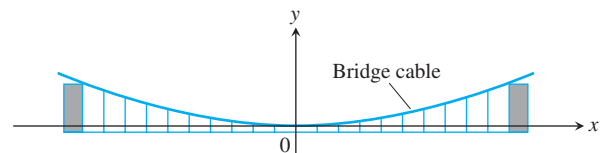

69. If lines are drawn parallel to the coordinate axes through a point P on the parabola $y^2 = kx$, $k > 0$, the parabola partitions the rectangular region bounded by these lines and the coordinate axes into two smaller regions, A and B .
- a. If the two smaller regions are revolved about the y -axis, show that they generate solids whose volumes have the ratio 4:1.
 b. What is the ratio of the volumes generated by revolving the regions about the x -axis?

70. **Suspension bridge cables hang in parabolas** The suspension bridge cable shown in the accompanying figure supports a uniform load of w newtons per horizontal meter. It can be shown that if H is the horizontal tension of the cable at the origin, then the curve of the cable satisfies the equation

$$\frac{dy}{dx} = \frac{w}{H}x.$$

Show that the cable hangs in a parabola by solving this differential equation subject to the initial condition that $y = 0$ when $x = 0$.

- 71. The width of a parabola at the focus** Show that the number $4p$ is the *width* of the parabola $x^2 = 4py$ ($p > 0$) at the focus by showing that the line $y = p$ cuts the parabola at points that are $4p$ units apart.
- 72. The asymptotes of $(x^2/a^2) - (y^2/b^2) = 1$** Show that the vertical distance between the line $y = (b/a)x$ and the upper half of the right-hand branch $y = (b/a)\sqrt{x^2 - a^2}$ of the hyperbola $(x^2/a^2) - (y^2/b^2) = 1$ approaches 0 by showing that
- $$\lim_{x \rightarrow \infty} \left(\frac{b}{a}x - \frac{b}{a}\sqrt{x^2 - a^2} \right) = \frac{b}{a} \lim_{x \rightarrow \infty} (x - \sqrt{x^2 - a^2}) = 0.$$
- Similar results hold for the remaining portions of the hyperbola and the lines $y = \pm(b/a)x$.
- 73. Area** Find the dimensions of the rectangle of largest area that can be inscribed in the ellipse $x^2 + 4y^2 = 4$ with its sides parallel to the coordinate axes. What is the area of the rectangle?
- 74. Volume** Find the volume of the solid generated by revolving the region enclosed by the ellipse $9x^2 + 4y^2 = 36$ about the (a) x -axis, (b) y -axis.
- 75. Volume** The “triangular” region in the first quadrant bounded by the x -axis, the line $x = 4$, and the hyperbola $9x^2 - 4y^2 = 36$ is revolved about the x -axis to generate a solid. Find the volume of the solid.
- 76. Tangents** Show that the tangents to the curve $y^2 = 4px$ from any point on the line $x = -p$ are perpendicular.
- 77. Tangents** Find equations for the tangents to the circle $(x - 2)^2 + (y - 1)^2 = 5$ at the points where the circle crosses the coordinate axes.
- 78. Volume** The region bounded on the left by the y -axis, on the right by the hyperbola $x^2 - y^2 = 1$, and above and below by the lines $y = \pm 3$ is revolved about the y -axis to generate a solid. Find the volume of the solid.
- 79. Centroid** Find the centroid of the region that is bounded below by the x -axis and above by the ellipse $(x^2/9) + (y^2/16) = 1$.

80. Surface area The curve $y = \sqrt{x^2 + 1}$, $0 \leq x \leq \sqrt{2}$, which is part of the upper branch of the hyperbola $y^2 - x^2 = 1$, is revolved about the x -axis to generate a surface. Find the area of the surface.

81. The reflective property of parabolas The accompanying figure shows a typical point $P(x_0, y_0)$ on the parabola $y^2 = 4px$. The line L is tangent to the parabola at P . The parabola's focus lies at $F(p, 0)$. The ray L' extending from P to the right is parallel to the x -axis. We show that light from F to P will be reflected out along L' by showing that β equals α . Establish this equality by taking the following steps.

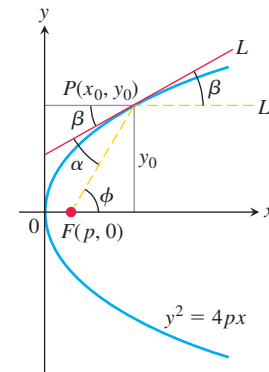

- Show that $\tan \beta = 2p/y_0$.
- Show that $\tan \phi = y_0/(x_0 - p)$.
- Use the identity

$$\tan \alpha = \frac{\tan \phi - \tan \beta}{1 + \tan \phi \tan \beta}$$

to show that $\tan \alpha = 2p/y_0$.

Since α and β are both acute, $\tan \beta = \tan \alpha$ implies $\beta = \alpha$.

This reflective property of parabolas is used in applications like car headlights, radio telescopes, and satellite TV dishes.

10.7 Conics in Polar Coordinates

Polar coordinates are especially important in astronomy and astronautical engineering because satellites, moons, planets, and comets all move approximately along ellipses, parabolas, and hyperbolas that can be described with a single relatively simple polar coordinate equation. We develop that equation here after first introducing the idea of a conic section's *eccentricity*. The eccentricity reveals the conic section's type (circle, ellipse, parabola, or hyperbola) and the degree to which it is “squashed” or flattened.

Eccentricity

Although the center-to-focus distance c does not appear in the standard Cartesian equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad (a > b)$$

for an ellipse, we can still determine c from the equation $c = \sqrt{a^2 - b^2}$. If we fix a and vary c over the interval $0 \leq c \leq a$, the resulting ellipses will vary in shape. They are circles if $c = 0$ (so that $a = b$) and flatten, becoming more oblong, as c increases. If $c = a$, the foci and vertices overlap and the ellipse degenerates into a line segment. Thus we are led to consider the ratio $e = c/a$. We use this ratio for hyperbolas as well, except in this

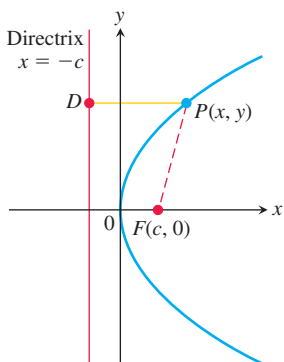

FIGURE 10.48 The distance from the focus F to any point P on a parabola equals the distance from P to the nearest point D on the directrix, so $PF = PD$.

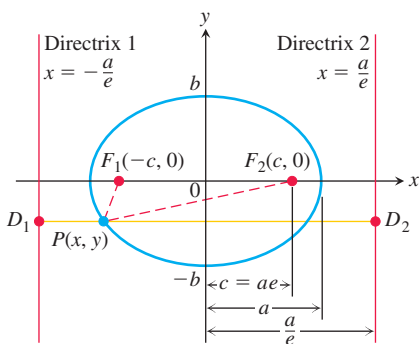

FIGURE 10.49 The foci and directrices of the ellipse $(x^2/a^2) + (y^2/b^2) = 1$. Directrix 1 corresponds to focus F_1 and directrix 2 to focus F_2 .

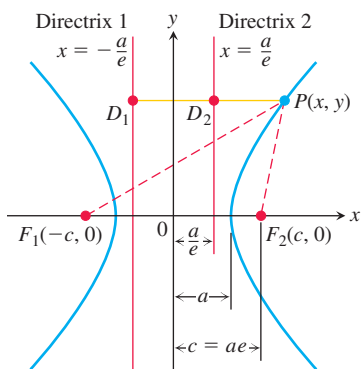

FIGURE 10.50 The foci and directrices of the hyperbola $(x^2/a^2) - (y^2/b^2) = 1$. No matter where P lies on the hyperbola, $PF_1 = e \cdot PD_1$ and $PF_2 = e \cdot PD_2$.

case c equals $\sqrt{a^2 + b^2}$ instead of $\sqrt{a^2 - b^2}$. We refer to this ratio as the *eccentricity* of the ellipse or hyperbola.

DEFINITION

The **eccentricity** of the ellipse $(x^2/a^2) + (y^2/b^2) = 1$ ($a > b$) is

$$e = \frac{c}{a} = \frac{\sqrt{a^2 - b^2}}{a}.$$

The **eccentricity** of the hyperbola $(x^2/a^2) - (y^2/b^2) = 1$ is

$$e = \frac{c}{a} = \frac{\sqrt{a^2 + b^2}}{a}.$$

The **eccentricity** of a parabola is $e = 1$.

Whereas a parabola has one focus and one directrix, each **ellipse** has two foci and two **directrices**. These are the lines perpendicular to the major axis at distances $\pm a/e$ from the center. From Figure 10.48 we see that a parabola has the property

$$PF = 1 \cdot PD \quad (1)$$

for any point P on it, where F is the focus and D is the point nearest P on the directrix. For an ellipse, it can be shown that the equations that replace Equation (1) are

$$PF_1 = e \cdot PD_1, \quad PF_2 = e \cdot PD_2. \quad (2)$$

Here, e is the eccentricity, P is any point on the ellipse, F_1 and F_2 are the foci, and D_1 and D_2 are the points on the directrices nearest P (Figure 10.49).

In both Equations (2) the directrix and focus must correspond; that is, if we use the distance from P to F_1 , we must also use the distance from P to the directrix at the same end of the ellipse. The directrix $x = -a/e$ corresponds to $F_1(-c, 0)$, and the directrix $x = a/e$ corresponds to $F_2(c, 0)$.

As with the ellipse, it can be shown that the lines $x = \pm a/e$ act as **directrices** for the **hyperbola** and that

$$PF_1 = e \cdot PD_1 \quad \text{and} \quad PF_2 = e \cdot PD_2. \quad (3)$$

Here P is any point on the hyperbola, F_1 and F_2 are the foci, and D_1 and D_2 are the points nearest P on the directrices (Figure 10.50).

In both the ellipse and the hyperbola, the eccentricity is the ratio of the distance between the foci to the distance between the vertices (because $c/a = 2c/2a$).

$$\text{Eccentricity} = \frac{\text{distance between foci}}{\text{distance between vertices}}$$

In an ellipse, the foci are closer together than the vertices and the ratio is less than 1. In a hyperbola, the foci are farther apart than the vertices and the ratio is greater than 1.

The “focus–directrix” equation $PF = e \cdot PD$ unites the parabola, ellipse, and hyperbola in the following way. Suppose that the distance PF of a point P from a fixed point F (the focus) is a constant multiple of its distance from a fixed line (the directrix). That is, suppose

$$PF = e \cdot PD, \quad (4)$$

where e is the constant of proportionality. Then the path traced by P is

- (a) a *parabola* if $e = 1$,
- (b) an *ellipse* of eccentricity e if $e < 1$, and
- (c) a *hyperbola* of eccentricity e if $e > 1$.

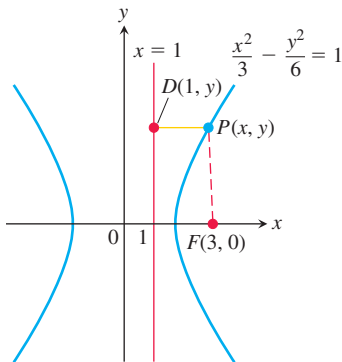

FIGURE 10.51 The hyperbola and directrix in Example 1.

As e increases ($e \rightarrow 1^-$), ellipses become more oblong, and ($e \rightarrow \infty$) hyperbolas flatten toward two lines parallel to the directrix. There are no coordinates in Equation (4), and when we try to translate it into Cartesian coordinate form, it translates in different ways depending on the size of e . However, as we are about to see, in polar coordinates the equation $PF = e \cdot PD$ translates into a single equation regardless of the value of e .

Given the focus and corresponding directrix of a hyperbola centered at the origin and with foci on the x -axis, we can use the dimensions shown in Figure 10.50 to find e . Knowing e , we can derive a Cartesian equation for the hyperbola from the equation $PF = e \cdot PD$, as in the next example. We can find equations for ellipses centered at the origin and with foci on the x -axis in a similar way, using the dimensions shown in Figure 10.49.

EXAMPLE 1 Find a Cartesian equation for the hyperbola centered at the origin that has a focus at $(3, 0)$ and the line $x = 1$ as the corresponding directrix.

Solution We first use the dimensions shown in Figure 10.50 to find the hyperbola's eccentricity. The focus is (see Figure 10.51)

$$(c, 0) = (3, 0), \quad \text{so} \quad c = 3.$$

Again from Figure 10.50, the directrix is the line

$$x = \frac{a}{e} = 1, \quad \text{so} \quad a = e.$$

When combined with the equation $e = c/a$ that defines eccentricity, these results give

$$e = \frac{c}{a} = \frac{3}{e}, \quad \text{so} \quad e^2 = 3 \quad \text{and} \quad e = \sqrt{3}.$$

Knowing e , we can now derive the equation we want from the equation $PF = e \cdot PD$. In the coordinates of Figure 10.51, we have

$$\begin{aligned} PF &= e \cdot PD && \text{Eq. (4)} \\ \sqrt{(x-3)^2 + (y-0)^2} &= \sqrt{3}|x-1| && e = \sqrt{3} \\ x^2 - 6x + 9 + y^2 &= 3(x^2 - 2x + 1) && \text{Square both sides.} \\ 2x^2 - y^2 &= 6 && \text{Simplify.} \\ \frac{x^2}{3} - \frac{y^2}{6} &= 1. \end{aligned}$$

Polar Equations

To find a polar equation for an ellipse, parabola, or hyperbola, we place one focus at the origin and the corresponding directrix to the right of the origin along the vertical line $x = k$ (Figure 10.52). In polar coordinates, this makes

$$PF = r$$

and

$$PD = k - FB = k - r \cos \theta.$$

The conic's focus-directrix equation $PF = e \cdot PD$ then becomes

$$r = e(k - r \cos \theta),$$

which can be solved for r to obtain the following expression.

Polar Equation for a Conic with Eccentricity e

$$r = \frac{ke}{1 + e \cos \theta}, \quad (5)$$

where $x = k > 0$ is the vertical directrix.

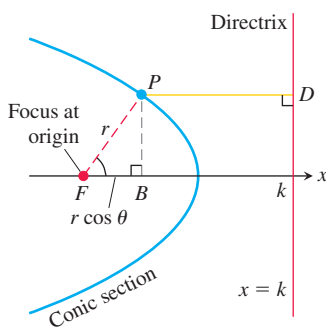

FIGURE 10.52 If a conic section is put in the position with its focus placed at the origin and a directrix perpendicular to the initial ray and right of the origin, we can find its polar equation from the conic's focus-directrix equation.

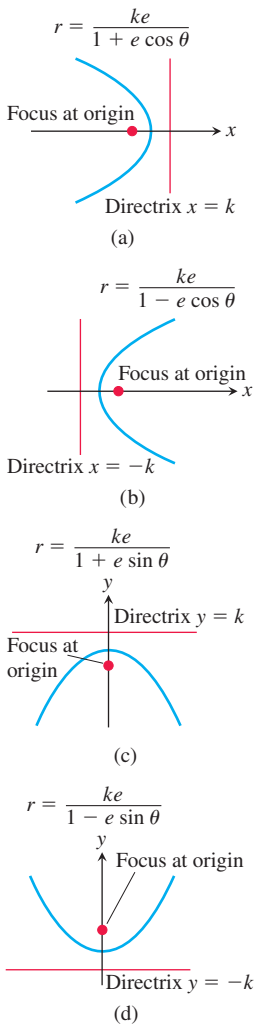

FIGURE 10.53 Equations for conic sections with eccentricity $e > 0$ but different locations of the directrix. The graphs here show a parabola, so $e = 1$.

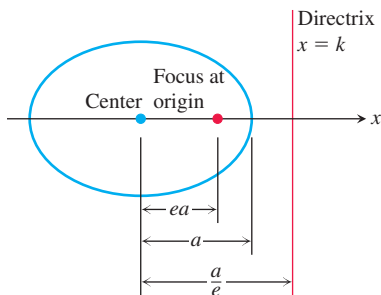

FIGURE 10.54 In an ellipse with semi-major axis a , the focus-directrix distance is $k = (a/e) - ea$, so $ke = a(1 - e^2)$.

EXAMPLE 2 Here are polar equations for three conics. The eccentricity values identifying the conic are the same for both polar and Cartesian coordinates.

$$e = \frac{1}{2}: \quad \text{ellipse} \quad r = \frac{k}{2 + \cos \theta}$$

$$e = 1: \quad \text{parabola} \quad r = \frac{k}{1 + \cos \theta}$$

$$e = 2: \quad \text{hyperbola} \quad r = \frac{2k}{1 + 2 \cos \theta}$$

You may see variations of Equation (5), depending on the location of the directrix. If the directrix is the line $x = -k$ to the left of the origin (the origin is still a focus), we replace Equation (5) with

$$r = \frac{ke}{1 - e \cos \theta}.$$

The denominator now has a $(-)$ instead of a $(+)$. If the directrix is either of the lines $y = k$ or $y = -k$, the equations have sines in them instead of cosines, as shown in Figure 10.53.

EXAMPLE 3 Find an equation for the hyperbola with eccentricity $3/2$ and directrix $x = 2$.

Solution We use Equation (5) with $k = 2$ and $e = 3/2$:

$$r = \frac{2(3/2)}{1 + (3/2)\cos \theta} \quad \text{or} \quad r = \frac{6}{2 + 3 \cos \theta}.$$

EXAMPLE 4 Find the directrix of the parabola $r = \frac{25}{10 + 10 \cos \theta}$.

Solution We divide the numerator and denominator by 10 to put the equation in standard polar form:

$$r = \frac{5/2}{1 + \cos \theta}.$$

This is the equation

$$r = \frac{ke}{1 + e \cos \theta}$$

with $k = 5/2$ and $e = 1$. The equation of the directrix is $x = 5/2$.

From the ellipse diagram in Figure 10.54, we see that k is related to the eccentricity e and the semimajor axis a by the equation

$$k = \frac{a}{e} - ea.$$

From this, we find that $ke = a(1 - e^2)$. Replacing ke in Equation (5) by $a(1 - e^2)$ gives the standard polar equation for an ellipse.

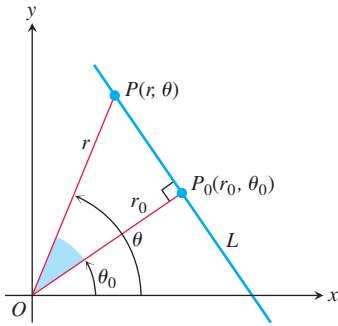

FIGURE 10.55 We can obtain a polar equation for line L by reading the relation $r_0 = r \cos(\theta - \theta_0)$ from the right triangle OP_0P .

Polar Equation for the Ellipse with Eccentricity e and Semimajor Axis a

$$r = \frac{a(1 - e^2)}{1 + e \cos \theta} \quad (6)$$

Notice that when $e = 0$, Equation (6) becomes $r = a$, which represents a circle.

Lines

Suppose the perpendicular from the origin to line L meets L at the point $P_0(r_0, \theta_0)$, with $r_0 \geq 0$ (Figure 10.55). Then, if $P(r, \theta)$ is any other point on L , the points P , P_0 , and O are the vertices of a right triangle, from which we can read the relation

$$r_0 = r \cos(\theta - \theta_0).$$

The Standard Polar Equation for Lines

If the point $P_0(r_0, \theta_0)$ is the foot of the perpendicular from the origin to the line L , and $r_0 \geq 0$, then an equation for L is

$$r \cos(\theta - \theta_0) = r_0. \quad (7)$$

For example, if $\theta_0 = \pi/3$ and $r_0 = 2$, we find that

$$r \cos\left(\theta - \frac{\pi}{3}\right) = 2$$

$$r \left(\cos \theta \cos \frac{\pi}{3} + \sin \theta \sin \frac{\pi}{3} \right) = 2$$

$$\frac{1}{2} r \cos \theta + \frac{\sqrt{3}}{2} r \sin \theta = 2, \quad \text{or} \quad x + \sqrt{3}y = 4.$$

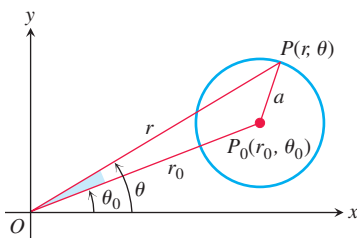

FIGURE 10.56 We can get a polar equation for this circle by applying the Law of Cosines to triangle OP_0P .

Circles

To find a polar equation for the circle of radius a centered at $P_0(r_0, \theta_0)$, we let $P(r, \theta)$ be a point on the circle and apply the Law of Cosines to triangle OP_0P (Figure 10.56). This gives

$$a^2 = r_0^2 + r^2 - 2r_0r \cos(\theta - \theta_0).$$

If the circle passes through the origin, then $r_0 = a$ and this equation simplifies to

$$a^2 = a^2 + r^2 - 2ar \cos(\theta - \theta_0)$$

$$r^2 = 2ar \cos(\theta - \theta_0)$$

$$r = 2a \cos(\theta - \theta_0).$$

If the circle's center lies on the positive x -axis, $\theta_0 = 0$, and we get the further simplification

$$r = 2a \cos \theta. \quad (8)$$

If the center lies on the positive y -axis, $\theta = \pi/2$, $\cos(\theta - \pi/2) = \sin \theta$, and the equation $r = 2a \cos(\theta - \theta_0)$ becomes

$$r = 2a \sin \theta. \quad (9)$$

Equations for circles through the origin centered on the negative x - and y -axes can be obtained by replacing r with $-r$ in the above equations.

EXAMPLE 5 Here are several polar equations given by Equations (8) and (9) for circles through the origin and having centers that lie on the x - or y -axis.

Radius	Center (polar coordinates)	Polar equation
3	$(3, 0)$	$r = 6 \cos \theta$
2	$(2, \pi/2)$	$r = 4 \sin \theta$
$1/2$	$(-1/2, 0)$	$r = -\cos \theta$
1	$(-1, \pi/2)$	$r = -2 \sin \theta$

EXERCISES 10.7

Ellipses and Eccentricity

In Exercises 1–8, find the eccentricity of the ellipse. Then find and graph the ellipse's foci and directrices.

- $16x^2 + 25y^2 = 400$
- $7x^2 + 16y^2 = 112$
- $2x^2 + y^2 = 2$
- $2x^2 + y^2 = 4$
- $3x^2 + 2y^2 = 6$
- $9x^2 + 10y^2 = 90$
- $6x^2 + 9y^2 = 54$
- $169x^2 + 25y^2 = 4225$

Exercises 9–12 give the foci or vertices and the eccentricities of ellipses centered at the origin of the xy -plane. In each case, find the ellipse's standard-form equation in Cartesian coordinates.

- Foci: $(0, \pm 3)$
Eccentricity: 0.5
- Foci: $(\pm 8, 0)$
Eccentricity: 0.2
- Vertices: $(0, \pm 7)$
Eccentricity: 0.1
- Vertices: $(\pm 10, 0)$
Eccentricity: 0.24

Exercises 13–16 give foci and corresponding directrices of ellipses centered at the origin of the xy -plane. In each case, use the dimensions in Figure 10.49 to find the eccentricity of the ellipse. Then find the ellipse's standard-form equation in Cartesian coordinates.

- Focus: $(\sqrt{5}, 0)$
Directrix: $x = \frac{9}{\sqrt{5}}$
- Focus: $(4, 0)$
Directrix: $x = \frac{16}{3}$
- Focus: $(-4, 0)$
Directrix: $x = -16$
- Focus: $(-\sqrt{2}, 0)$
Directrix: $x = -2\sqrt{2}$

Hyperbolas and Eccentricity

In Exercises 17–24, find the eccentricity of the hyperbola. Then find and graph the hyperbola's foci and directrices.

- $x^2 - y^2 = 1$
- $9x^2 - 16y^2 = 144$
- $y^2 - x^2 = 8$
- $y^2 - x^2 = 4$

- $8x^2 - 2y^2 = 16$
- $y^2 - 3x^2 = 3$
- $8y^2 - 2x^2 = 16$
- $64x^2 - 36y^2 = 2304$

Exercises 25–28 give the eccentricities and the vertices or foci of hyperbolas centered at the origin of the xy -plane. In each case, find the hyperbola's standard-form equation in Cartesian coordinates.

- Eccentricity: 3
Vertices: $(0, \pm 1)$
- Eccentricity: 2
Vertices: $(\pm 2, 0)$
- Eccentricity: 3
Foci: $(\pm 3, 0)$
- Eccentricity: 1.25
Foci: $(0, \pm 5)$

Eccentricities and Directrices

Exercises 29–36 give the eccentricities of conic sections with one focus at the origin along with the directrix corresponding to that focus. Find a polar equation for each conic section.

- $e = 1, x = 2$
- $e = 1, y = 2$
- $e = 5, y = -6$
- $e = 2, x = 4$
- $e = 1/2, x = 1$
- $e = 1/4, x = -2$
- $e = 1/5, y = -10$
- $e = 1/3, y = 6$

Parabolas and Ellipses

Sketch the parabolas and ellipses in Exercises 37–44. Include the directrix that corresponds to the focus at the origin. Label the vertices with appropriate polar coordinates. Label the centers of the ellipses as well.

- $r = \frac{1}{1 + \cos \theta}$
- $r = \frac{6}{2 + \cos \theta}$
- $r = \frac{25}{10 - 5 \cos \theta}$
- $r = \frac{4}{2 - 2 \cos \theta}$
- $r = \frac{400}{16 + 8 \sin \theta}$
- $r = \frac{12}{3 + 3 \sin \theta}$
- $r = \frac{8}{2 - 2 \sin \theta}$
- $r = \frac{4}{2 - \sin \theta}$

Lines

Sketch the lines in Exercises 45–48 and find Cartesian equations for them.

$$45. r \cos\left(\theta - \frac{\pi}{4}\right) = \sqrt{2} \qquad 46. r \cos\left(\theta + \frac{3\pi}{4}\right) = 1$$

$$47. r \cos\left(\theta - \frac{2\pi}{3}\right) = 3 \qquad 48. r \cos\left(\theta + \frac{\pi}{3}\right) = 2$$

Find a polar equation in the form $r \cos(\theta - \theta_0) = r_0$ for each of the lines in Exercises 49–52.

$$49. \sqrt{2}x + \sqrt{2}y = 6 \qquad 50. \sqrt{3}x - y = 1$$

$$51. y = -5 \qquad 52. x = -4$$

Circles

Sketch the circles in Exercises 53–56. Give polar coordinates for their centers and identify their radii.

$$53. r = 4 \cos \theta \qquad 54. r = 6 \sin \theta$$

$$55. r = -2 \cos \theta \qquad 56. r = -8 \sin \theta$$

Find polar equations for the circles in Exercises 57–64. Sketch each circle in the coordinate plane and label it with both its Cartesian and polar equations.

$$57. (x - 6)^2 + y^2 = 36 \qquad 58. (x + 2)^2 + y^2 = 4$$

$$59. x^2 + (y - 5)^2 = 25 \qquad 60. x^2 + (y + 7)^2 = 49$$

$$61. x^2 + 2x + y^2 = 0 \qquad 62. x^2 - 16x + y^2 = 0$$

$$63. x^2 + y^2 + y = 0 \qquad 64. x^2 + y^2 - \frac{4}{3}y = 0$$

Examples of Polar Equations

T Graph the lines and conic sections in Exercises 65–74.

$$65. r = 3 \sec(\theta - \pi/3) \qquad 66. r = 4 \sec(\theta + \pi/6)$$

$$67. r = 4 \sin \theta \qquad 68. r = -2 \cos \theta$$

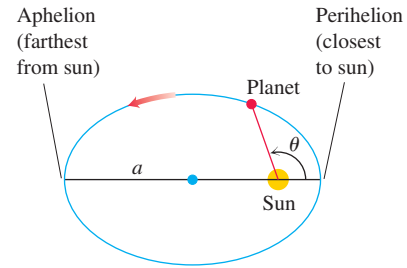

$$69. r = 8/(4 + \cos \theta) \qquad 70. r = 8/(4 + \sin \theta)$$

$$71. r = 1/(1 - \sin \theta) \qquad 72. r = 1/(1 + \cos \theta)$$

$$73. r = 1/(1 + 2 \sin \theta) \qquad 74. r = 1/(1 + 2 \cos \theta)$$

75. Perihelion and aphelion A planet travels about its sun in an ellipse whose semimajor axis has length a . (See accompanying figure.)

- Show that $r = a(1 - e)$ when the planet is closest to the sun and that $r = a(1 + e)$ when the planet is farthest from the sun.
- Use the data in the table in Exercise 76 to find how close each planet in our solar system comes to the sun and how far away each planet gets from the sun.

76. Planetary orbits Use the data in the table below and Equation (6) to find polar equations for the orbits of the planets.

Planet	Semimajor axis (astronomical units)	Eccentricity
Mercury	0.3871	0.2056
Venus	0.7233	0.0068
Earth	1.000	0.0167
Mars	1.524	0.0934
Jupiter	5.203	0.0484
Saturn	9.539	0.0543
Uranus	19.18	0.0460
Neptune	30.06	0.0082

CHAPTER 10 Questions to Guide Your Review

- What is a parametrization of a curve in the xy -plane? Does a function $y = f(x)$ always have a parametrization? Are parametrizations of a curve unique? Give examples.
- Give some typical parametrizations for lines, circles, parabolas, ellipses, and hyperbolas. How might the parametrized curve differ from the graph of its Cartesian equation?
- What is a cycloid? What are typical parametric equations for cycloids? What physical properties account for the importance of cycloids?
- What is the formula for the slope dy/dx of a parametrized curve $x = f(t)$, $y = g(t)$? When does the formula apply? When can you expect to be able to find d^2y/dx^2 as well? Give examples.
- How can you sometimes find the area bounded by a parametrized curve and one of the coordinate axes?
- How do you find the length of a smooth parametrized curve $x = f(t)$, $y = g(t)$, $a \leq t \leq b$? What does smoothness have to do with length? What else do you need to know about the parametrization in order to find the curve's length? Give examples.
- What is the arc length function for a smooth parametrized curve? What is its arc length differential?
- Under what conditions can you find the area of the surface generated by revolving a curve $x = f(t)$, $y = g(t)$, $a \leq t \leq b$, about the x -axis? the y -axis? Give examples.
- What are polar coordinates? What equations relate polar coordinates to Cartesian coordinates? Why might you want to change from one coordinate system to the other?
- What consequence does the lack of uniqueness of polar coordinates have for graphing? Give an example.

- How do you graph equations in polar coordinates? Include in your discussion symmetry, slope, behavior at the origin, and the use of Cartesian graphs. Give examples.
- How do you find the area of a region $0 \leq r_1(\theta) \leq r \leq r_2(\theta)$, $\alpha \leq \theta \leq \beta$, in the polar coordinate plane? Give examples.
- Under what conditions can you find the length of a curve $r = f(\theta)$, $\alpha \leq \theta \leq \beta$, in the polar coordinate plane? Give an example of a typical calculation.
- What is a parabola? What are the Cartesian equations for parabolas whose vertices lie at the origin and whose foci lie on the coordinate axes? How can you find the focus and directrix of such a parabola from its equation?
- What is an ellipse? What are the Cartesian equations for ellipses centered at the origin with foci on one of the coordinate axes? How can you find the foci, vertices, and directrices of such an ellipse from its equation?
- What is a hyperbola? What are the Cartesian equations for hyperbolas centered at the origin with foci on one of the coordinate axes? How can you find the foci, vertices, and directrices of such an ellipse from its equation?
- What is the eccentricity of a conic section? How can you classify conic sections by eccentricity? How does eccentricity change the shape of ellipses and hyperbolas?
- Explain the equation $PF = e \cdot PD$.
- What are the standard equations for lines and conic sections in polar coordinates? Give examples.

CHAPTER 10 Practice Exercises

Identifying Parametric Equations in the Plane

Exercises 1–6 give parametric equations and parameter intervals for the motion of a particle in the xy -plane. Identify the particle's path by finding a Cartesian equation for it. Graph the Cartesian equation and indicate the direction of motion and the portion traced by the particle.

- $x = t/2$, $y = t + 1$, $-\infty < t < \infty$
- $x = \sqrt{t}$, $y = 1 - \sqrt{t}$, $t \geq 0$
- $x = (1/2)\tan t$, $y = (1/2)\sec t$, $-\pi/2 < t < \pi/2$
- $x = -2\cos t$, $y = 2\sin t$, $0 \leq t \leq \pi$
- $x = -\cos t$, $y = \cos^2 t$, $0 \leq t \leq \pi$
- $x = 4\cos t$, $y = 9\sin t$, $0 \leq t \leq 2\pi$

Finding Parametric Equations and Tangent Lines

- Find parametric equations and a parameter interval for the motion of a particle in the xy -plane that traces the ellipse $16x^2 + 9y^2 = 144$ once counterclockwise. (There are many ways to do this.)
- Find parametric equations and a parameter interval for the motion of a particle that starts at the point $(-2, 0)$ in the xy -plane and traces the circle $x^2 + y^2 = 4$ three times clockwise. (There are many ways to do this.)

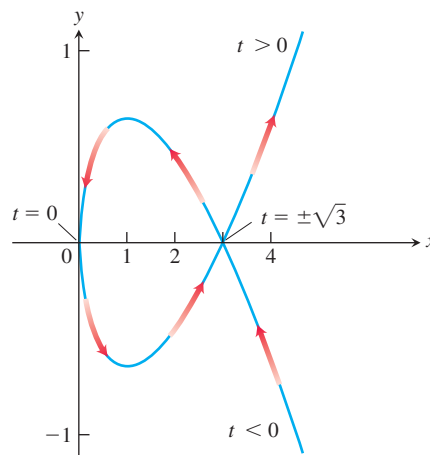

In Exercises 9 and 10, find an equation for the line in the xy -plane that is tangent to the curve at the point corresponding to the given value of t . Also, find the value of d^2y/dx^2 at this point.

- $x = (1/2)\tan t$, $y = (1/2)\sec t$, $t = \pi/3$
- $x = 1 + 1/t^2$, $y = 1 - 3/t$, $t = 2$
- Eliminate the parameter to express the curve in the form $y = f(x)$.
 - $x = 4t^2$, $y = t^3 - 1$
 - $x = \cos t$, $y = \tan t$
- Find parametric equations for the given curve.
 - Line through $(1, -2)$ with slope 3
 - $(x - 1)^2 + (y + 2)^2 = 9$
 - $y = 4x^2 - x$
 - $9x^2 + 4y^2 = 36$

Lengths of Curves

Find the lengths of the curves in Exercises 13–19.

- $y = x^{1/2} - (1/3)x^{3/2}$, $1 \leq x \leq 4$
- $x = y^{2/3}$, $1 \leq y \leq 8$
- $y = (5/12)x^{6/5} - (5/8)x^{4/5}$, $1 \leq x \leq 32$
- $x = (y^3/12) + (1/y)$, $1 \leq y \leq 2$
- $x = 5\cos t - \cos 5t$, $y = 5\sin t - \sin 5t$, $0 \leq t \leq \pi/2$
- $x = t^3 - 6t^2$, $y = t^3 + 6t^2$, $0 \leq t \leq 1$
- $x = 3\cos \theta$, $y = 3\sin \theta$, $0 \leq \theta \leq \frac{3\pi}{2}$
- Find the length of the enclosed loop $x = t^2$, $y = (t^3/3) - t$ shown here. The loop starts at $t = -\sqrt{3}$ and ends at $t = \sqrt{3}$.

Surface Areas

Find the areas of the surfaces generated by revolving the curves in Exercises 21 and 22 about the indicated axes.

- $x = t^2/2$, $y = 2t$, $0 \leq t \leq \sqrt{5}$, x -axis
- $x = t^2 + 1/(2t)$, $y = 4\sqrt{t}$, $1/\sqrt{2} \leq t \leq 1$, y -axis

Polar to Cartesian Equations

Sketch the lines in Exercises 23–28. Also, find a Cartesian equation for each line.

23. $r \cos\left(\theta + \frac{\pi}{3}\right) = 2\sqrt{3}$

24. $r \cos\left(\theta - \frac{3\pi}{4}\right) = \frac{\sqrt{2}}{2}$

25. $r = 2 \sec \theta$

26. $r = -\sqrt{2} \sec \theta$

27. $r = -(3/2) \csc \theta$

28. $r = (3\sqrt{3}) \csc \theta$

Find Cartesian equations for the circles in Exercises 29–32. Sketch each circle in the coordinate plane and label it with both its Cartesian and polar equations.

29. $r = -4 \sin \theta$

30. $r = 3\sqrt{3} \sin \theta$

31. $r = 2\sqrt{2} \cos \theta$

32. $r = -6 \cos \theta$

Cartesian to Polar Equations

Find polar equations for the circles in Exercises 33–36. Sketch each circle in the coordinate plane and label it with both its Cartesian and polar equations.

33. $x^2 + y^2 + 5y = 0$

34. $x^2 + y^2 - 2y = 0$

35. $x^2 + y^2 - 3x = 0$

36. $x^2 + y^2 + 4x = 0$

Graphs in Polar Coordinates

Sketch the regions defined by the polar coordinate inequalities in Exercises 37 and 38.

37. $0 \leq r \leq 6 \cos \theta$

38. $-4 \sin \theta \leq r \leq 0$

Match each graph in Exercises 39–46 with the appropriate equation (a)–(l). There are more equations than graphs, so some equations will not be matched.

a. $r = \cos 2\theta$

b. $r \cos \theta = 1$

c. $r = \frac{6}{1 - 2 \cos \theta}$

d. $r = \sin 2\theta$

e. $r = \theta$

f. $r^2 = \cos 2\theta$

g. $r = 1 + \cos \theta$

h. $r = 1 - \sin \theta$

i. $r = \frac{2}{1 - \cos \theta}$

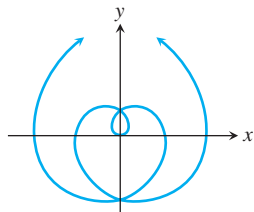

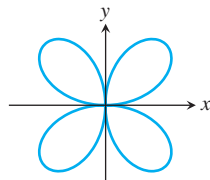

j. $r^2 = \sin 2\theta$

k. $r = -\sin \theta$

l. $r = 2 \cos \theta + 1$

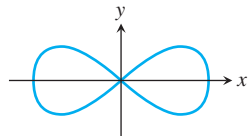

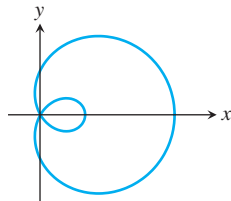

39. Four-leaved rose

40. Spiral

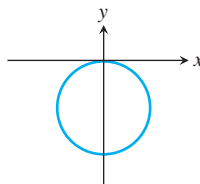

41. Limaçon

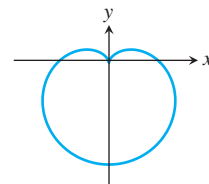

42. Lemniscate

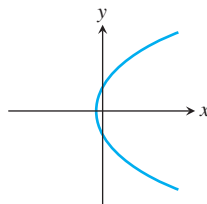

43. Circle

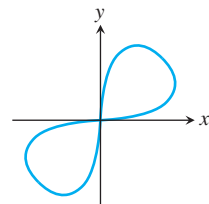

44. Cardioid

45. Parabola

46. Lemniscate

**Area in Polar Coordinates**

Find the areas of the regions in the polar coordinate plane described in Exercises 47–50.

47. Enclosed by the limaçon $r = 2 - \cos \theta$ 48. Enclosed by one leaf of the three-leaved rose $r = \sin 3\theta$ 49. Inside the “figure eight” $r = 1 + \cos 2\theta$ and outside the circle $r = 1$ 50. Inside the cardioid $r = 2(1 + \sin \theta)$ and outside the circle $r = 2 \sin \theta$ **Length in Polar Coordinates**

Find the lengths of the curves given by the polar coordinate equations in Exercises 51–54.

51. $r = -1 + \cos \theta$

52. $r = 2 \sin \theta + 2 \cos \theta$, $0 \leq \theta \leq \pi/2$

53. $r = 8 \sin^3(\theta/3)$, $0 \leq \theta \leq \pi/4$

54. $r = \sqrt{1 + \cos 2\theta}$, $-\pi/2 \leq \theta \leq \pi/2$

Graphing Conic Sections

Sketch the parabolas in Exercises 55–58. Include the focus and directrix in each sketch.

55. $x^2 = -4y$

56. $x^2 = 2y$

57. $y^2 = 3x$

58. $y^2 = -(8/3)x$

Find the eccentricities of the ellipses and hyperbolas in Exercises 59–62. Sketch each conic section. Include the foci, vertices, and asymptotes (as appropriate) in your sketch.

59. $16x^2 + 7y^2 = 112$

60. $x^2 + 2y^2 = 4$

61. $3x^2 - y^2 = 3$

62. $5y^2 - 4x^2 = 20$

Exercises 63–68 give equations for conic sections and tell how many units up or down and to the right or left each curve is to be shifted. Find an equation for the new conic section, and find the new foci, vertices, centers, and asymptotes, as appropriate. If the curve is a parabola, find the new directrix as well.

63. $x^2 = -12y$, right 2, up 3

64. $y^2 = 10x$, left 1/2, down 1

65. $\frac{x^2}{9} + \frac{y^2}{25} = 1$, left 3, down 5

66. $\frac{x^2}{169} + \frac{y^2}{144} = 1$, right 5, up 12

67. $\frac{y^2}{8} - \frac{x^2}{2} = 1$, right 2, up $2\sqrt{2}$

68. $\frac{x^2}{36} - \frac{y^2}{64} = 1$, left 10, down 3

Identifying Conic Sections

Complete the squares to identify the conic sections in Exercises 69–76. Find their foci, vertices, centers, and asymptotes (as appropriate). If the curve is a parabola, find its directrix as well.

69. $x^2 - 4x - 4y^2 = 0$ 70. $4x^2 - y^2 + 4y = 8$

71. $y^2 - 2y + 16x = -49$ 72. $x^2 - 2x + 8y = -17$

73. $9x^2 + 16y^2 + 54x - 64y = -1$

74. $25x^2 + 9y^2 - 100x + 54y = 44$

75. $x^2 + y^2 - 2x - 2y = 0$ 76. $x^2 + y^2 + 4x + 2y = 1$

Conics in Polar Coordinates

Sketch the conic sections whose polar coordinate equations are given in Exercises 77–80. Give polar coordinates for the vertices and, in the case of ellipses, for the centers as well.

77. $r = \frac{2}{1 + \cos \theta}$ 78. $r = \frac{8}{2 + \cos \theta}$

79. $r = \frac{6}{1 - 2 \cos \theta}$ 80. $r = \frac{12}{3 + \sin \theta}$

Exercises 81–84 give the eccentricities of conic sections with one focus at the origin of the polar coordinate plane, along with the directrix for that focus. Find a polar equation for each conic section.

81. $e = 2$, $r \cos \theta = 2$ 82. $e = 1$, $r \cos \theta = -4$

83. $e = 1/2$, $r \sin \theta = 2$ 84. $e = 1/3$, $r \sin \theta = -6$

Theory and Examples

85. Find the volume of the solid generated by revolving the region enclosed by the ellipse $9x^2 + 4y^2 = 36$ about (a) the x -axis, (b) the y -axis.

86. The “triangular” region in the first quadrant bounded by the x -axis, the line $x = 4$, and the hyperbola $9x^2 - 4y^2 = 36$ is revolved about the x -axis to generate a solid. Find the volume of the solid.

87. Show that the equations $x = r \cos \theta$, $y = r \sin \theta$ transform the polar equation

$$r = \frac{k}{1 + e \cos \theta}$$

into the Cartesian equation

$$(1 - e^2)x^2 + y^2 + 2kex - k^2 = 0.$$

88. **Archimedes spirals** The graph of an equation of the form $r = a\theta$, where a is a nonzero constant, is called an *Archimedes spiral*. Is there anything special about the widths between the successive turns of such a spiral?

CHAPTER 10 Additional and Advanced Exercises**Finding Conic Sections**

- Find an equation for the parabola with focus $(4, 0)$ and directrix $x = 3$. Sketch the parabola together with its vertex, focus, and directrix.
- Find the vertex, focus, and directrix of the parabola

$$x^2 - 6x - 12y + 9 = 0.$$
- Find an equation for the curve traced by the point $P(x, y)$ if the distance from P to the vertex of the parabola $x^2 = 4y$ is twice the distance from P to the focus. Identify the curve.
- A line segment of length $a + b$ runs from the x -axis to the y -axis. The point P on the segment lies a units from one end and b units from the other end. Show that P traces an ellipse as the ends of the segment slide along the axes.
- The vertices of an ellipse of eccentricity 0.5 lie at the points $(0, \pm 2)$. Where do the foci lie?
- Find an equation for the ellipse of eccentricity $2/3$ that has the line $x = 2$ as a directrix and the point $(4, 0)$ as the corresponding focus.
- One focus of a hyperbola lies at the point $(0, -7)$ and the corresponding directrix is the line $y = -1$. Find an equation for the hyperbola if its eccentricity is (a) 2, (b) 5.

8. Find an equation for the hyperbola with foci $(0, -2)$ and $(0, 2)$ that passes through the point $(12, 7)$.

9. Show that the line

$$b^2xx_1 + a^2yy_1 - a^2b^2 = 0$$

is tangent to the ellipse $b^2x^2 + a^2y^2 - a^2b^2 = 0$ at the point (x_1, y_1) on the ellipse.

10. Show that the line

$$b^2xx_1 - a^2yy_1 - a^2b^2 = 0$$

is tangent to the hyperbola $b^2x^2 - a^2y^2 - a^2b^2 = 0$ at the point (x_1, y_1) on the hyperbola.

Equations and Inequalities

What points in the xy -plane satisfy the equations and inequalities in Exercises 11–16? Draw a figure for each exercise.

11. $(x^2 - y^2 - 1)(x^2 + y^2 - 25)(x^2 + 4y^2 - 4) = 0$

12. $(x + y)(x^2 + y^2 - 1) = 0$

13. $(x^2/9) + (y^2/16) \leq 1$

14. $(x^2/9) - (y^2/16) \leq 1$

15. $(9x^2 + 4y^2 - 36)(4x^2 + 9y^2 - 16) \leq 0$

16. $(9x^2 + 4y^2 - 36)(4x^2 + 9y^2 - 16) > 0$

Polar Coordinates

17. a. Find an equation in polar coordinates for the curve

$$x = e^{2t} \cos t, \quad y = e^{2t} \sin t, \quad -\infty < t < \infty.$$

- b. Find the length of the curve from $t = 0$ to $t = 2\pi$.

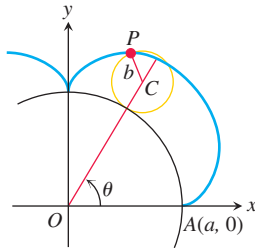

18. Find the length of the curve $r = 2 \sin^3(\theta/3)$, $0 \leq \theta \leq 3\pi$, in the polar coordinate plane.

Exercises 19–22 give the eccentricities of conic sections with one focus at the origin of the polar coordinate plane, along with the directrix for that focus. Find a polar equation for each conic section.

19. $e = 2$, $r \cos \theta = 2$ 20. $e = 1$, $r \cos \theta = -4$
 21. $e = 1/2$, $r \sin \theta = 2$ 22. $e = 1/3$, $r \sin \theta = -6$

Theory and Examples

23. **Epicycloids** When a circle rolls externally along the circumference of a second, fixed circle, any point P on the circumference of the rolling circle describes an *epicycloid*, as shown here. Let the fixed circle have its center at the origin O and have radius a .

Let the radius of the rolling circle be b and let the initial position of the tracing point P be $A(a, 0)$. Find parametric equations for the epicycloid, using as the parameter the angle θ from the positive x -axis to the line through the circles' centers.

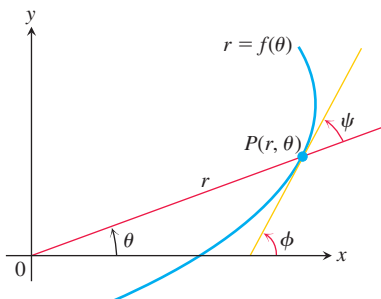

24. Find the centroid of the region enclosed by the x -axis and the cycloid arch

$$x = a(t - \sin t), \quad y = a(1 - \cos t); \quad 0 \leq t \leq 2\pi.$$

The Angle Between the Radius Vector and the Tangent Line to a Polar Coordinate Curve In Cartesian coordinates, when we want to discuss the direction of a curve at a point, we use the angle ϕ measured counterclockwise from the positive x -axis to the tangent line. In polar coordinates, it is more convenient to calculate the angle ψ from the *radius vector* to the tangent line (see the accompanying figure). The angle ϕ can then be calculated from the relation

$$\phi = \theta + \psi, \quad (1)$$

which comes from applying the Exterior Angle Theorem to the triangle in the accompanying figure.

Suppose the equation of the curve is given in the form $r = f(\theta)$, where $f(\theta)$ is a differentiable function of θ . Then

$$x = r \cos \theta \quad \text{and} \quad y = r \sin \theta \quad (2)$$

are differentiable functions of θ with

$$\begin{aligned} \frac{dx}{d\theta} &= -r \sin \theta + \cos \theta \frac{dr}{d\theta}, \\ \frac{dy}{d\theta} &= r \cos \theta + \sin \theta \frac{dr}{d\theta}. \end{aligned} \quad (3)$$

Since $\psi = \phi - \theta$ from (1),

$$\tan \psi = \tan(\phi - \theta) = \frac{\tan \phi - \tan \theta}{1 + \tan \phi \tan \theta}.$$

Furthermore,

$$\tan \phi = \frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta}$$

because $\tan \phi$ is the slope of the curve at P . Also,

$$\tan \theta = \frac{y}{x}.$$

Hence

$$\tan \psi = \frac{\frac{dy/d\theta}{dx/d\theta} - \frac{y}{x}}{1 + \frac{y}{x} \frac{dy/d\theta}{dx/d\theta}} = \frac{x \frac{dy}{d\theta} - y \frac{dx}{d\theta}}{x \frac{dx}{d\theta} + y \frac{dy}{d\theta}}. \quad (4)$$

The numerator in the last expression in Equation (4) is found from Equations (2) and (3) to be

$$x \frac{dy}{d\theta} - y \frac{dx}{d\theta} = r^2.$$

Similarly, the denominator is

$$x \frac{dx}{d\theta} + y \frac{dy}{d\theta} = r \frac{dr}{d\theta}.$$

When we substitute these into Equation (4), we obtain

$$\tan \psi = \frac{r}{dr/d\theta}. \quad (5)$$

This is the equation we use for finding ψ as a function of θ .

25. Show, by reference to a figure, that the angle β between the tangents to two curves at a point of intersection may be found from the formula

$$\tan \beta = \frac{\tan \psi_2 - \tan \psi_1}{1 + \tan \psi_2 \tan \psi_1}. \quad (6)$$

When will the two curves intersect at right angles?

26. Find the value of $\tan \psi$ for the curve $r = \sin^4(\theta/4)$.

27. Find the angle between the radius vector to the curve $r = 2a \sin 3\theta$ and its tangent when $\theta = \pi/6$.
- T** 28. a. Graph the hyperbolic spiral $r\theta = 1$. What appears to happen to ψ as the spiral winds in around the origin?
b. Confirm your finding in part (a) analytically.
29. The circles $r = \sqrt{3} \cos \theta$ and $r = \sin \theta$ intersect at the point $(\sqrt{3}/2, \pi/3)$. Show that their tangents are perpendicular there.
30. Find the angle at which the cardioid $r = a(1 - \cos \theta)$ crosses the ray $\theta = \pi/2$.

CHAPTER 10 Technology Application Projects

Mathematica/Maple Projects

Projects can be found within MyLab Math.

- **Radar Tracking of a Moving Object**
Part I: Convert from polar to Cartesian coordinates.
- **Parametric and Polar Equations with a Figure Skater**
Part I: Visualize position, velocity, and acceleration to analyze motion defined by parametric equations.
Part II: Find and analyze the equations of motion for a figure skater tracing a polar plot.

11

Vectors and the Geometry of Space

OVERVIEW In this chapter we begin the study of multivariable calculus. To apply calculus in many real-world situations, we introduce three-dimensional coordinate systems and vectors. We establish coordinates in space by adding a third axis that measures distance above and below the xy -plane. Then we define vectors, which provide simple ways to introduce equations for lines, planes, curves, and surfaces in space.

11.1 Three-Dimensional Coordinate Systems

To locate a point in space, we use three mutually perpendicular coordinate axes, arranged as in Figure 11.1. The axes shown there make a *right-handed* coordinate frame. When you hold your right hand so that the fingers curl from the positive x -axis toward the positive y -axis, your thumb points along the positive z -axis. So when you look down on the xy -plane from the positive direction of the z -axis, positive angles in the plane are measured counterclockwise from the positive x -axis and around the positive z -axis. (In a *left-handed* coordinate frame, the z -axis would point downward in Figure 11.1, and angles in the plane would be positive when measured clockwise from the positive x -axis. Right-handed and left-handed coordinate frames are not equivalent.)

The Cartesian coordinates (x, y, z) of a point P in space are the values at which the planes through P perpendicular to the axes cut the axes. Cartesian coordinates for space are also called **rectangular coordinates** because the axes that define them meet at right angles. Points on the x -axis have y - and z -coordinates equal to zero. That is, they have coordinates of the form $(x, 0, 0)$. Similarly, points on the y -axis have coordinates of the form $(0, y, 0)$, and points on the z -axis have coordinates of the form $(0, 0, z)$.

The planes determined by the coordinate axes are the **xy -plane**, whose standard equation is $z = 0$; the **yz -plane**, whose standard equation is $x = 0$; and the **xz -plane**, whose standard equation is $y = 0$. They meet at the **origin** $(0, 0, 0)$ (Figure 11.2), which is also identified by 0 or the letter O .

The three **coordinate planes** $x = 0$, $y = 0$, and $z = 0$ divide space into eight cells called **octants**. The octant in which the point coordinates are all positive is called the **first octant**; there is no convention for numbering the other seven octants.

The points in a plane perpendicular to the x -axis all have the same x -coordinate, this being the number at which that plane cuts the x -axis. The y - and z -coordinates can be any numbers. Similarly, the points in a plane perpendicular to the y -axis have a common y -coordinate, and the points in a plane perpendicular to the z -axis have a common z -coordinate. To write equations for these planes, we name the common coordinate's value. The plane $x = 2$ is the plane perpendicular to the x -axis at $x = 2$. The plane $y = 3$ is the plane perpendicular to the y -axis at $y = 3$. The plane $z = 5$ is the plane perpendicular to the z -axis at $z = 5$. Figure 11.3 shows the planes $x = 2$, $y = 3$, and $z = 5$, together with their intersection point $(2, 3, 5)$.

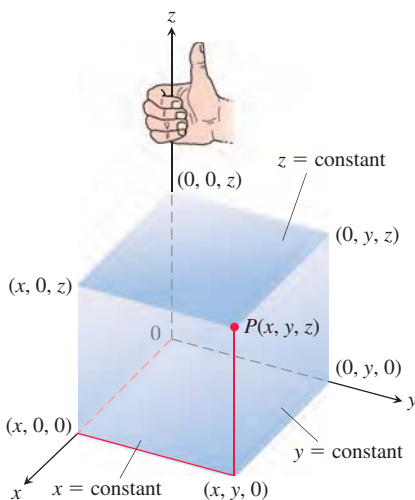

FIGURE 11.1 The Cartesian coordinate system is right-handed.

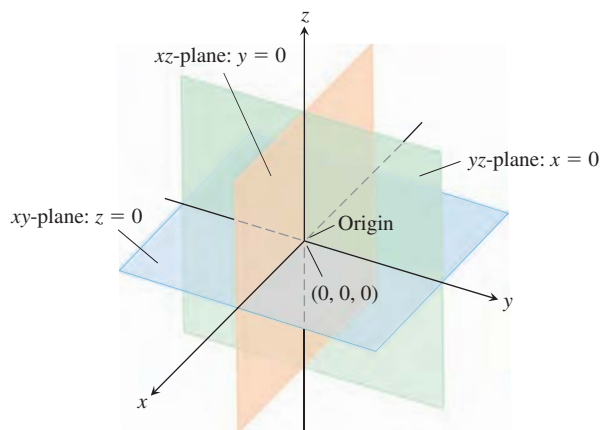

FIGURE 11.2 The planes $x = 0$, $y = 0$, and $z = 0$ divide space into eight octants.

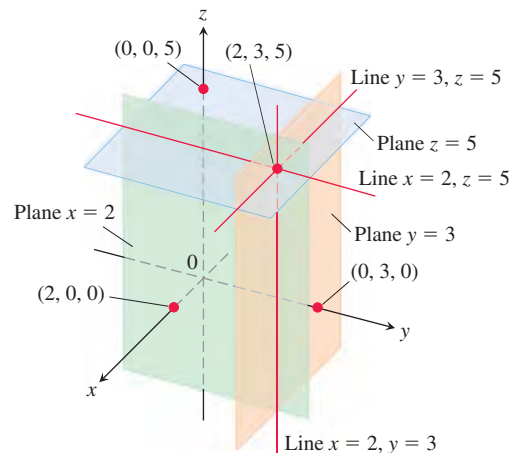

FIGURE 11.3 The planes $x = 2$, $y = 3$, and $z = 5$ determine three lines through the point $(2, 3, 5)$.

The planes $x = 2$ and $y = 3$ in Figure 11.3 intersect in a line parallel to the z -axis. This line is described by the *pair* of equations $x = 2$, $y = 3$. A point (x, y, z) lies on the line if and only if $x = 2$ and $y = 3$. Similarly, the line of intersection of the planes $y = 3$ and $z = 5$ is described by the equation pair $y = 3$, $z = 5$. This line runs parallel to the x -axis. The line of intersection of the planes $x = 2$ and $z = 5$, parallel to the y -axis, is described by the equation pair $x = 2$, $z = 5$.

In the following examples, we match coordinate equations and inequalities with the sets of points they define in space.

EXAMPLE 1 We interpret these equations and inequalities geometrically.

- | | |
|--|--|
| (a) $z \geq 0$ | The half-space consisting of the points on and above the xy -plane. |
| (b) $x = -3$ | The plane perpendicular to the x -axis at $x = -3$. This plane lies parallel to the yz -plane and 3 units behind it. |
| (c) $z = 0$, $x \leq 0$, $y \geq 0$ | The second quadrant of the xy -plane. |
| (d) $x \geq 0$, $y \geq 0$, $z \geq 0$ | The first octant. |
| (e) $-1 \leq y \leq 1$ | The slab between the planes $y = -1$ and $y = 1$ (planes included). |
| (f) $y = -2$, $z = 2$ | The line in which the planes $y = -2$ and $z = 2$ intersect. Alternatively, the line through the point $(0, -2, 2)$ parallel to the x -axis. ■ |

EXAMPLE 2 What points (x, y, z) satisfy the equations

$$x^2 + y^2 = 4 \quad \text{and} \quad z = 3?$$

Solution The points lie in the horizontal plane $z = 3$ and, in this plane, make up the circle $x^2 + y^2 = 4$. We call this set of points “the circle $x^2 + y^2 = 4$ in the plane $z = 3$ ” or, more simply, “the circle $x^2 + y^2 = 4$, $z = 3$ ” (Figure 11.4). ■

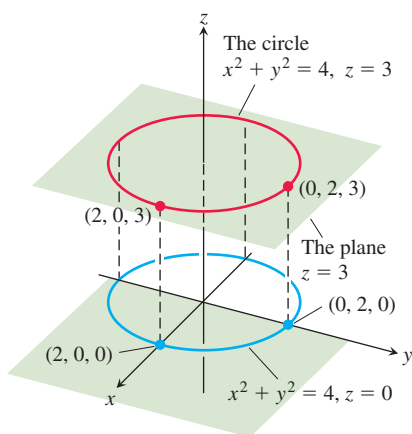

FIGURE 11.4 The circle $x^2 + y^2 = 4$ in the plane $z = 3$ (Example 2).

Distance and Spheres in Space

The formula for the distance between two points in the xy -plane extends to points in space.

The Distance Between $P_1(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$

$$|P_1P_2| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

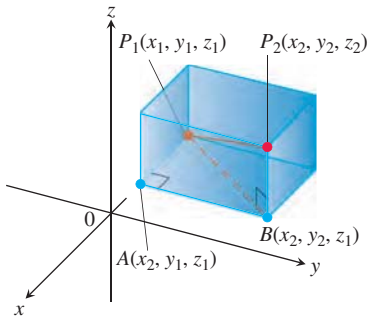

FIGURE 11.5 We find the distance between P_1 and P_2 by applying the Pythagorean theorem to the right triangles P_1AB and P_1BP_2 .

Proof We construct a rectangular box with faces parallel to the coordinate planes and the points P_1 and P_2 at opposite corners of the box (Figure 11.5). If $A(x_2, y_1, z_1)$ and $B(x_2, y_2, z_1)$ are the vertices of the box indicated in the figure, then the three box edges P_1A , AB , and BP_2 have lengths

$$|P_1A| = |x_2 - x_1|, \quad |AB| = |y_2 - y_1|, \quad |BP_2| = |z_2 - z_1|.$$

Because triangles P_1BP_2 and P_1AB are both right-angled, two applications of the Pythagorean theorem give

$$|P_1P_2|^2 = |P_1B|^2 + |BP_2|^2 \quad \text{and} \quad |P_1B|^2 = |P_1A|^2 + |AB|^2$$

(see Figure 11.5). So

$$\begin{aligned} |P_1P_2|^2 &= |P_1B|^2 + |BP_2|^2 \\ &= |P_1A|^2 + |AB|^2 + |BP_2|^2 && \text{Substitute } |P_1B|^2 = |P_1A|^2 + |AB|^2. \\ &= |x_2 - x_1|^2 + |y_2 - y_1|^2 + |z_2 - z_1|^2 \\ &= (x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2. \end{aligned}$$

Therefore,

$$|P_1P_2| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}. \quad \blacksquare$$

EXAMPLE 3 The distance between $P_1(2, 1, 5)$ and $P_2(-2, 3, 0)$ is

$$\begin{aligned} |P_1P_2| &= \sqrt{(-2 - 2)^2 + (3 - 1)^2 + (0 - 5)^2} \\ &= \sqrt{16 + 4 + 25} \\ &= \sqrt{45} \approx 6.708. \quad \blacksquare \end{aligned}$$

We can use the distance formula to write equations for spheres in space (Figure 11.6). A point $P(x, y, z)$ lies on the sphere of radius a centered at $P_0(x_0, y_0, z_0)$ precisely when $|P_0P| = a$, or

$$(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = a^2.$$

The Standard Equation for the Sphere of Radius a and Center (x_0, y_0, z_0)

$$(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = a^2$$

EXAMPLE 4 Find the center and radius of the sphere

$$x^2 + y^2 + z^2 + 3x - 4z + 1 = 0.$$

Solution We find the center and radius of a sphere the way we find the center and radius of a circle: Complete the squares on the x -, y -, and z -terms as necessary and write each

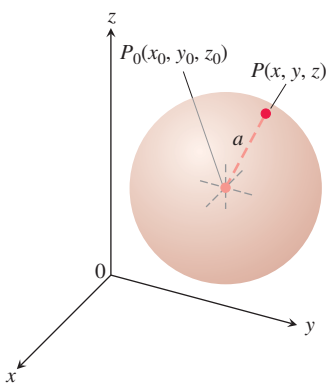

FIGURE 11.6 The sphere of radius a centered at the point (x_0, y_0, z_0) .

quadratic as a squared linear expression. Then, from the equation in standard form, read off the center and radius. For this sphere, we have

$$\begin{aligned}x^2 + y^2 + z^2 + 3x - 4z + 1 &= 0 \\(x^2 + 3x) + y^2 + (z^2 - 4z) &= -1 \\ \left(x^2 + 3x + \left(\frac{3}{2}\right)^2\right) + y^2 + \left(z^2 - 4z + \left(\frac{-4}{2}\right)^2\right) &= -1 + \left(\frac{3}{2}\right)^2 + \left(\frac{-4}{2}\right)^2 \\ \left(x + \frac{3}{2}\right)^2 + y^2 + (z - 2)^2 &= \frac{21}{4}.\end{aligned}$$

From this standard form, we read that $x_0 = -3/2$, $y_0 = 0$, $z_0 = 2$, and $a = \sqrt{21}/2$. The center is $(-3/2, 0, 2)$. The radius is $\sqrt{21}/2$. ■

EXAMPLE 5 Here are some geometric interpretations of inequalities and equations involving spheres.

- | | |
|-------------------------------------|--|
| (a) $x^2 + y^2 + z^2 < 4$ | The interior of the sphere $x^2 + y^2 + z^2 = 4$. |
| (b) $x^2 + y^2 + z^2 \leq 4$ | The solid ball bounded by the sphere $x^2 + y^2 + z^2 = 4$. Alternatively, the sphere $x^2 + y^2 + z^2 = 4$ together with its interior. |
| (c) $x^2 + y^2 + z^2 > 4$ | The exterior of the sphere $x^2 + y^2 + z^2 = 4$. |
| (d) $x^2 + y^2 + z^2 = 4, z \leq 0$ | The lower hemisphere cut from the sphere $x^2 + y^2 + z^2 = 4$ by the xy -plane (the plane $z = 0$). ■ |

Just as polar coordinates give another way to locate points in the xy -plane (Section 10.3), alternative coordinate systems, different from the Cartesian coordinate system developed here, exist for three-dimensional space. We examine two of these coordinate systems in Section 14.7.

EXERCISES 11.1

Geometric Interpretations of Equations

In Exercises 1–16, give a geometric description of the set of points in space whose coordinates satisfy the given pairs of equations.

- $x = 2, y = 3$
- $x = -1, z = 0$
- $y = 0, z = 0$
- $x = 1, y = 0$
- $x^2 + y^2 = 4, z = 0$
- $x^2 + y^2 = 4, z = -2$
- $x^2 + z^2 = 4, y = 0$
- $y^2 + z^2 = 1, x = 0$
- $x^2 + y^2 + z^2 = 1, x = 0$
- $x^2 + y^2 + z^2 = 25, y = -4$
- $x^2 + y^2 + (z + 3)^2 = 25, z = 0$
- $x^2 + (y - 1)^2 + z^2 = 4, y = 0$
- $x^2 + y^2 = 4, z = y$
- $x^2 + y^2 + z^2 = 4, y = x$
- $y = x^2, z = 0$
- $z = y^2, x = 1$

Geometric Interpretations of Inequalities and Equations

In Exercises 17–24, describe the sets of points in space whose coordinates satisfy the given inequalities or combinations of equations and inequalities.

- $x \geq 0, y \geq 0, z = 0$
 - $x \geq 0, y \leq 0, z = 0$
- $0 \leq x \leq 1$
 - $0 \leq x \leq 1, 0 \leq y \leq 1$
 - $0 \leq x \leq 1, 0 \leq y \leq 1, 0 \leq z \leq 1$
- $x^2 + y^2 + z^2 \leq 1$
 - $x^2 + y^2 + z^2 > 1$
- $x^2 + y^2 \leq 1, z = 0$
 - $x^2 + y^2 \leq 1, z = 3$
 - $x^2 + y^2 \leq 1$, no restriction on z
- $1 \leq x^2 + y^2 + z^2 \leq 4$
 - $x^2 + y^2 + z^2 \leq 1, z \geq 0$
- $x = y, z = 0$
 - $x = y$, no restriction on z
- $y \geq x^2, z \geq 0$
 - $x \leq y^2, 0 \leq z \leq 2$
- $z = 1 - y$, no restriction on x
 - $z = y^3, x = 2$

Distance

In Exercises 25–30, find the distance between points P_1 and P_2 .

25. $P_1(1, 1, 1)$, $P_2(3, 3, 0)$
 26. $P_1(-1, 1, 5)$, $P_2(2, 5, 0)$
 27. $P_1(1, 4, 5)$, $P_2(4, -2, 7)$
 28. $P_1(3, 4, 5)$, $P_2(2, 3, 4)$
 29. $P_1(0, 0, 0)$, $P_2(2, -2, -2)$
 30. $P_1(5, 3, -2)$, $P_2(0, 0, 0)$
31. Find the distance from the point $(3, -4, 2)$ to the
 a. xy -plane b. yz -plane c. xz -plane
32. Find the distance from the point $(-2, 1, 4)$ to the
 a. plane $x = 3$ b. plane $y = -5$ c. plane $z = -1$
33. Find the distance from the point $(4, 3, 0)$ to the
 a. x -axis b. y -axis c. z -axis
34. Find the distance from the
 a. x -axis to the plane $z = 3$.
 b. origin to the plane $2 = z - x$.
 c. point $(0, 4, 0)$ to the plane $y = x$.

In Exercises 35–44, describe the given set with a single equation or with a pair of equations.

35. The plane perpendicular to the
 a. x -axis at $(3, 0, 0)$ b. y -axis at $(0, -1, 0)$
 c. z -axis at $(0, 0, -2)$
36. The plane through the point $(3, -1, 2)$ perpendicular to the
 a. x -axis b. y -axis c. z -axis
37. The plane through the point $(3, -1, 1)$ parallel to the
 a. xy -plane b. yz -plane c. xz -plane
38. The circle of radius 2 centered at $(0, 0, 0)$ and lying in the
 a. xy -plane b. yz -plane c. xz -plane
39. The circle of radius 2 centered at $(0, 2, 0)$ and lying in the
 a. xy -plane b. yz -plane c. plane $y = 2$
40. The circle of radius 1 centered at $(-3, 4, 1)$ and lying in a plane parallel to the
 a. xy -plane b. yz -plane c. xz -plane
41. The line through the point $(1, 3, -1)$ parallel to the
 a. x -axis b. y -axis c. z -axis
42. The set of points in space equidistant from the origin and the point $(0, 2, 0)$
43. The circle in which the plane through the point $(1, 1, 3)$ perpendicular to the z -axis meets the sphere of radius 5 centered at the origin
44. The set of points in space that lie 2 units from the point $(0, 0, 1)$ and, at the same time, 2 units from the point $(0, 0, -1)$

Inequalities to Describe Sets of Points

Write inequalities to describe the sets in Exercises 45–50.

45. The slab bounded by the planes $z = 0$ and $z = 1$ (planes included)

46. The solid cube in the first octant bounded by the coordinate planes and the planes $x = 2$, $y = 2$, and $z = 2$
47. The half-space consisting of the points on and below the xy -plane
48. The upper hemisphere of the sphere of radius 1 centered at the origin
49. The (a) interior and (b) exterior of the sphere of radius 1 centered at the point $(1, 1, 1)$
50. The closed region bounded by the spheres of radius 1 and radius 2 centered at the origin. (*Closed* means the spheres are to be included. Had we wanted the spheres left out, we would have asked for the *open* region bounded by the spheres. This is analogous to the way we use *closed* and *open* to describe intervals: *closed* means endpoints included, *open* means endpoints left out. Closed sets include boundaries; open sets leave them out.)

Spheres

Find the center C and the radius a for the spheres in Exercises 51–60.

51. $(x + 2)^2 + y^2 + (z - 2)^2 = 8$
52. $(x - 1)^2 + \left(y + \frac{1}{2}\right)^2 + (z + 3)^2 = 25$
53. $(x - \sqrt{2})^2 + (y - \sqrt{2})^2 + (z + \sqrt{2})^2 = 2$
54. $x^2 + \left(y + \frac{1}{3}\right)^2 + \left(z - \frac{1}{3}\right)^2 = \frac{16}{9}$
55. $x^2 + y^2 + z^2 + 4x - 4z = 0$
56. $x^2 + y^2 + z^2 - 6y + 8z = 0$
57. $2x^2 + 2y^2 + 2z^2 + x + y + z = 9$
58. $3x^2 + 3y^2 + 3z^2 + 2y - 2z = 9$
59. $x^2 + y^2 + z^2 - 4x + 6y - 10z = 11$
60. $(x - 1)^2 + (y - 2)^2 + (z + 1)^2 = 103 + 2x + 4y - 2z$

Find equations for the spheres whose centers and radii are given in Exercises 61–64.

Center	Radius
61. $(1, 2, 3)$	$\sqrt{14}$
62. $(0, -1, 5)$	2
63. $\left(-1, \frac{1}{2}, -\frac{2}{3}\right)$	$\frac{4}{9}$
64. $(0, -7, 0)$	7

Theory and Examples

65. Find a formula for the distance from the point $P(x, y, z)$ to the
 a. x -axis. b. y -axis. c. z -axis.
66. Find a formula for the distance from the point $P(x, y, z)$ to the
 a. xy -plane. b. yz -plane. c. xz -plane.
67. Find the perimeter of the triangle with vertices $A(-1, 2, 1)$, $B(1, -1, 3)$, and $C(3, 4, 5)$.
68. Show that the point $P(3, 1, 2)$ is equidistant from the points $A(2, -1, 3)$ and $B(4, 3, 1)$.
69. Find an equation for the set of all points equidistant from the planes $y = 3$ and $y = -1$.
70. Find an equation for the set of all points equidistant from the point $(0, 0, 2)$ and the xy -plane.

71. Find the point on the sphere $x^2 + (y - 3)^2 + (z + 5)^2 = 4$ nearest
- the xy -plane.
 - the point $(0, 7, -5)$.
72. Find the point equidistant from the points $(0, 0, 0)$, $(0, 4, 0)$, $(3, 0, 0)$, and $(2, 2, -3)$.
73. Find an equation for the set of points equidistant from the point $(0, 0, 2)$ and the x -axis.
74. Find an equation for the set of points equidistant from the y -axis and the plane $z = 6$.
75. Find an equation for the set of points equidistant from the
- xy -plane and the yz -plane.
 - x -axis and the y -axis.
76. Find all points that simultaneously lie 3 units from each of the points $(2, 0, 0)$, $(0, 2, 0)$, and $(0, 0, 2)$.

11.2 Vectors

Some of the things we measure are determined simply by their magnitudes. To record mass, length, or time, for example, we need only write down a number and name an appropriate unit of measure. We need more information to describe a force, displacement, or velocity. To describe a force, we need to record the direction in which it acts as well as how large it is. To describe a body's displacement, we have to say in what direction it moved as well as how far. To describe a body's velocity, we have to know its direction of motion, as well as how fast it is going. In this section we show how to represent things that have both magnitude and direction in the plane or in space.

Component Form

A quantity such as force, displacement, or velocity is called a **vector** and is represented by a **directed line segment** (Figure 11.7). The arrow points in the direction of the action and its length gives the magnitude of the action in terms of a suitably chosen unit. For example, a force vector points in the direction in which the force acts and its length is a measure of the force's strength; a velocity vector points in the direction of motion and its length is the speed of the moving object. Figure 11.8 displays the velocity vector \mathbf{v} at a specific location for a particle moving along a path in the plane or in space. (This application of vectors is studied in Chapter 12.)

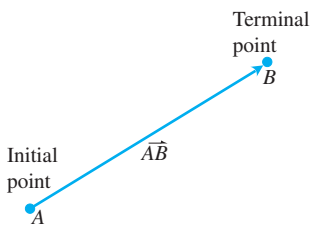

FIGURE 11.7 The directed line segment \overline{AB} is called a vector.

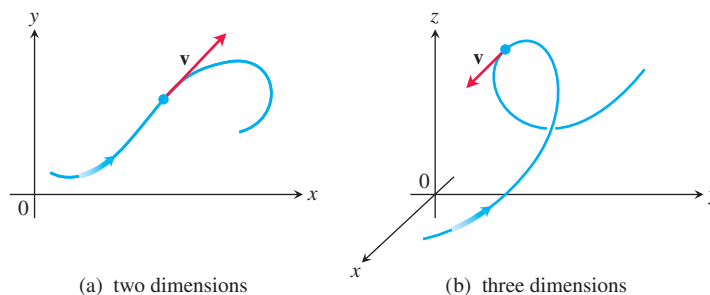

FIGURE 11.8 The velocity vector of a particle moving along a path (a) in the plane (b) in space. The arrowhead on the path indicates the direction of motion of the particle.

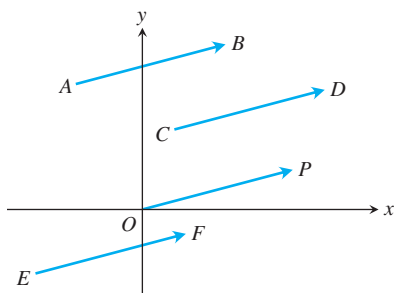

FIGURE 11.9 The four arrows in the plane (directed line segments) shown here have the same length and direction. They therefore represent the same vector, and we write $\overline{AB} = \overline{CD} = \overline{OP} = \overline{EF}$.

DEFINITIONS The vector represented by the directed line segment \overline{AB} has **initial point** A and **terminal point** B , and its **length** is denoted by $|\overline{AB}|$. Two vectors are **equal** if they have the same length and direction.

The arrows we use when we draw vectors are understood to represent the same vector if they have the same length, are parallel, and point in the same direction (Figure 11.9) regardless of the initial point.

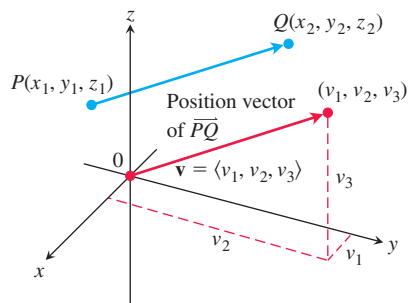

FIGURE 11.10 A vector \overline{PQ} in standard position has its initial point at the origin. The directed line segments \overline{PQ} and \mathbf{v} are parallel and have the same length.

In texts, vectors are usually written in lowercase boldface letters—for example \mathbf{u} , \mathbf{v} , and \mathbf{w} . Sometimes we use uppercase boldface letters, such as \mathbf{F} , to denote a force vector. In handwritten form, it is customary to draw small arrows above the letters—for example \vec{u} , \vec{v} , \vec{w} , and \vec{F} .

We need a way to represent vectors algebraically so that we can be more precise about the direction of a vector. Let $\mathbf{v} = \overline{PQ}$. There is one directed line segment equal to \overline{PQ} whose initial point is the origin (Figure 11.10). It is the representative of \mathbf{v} in **standard position** and is the vector we normally use to represent \mathbf{v} . We can specify \mathbf{v} by writing the coordinates of its terminal point (v_1, v_2, v_3) when \mathbf{v} is in standard position. If \mathbf{v} is a vector in the plane, its terminal point (v_1, v_2) has two coordinates.

DEFINITION If \mathbf{v} is a **two-dimensional** vector in the plane equal to the vector with initial point at the origin and terminal point (v_1, v_2) , then the **component form** of \mathbf{v} is

$$\mathbf{v} = \langle v_1, v_2 \rangle.$$

If \mathbf{v} is a **three-dimensional** vector equal to the vector with initial point at the origin and terminal point (v_1, v_2, v_3) , then the **component form** of \mathbf{v} is

$$\mathbf{v} = \langle v_1, v_2, v_3 \rangle.$$

HISTORICAL BIOGRAPHY

Carl Friedrich Gauss
(1777–1855)

Gauss was born in Brunswick, Germany. The list of Gauss's accomplishments in science and mathematics is astonishing, ranging from the invention of the electric telegraph (with Wilhelm Weber in 1833) to the development of a theory of planetary orbits and the development of an accurate theory of non-Euclidean geometry.

To know more, visit the companion Website.

Thus a two-dimensional vector is an ordered pair $\mathbf{v} = \langle v_1, v_2 \rangle$ of real numbers, and a three-dimensional vector is an ordered triple $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ of real numbers. The numbers v_1 , v_2 , and v_3 are the **components** of \mathbf{v} .

If $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is represented by the directed line segment \overline{PQ} , where the initial point is $P(x_1, y_1, z_1)$ and the terminal point is $Q(x_2, y_2, z_2)$, then $x_1 + v_1 = x_2$, $y_1 + v_2 = y_2$, and $z_1 + v_3 = z_2$ (see Figure 11.10). Thus $v_1 = x_2 - x_1$, $v_2 = y_2 - y_1$, and $v_3 = z_2 - z_1$ are the components of \overline{PQ} .

In summary, given the points $P(x_1, y_1, z_1)$ and $Q(x_2, y_2, z_2)$, the standard position vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ equal to \overline{PQ} is

$$\mathbf{v} = \langle x_2 - x_1, y_2 - y_1, z_2 - z_1 \rangle.$$

If \mathbf{v} is two-dimensional with $P(x_1, y_1)$ and $Q(x_2, y_2)$ as points in the plane, then $\mathbf{v} = \langle x_2 - x_1, y_2 - y_1 \rangle$. There is no third component for planar vectors. With this understanding, we will develop the algebra of three-dimensional vectors and simply drop the third component when the vector is two-dimensional (a planar vector).

Two vectors are equal if and only if their standard position vectors are identical. Thus $\langle u_1, u_2, u_3 \rangle$ and $\langle v_1, v_2, v_3 \rangle$ are **equal** if and only if $u_1 = v_1$, $u_2 = v_2$, and $u_3 = v_3$.

The **magnitude** or **length** of the vector \overline{PQ} is the length of any of its equivalent directed line segment representations. In particular, if $\mathbf{v} = \langle x_2 - x_1, y_2 - y_1, z_2 - z_1 \rangle$ is the component form of \overline{PQ} , then the distance formula gives the magnitude or length of \mathbf{v} , denoted by the symbol $|\mathbf{v}|$ or (in some texts) $\|\mathbf{v}\|$.

The **magnitude** or **length** of the vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle = \langle x_2 - x_1, y_2 - y_1, z_2 - z_1 \rangle$ is the nonnegative number

$$|\mathbf{v}| = \sqrt{v_1^2 + v_2^2 + v_3^2} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

(see Figure 11.10).

The only vector with length 0 is the **zero vector** $\mathbf{0} = \langle 0, 0 \rangle$ or $\mathbf{0} = \langle 0, 0, 0 \rangle$. This vector is also the only vector with no specific direction.

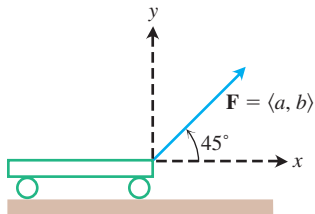

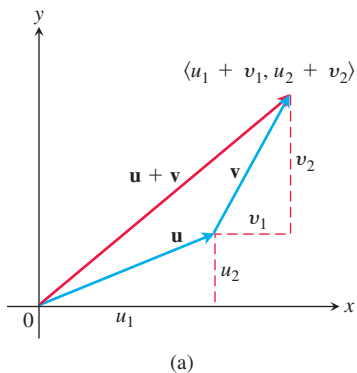

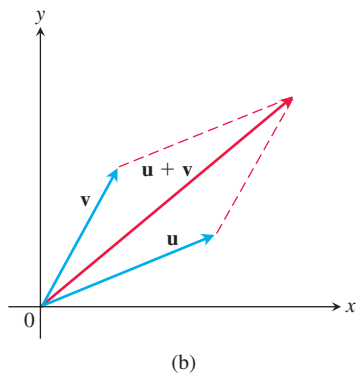

FIGURE 11.11 The force pulling the cart forward is represented by the vector \mathbf{F} whose horizontal component is the effective force (Example 2).

(a)

(b)

FIGURE 11.12 (a) Geometric interpretation of the vector sum. (b) The parallelogram law of vector addition in which both vectors are in standard position.

EXAMPLE 1 Find the (a) component form and (b) length of the vector with initial point $P(-3, 4, 1)$ and terminal point $Q(-5, 2, 2)$.

Solution

(a) The vector $\mathbf{v} = \overline{PQ}$ has components

$$v_1 = x_2 - x_1 = -5 - (-3) = -2, \quad v_2 = y_2 - y_1 = 2 - 4 = -2,$$

and

$$v_3 = z_2 - z_1 = 2 - 1 = 1.$$

The component form of \overline{PQ} is

$$\mathbf{v} = \langle -2, -2, 1 \rangle.$$

(b) The length, or magnitude, of $\mathbf{v} = \overline{PQ}$ is

$$|\mathbf{v}| = \sqrt{(-2)^2 + (-2)^2 + (1)^2} = \sqrt{9} = 3. \quad \blacksquare$$

EXAMPLE 2 A small cart is being pulled along a smooth horizontal floor with a 20-N force \mathbf{F} making a 45° angle to the floor (Figure 11.11). What is the *effective* force moving the cart forward?

Solution The effective force is the horizontal component of $\mathbf{F} = \langle a, b \rangle$, given by

$$a = \mathbf{F} \cos 45^\circ = (20) \left(\frac{\sqrt{2}}{2} \right) \approx 14.14 \text{ N}.$$

Notice that \mathbf{F} is a two-dimensional vector. \(\blacksquare\)

Vector Algebra Operations

Two principal operations involving vectors are *vector addition* and *scalar multiplication*. A **scalar** is simply a real number; we call it a scalar when we want to draw attention to the differences between numbers and vectors. Scalars can be positive, negative, or zero and are used to “scale” a vector by multiplication.

DEFINITIONS Let $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ be vectors with k a scalar.

Addition: $\mathbf{u} + \mathbf{v} = \langle u_1 + v_1, u_2 + v_2, u_3 + v_3 \rangle$

Scalar multiplication: $k\mathbf{u} = \langle ku_1, ku_2, ku_3 \rangle$

We add vectors by adding the corresponding components of the vectors. We multiply a vector by a scalar by multiplying each component by the scalar. The definitions also apply to planar vectors, except in that case there are only two components, $\langle u_1, u_2 \rangle$ and $\langle v_1, v_2 \rangle$.

The definition of vector addition is illustrated geometrically for planar vectors in Figure 11.12a, where the initial point of one vector is placed at the terminal point of the other. Another interpretation is shown in Figure 11.12b. In this **parallelogram law** of addition, the sum, called the **resultant vector**, is the diagonal of the parallelogram. In physics, forces add vectorially, as do velocities, accelerations, and so on. So the force acting on a particle subject to two gravitational forces, for example, is obtained by adding the two force vectors.

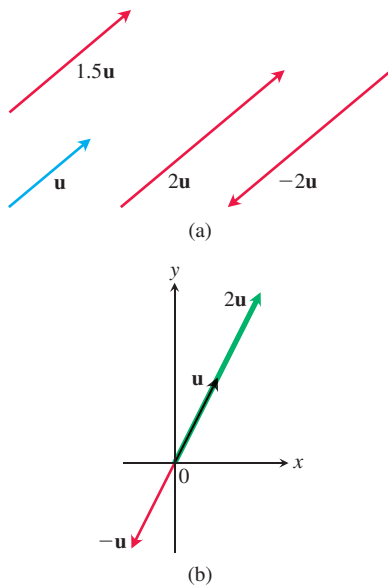

FIGURE 11.13 (a) Scalar multiples of \mathbf{u} . (b) Scalar multiples of a vector \mathbf{u} in standard position.

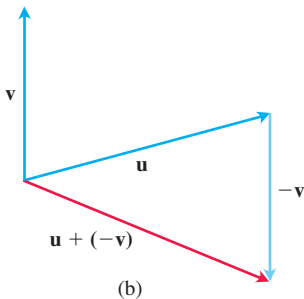

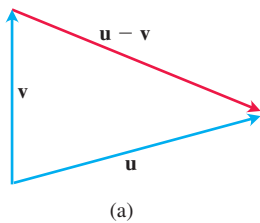

FIGURE 11.14 (a) The vector $\mathbf{u} - \mathbf{v}$, when added to \mathbf{v} , gives \mathbf{u} . (b) $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-\mathbf{v})$.

Figure 11.13 displays a geometric interpretation of the product $k\mathbf{u}$ of the scalar k and vector \mathbf{u} . If $k > 0$, then $k\mathbf{u}$ has the same direction as \mathbf{u} ; if $k < 0$, then the direction of $k\mathbf{u}$ is opposite to that of \mathbf{u} . Comparing the lengths of \mathbf{u} and $k\mathbf{u}$, we see that

$$\begin{aligned} |\mathbf{k}\mathbf{u}| &= \sqrt{(k u_1)^2 + (k u_2)^2 + (k u_3)^2} = \sqrt{k^2(u_1^2 + u_2^2 + u_3^2)} \\ &= \sqrt{k^2} \sqrt{u_1^2 + u_2^2 + u_3^2} = |k| |\mathbf{u}|. \end{aligned}$$

The length of $k\mathbf{u}$ is the absolute value of the scalar k times the length of \mathbf{u} . The vector $(-1)\mathbf{u} = -\mathbf{u}$ has the same length as \mathbf{u} but points in the opposite direction. For $k \neq 0$, we often express the scalar multiple $(1/k)\mathbf{u}$ as \mathbf{u}/k .

The **difference** $\mathbf{u} - \mathbf{v}$ of two vectors is defined by

$$\mathbf{u} - \mathbf{v} = \mathbf{u} + (-\mathbf{v}).$$

If $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$, then

$$\mathbf{u} - \mathbf{v} = \langle u_1 - v_1, u_2 - v_2, u_3 - v_3 \rangle.$$

Note that $(\mathbf{u} - \mathbf{v}) + \mathbf{v} = \mathbf{u}$, so adding the vector $(\mathbf{u} - \mathbf{v})$ to \mathbf{v} gives \mathbf{u} (Figure 11.14a). Figure 11.14b shows the difference $\mathbf{u} - \mathbf{v}$ as the sum $\mathbf{u} + (-\mathbf{v})$.

EXAMPLE 3 Let $\mathbf{u} = \langle -1, 3, 1 \rangle$ and $\mathbf{v} = \langle 4, 7, 0 \rangle$. Find the components of

(a) $2\mathbf{u} + 3\mathbf{v}$ (b) $\mathbf{u} - \mathbf{v}$ (c) $\left| \frac{1}{2}\mathbf{u} \right|$.

Solution

(a) $2\mathbf{u} + 3\mathbf{v} = 2\langle -1, 3, 1 \rangle + 3\langle 4, 7, 0 \rangle = \langle -2, 6, 2 \rangle + \langle 12, 21, 0 \rangle = \langle 10, 27, 2 \rangle$

(b) $\mathbf{u} - \mathbf{v} = \langle -1, 3, 1 \rangle - \langle 4, 7, 0 \rangle = \langle -1 - 4, 3 - 7, 1 - 0 \rangle = \langle -5, -4, 1 \rangle$

(c) $\left| \frac{1}{2}\mathbf{u} \right| = \left| \left\langle -\frac{1}{2}, \frac{3}{2}, \frac{1}{2} \right\rangle \right| = \sqrt{\left(-\frac{1}{2}\right)^2 + \left(\frac{3}{2}\right)^2 + \left(\frac{1}{2}\right)^2} = \frac{1}{2}\sqrt{11}$. ■

Vector operations have many of the properties of ordinary arithmetic.

Properties of Vector Operations

Let $\mathbf{u}, \mathbf{v}, \mathbf{w}$ be vectors and a, b be scalars.

- | | |
|--|--|
| 1. $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$ | 2. $(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w})$ |
| 3. $\mathbf{u} + \mathbf{0} = \mathbf{u}$ | 4. $\mathbf{u} + (-\mathbf{u}) = \mathbf{0}$ |
| 5. $0\mathbf{u} = \mathbf{0}$ | 6. $1\mathbf{u} = \mathbf{u}$ |
| 7. $a(b\mathbf{u}) = (ab)\mathbf{u}$ | 8. $a(\mathbf{u} + \mathbf{v}) = a\mathbf{u} + a\mathbf{v}$ |
| 9. $(a + b)\mathbf{u} = a\mathbf{u} + b\mathbf{u}$ | |

These properties are readily verified using the definitions of vector addition and multiplication by a scalar. For instance, to establish Property 1, we have

$$\begin{aligned} \mathbf{u} + \mathbf{v} &= \langle u_1, u_2, u_3 \rangle + \langle v_1, v_2, v_3 \rangle \\ &= \langle u_1 + v_1, u_2 + v_2, u_3 + v_3 \rangle && \text{Definition of vector addition} \\ &= \langle v_1 + u_1, v_2 + u_2, v_3 + u_3 \rangle && \text{Commutativity of real numbers (in each component)} \\ &= \langle v_1, v_2, v_3 \rangle + \langle u_1, u_2, u_3 \rangle && \text{Definition of vector addition} \\ &= \mathbf{v} + \mathbf{u}. \end{aligned}$$

When three or more space vectors lie in the same plane, we say they are **coplanar** vectors. For example, the vectors \mathbf{u} , \mathbf{v} , and $\mathbf{u} + \mathbf{v}$ are always coplanar.

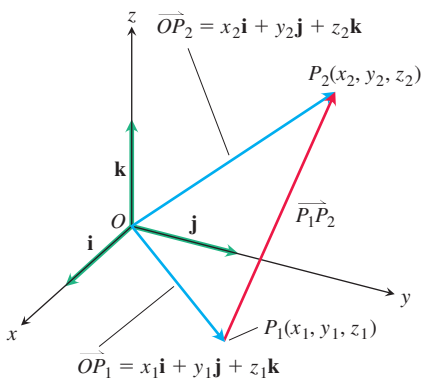

FIGURE 11.15 The vector from P_1 to P_2 is $\overrightarrow{P_1P_2} = (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} + (z_2 - z_1)\mathbf{k}$.

Unit Vectors

A vector \mathbf{v} of length 1 is called a **unit vector**. The **standard unit vectors** are

$$\mathbf{i} = \langle 1, 0, 0 \rangle, \quad \mathbf{j} = \langle 0, 1, 0 \rangle, \quad \text{and} \quad \mathbf{k} = \langle 0, 0, 1 \rangle.$$

Any vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ can be written as a *linear combination* of the standard unit vectors as follows:

$$\begin{aligned} \mathbf{v} &= \langle v_1, v_2, v_3 \rangle = \langle v_1, 0, 0 \rangle + \langle 0, v_2, 0 \rangle + \langle 0, 0, v_3 \rangle \\ &= v_1\langle 1, 0, 0 \rangle + v_2\langle 0, 1, 0 \rangle + v_3\langle 0, 0, 1 \rangle \\ &= v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}. \end{aligned}$$

We call the scalar (or number) v_1 the **i-component** of the vector \mathbf{v} , v_2 the **j-component**, and v_3 the **k-component**. As shown in Figure 11.15, the component form of the vector from $P_1(x_1, y_1, z_1)$ to $P_2(x_2, y_2, z_2)$ is

$$\overrightarrow{P_1P_2} = (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} + (z_2 - z_1)\mathbf{k}.$$

If $\mathbf{v} \neq \mathbf{0}$, then its length $|\mathbf{v}|$ is not zero and

$$\left| \frac{1}{|\mathbf{v}|} \mathbf{v} \right| = \frac{1}{|\mathbf{v}|} |\mathbf{v}| = 1.$$

That is, if the vector \mathbf{v} is not the zero vector, then $\mathbf{v}/|\mathbf{v}|$ is a **unit vector in the direction of \mathbf{v}** , and it is also called the **direction** of \mathbf{v} .

EXAMPLE 4 Find a unit vector \mathbf{u} in the direction of the vector from $P_1(1, 0, 1)$ to $P_2(3, 2, 0)$.

Solution We write $\overrightarrow{P_1P_2}$ as a linear combination of the standard unit vectors and then divide it by its length:

$$\begin{aligned} \overrightarrow{P_1P_2} &= (3 - 1)\mathbf{i} + (2 - 0)\mathbf{j} + (0 - 1)\mathbf{k} = 2\mathbf{i} + 2\mathbf{j} - \mathbf{k} \\ |\overrightarrow{P_1P_2}| &= \sqrt{(2)^2 + (2)^2 + (-1)^2} = \sqrt{4 + 4 + 1} = \sqrt{9} = 3 \\ \mathbf{u} &= \frac{\overrightarrow{P_1P_2}}{|\overrightarrow{P_1P_2}|} = \frac{2\mathbf{i} + 2\mathbf{j} - \mathbf{k}}{3} = \frac{2}{3}\mathbf{i} + \frac{2}{3}\mathbf{j} - \frac{1}{3}\mathbf{k}. \end{aligned}$$

This unit vector \mathbf{u} is the direction of $\overrightarrow{P_1P_2}$. ■

EXAMPLE 5 If $\mathbf{v} = 3\mathbf{i} - 4\mathbf{j}$ is a velocity vector, express \mathbf{v} as a product of its magnitude (its speed) times its direction.

Solution Speed is the magnitude (length) of \mathbf{v} :

$$|\mathbf{v}| = \sqrt{(3)^2 + (-4)^2} = \sqrt{9 + 16} = 5.$$

The unit vector $\mathbf{v}/|\mathbf{v}|$ is the direction of \mathbf{v} :

$$\frac{\mathbf{v}}{|\mathbf{v}|} = \frac{3\mathbf{i} - 4\mathbf{j}}{5} = \frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}.$$

So

$$\mathbf{v} = 3\mathbf{i} - 4\mathbf{j} = 5 \left(\frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j} \right).$$

Length (speed)
Direction of motion

HISTORICAL BIOGRAPHY

Hermann Grassmann
(1809–1877)

Grassmann was born in Prussia (modern-day Poland) and attended the University of Berlin. However, his study of mathematics and physics was done on his own. In 1844, he published *Die lineale Ausdehnungslehre*, which contained new concepts in geometric calculus. He introduced the n -dimensional vector space and new concepts and structures in linear algebra.

To know more, visit the companion Website.

In summary, we can express any nonzero vector \mathbf{v} in terms of its two important features, length and direction, by writing $\mathbf{v} = |\mathbf{v}|\frac{\mathbf{v}}{|\mathbf{v}|}$.

If $\mathbf{v} \neq \mathbf{0}$, then

1. $\frac{\mathbf{v}}{|\mathbf{v}|}$ is a unit vector called the direction of \mathbf{v} ;
2. the equation $\mathbf{v} = |\mathbf{v}|\frac{\mathbf{v}}{|\mathbf{v}|}$ expresses \mathbf{v} as its length times its direction.

EXAMPLE 6 A force of 6 newtons is applied in the direction of the vector $\mathbf{v} = 2\mathbf{i} + 2\mathbf{j} - \mathbf{k}$. Express the force \mathbf{F} as a product of its magnitude and direction.

Solution The force vector has magnitude 6 and direction $\frac{\mathbf{v}}{|\mathbf{v}|}$, so

$$\begin{aligned}\mathbf{F} &= 6\frac{\mathbf{v}}{|\mathbf{v}|} = 6\frac{2\mathbf{i} + 2\mathbf{j} - \mathbf{k}}{\sqrt{2^2 + 2^2 + (-1)^2}} = 6\frac{2\mathbf{i} + 2\mathbf{j} - \mathbf{k}}{3} \\ &= 6\left(\frac{2}{3}\mathbf{i} + \frac{2}{3}\mathbf{j} - \frac{1}{3}\mathbf{k}\right).\end{aligned}$$

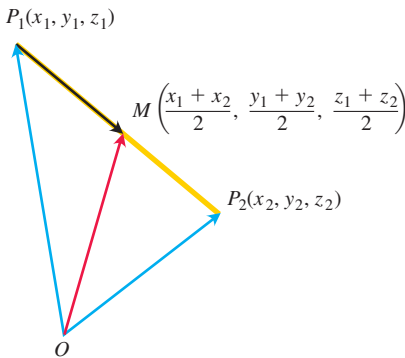

FIGURE 11.16 The coordinates of the midpoint are the averages of the coordinates of P_1 and P_2 .

Midpoint of a Line Segment

Vectors are often useful in geometry. For example, the coordinates of the midpoint of a line segment are found by averaging.

The **midpoint** M of the line segment joining points $P_1(x_1, y_1, z_1)$ and $P_2(x_2, y_2, z_2)$ is the point

$$\left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}, \frac{z_1 + z_2}{2}\right).$$

To see why, observe (Figure 11.16) that

$$\begin{aligned}\overline{OM} &= \overline{OP_1} + \frac{1}{2}(\overline{P_1P_2}) = \overline{OP_1} + \frac{1}{2}(\overline{OP_2} - \overline{OP_1}) \\ &= \frac{1}{2}(\overline{OP_1} + \overline{OP_2}) \\ &= \frac{x_1 + x_2}{2}\mathbf{i} + \frac{y_1 + y_2}{2}\mathbf{j} + \frac{z_1 + z_2}{2}\mathbf{k}.\end{aligned}$$

EXAMPLE 7 The midpoint of the segment joining $P_1(3, -2, 0)$ and $P_2(7, 4, 4)$ is

$$\left(\frac{3 + 7}{2}, \frac{-2 + 4}{2}, \frac{0 + 4}{2}\right) = (5, 1, 2).$$

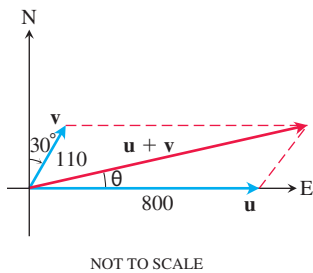

FIGURE 11.17 Vectors representing the velocities of the airplane \mathbf{u} and tailwind \mathbf{v} in Example 8.

Applications

An important application of vectors occurs in navigation.

EXAMPLE 8 A jet airliner, flying due east at 800 km/h in still air, encounters a 110 km/h tailwind blowing in the direction 60° north of east. The airplane holds its compass heading due east but, because of the wind, acquires a new ground speed and direction. What are they?

Solution If \mathbf{u} is the velocity of the airplane alone and \mathbf{v} is the velocity of the tailwind, then $|\mathbf{u}| = 800$ and $|\mathbf{v}| = 110$ (Figure 11.17). The velocity of the airplane with respect to the ground is given by the magnitude and direction of the resultant vector $\mathbf{u} + \mathbf{v}$. If we let the positive x -axis represent east and the positive y -axis represent north, then the component forms of \mathbf{u} and \mathbf{v} are

$$\mathbf{u} = \langle 800, 0 \rangle \quad \text{and} \quad \mathbf{v} = \langle 110 \cos 60^\circ, 110 \sin 60^\circ \rangle = \langle 55, 55\sqrt{3} \rangle.$$

Therefore,

$$\mathbf{u} + \mathbf{v} = \langle 855, 55\sqrt{3} \rangle = 855\mathbf{i} + 55\sqrt{3}\mathbf{j}$$

$$|\mathbf{u} + \mathbf{v}| = \sqrt{855^2 + (55\sqrt{3})^2} \approx 860.3$$

and

$$\theta = \tan^{-1} \frac{55\sqrt{3}}{855} \approx 6.4^\circ.$$

The new ground speed of the airplane is about 860.3 km/h, and its new direction is about 6.4° north of east. ■

Another important application occurs in physics and engineering when several forces are acting on a single object.

EXAMPLE 9 A 75-N weight is suspended by two wires, as shown in Figure 11.18a. Find the forces \mathbf{F}_1 and \mathbf{F}_2 acting in both wires.

Solution The force vectors \mathbf{F}_1 and \mathbf{F}_2 have magnitudes $|\mathbf{F}_1|$ and $|\mathbf{F}_2|$ and components that are measured in newtons. The resultant force is the sum $\mathbf{F}_1 + \mathbf{F}_2$, which must be equal in magnitude to the weight vector \mathbf{w} but acting in the opposite (or upward) direction (see Figure 11.18b). It follows from the figure that

$$\mathbf{F}_1 = \langle -|\mathbf{F}_1| \cos 55^\circ, |\mathbf{F}_1| \sin 55^\circ \rangle \quad \text{and} \quad \mathbf{F}_2 = \langle |\mathbf{F}_2| \cos 40^\circ, |\mathbf{F}_2| \sin 40^\circ \rangle.$$

Since $\mathbf{F}_1 + \mathbf{F}_2 = \langle 0, 75 \rangle$, the resultant vector leads to the system of equations

$$\begin{aligned} -|\mathbf{F}_1| \cos 55^\circ + |\mathbf{F}_2| \cos 40^\circ &= 0 \\ |\mathbf{F}_1| \sin 55^\circ + |\mathbf{F}_2| \sin 40^\circ &= 75. \end{aligned}$$

Solving for $|\mathbf{F}_2|$ in the first equation and substituting the result into the second equation, we get

$$|\mathbf{F}_2| = \frac{|\mathbf{F}_1| \cos 55^\circ}{\cos 40^\circ} \quad \text{and} \quad |\mathbf{F}_1| \sin 55^\circ + \frac{|\mathbf{F}_1| \cos 55^\circ}{\cos 40^\circ} \sin 40^\circ = 75.$$

It follows that

$$|\mathbf{F}_1| = \frac{75}{\sin 55^\circ + \cos 55^\circ \tan 40^\circ} \approx 57.67 \text{ N}$$

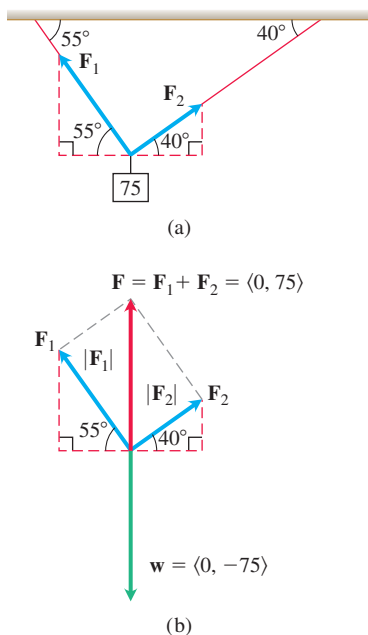

FIGURE 11.18 The suspended weight in Example 9.

and

$$|\mathbf{F}_2| = \frac{|\mathbf{F}_1| \cos 55^\circ}{\cos 40^\circ} = \frac{75}{\sin 55^\circ + \cos 55^\circ \tan 40^\circ} \frac{\cos 55^\circ}{\cos 40^\circ} \approx 43.18 \text{ N.}$$

The force vectors are then

$$\mathbf{F}_1 = \langle -|\mathbf{F}_1| \cos 55^\circ, |\mathbf{F}_1| \sin 55^\circ \rangle \approx \langle -33.08, 47.24 \rangle$$

and

$$\mathbf{F}_2 = \langle |\mathbf{F}_2| \cos 40^\circ, |\mathbf{F}_2| \sin 40^\circ \rangle \approx \langle 33.08, 27.76 \rangle. \quad \blacksquare$$

Vectors in n Dimensions

So far in this section, we introduced two- and three-dimensional vectors. We extend these notions by considering an n -dimensional vector $\mathbf{v} = \langle v_1, v_2, \dots, v_n \rangle$ (an n -tuple of real numbers). We define

1. the magnitude or length of \mathbf{v} : $|\mathbf{v}| = \sqrt{v_1^2 + v_2^2 + \dots + v_n^2}$;
2. addition of two vectors:

$$\langle u_1, u_2, \dots, u_n \rangle + \langle v_1, v_2, \dots, v_n \rangle = \langle u_1 + v_1, u_2 + v_2, \dots, u_n + v_n \rangle;$$

3. scalar multiplication of a vector by a real number:

$$k \langle v_1, v_2, \dots, v_n \rangle = \langle kv_1, kv_2, \dots, kv_n \rangle.$$

The Properties of Vector Operations stated earlier in this section hold for n -dimensional vectors.

When discussing vectors in this text, we will usually focus on the cases where $n = 2$ and $n = 3$ since these correspond to vectors in the plane and vectors in three-dimensional space, which are used in many applications (for instance, such vectors can represent velocity or force). Vectors with more than three components do arise in applications, but in those contexts they do not correspond to line segments in the plane or in three-dimensional space.

EXAMPLE 10 The components of the vector $\mathbf{u} = \langle 70.9, 63.2, 77.2, 47.1, 55.6 \rangle$ contain the average temperatures (in degrees Fahrenheit) recorded between the years 2006 and 2010 in Houston, Los Angeles, Miami, Minneapolis, and New York. Likewise, the vectors $\mathbf{v} = \langle 71.2, 64.3, 78.0, 47.1, 56.0 \rangle$ and $\mathbf{w} = \langle 72.5, 64.7, 78.6, 47.6, 56.5 \rangle$ represent average temperatures in the same cities over the periods 2011 through 2015 and 2016 through 2020. Find the vector whose components are the average temperatures between the year 2006 and the year 2020 in these cities.

Solution To find the vector containing average temperatures, we add scalar multiples of the three vectors (in other words, we evaluate a linear combination):

$$\begin{aligned} \mathbf{a} &= \frac{1}{3}\mathbf{u} + \frac{1}{3}\mathbf{v} + \frac{1}{3}\mathbf{w} \\ &= \frac{1}{3}\langle 70.9, 63.2, 77.2, 47.1, 55.6 \rangle + \frac{1}{3}\langle 71.2, 64.3, 78.0, 47.1, 56.0 \rangle \\ &\quad + \frac{1}{3}\langle 72.5, 64.7, 78.6, 47.6, 56.5 \rangle \\ &\approx \langle 71.5, 64.1, 77.9, 47.3, 56.0 \rangle. \quad \blacksquare \end{aligned}$$

EXAMPLE 11 A rectangular grayscale image m pixels (dots) wide and n pixels tall can be represented on a computer as a vector with $m \cdot n$ components. A common format assigns an integer between 0 and 255 to each pixel, with 255 corresponding to the highest intensity (white), 0 to the lowest (black), and intermediate values to various shades of gray.

Using this format, the 400×400 image containing all white pixels is represented by the 160,000-dimensional vector $\mathbf{w} = \langle 255, \dots, 255 \rangle$. Figures 11.19a and b can be similarly represented by vectors \mathbf{u} and \mathbf{v} , respectively.

In parts c, d, and e of Figure 11.19, we show different linear combinations of the vectors \mathbf{u} and \mathbf{v} . Notice how changing the scalar in front of each vector affects the resulting image.

In Figure 11.19f, the image corresponds to the difference $\mathbf{w} - \mathbf{v}$, effectively inverting the grayscale in that image. ■

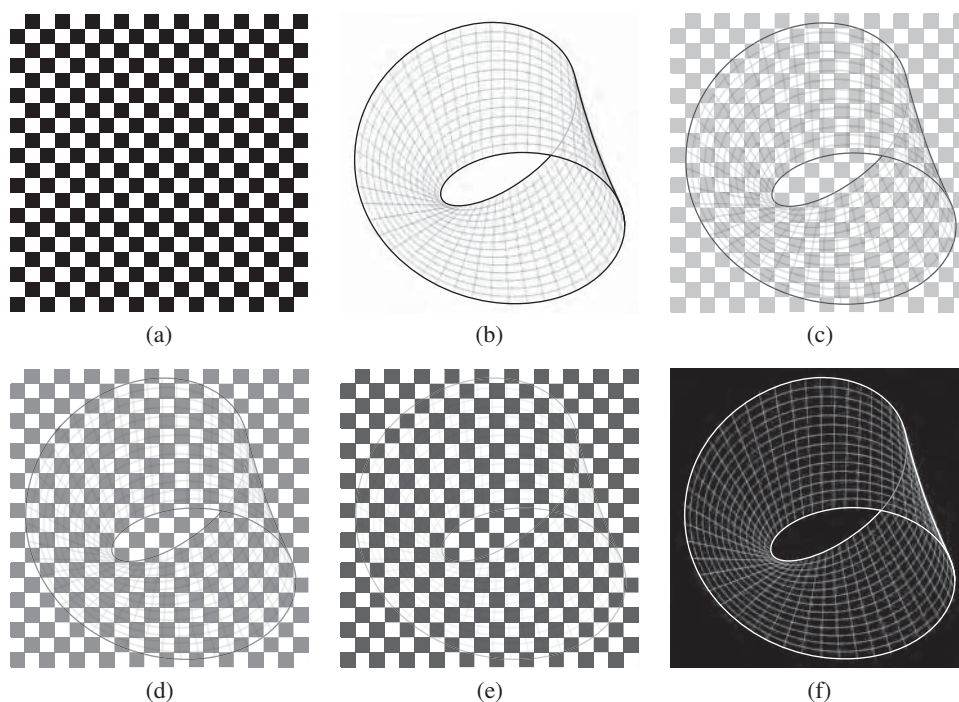

FIGURE 11.19 Each 400×400 pixel image corresponds to a 160,000-dimensional vector: (a) \mathbf{u} ; (b) \mathbf{v} ; (c) $\frac{1}{4}\mathbf{u} + \frac{3}{4}\mathbf{v}$; (d) $\frac{1}{2}\mathbf{u} + \frac{1}{2}\mathbf{v}$; (e) $\frac{3}{4}\mathbf{u} + \frac{1}{4}\mathbf{v}$; (f) $\mathbf{w} - \mathbf{v}$.

EXERCISES 11.2

Vectors in the Plane

In Exercises 1–8, let $\mathbf{u} = \langle 3, -2 \rangle$ and $\mathbf{v} = \langle -2, 5 \rangle$. Find the (a) component form and (b) magnitude (length) of the vector.

1. $3\mathbf{u}$

2. $-2\mathbf{v}$

3. $\mathbf{u} + \mathbf{v}$

5. $2\mathbf{u} - 3\mathbf{v}$

7. $\frac{3}{5}\mathbf{u} + \frac{4}{5}\mathbf{v}$

4. $\mathbf{u} - \mathbf{v}$

6. $-2\mathbf{u} + 5\mathbf{v}$

8. $-\frac{5}{13}\mathbf{u} + \frac{12}{13}\mathbf{v}$

In Exercises 9–16, find the component form of the vector.

9. The vector \overrightarrow{PQ} , where $P = (1, 3)$ and $Q = (2, -1)$
10. The vector \overrightarrow{OP} , where O is the origin and P is the midpoint of segment RS , where $R = (2, -1)$ and $S = (-4, 3)$
11. The vector from the point $A = (2, 3)$ to the origin
12. The sum of \overrightarrow{AB} and \overrightarrow{CD} , where $A = (1, -1)$, $B = (2, 0)$, $C = (-1, 3)$, and $D = (-2, 2)$
13. The unit vector that makes an angle $\theta = 2\pi/3$ with the positive x -axis
14. The unit vector that makes an angle $\theta = -3\pi/4$ with the positive x -axis
15. The unit vector obtained by rotating the vector $\langle 0, 1 \rangle$ by 120° counterclockwise about the origin
16. The unit vector obtained by rotating the vector $\langle 1, 0 \rangle$ by 135° counterclockwise about the origin

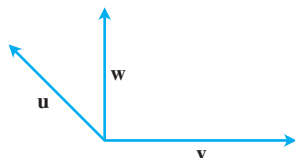

Vectors in Space

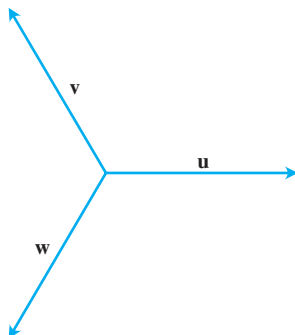

In Exercises 17–22, express each vector in the form $\mathbf{w} = w_1\mathbf{i} + w_2\mathbf{j} + w_3\mathbf{k}$.

17. $\overrightarrow{P_1P_2}$ if P_1 is the point $(5, 7, -1)$ and P_2 is the point $(2, 9, -2)$
18. $\overrightarrow{P_1P_2}$ if P_1 is the point $(1, 2, 0)$ and P_2 is the point $(-3, 0, 5)$
19. \overrightarrow{AB} if A is the point $(-7, -8, 1)$ and B is the point $(-10, 8, 1)$
20. \overrightarrow{AB} if A is the point $(1, 0, 3)$ and B is the point $(-1, 4, 5)$
21. $5\mathbf{u} - \mathbf{v}$ if $\mathbf{u} = \langle 1, 1, -1 \rangle$ and $\mathbf{v} = \langle 2, 0, 3 \rangle$
22. $-2\mathbf{u} + 3\mathbf{v}$ if $\mathbf{u} = \langle -1, 0, 2 \rangle$ and $\mathbf{v} = \langle 1, 1, 1 \rangle$

Geometric Representations

In Exercises 23 and 24, copy vectors \mathbf{u} , \mathbf{v} , and \mathbf{w} head to tail as needed to sketch the indicated vector.

23. 
 - a. $\mathbf{u} + \mathbf{v}$
 - b. $\mathbf{u} + \mathbf{v} + \mathbf{w}$
 - c. $\mathbf{u} - \mathbf{v}$
 - d. $\mathbf{u} - \mathbf{w}$

24. 
 - a. $\mathbf{u} - \mathbf{v}$
 - b. $\mathbf{u} - \mathbf{v} + \mathbf{w}$
 - c. $2\mathbf{u} - \mathbf{v}$
 - d. $\mathbf{u} + \mathbf{v} + \mathbf{w}$

Length and Direction

In Exercises 25–30, express each vector as a product of its length and direction.

25. $2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$
26. $9\mathbf{i} - 2\mathbf{j} + 6\mathbf{k}$
27. $5\mathbf{k}$
28. $\frac{3}{5}\mathbf{i} + \frac{4}{5}\mathbf{k}$
29. $\frac{1}{\sqrt{6}}\mathbf{i} - \frac{1}{\sqrt{6}}\mathbf{j} - \frac{1}{\sqrt{6}}\mathbf{k}$
30. $\frac{\mathbf{i}}{\sqrt{3}} + \frac{\mathbf{j}}{\sqrt{3}} + \frac{\mathbf{k}}{\sqrt{3}}$

31. Find the vectors whose lengths and directions are given. Try to do the calculations without writing.

Length	Direction
a. 2	\mathbf{i}
b. $\sqrt{3}$	$-\mathbf{k}$
c. $\frac{1}{2}$	$\frac{3}{5}\mathbf{j} + \frac{4}{5}\mathbf{k}$
d. 7	$\frac{6}{7}\mathbf{i} - \frac{2}{7}\mathbf{j} + \frac{3}{7}\mathbf{k}$

32. Find the vectors whose lengths and directions are given. Try to do the calculations without writing.

Length	Direction
a. 7	$-\mathbf{j}$
b. $\sqrt{2}$	$-\frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{k}$
c. $\frac{13}{12}$	$\frac{3}{13}\mathbf{i} - \frac{4}{13}\mathbf{j} - \frac{12}{13}\mathbf{k}$
d. $a > 0$	$\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} - \frac{1}{\sqrt{6}}\mathbf{k}$

33. Find a vector of magnitude 7 in the direction of $\mathbf{v} = 12\mathbf{i} - 5\mathbf{k}$.

34. Find a vector of magnitude 3 in the direction opposite to the direction of $\mathbf{v} = (1/2)\mathbf{i} - (1/2)\mathbf{j} - (1/2)\mathbf{k}$.

Direction and Midpoints

In Exercises 35–38, find **a.** the direction of $\overrightarrow{P_1P_2}$ and **b.** the midpoint of line segment P_1P_2 .

35. $P_1(-1, 1, 5)$ $P_2(2, 5, 0)$
36. $P_1(1, 4, 5)$ $P_2(4, -2, 7)$
37. $P_1(3, 4, 5)$ $P_2(2, 3, 4)$
38. $P_1(0, 0, 0)$ $P_2(2, -2, -2)$
39. If $\overrightarrow{AB} = \mathbf{i} + 4\mathbf{j} - 2\mathbf{k}$ and B is the point $(5, 1, 3)$, find A .
40. If $\overrightarrow{AB} = -7\mathbf{i} + 3\mathbf{j} + 8\mathbf{k}$ and A is the point $(-2, -3, 6)$, find B .

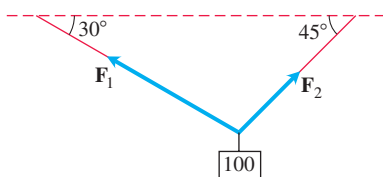

Theory and Applications

41. **Linear combination** Let $\mathbf{u} = 2\mathbf{i} + \mathbf{j}$, $\mathbf{v} = \mathbf{i} + \mathbf{j}$, and $\mathbf{w} = \mathbf{i} - \mathbf{j}$. Find scalars a and b such that $\mathbf{u} = a\mathbf{v} + b\mathbf{w}$.
42. **Linear combination** Let $\mathbf{u} = \mathbf{i} - 2\mathbf{j}$, $\mathbf{v} = 2\mathbf{i} + 3\mathbf{j}$, and $\mathbf{w} = \mathbf{i} + \mathbf{j}$. Write $\mathbf{u} = \mathbf{u}_1 + \mathbf{u}_2$, where \mathbf{u}_1 is parallel to \mathbf{v} and \mathbf{u}_2 is parallel to \mathbf{w} . (See Exercise 41.)
43. **Linear combination** Let $\mathbf{u} = \langle 1, 2, 1 \rangle$, $\mathbf{v} = \langle 1, -1, -1 \rangle$, $\mathbf{w} = \langle 1, 1, -1 \rangle$, and $\mathbf{z} = \langle 2, -3, -4 \rangle$. Find scalars a , b , and c such that $\mathbf{z} = a\mathbf{u} + b\mathbf{v} + c\mathbf{w}$.
44. **Linear combination** Let $\mathbf{u} = \langle 1, 2, 2 \rangle$, $\mathbf{v} = \langle 1, -1, -1 \rangle$, $\mathbf{w} = \langle 1, 3, -1 \rangle$, and $\mathbf{z} = \langle 2, 11, 8 \rangle$. Write $\mathbf{z} = \mathbf{u}_1 + \mathbf{u}_2 + \mathbf{u}_3$, where \mathbf{u}_1 is parallel to \mathbf{u} , \mathbf{u}_2 is parallel to \mathbf{v} , and \mathbf{u}_3 is parallel to \mathbf{w} . What are \mathbf{u}_1 , \mathbf{u}_2 , \mathbf{u}_3 ?

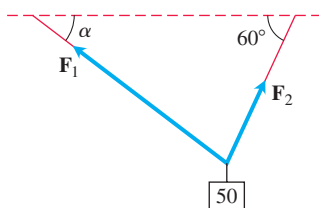

When solving Exercises 45–50, you may need to use a calculator or a computer.

45. **Velocity** An airplane is flying in the direction 25° west of north at 800 km/h. Find the component form of the velocity of the airplane, assuming that the positive x -axis represents due east and the positive y -axis represents due north.

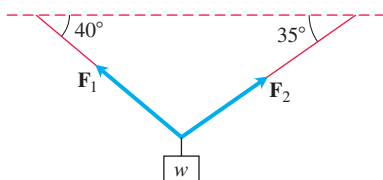

46. (Continuation of Example 8.) What speed and direction should the jetliner in Example 8 have in order for the resultant vector to be 800 km/h due east?
47. Consider a 100-N weight suspended by two wires as shown in the accompanying figure. Find the magnitudes and components of the force vectors \mathbf{F}_1 and \mathbf{F}_2 .

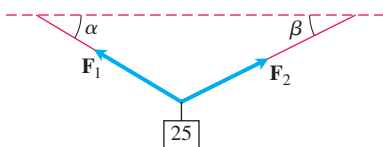

48. Consider a 50-N weight suspended by two wires as shown in the accompanying figure. If the magnitude of vector \mathbf{F}_1 is 35 N, find angle α and the magnitude of vector \mathbf{F}_2 .

49. Consider a w -N weight suspended by two wires as shown in the accompanying figure. If the magnitude of vector \mathbf{F}_2 is 100 N, find w and the magnitude of vector \mathbf{F}_1 .

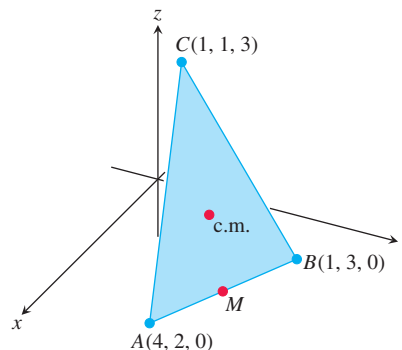

50. Consider a 25-N weight suspended by two wires as shown in the accompanying figure. If the magnitudes of vectors \mathbf{F}_1 and \mathbf{F}_2 are both 75 N, then angles α and β are equal. Find α .

51. **Location** A bird flies from its nest 5 km in the direction 60° north of east, where it stops to rest on a tree. It then flies 10 km in the direction due southeast and lands atop a telephone pole. Place an xy -coordinate system so that the origin is the bird's nest, the x -axis points east, and the y -axis points north.
- At what point is the tree located?
 - At what point is the telephone pole?

52. Use similar triangles to find the coordinates of the point Q that divides the segment from $P_1(x_1, y_1, z_1)$ to $P_2(x_2, y_2, z_2)$ into two lengths whose ratio is $p/q = r$.
53. **Medians of a triangle** Suppose that A , B , and C are the corner points of the thin triangular plate of constant density shown here.
- Find the vector from C to the midpoint M of side AB .
 - Find the vector from C to the point that lies two-thirds of the way from C to M on the median CM .
 - Find the coordinates of the point in which the medians of $\triangle ABC$ intersect. According to Exercise 27, Section 6.6, this point is the plate's center of mass. (See the figure.)

54. Find the vector from the origin to the point of intersection of the medians of the triangle whose vertices are

$$A(1, -1, 2), \quad B(2, 1, 3), \quad \text{and} \quad C(-1, 2, -1).$$

55. Let $ABCD$ be a general, not necessarily planar, quadrilateral in space. Show that the two segments joining the midpoints of opposite sides of $ABCD$ bisect each other. (*Hint*: Show that the segments have the same midpoint.)
56. Vectors are drawn from the center of a regular n -sided polygon in the plane to the vertices of the polygon. Show that the sum of the vectors is zero. (*Hint*: What happens to the sum if you rotate the polygon about its center?)
57. Suppose that A , B , and C are vertices of a triangle and that a , b , and c are, respectively, the midpoints of the opposite sides. Show that $\overrightarrow{Aa} + \overrightarrow{Bb} + \overrightarrow{Cc} = \mathbf{0}$.
58. **Unit vectors in the plane** Show that a unit vector in the plane can be expressed as $\mathbf{u} = (\cos \theta)\mathbf{i} + (\sin \theta)\mathbf{j}$, obtained by rotating \mathbf{i} through an angle θ in the counterclockwise direction. Explain why this form gives every unit vector in the plane.
59. Consider a triangle whose vertices are $A(2, -3, 4)$, $B(1, 0, -1)$, and $C(3, 1, 2)$.
- Find $\overrightarrow{AB} + \overrightarrow{BC} + \overrightarrow{CA}$.
 - Find $\overrightarrow{BA} + \overrightarrow{AC} + \overrightarrow{CB}$.

n -Dimensional Vectors

In Exercises 60–65, let $\mathbf{u} = \langle 2, -3, 0, 1 \rangle$ and $\mathbf{v} = \langle 0, -4, -1, 3 \rangle$. Find the (a) component form and (b) magnitude (length) of the vector.

- $2\mathbf{u}$
- $\mathbf{u} + \mathbf{v}$
- $3\mathbf{u} - 2\mathbf{v}$
- $-4\mathbf{v}$
- $\mathbf{v} - \mathbf{u}$
- $4\mathbf{u} + 3\mathbf{v}$

11.3 The Dot Product

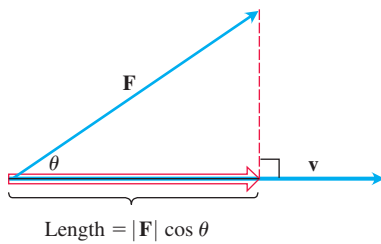

FIGURE 11.20 The magnitude of the force \mathbf{F} in the direction of vector \mathbf{v} is the length $|\mathbf{F}|\cos\theta$ of the projection of \mathbf{F} onto \mathbf{v} .

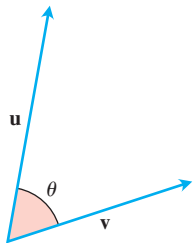

FIGURE 11.21 The angle between \mathbf{u} and \mathbf{v} given by Theorem 1 lies in the interval $[0, \pi]$.

If a force \mathbf{F} is applied to a particle moving along a path, we often need to know the magnitude of the force in the direction of motion. If \mathbf{v} is parallel to the tangent line to the path at the point where \mathbf{F} is applied, then we want the magnitude of \mathbf{F} in the direction of \mathbf{v} . Figure 11.20 shows that the scalar quantity we seek is the length $|\mathbf{F}|\cos\theta$, where θ is the angle between the two vectors \mathbf{F} and \mathbf{v} .

In this section we show how to calculate easily the angle between two vectors directly from their components. A key part of the calculation is an expression called the *dot product*. Dot products are also called *inner* or *scalar* products because the product results in a scalar, not a vector. After investigating the dot product, we apply it to finding the projection of one vector onto another (as displayed in Figure 11.20) and to finding the work done by a constant force acting through a displacement.

Angle Between Vectors

When two nonzero vectors \mathbf{u} and \mathbf{v} are placed so their initial points coincide, they form an angle θ of measure $0 \leq \theta \leq \pi$ (Figure 11.21). If the vectors do not lie along the same line, the angle θ is measured in the plane containing both of them. If they do lie along the same line, the angle between them is 0 if they point in the same direction and π if they point in opposite directions. The angle θ is the **angle between \mathbf{u} and \mathbf{v}** . Theorem 1 gives a formula to determine this angle.

THEOREM 1—Angle Between Two Vectors

The angle θ between two nonzero vectors $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is given by

$$\theta = \arccos\left(\frac{u_1v_1 + u_2v_2 + u_3v_3}{|\mathbf{u}||\mathbf{v}|}\right).$$

We use the law of cosines to prove Theorem 1, but before doing so, we focus attention on the expression $u_1v_1 + u_2v_2 + u_3v_3$ in the calculation for θ . This expression is the sum of the products of the corresponding components of the vectors \mathbf{u} and \mathbf{v} .

DEFINITION The **dot product $\mathbf{u} \cdot \mathbf{v}$** (“**u dot v**”) of vectors $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is the scalar

$$\mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + u_3v_3.$$

EXAMPLE 1 We illustrate the definition.

$$\begin{aligned} \text{(a)} \quad \langle 1, -2, -1 \rangle \cdot \langle -6, 2, -3 \rangle &= (1)(-6) + (-2)(2) + (-1)(-3) \\ &= -6 - 4 + 3 = -7 \end{aligned}$$

$$\text{(b)} \quad \left(\frac{1}{2}\mathbf{i} + 3\mathbf{j} + \mathbf{k}\right) \cdot (4\mathbf{i} - \mathbf{j} + 2\mathbf{k}) = \left(\frac{1}{2}\right)(4) + (3)(-1) + (1)(2) = 1 \quad \blacksquare$$

The dot product of a pair of two-dimensional vectors is defined in a similar fashion:

$$\langle u_1, u_2 \rangle \cdot \langle v_1, v_2 \rangle = u_1v_1 + u_2v_2.$$

We will see throughout the remainder of this text that the dot product is a key tool for many important geometric and physical calculations in space (and the plane).

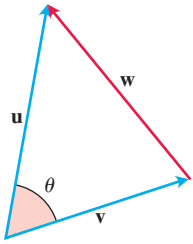

FIGURE 11.22 The parallelogram law of addition of vectors gives $\mathbf{w} = \mathbf{u} - \mathbf{v}$.

Proof of Theorem 1 Applying the law of cosines (Equation (8), Section 1.3) to the triangle in Figure 11.22, we find that

$$|\mathbf{w}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2 - 2|\mathbf{u}||\mathbf{v}|\cos \theta \quad \text{Law of cosines}$$

$$2|\mathbf{u}||\mathbf{v}|\cos \theta = |\mathbf{u}|^2 + |\mathbf{v}|^2 - |\mathbf{w}|^2.$$

Because $\mathbf{w} = \mathbf{u} - \mathbf{v}$, the component form of \mathbf{w} is $\langle u_1 - v_1, u_2 - v_2, u_3 - v_3 \rangle$. So

$$|\mathbf{u}|^2 = (\sqrt{u_1^2 + u_2^2 + u_3^2})^2 = u_1^2 + u_2^2 + u_3^2$$

$$|\mathbf{v}|^2 = (\sqrt{v_1^2 + v_2^2 + v_3^2})^2 = v_1^2 + v_2^2 + v_3^2$$

$$\begin{aligned} |\mathbf{w}|^2 &= (\sqrt{(u_1 - v_1)^2 + (u_2 - v_2)^2 + (u_3 - v_3)^2})^2 \\ &= (u_1 - v_1)^2 + (u_2 - v_2)^2 + (u_3 - v_3)^2 \\ &= u_1^2 - 2u_1v_1 + v_1^2 + u_2^2 - 2u_2v_2 + v_2^2 + u_3^2 - 2u_3v_3 + v_3^2 \end{aligned}$$

and

$$|\mathbf{u}|^2 + |\mathbf{v}|^2 - |\mathbf{w}|^2 = 2(u_1v_1 + u_2v_2 + u_3v_3).$$

Therefore,

$$2|\mathbf{u}||\mathbf{v}|\cos \theta = |\mathbf{u}|^2 + |\mathbf{v}|^2 - |\mathbf{w}|^2 = 2(u_1v_1 + u_2v_2 + u_3v_3)$$

$$|\mathbf{u}||\mathbf{v}|\cos \theta = u_1v_1 + u_2v_2 + u_3v_3$$

$$\cos \theta = \frac{u_1v_1 + u_2v_2 + u_3v_3}{|\mathbf{u}||\mathbf{v}|}.$$

Thus, for $0 \leq \theta \leq \pi$, we have $\theta = \arccos\left(\frac{u_1v_1 + u_2v_2 + u_3v_3}{|\mathbf{u}||\mathbf{v}|}\right)$. ■

Dot Product and Angles

The angle between two nonzero vectors \mathbf{u} and \mathbf{v} is $\theta = \arccos\left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}\right)$.

The dot product of two vectors \mathbf{u} and \mathbf{v} is given by $\mathbf{u} \cdot \mathbf{v} = |\mathbf{u}||\mathbf{v}|\cos \theta$.

EXAMPLE 2 Find the angle between $\mathbf{u} = \mathbf{i} - 2\mathbf{j} - 2\mathbf{k}$ and $\mathbf{v} = 6\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$.

Solution We use the formula above:

$$\mathbf{u} \cdot \mathbf{v} = (1)(6) + (-2)(3) + (-2)(2) = 6 - 6 - 4 = -4$$

$$|\mathbf{u}| = \sqrt{(1)^2 + (-2)^2 + (-2)^2} = \sqrt{9} = 3$$

$$|\mathbf{v}| = \sqrt{(6)^2 + (3)^2 + (2)^2} = \sqrt{49} = 7$$

$$\theta = \arccos\left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}\right) = \arccos\left(\frac{-4}{(3)(7)}\right) \approx 1.76 \text{ radians or } 100.98^\circ. \quad \blacksquare$$

The angle formula applies to two-dimensional vectors as well. Note that the angle θ is acute if $\mathbf{u} \cdot \mathbf{v} > 0$ and obtuse if $\mathbf{u} \cdot \mathbf{v} < 0$.

EXAMPLE 3 Find the angle θ in the triangle ABC determined by the vertices $A = (0, 0)$, $B = (3, 5)$, and $C = (5, 2)$ (Figure 11.23).

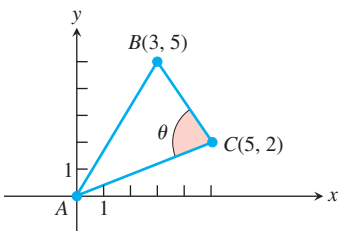

FIGURE 11.23 The triangle in Example 3.

Solution The angle θ is the angle between the vectors \overline{CA} and \overline{CB} . The component forms of these two vectors are

$$\overline{CA} = \langle -5, -2 \rangle \quad \text{and} \quad \overline{CB} = \langle -2, 3 \rangle.$$

First we calculate the dot product and magnitudes of these two vectors.

$$\overline{CA} \cdot \overline{CB} = (-5)(-2) + (-2)(3) = 4$$

$$|\overline{CA}| = \sqrt{(-5)^2 + (-2)^2} = \sqrt{29}$$

$$|\overline{CB}| = \sqrt{(-2)^2 + (3)^2} = \sqrt{13}$$

Then, applying the angle formula, we have

$$\begin{aligned} \theta &= \arccos \left(\frac{\overline{CA} \cdot \overline{CB}}{|\overline{CA}| |\overline{CB}|} \right) = \arccos \left(\frac{4}{(\sqrt{29})(\sqrt{13})} \right) \\ &\approx 78.1^\circ \text{ or } 1.36 \text{ radians.} \end{aligned}$$

Orthogonal Vectors

Two nonzero vectors \mathbf{u} and \mathbf{v} are perpendicular if the angle between them is $\pi/2$. For such vectors, we have $\mathbf{u} \cdot \mathbf{v} = 0$ because $\cos(\pi/2) = 0$. The converse is also true. If \mathbf{u} and \mathbf{v} are nonzero vectors with $\mathbf{u} \cdot \mathbf{v} = |\mathbf{u}| |\mathbf{v}| \cos \theta = 0$, then $\cos \theta = 0$ and $\theta = \arccos 0 = \pi/2$. The following definition also allows for one or both of the vectors to be the zero vector.

DEFINITION Vectors \mathbf{u} and \mathbf{v} are orthogonal if $\mathbf{u} \cdot \mathbf{v} = 0$.

EXAMPLE 4 To determine if two vectors are orthogonal, calculate their dot product.

(a) $\mathbf{u} = \langle 3, -2 \rangle$ and $\mathbf{v} = \langle 4, 6 \rangle$ are orthogonal because $\mathbf{u} \cdot \mathbf{v} = (3)(4) + (-2)(6) = 0$.

(b) $\mathbf{u} = 3\mathbf{i} - 2\mathbf{j} + \mathbf{k}$ and $\mathbf{v} = 2\mathbf{j} + 4\mathbf{k}$ are orthogonal because

$$\mathbf{u} \cdot \mathbf{v} = (3)(0) + (-2)(2) + (1)(4) = 0.$$

(c) $\mathbf{0}$ is orthogonal to every vector \mathbf{u} because

$$\begin{aligned} \mathbf{0} \cdot \mathbf{u} &= \langle 0, 0, 0 \rangle \cdot \langle u_1, u_2, u_3 \rangle \\ &= (0)(u_1) + (0)(u_2) + (0)(u_3) = 0. \end{aligned}$$

Dot Product Properties and Vector Projections

The dot product obeys many of the laws that hold for ordinary products of real numbers (scalars).

Properties of the Dot Product

If \mathbf{u} , \mathbf{v} , and \mathbf{w} are any vectors and c is a scalar, then

- | | |
|---|---|
| 1. $\mathbf{u} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{u}$ | 2. $(c\mathbf{u}) \cdot \mathbf{v} = \mathbf{u} \cdot (c\mathbf{v}) = c(\mathbf{u} \cdot \mathbf{v})$ |
| 3. $\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}$ | 4. $\mathbf{u} \cdot \mathbf{u} = \mathbf{u} ^2$ |
| 5. $\mathbf{0} \cdot \mathbf{u} = 0$. | |

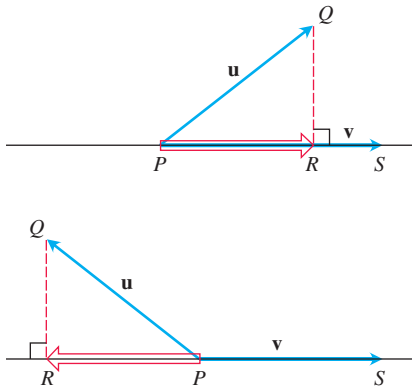

FIGURE 11.24 The vector projection of \mathbf{u} onto \mathbf{v} .

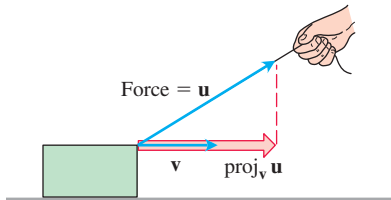

FIGURE 11.25 If we pull on the box with force \mathbf{u} , the effective force moving the box forward in the direction \mathbf{v} is the projection of \mathbf{u} onto \mathbf{v} .

Proofs of Properties 1 and 3 The properties are easy to prove using the definition. For instance, here are the proofs of Properties 1 and 3.

$$1. \mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + u_3v_3 = v_1u_1 + v_2u_2 + v_3u_3 = \mathbf{v} \cdot \mathbf{u}$$

$$\begin{aligned} 3. \mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) &= \langle u_1, u_2, u_3 \rangle \cdot \langle v_1 + w_1, v_2 + w_2, v_3 + w_3 \rangle \\ &= u_1(v_1 + w_1) + u_2(v_2 + w_2) + u_3(v_3 + w_3) \\ &= u_1v_1 + u_1w_1 + u_2v_2 + u_2w_2 + u_3v_3 + u_3w_3 \\ &= (u_1v_1 + u_2v_2 + u_3v_3) + (u_1w_1 + u_2w_2 + u_3w_3) \\ &= \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w} \end{aligned}$$

We now return to the problem of projecting one vector onto another, posed in the opening to this section. The **vector projection** of $\mathbf{u} = \overline{PQ}$ onto a nonzero vector $\mathbf{v} = \overline{PS}$ (Figure 11.24) is the vector \overline{PR} determined by dropping a perpendicular from Q to the line PS . The notation for this vector is

$$\text{proj}_{\mathbf{v}} \mathbf{u} \quad (\text{“the vector projection of } \mathbf{u} \text{ onto } \mathbf{v}\text{”}).$$

If \mathbf{u} represents a force, then $\text{proj}_{\mathbf{v}} \mathbf{u}$ represents the effective force in the direction of \mathbf{v} (Figure 11.25).

If the angle θ between \mathbf{u} and \mathbf{v} is acute, $\text{proj}_{\mathbf{v}} \mathbf{u}$ has length $|\mathbf{u}| \cos \theta$ and direction $\mathbf{v}/|\mathbf{v}|$ (Figure 11.26). If θ is obtuse, $\cos \theta < 0$ and $\text{proj}_{\mathbf{v}} \mathbf{u}$ has length $-|\mathbf{u}| \cos \theta$ and direction $-\mathbf{v}/|\mathbf{v}|$. In both cases,

$$\begin{aligned} \text{proj}_{\mathbf{v}} \mathbf{u} &= (|\mathbf{u}| \cos \theta) \frac{\mathbf{v}}{|\mathbf{v}|} \\ &= \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|} \right) \frac{\mathbf{v}}{|\mathbf{v}|} & |\mathbf{u}| \cos \theta &= \frac{|\mathbf{u}| |\mathbf{v}| \cos \theta}{|\mathbf{v}|} = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|} \\ &= \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} \right) \mathbf{v}. \end{aligned}$$

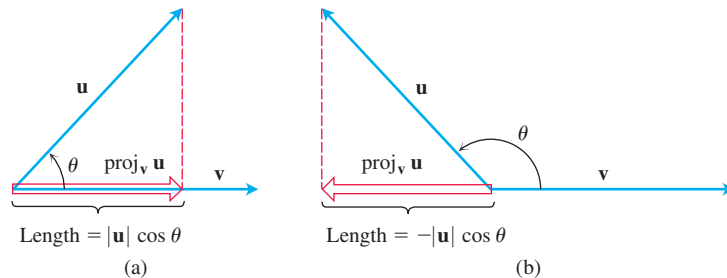

FIGURE 11.26 The length of $\text{proj}_{\mathbf{v}} \mathbf{u}$ is (a) $|\mathbf{u}| \cos \theta$ if $\cos \theta \geq 0$ and (b) $-|\mathbf{u}| \cos \theta$ if $\cos \theta < 0$.

The number $|\mathbf{u}| \cos \theta$ is called the **scalar component of \mathbf{u} in the direction of \mathbf{v}** . To summarize,

The vector projection of \mathbf{u} onto \mathbf{v} is the vector

$$\text{proj}_{\mathbf{v}} \mathbf{u} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} \right) \mathbf{v} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|} \right) \frac{\mathbf{v}}{|\mathbf{v}|}. \quad (1)$$

The scalar component of \mathbf{u} in the direction of \mathbf{v} is the scalar

$$|\mathbf{u}| \cos \theta = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|} = \mathbf{u} \cdot \frac{\mathbf{v}}{|\mathbf{v}|}. \quad (2)$$

Note that both the vector projection of \mathbf{u} onto \mathbf{v} and the scalar component of \mathbf{u} in the direction of \mathbf{v} depend only on the direction of the vector \mathbf{v} , not on its length. This is because in both cases we take the dot product of \mathbf{u} with the direction vector $\mathbf{v}/|\mathbf{v}|$, which is the direction of \mathbf{v} , and for the projection we go on to multiply the result by the direction vector.

EXAMPLE 5 Find the vector projection of $\mathbf{u} = 6\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ onto $\mathbf{v} = \mathbf{i} - 2\mathbf{j} - 2\mathbf{k}$ and the scalar component of \mathbf{u} in the direction of \mathbf{v} .

Solution We find $\text{proj}_{\mathbf{v}} \mathbf{u}$ from Equation (1):

$$\begin{aligned}\text{proj}_{\mathbf{v}} \mathbf{u} &= \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} \mathbf{v} = \frac{\mathbf{u} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}} \mathbf{v} = \frac{6 - 6 - 4}{1 + 4 + 4}(\mathbf{i} - 2\mathbf{j} - 2\mathbf{k}) \\ &= -\frac{4}{9}(\mathbf{i} - 2\mathbf{j} - 2\mathbf{k}) = -\frac{4}{9}\mathbf{i} + \frac{8}{9}\mathbf{j} + \frac{8}{9}\mathbf{k}.\end{aligned}$$

We find the scalar component of \mathbf{u} in the direction of \mathbf{v} from Equation (2):

$$\begin{aligned}|\mathbf{u}| \cos \theta &= \mathbf{u} \cdot \frac{\mathbf{v}}{|\mathbf{v}|} = (6\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}) \cdot \left(\frac{1}{3}\mathbf{i} - \frac{2}{3}\mathbf{j} - \frac{2}{3}\mathbf{k}\right) \\ &= 2 - 2 - \frac{4}{3} = -\frac{4}{3}.\end{aligned}$$

Equations (1) and (2) also apply to two-dimensional vectors. We demonstrate this in the next example.

EXAMPLE 6 Find the vector projection of a force $\mathbf{F} = 5\mathbf{i} + 2\mathbf{j}$ onto $\mathbf{v} = \mathbf{i} - 3\mathbf{j}$ and the scalar component of \mathbf{F} in the direction of \mathbf{v} .

Solution The vector projection is

$$\begin{aligned}\text{proj}_{\mathbf{v}} \mathbf{F} &= \left(\frac{\mathbf{F} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right) \mathbf{v} = \left(\frac{\mathbf{F} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\right) \mathbf{v} \\ &= \frac{5 - 6}{1 + 9}(\mathbf{i} - 3\mathbf{j}) = -\frac{1}{10}(\mathbf{i} - 3\mathbf{j}) \\ &= -\frac{1}{10}\mathbf{i} + \frac{3}{10}\mathbf{j}.\end{aligned}$$

The scalar component of \mathbf{F} in the direction of \mathbf{v} is

$$|\mathbf{F}| \cos \theta = \frac{\mathbf{F} \cdot \mathbf{v}}{|\mathbf{v}|} = \frac{5 - 6}{\sqrt{1 + 9}} = -\frac{1}{\sqrt{10}}.$$

EXAMPLE 7 Verify that the vector $\mathbf{u} - \text{proj}_{\mathbf{v}} \mathbf{u}$ is orthogonal to the projection vector $\text{proj}_{\mathbf{v}} \mathbf{u}$.

Solution The vector $\text{proj}_{\mathbf{v}} \mathbf{u} = \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right) \mathbf{v}$ is parallel to \mathbf{v} . So it suffices to show that the vector $\mathbf{u} - \text{proj}_{\mathbf{v}} \mathbf{u}$ is orthogonal to \mathbf{v} . We verify orthogonality by showing that the dot product of $\mathbf{u} - \text{proj}_{\mathbf{v}} \mathbf{u}$ with \mathbf{v} is zero:

$$\begin{aligned}(\mathbf{u} - \text{proj}_{\mathbf{v}} \mathbf{u}) \cdot \mathbf{v} &= \mathbf{u} \cdot \mathbf{v} - \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} \mathbf{v}\right) \cdot \mathbf{v} && \text{Definition of } \text{proj}_{\mathbf{v}} \mathbf{u} \\ &= \mathbf{u} \cdot \mathbf{v} - \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} (\mathbf{v} \cdot \mathbf{v}) && \text{Dot product property (2)} \\ &= \mathbf{u} \cdot \mathbf{v} - \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} |\mathbf{v}|^2 && \mathbf{v} \cdot \mathbf{v} = |\mathbf{v}|^2 \\ &= \mathbf{u} \cdot \mathbf{v} - \mathbf{u} \cdot \mathbf{v} = 0.\end{aligned}$$

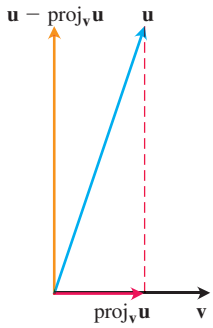

FIGURE 11.27 The vector \mathbf{u} is the sum of two perpendicular vectors: a vector $\text{proj}_v \mathbf{u}$, parallel to \mathbf{v} , and a vector $\mathbf{u} - \text{proj}_v \mathbf{u}$, perpendicular to \mathbf{v} .

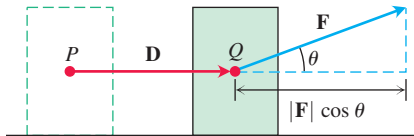

FIGURE 11.28 The work done by a constant force \mathbf{F} during a displacement \mathbf{D} is $(|\mathbf{F}|\cos\theta)|\mathbf{D}|$, which is the dot product $\mathbf{F} \cdot \mathbf{D}$.

Example 7 verifies that the vector $\mathbf{u} - \text{proj}_v \mathbf{u}$ is orthogonal to the projection vector $\text{proj}_v \mathbf{u}$ (which has the same direction as \mathbf{v}). So the equation

$$\mathbf{u} = \text{proj}_v \mathbf{u} + (\mathbf{u} - \text{proj}_v \mathbf{u}) = \underbrace{\left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right) \mathbf{v}}_{\text{Parallel to } \mathbf{v}} + \underbrace{\left(\mathbf{u} - \left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2}\right) \mathbf{v}\right)}_{\text{Orthogonal to } \mathbf{v}}$$

expresses \mathbf{u} as a sum of orthogonal vectors (see Figure 11.27).

Work

In Chapter 6, we calculated the work done by a constant force of magnitude F in moving an object through a distance d as $W = Fd$. That formula holds only if the force is directed along the line of motion. If a force \mathbf{F} moving an object through a displacement $\mathbf{D} = \overline{PQ}$ has some other direction, the work is performed by the component of \mathbf{F} in the direction of \mathbf{D} . If θ is the angle between \mathbf{F} and \mathbf{D} (Figure 11.28), then

$$\begin{aligned} \text{Work} &= \left(\begin{array}{l} \text{scalar component of } \mathbf{F} \\ \text{in the direction of } \mathbf{D} \end{array} \right) (\text{length of } \mathbf{D}) \\ &= (|\mathbf{F}|\cos\theta)|\mathbf{D}| \\ &= \mathbf{F} \cdot \mathbf{D}. \end{aligned}$$

DEFINITION The work done by a constant force \mathbf{F} acting through a displacement $\mathbf{D} = \overline{PQ}$ is

$$W = \mathbf{F} \cdot \mathbf{D}.$$

EXAMPLE 8 If $|\mathbf{F}| = 40$ N (newtons), $|\mathbf{D}| = 3$ m, and $\theta = 60^\circ$, the work done by \mathbf{F} in acting from P to Q is

$$\begin{aligned} \text{Work} &= \mathbf{F} \cdot \mathbf{D} && \text{Definition} \\ &= |\mathbf{F}||\mathbf{D}|\cos\theta \\ &= (40)(3)\cos 60^\circ && \text{Given values} \\ &= (120)(1/2) = 60 \text{ J(joules)}. \end{aligned}$$

We encounter more challenging work problems in Chapter 15 when we learn to find the work done by a variable force along a more general *path* in space.

The Dot Product of Two n -Dimensional Vectors

If $\mathbf{u} = \langle u_1, u_2, \dots, u_n \rangle$ and $\mathbf{v} = \langle v_1, v_2, \dots, v_n \rangle$ are n -dimensional vectors, then we define the dot product to be

$$\mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + \cdots + u_nv_n.$$

As for two- and three-dimensional vectors, the dot product is calculated by adding the products of the corresponding components of the two vectors.

This generalized dot product can be shown to satisfy the Properties of the Dot Product that were introduced earlier in this section, and similar terminology is used. If \mathbf{u} and \mathbf{v} are n -dimensional vectors, then

1. \mathbf{u} and \mathbf{v} are said to be orthogonal if $\mathbf{u} \cdot \mathbf{v} = 0$,
2. the vector projection of \mathbf{u} onto \mathbf{v} is $\text{proj}_v \mathbf{u} = \frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{v}|^2} \mathbf{v}$, and

3. the angle between the vectors \mathbf{u} and \mathbf{v} is defined as $\theta = \arccos\left(\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}\right)$. (The Cauchy-Schwarz inequality, $|\mathbf{u} \cdot \mathbf{v}| \leq |\mathbf{u}||\mathbf{v}|$, stated in Exercise 27 can be extended to n -dimensional vectors. This guarantees that $\frac{\mathbf{u} \cdot \mathbf{v}}{|\mathbf{u}||\mathbf{v}|}$ is within the interval $[-1, 1]$.)

EXAMPLE 9 An automobile assembly plant makes four different car models. The components of the vector $\mathbf{u} = \langle 36, 50, 24, 10 \rangle$ indicate the plant's output of each model per hour, whereas the revenue per vehicle (in US dollars) of each model is represented by the vector $\mathbf{v} = \langle 24,000, 31,000, 39,000, 52,000 \rangle$. Calculate the dot product $\mathbf{u} \cdot \mathbf{v}$ and explain the significance of the value that was obtained.

Solution

$$\mathbf{u} \cdot \mathbf{v} = (36)(24,000) + (50)(31,000) + (24)(39,000) + (10)(52,000) = 3,870,000.$$

The value \$3,870,000 represents the total hourly revenue. ■

EXERCISES 11.3

For some exercises, a calculator may be helpful when expressing answers in decimal form.

Dot Product and Projections

In Exercises 1–8, find

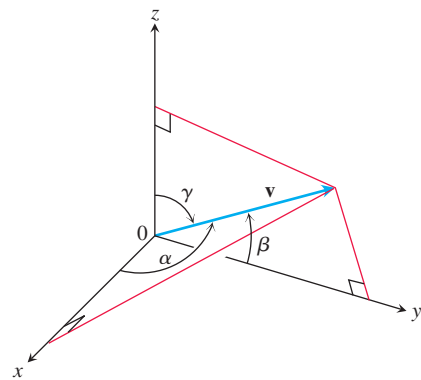

- $\mathbf{v} \cdot \mathbf{u}$, $|\mathbf{v}|$, $|\mathbf{u}|$
 - the cosine of the angle between \mathbf{v} and \mathbf{u}
 - the scalar component of \mathbf{u} in the direction of \mathbf{v}
 - the vector $\text{proj}_{\mathbf{v}} \mathbf{u}$.
- $\mathbf{v} = 2\mathbf{i} - 4\mathbf{j} + \sqrt{5}\mathbf{k}$, $\mathbf{u} = -2\mathbf{i} + 4\mathbf{j} - \sqrt{5}\mathbf{k}$
 - $\mathbf{v} = (3/5)\mathbf{i} + (4/5)\mathbf{k}$, $\mathbf{u} = 5\mathbf{i} + 12\mathbf{j}$
 - $\mathbf{v} = 10\mathbf{i} + 11\mathbf{j} - 2\mathbf{k}$, $\mathbf{u} = 3\mathbf{j} + 4\mathbf{k}$
 - $\mathbf{v} = 2\mathbf{i} + 10\mathbf{j} - 11\mathbf{k}$, $\mathbf{u} = 2\mathbf{i} + 2\mathbf{j} + \mathbf{k}$
 - $\mathbf{v} = 5\mathbf{j} - 3\mathbf{k}$, $\mathbf{u} = \mathbf{i} + \mathbf{j} + \mathbf{k}$
 - $\mathbf{v} = -\mathbf{i} + \mathbf{j}$, $\mathbf{u} = \sqrt{2}\mathbf{i} + \sqrt{3}\mathbf{j} + 2\mathbf{k}$
 - $\mathbf{v} = 5\mathbf{i} + \mathbf{j}$, $\mathbf{u} = 2\mathbf{i} + \sqrt{17}\mathbf{j}$
 - $\mathbf{v} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{3}} \right\rangle$, $\mathbf{u} = \left\langle \frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{3}} \right\rangle$

Angle Between Vectors

Find the angles between the vectors in Exercises 9–12 to the nearest hundredth of a radian.

- $\mathbf{u} = 2\mathbf{i} + \mathbf{j}$, $\mathbf{v} = \mathbf{i} + 2\mathbf{j} - \mathbf{k}$
 - $\mathbf{u} = 2\mathbf{i} - 2\mathbf{j} + \mathbf{k}$, $\mathbf{v} = 3\mathbf{i} + 4\mathbf{k}$
 - $\mathbf{u} = \sqrt{3}\mathbf{i} - 7\mathbf{j}$, $\mathbf{v} = \sqrt{3}\mathbf{i} + \mathbf{j} - 2\mathbf{k}$
 - $\mathbf{u} = \mathbf{i} + \sqrt{2}\mathbf{j} - \sqrt{2}\mathbf{k}$, $\mathbf{v} = -\mathbf{i} + \mathbf{j} + \mathbf{k}$
13. **Triangle** Find the measures of the angles of the triangle whose vertices are $A = (-1, 0)$, $B = (2, 1)$, and $C = (1, -2)$.
14. **Rectangle** Find the measures of the angles between the diagonals of the rectangle whose vertices are $A = (1, 0)$, $B = (0, 3)$, $C = (3, 4)$, and $D = (4, 1)$.

15. **Direction angles and direction cosines** The *direction angles* α , β , and γ of a vector $\mathbf{v} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$ are defined as follows: α is the angle between \mathbf{v} and the positive x -axis ($0 \leq \alpha \leq \pi$). β is the angle between \mathbf{v} and the positive y -axis ($0 \leq \beta \leq \pi$). γ is the angle between \mathbf{v} and the positive z -axis ($0 \leq \gamma \leq \pi$).

- a. Show that

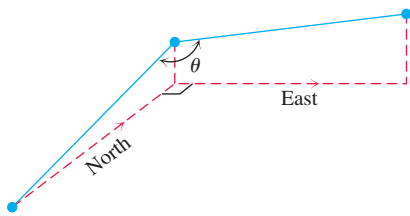

$$\cos \alpha = \frac{a}{|\mathbf{v}|}, \quad \cos \beta = \frac{b}{|\mathbf{v}|}, \quad \cos \gamma = \frac{c}{|\mathbf{v}|},$$

and $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$. These cosines are called the *direction cosines* of \mathbf{v} .

- b. **Unit vectors are built from direction cosines** Show that if $\mathbf{v} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$ is a unit vector, then a , b , and c are the direction cosines of \mathbf{v} .

16. **Water main construction** A water main is to be constructed with a 20% grade in the north direction and a 10% grade in the

east direction. Determine the angle θ required in the water main for the turn from north to east.

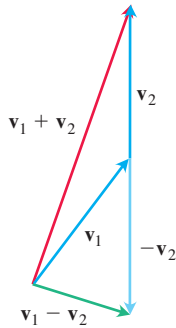

For Exercises 17 and 18, find the acute angle between the given lines by using vectors parallel to the lines.

17. $y = x$, $y = 2x + 3$

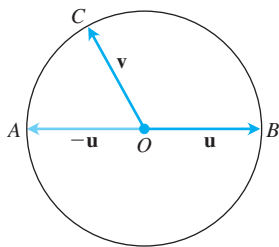

18. $2 - x + 2y = 0$, $3x - 4y = -12$

Theory and Examples

19. Sums and differences In the accompanying figure, it looks as if $\mathbf{v}_1 + \mathbf{v}_2$ and $\mathbf{v}_1 - \mathbf{v}_2$ are orthogonal. Is this mere coincidence, or are there circumstances under which we may expect the sum of two vectors to be orthogonal to their difference? Give reasons for your answer.

20. Orthogonality on a circle Suppose that AB is the diameter of a circle with center O and that C is a point on one of the two arcs joining A and B . Show that \overline{CA} and \overline{CB} are orthogonal.

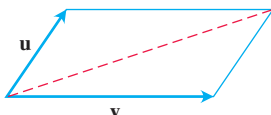

21. Diagonals of a rhombus Show that the diagonals of a rhombus (parallelogram with sides of equal length) are perpendicular.

22. Perpendicular diagonals Show that squares are the only rectangles with perpendicular diagonals.

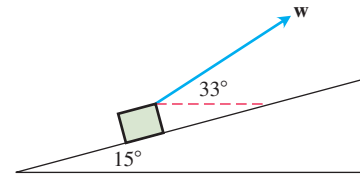

23. When parallelograms are rectangles Prove that a parallelogram is a rectangle if and only if its diagonals are equal in length. (This fact is often exploited by carpenters.)

24. Diagonal of parallelogram Show that the indicated diagonal of the parallelogram determined by vectors \mathbf{u} and \mathbf{v} bisects the angle between \mathbf{u} and \mathbf{v} if $|\mathbf{u}| = |\mathbf{v}|$.

25. Projectile motion A gun with muzzle velocity of 400 m/s is fired at an angle of 8° above the horizontal. Find the horizontal and vertical components of the velocity.

26. Inclined plane Suppose that a box is being towed up an inclined plane as shown in the figure. Find the force \mathbf{w} needed to make the component of the force parallel to the inclined plane equal to 2.5 N.

27. a. Cauchy-Schwarz inequality Since $\mathbf{u} \cdot \mathbf{v} = |\mathbf{u}||\mathbf{v}|\cos\theta$, show that the inequality $|\mathbf{u} \cdot \mathbf{v}| \leq |\mathbf{u}||\mathbf{v}|$ holds for any vectors \mathbf{u} and \mathbf{v} .

b. Under what circumstances, if any, does $|\mathbf{u} \cdot \mathbf{v}|$ equal $|\mathbf{u}||\mathbf{v}|$? Give reasons for your answer.

28. Dot multiplication is positive definite Show that dot multiplication of vectors is *positive definite*; that is, show that $\mathbf{u} \cdot \mathbf{u} \geq 0$ for every vector \mathbf{u} and that $\mathbf{u} \cdot \mathbf{u} = 0$ if and only if $\mathbf{u} = \mathbf{0}$.

29. Orthogonal unit vectors If \mathbf{u}_1 and \mathbf{u}_2 are orthogonal unit vectors and $\mathbf{v} = a\mathbf{u}_1 + b\mathbf{u}_2$, find $\mathbf{v} \cdot \mathbf{u}_1$.

30. Cancellation in dot products In real-number multiplication, if $uv_1 = uv_2$ and $u \neq 0$, we can cancel the u and conclude that $v_1 = v_2$. Does the same rule hold for the dot product? That is, if $\mathbf{u} \cdot \mathbf{v}_1 = \mathbf{u} \cdot \mathbf{v}_2$ and $\mathbf{u} \neq \mathbf{0}$, can you conclude that $\mathbf{v}_1 = \mathbf{v}_2$? Give reasons for your answer.

31. If \mathbf{u} and \mathbf{v} are orthogonal, show that $\text{proj}_{\mathbf{v}} \mathbf{u} = \mathbf{0}$.

32. A force $\mathbf{F} = 2\mathbf{i} + \mathbf{j} - 3\mathbf{k}$ is applied to a spacecraft with velocity vector $\mathbf{v} = 3\mathbf{i} - \mathbf{j}$. Express \mathbf{F} as a sum of a vector parallel to \mathbf{v} and a vector orthogonal to \mathbf{v} .

Equations for Lines in the Plane

33. Line perpendicular to a vector Show that $\mathbf{v} = a\mathbf{i} + b\mathbf{j}$ is perpendicular to the line $ax + by = c$. (*Hint:* For a and b nonzero, establish that the slope of the vector \mathbf{v} is the negative reciprocal of the slope of the given line. Also verify the statement when $a = 0$ or $b = 0$.)

34. Line parallel to a vector Show that the vector $\mathbf{v} = a\mathbf{i} + b\mathbf{j}$ is parallel to the line $bx - ay = c$. (*Hint:* For a and b nonzero, establish that the slope of the line segment representing \mathbf{v} is the same as the slope of the given line. Also verify the statement when $a = 0$ or $b = 0$.)

In Exercises 35–38, use the result of Exercise 33 to find an equation for the line through P perpendicular to \mathbf{v} . Then sketch the line. Include \mathbf{v} in your sketch as a vector starting at the origin.

35. $P(2, 1)$, $\mathbf{v} = \mathbf{i} + 2\mathbf{j}$

36. $P(-1, 2)$, $\mathbf{v} = -2\mathbf{i} - \mathbf{j}$

37. $P(-2, -7)$, $\mathbf{v} = -2\mathbf{i} + \mathbf{j}$

38. $P(11, 10)$, $\mathbf{v} = 2\mathbf{i} - 3\mathbf{j}$

In Exercises 39–42, use the result of Exercise 34 to find an equation for the line through P parallel to \mathbf{v} . Then sketch the line. Include \mathbf{v} in your sketch as a vector starting at the origin.

39. $P(-2, 1)$, $\mathbf{v} = \mathbf{i} - \mathbf{j}$

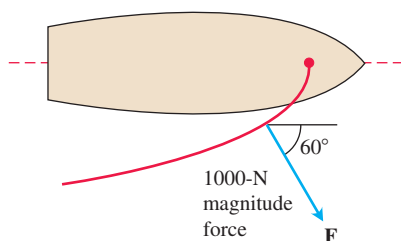

40. $P(0, -2)$, $\mathbf{v} = 2\mathbf{i} + 3\mathbf{j}$

41. $P(1, 2)$, $\mathbf{v} = -\mathbf{i} - 2\mathbf{j}$

42. $P(1, 3)$, $\mathbf{v} = 3\mathbf{i} - 2\mathbf{j}$

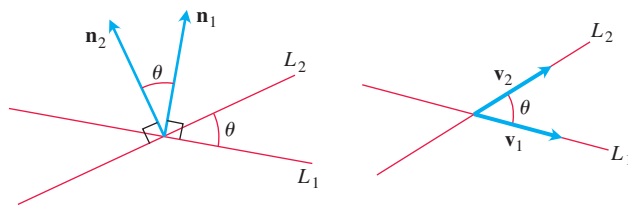

Work

- 43. Work along a line** Find the work done by a force $\mathbf{F} = 5\mathbf{i}$ (magnitude 5 N) in moving an object along the line from the origin to the point $(1, 1)$ (distance in meters).
- 44. Locomotive** The Union Pacific's *Big Boy* locomotive could pull 6000-tonne trains with a tractive effort (pull) of 602,148 N. At this level of effort, about how much work did *Big Boy* do on the (approximately straight) 605-km journey from San Francisco to Los Angeles?
- 45. Inclined plane** How much work does it take to slide a crate 20 m along a loading dock by pulling on it with a 200-N force at an angle of 30° from the horizontal?
- 46. Sailboat** The wind passing over a boat's sail exerted a 1000 N magnitude force \mathbf{F} as shown here. How much work did the wind perform in moving the boat forward 1 km? Answer in joules.

Angles Between Lines in the Plane

The **acute angle between intersecting lines** that do not cross at right angles is the same as the angle determined by vectors normal to the lines or by vectors parallel to the lines.

Use this fact and the results of Exercise 33 or 34 to find the acute angles between the lines in Exercises 47–52.

- 47.** $3x + y = 5$, $2x - y = 4$
- 48.** $y = \sqrt{3}x - 1$, $y = -\sqrt{3}x + 2$
- 49.** $\sqrt{3}x - y = -2$, $x - \sqrt{3}y = 1$
- 50.** $x + \sqrt{3}y = 1$, $(1 - \sqrt{3})x + (1 + \sqrt{3})y = 8$
- 51.** $3x - 4y = 3$, $x - y = 7$
- 52.** $12x + 5y = 1$, $2x - 2y = 3$

Dot Products of n -Dimensional Vectors

In Exercises 53–56, (a) find $\mathbf{u} \cdot \mathbf{v}$ and (b) determine whether the vectors \mathbf{u} and \mathbf{v} are orthogonal.

- 53.** $\mathbf{u} = \langle 3, 2, -4, 0 \rangle$, $\mathbf{v} = \langle 1, 0, 0, 2 \rangle$
- 54.** $\mathbf{u} = \langle -2, 1, 1, 2 \rangle$, $\mathbf{v} = \langle -1, 2, -2, -1 \rangle$
- 55.** $\mathbf{u} = \langle 6, 3, 0, 1, -2 \rangle$, $\mathbf{v} = \langle 0, 2, -7, 0, 3 \rangle$
- 56.** $\mathbf{u} = \langle 4, 2, -3, -2, 1, 5 \rangle$, $\mathbf{v} = \langle 3, -3, 2, -2, 1, -1 \rangle$

11.4 The Cross Product

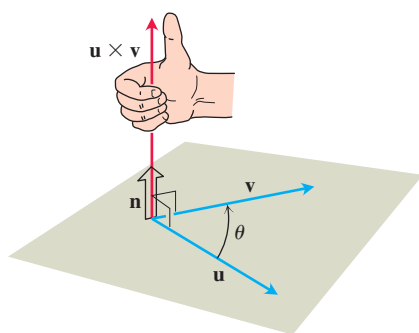

FIGURE 11.29 The construction of $\mathbf{u} \times \mathbf{v}$.

In studying lines in the plane, when we needed to describe how a line was tilting, we used the notions of slope and angle of inclination. In space, we want a way to describe how a *plane* is tilting. We accomplish this by multiplying two vectors in the plane together to get a third vector perpendicular to the plane. The direction of this third vector tells us the “inclination” of the plane. The product we use to multiply the vectors together is the *vector* or *cross product*, the second of the two vector multiplication methods. The cross product gives us a simple way to find a variety of geometric quantities, including volumes, areas, and perpendicular vectors. We study the cross product in this section.

The Cross Product of Two Vectors in Space

We start with two nonzero vectors \mathbf{u} and \mathbf{v} in space. Two vectors are *parallel* if one is a nonzero multiple of the other. If \mathbf{u} and \mathbf{v} are not parallel, they determine a plane. The vectors in this plane are linear combinations of \mathbf{u} and \mathbf{v} , so they can be written as a sum $a\mathbf{u} + b\mathbf{v}$. We select the unit vector \mathbf{n} perpendicular to the plane by the **right-hand rule**. This means that we choose \mathbf{n} to be the unit normal vector that points the way your right thumb points when your fingers curl through the angle θ from \mathbf{u} to \mathbf{v} (Figure 11.29). Then we define a new vector as follows.

DEFINITION The **cross product** $\mathbf{u} \times \mathbf{v}$ (“**u cross v**”) is the vector

$$\mathbf{u} \times \mathbf{v} = (|\mathbf{u}||\mathbf{v}| \sin \theta) \mathbf{n}.$$

Unlike the dot product, the cross product is a vector. For this reason it is also called the **vector product** of \mathbf{u} and \mathbf{v} , and can be applied *only* to vectors in space. The vector $\mathbf{u} \times \mathbf{v}$ is orthogonal to both \mathbf{u} and \mathbf{v} because it is a scalar multiple of \mathbf{n} .

There is a straightforward way to calculate the cross product of two vectors from their components. The method does not require that we know the angle between them (as suggested by the definition), but we postpone that calculation momentarily so we can focus first on the properties of the cross product.

Because the sines of 0 and π are both zero, it makes sense to define the cross product of two parallel nonzero vectors to be $\mathbf{0}$. If one or both of \mathbf{u} and \mathbf{v} are zero, we also define $\mathbf{u} \times \mathbf{v}$ to be zero. This way, the cross product of two vectors \mathbf{u} and \mathbf{v} is zero if and only if \mathbf{u} and \mathbf{v} are parallel or one or both of them are zero.

Parallel Vectors

Nonzero vectors \mathbf{u} and \mathbf{v} are parallel if and only if $\mathbf{u} \times \mathbf{v} = \mathbf{0}$.

The cross product obeys the following laws.

Properties of the Cross Product

If \mathbf{u} , \mathbf{v} , and \mathbf{w} are any vectors and r, s are scalars, then

1. $(r\mathbf{u}) \times (s\mathbf{v}) = (rs)(\mathbf{u} \times \mathbf{v})$
2. $\mathbf{u} \times (\mathbf{v} + \mathbf{w}) = \mathbf{u} \times \mathbf{v} + \mathbf{u} \times \mathbf{w}$
3. $\mathbf{v} \times \mathbf{u} = -(\mathbf{u} \times \mathbf{v})$
4. $(\mathbf{v} + \mathbf{w}) \times \mathbf{u} = \mathbf{v} \times \mathbf{u} + \mathbf{w} \times \mathbf{u}$
5. $\mathbf{0} \times \mathbf{u} = \mathbf{0}$
6. $\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = (\mathbf{u} \cdot \mathbf{w})\mathbf{v} - (\mathbf{u} \cdot \mathbf{v})\mathbf{w}$

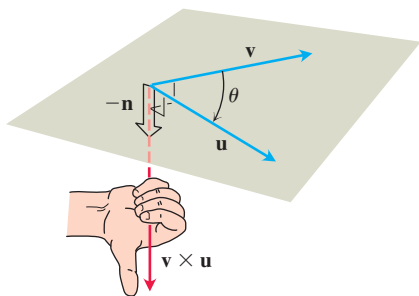

FIGURE 11.30 The construction of $\mathbf{v} \times \mathbf{u}$.

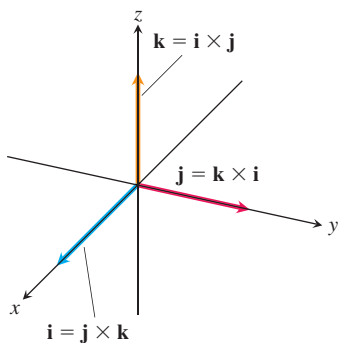

FIGURE 11.31 The pairwise cross products of \mathbf{i} , \mathbf{j} , and \mathbf{k} .

To visualize Property 3, for example, notice that when the fingers of your right hand curl through the angle θ from \mathbf{v} to \mathbf{u} , your thumb points the opposite way; the unit vector we choose in forming $\mathbf{v} \times \mathbf{u}$ is the negative of the one we choose in forming $\mathbf{u} \times \mathbf{v}$ (Figure 11.30).

Property 1 can be verified by applying the definition of cross product to both sides of the equation and comparing the results. Property 2 is proved in Appendix A.9. Property 4 follows by multiplying both sides of the equation in Property 2 by -1 and reversing the order of the products using Property 3. Property 5 is a definition. As a rule, cross product multiplication is *not associative* so $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w}$ does not generally equal $\mathbf{u} \times (\mathbf{v} \times \mathbf{w})$. (See Additional Exercise 17.)

When we apply the definition and Property 3 to calculate the pairwise cross products of \mathbf{i} , \mathbf{j} , and \mathbf{k} , we find (Figure 11.31)

$$\begin{aligned}\mathbf{i} \times \mathbf{j} &= -(\mathbf{j} \times \mathbf{i}) = \mathbf{k} \\ \mathbf{j} \times \mathbf{k} &= -(\mathbf{k} \times \mathbf{j}) = \mathbf{i} \\ \mathbf{k} \times \mathbf{i} &= -(\mathbf{i} \times \mathbf{k}) = \mathbf{j}\end{aligned}$$

and

$$\mathbf{i} \times \mathbf{i} = \mathbf{j} \times \mathbf{j} = \mathbf{k} \times \mathbf{k} = \mathbf{0}.$$

$|\mathbf{u} \times \mathbf{v}|$ Is the Area of a Parallelogram

Because \mathbf{n} is a unit vector, the magnitude of $\mathbf{u} \times \mathbf{v}$ is

$$|\mathbf{u} \times \mathbf{v}| = |\mathbf{u}||\mathbf{v}||\sin \theta||\mathbf{n}| = |\mathbf{u}||\mathbf{v}|\sin \theta.$$

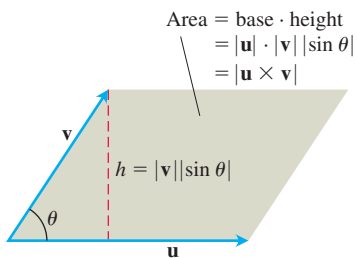

FIGURE 11.32 The parallelogram determined by \mathbf{u} and \mathbf{v} .

This is the area of the parallelogram determined by \mathbf{u} and \mathbf{v} (Figure 11.32), $|\mathbf{u}|$ being the base of the parallelogram and $|\mathbf{v}|\sin\theta$ being the height.

Determinant Formula for $\mathbf{u} \times \mathbf{v}$

Our next objective is to calculate $\mathbf{u} \times \mathbf{v}$ from the components of \mathbf{u} and \mathbf{v} relative to a Cartesian coordinate system.

Suppose that

$$\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k} \quad \text{and} \quad \mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}.$$

Then the distributive laws and the rules for multiplying \mathbf{i} , \mathbf{j} , and \mathbf{k} tell us that

$$\begin{aligned} \mathbf{u} \times \mathbf{v} &= (u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}) \times (v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}) \\ &= u_1v_1\mathbf{i} \times \mathbf{i} + u_1v_2\mathbf{i} \times \mathbf{j} + u_1v_3\mathbf{i} \times \mathbf{k} \\ &\quad + u_2v_1\mathbf{j} \times \mathbf{i} + u_2v_2\mathbf{j} \times \mathbf{j} + u_2v_3\mathbf{j} \times \mathbf{k} \\ &\quad + u_3v_1\mathbf{k} \times \mathbf{i} + u_3v_2\mathbf{k} \times \mathbf{j} + u_3v_3\mathbf{k} \times \mathbf{k} \\ &= (u_2v_3 - u_3v_2)\mathbf{i} - (u_1v_3 - u_3v_1)\mathbf{j} + (u_1v_2 - u_2v_1)\mathbf{k}. \end{aligned}$$

The component terms in the last line are hard to remember, but they are the same as the terms in the expansion of the symbolic determinant

$$\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}.$$

So we restate the calculation in the following easy-to-remember form.

Calculating the Cross Product as a Determinant

If $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ and $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$, then

$$\mathbf{u} \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \end{vmatrix}.$$

EXAMPLE 1 Find $\mathbf{u} \times \mathbf{v}$ and $\mathbf{v} \times \mathbf{u}$ if $\mathbf{u} = 2\mathbf{i} + \mathbf{j} + \mathbf{k}$ and $\mathbf{v} = -4\mathbf{i} + 3\mathbf{j} + \mathbf{k}$.

Solution We expand the symbolic determinant.

$$\begin{aligned} \mathbf{u} \times \mathbf{v} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & 1 \\ -4 & 3 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 3 & 1 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 2 & 1 \\ -4 & 1 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 2 & 1 \\ -4 & 3 \end{vmatrix} \mathbf{k} \\ &= -2\mathbf{i} - 6\mathbf{j} + 10\mathbf{k} \\ \mathbf{v} \times \mathbf{u} &= -(\mathbf{u} \times \mathbf{v}) = 2\mathbf{i} + 6\mathbf{j} - 10\mathbf{k} \end{aligned}$$

Property 3

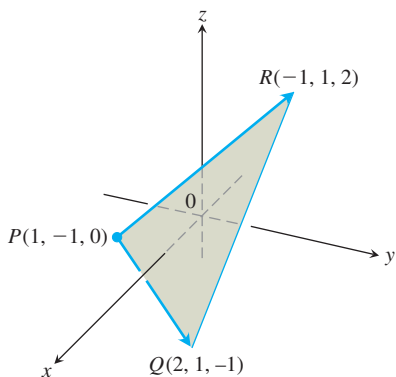

FIGURE 11.33 The vector $\overline{PQ} \times \overline{PR}$ is perpendicular to the plane of triangle PQR (Example 2). The area of triangle PQR is half of $|\overline{PQ} \times \overline{PR}|$ (Example 3).

EXAMPLE 2 Find a vector perpendicular to the plane of $P(1, -1, 0)$, $Q(2, 1, -1)$, and $R(-1, 1, 2)$ (Figure 11.33).

Solution The vector $\overline{PQ} \times \overline{PR}$ is perpendicular to the plane because it is perpendicular to both vectors. In terms of components,

$$\begin{aligned}\overline{PQ} &= (2-1)\mathbf{i} + (1+1)\mathbf{j} + (-1-0)\mathbf{k} = \mathbf{i} + 2\mathbf{j} - \mathbf{k} \\ \overline{PR} &= (-1-1)\mathbf{i} + (1+1)\mathbf{j} + (2-0)\mathbf{k} = -2\mathbf{i} + 2\mathbf{j} + 2\mathbf{k} \\ \overline{PQ} \times \overline{PR} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & -1 \\ -2 & 2 & 2 \end{vmatrix} = \begin{vmatrix} 2 & -1 \\ 2 & 2 \end{vmatrix} \mathbf{i} - \begin{vmatrix} 1 & -1 \\ -2 & 2 \end{vmatrix} \mathbf{j} + \begin{vmatrix} 1 & 2 \\ -2 & 2 \end{vmatrix} \mathbf{k} \\ &= 6\mathbf{i} + 6\mathbf{k}. \quad \blacksquare\end{aligned}$$

EXAMPLE 3 Find the area of the triangle with vertices $P(1, -1, 0)$, $Q(2, 1, -1)$, and $R(-1, 1, 2)$ (Figure 11.33).

Solution The area of the parallelogram determined by P , Q , and R is

$$\begin{aligned}|\overline{PQ} \times \overline{PR}| &= |6\mathbf{i} + 6\mathbf{k}| && \text{Values from Example 2} \\ &= \sqrt{(6)^2 + (6)^2} = \sqrt{2 \cdot 36} = 6\sqrt{2}.\end{aligned}$$

The triangle's area is half of this, or $3\sqrt{2}$. ■

EXAMPLE 4 Find a unit vector perpendicular to the plane of $P(1, -1, 0)$, $Q(2, 1, -1)$, and $R(-1, 1, 2)$.

Solution Since $\overline{PQ} \times \overline{PR}$ is perpendicular to the plane, its direction \mathbf{n} is a unit vector perpendicular to the plane. Taking values from Examples 2 and 3, we have

$$\mathbf{n} = \frac{\overline{PQ} \times \overline{PR}}{|\overline{PQ} \times \overline{PR}|} = \frac{6\mathbf{i} + 6\mathbf{k}}{6\sqrt{2}} = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{k}. \quad \blacksquare$$

For ease in calculating the cross product using determinants, we usually write vectors in the form $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ rather than as ordered triples $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$.

Torque

When we turn a bolt by applying a force \mathbf{F} to a wrench (Figure 11.34), we produce a torque that causes the bolt to rotate. The **torque vector** points in the direction of the axis of the bolt according to the right-hand rule (so the rotation is counterclockwise when viewed from the *tip* of the vector). The magnitude of the torque depends on how far out on the wrench the force is applied and on how much of the force is perpendicular to the wrench at the point of application. The number we use to measure the torque's magnitude is the product of the length of the lever arm \mathbf{r} and the scalar component of \mathbf{F} perpendicular to \mathbf{r} . In the notation of Figure 11.34,

$$\text{Magnitude of torque vector} = |\mathbf{r}||\mathbf{F}| \sin \theta,$$

or $|\mathbf{r} \times \mathbf{F}|$. If we let \mathbf{n} be a unit vector along the axis of the bolt in the direction of the torque, then a complete description of the torque vector is $\mathbf{r} \times \mathbf{F}$, or

$$\text{Torque vector} = \mathbf{r} \times \mathbf{F} = (|\mathbf{r}||\mathbf{F}| \sin \theta) \mathbf{n}.$$

Recall that we defined $\mathbf{u} \times \mathbf{v}$ to be $\mathbf{0}$ when \mathbf{u} and \mathbf{v} are parallel. This is consistent with the torque interpretation as well. If the force \mathbf{F} in Figure 11.34 is parallel to the wrench, meaning that we are trying to turn the bolt by pushing or pulling along the line of the wrench's handle, the torque produced is zero.

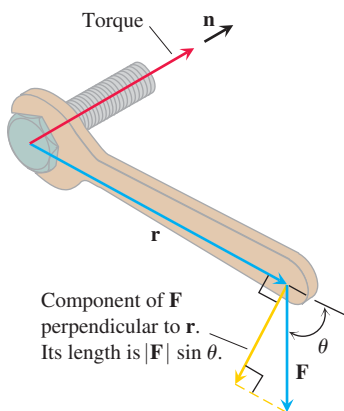

FIGURE 11.34 The torque vector describes the tendency of the force \mathbf{F} to drive the bolt forward.

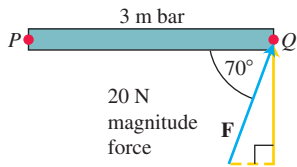

FIGURE 11.35 The magnitude of the torque exerted by \mathbf{F} at P is about $56.4 \text{ N} \cdot \text{m}$ (Example 5). The bar rotates counter-clockwise around P .

EXAMPLE 5 The magnitude of the torque generated by force \mathbf{F} at the pivot point P in Figure 11.35 is

$$|\overrightarrow{PQ} \times \mathbf{F}| = |\overrightarrow{PQ}||\mathbf{F}| \sin 70^\circ \approx (3)(20)(0.94) \approx 56.4 \text{ N} \cdot \text{m}.$$

In this example, the torque vector is pointing out of the page toward you. ■

Triple Scalar or Box Product

The product $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}$ is called the **triple scalar product** of \mathbf{u} , \mathbf{v} , and \mathbf{w} (in that order). As you can see from the formula

$$|(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}| = |\mathbf{u} \times \mathbf{v}||\mathbf{w}|\cos \theta|,$$

the absolute value of this product is the volume of the parallelepiped (parallelogram-sided box) determined by \mathbf{u} , \mathbf{v} , and \mathbf{w} (Figure 11.36). The number $|\mathbf{u} \times \mathbf{v}|$ is the area of the base parallelogram. The number $|\mathbf{w}|\cos \theta$ is the parallelepiped's height. Because of this geometry, $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}$ is also called the **box product** of \mathbf{u} , \mathbf{v} , and \mathbf{w} .

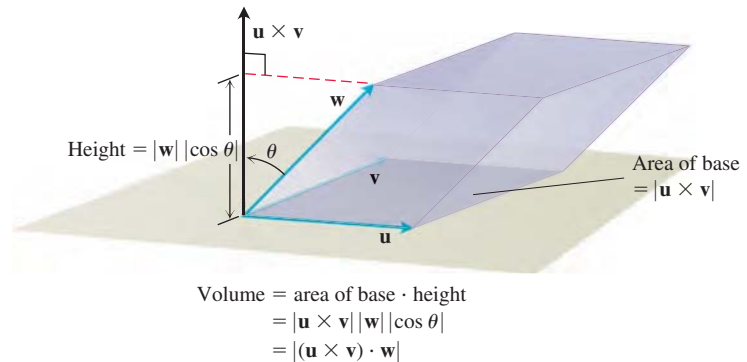

FIGURE 11.36 The number $|(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}|$ is the volume of a parallelepiped.

By treating the planes of \mathbf{v} and \mathbf{w} and of \mathbf{w} and \mathbf{u} as the base planes of the parallelepiped determined by \mathbf{u} , \mathbf{v} , and \mathbf{w} , we see that

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = (\mathbf{v} \times \mathbf{w}) \cdot \mathbf{u} = (\mathbf{w} \times \mathbf{u}) \cdot \mathbf{v}.$$

Since the dot product is commutative, we also have

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = \mathbf{u} \cdot (\mathbf{v} \times \mathbf{w}).$$

The triple scalar product can be evaluated as a determinant:

$$\begin{aligned} (\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} &= \left(\begin{vmatrix} u_2 & u_3 \\ v_2 & v_3 \end{vmatrix} \mathbf{i} - \begin{vmatrix} u_1 & u_3 \\ v_1 & v_3 \end{vmatrix} \mathbf{j} + \begin{vmatrix} u_1 & u_2 \\ v_1 & v_2 \end{vmatrix} \mathbf{k} \right) \cdot \mathbf{w} \\ &= w_1 \begin{vmatrix} u_2 & u_3 \\ v_2 & v_3 \end{vmatrix} - w_2 \begin{vmatrix} u_1 & u_3 \\ v_1 & v_3 \end{vmatrix} + w_3 \begin{vmatrix} u_1 & u_2 \\ v_1 & v_2 \end{vmatrix} \\ &= \begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix}. \end{aligned}$$

The dot and cross may be interchanged in a triple scalar product without altering its value.

Calculating the Triple Scalar Product as a Determinant

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = \begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix}$$

$$\begin{vmatrix} u_1 & u_2 & u_3 \\ v_1 & v_2 & v_3 \\ w_1 & w_2 & w_3 \end{vmatrix} = - \begin{vmatrix} w_1 & w_2 & w_3 \\ v_1 & v_2 & v_3 \\ u_1 & u_2 & u_3 \end{vmatrix}$$

Any two rows of a matrix can be interchanged without changing the *absolute value* of the determinant. So we can take the vectors \mathbf{u} , \mathbf{v} , \mathbf{w} in any order when calculating the absolute value of the triple product.

EXAMPLE 6 Find the volume of the box (parallelepiped) that is determined by $\mathbf{u} = \mathbf{i} + 2\mathbf{j} - \mathbf{k}$, $\mathbf{v} = -2\mathbf{i} + 3\mathbf{k}$, and $\mathbf{w} = 7\mathbf{j} - 4\mathbf{k}$.

Solution Using the rule for calculating a 3×3 determinant, we find

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = \begin{vmatrix} 1 & 2 & -1 \\ -2 & 0 & 3 \\ 0 & 7 & -4 \end{vmatrix} = (1) \begin{vmatrix} 0 & 3 \\ 7 & -4 \end{vmatrix} - (2) \begin{vmatrix} -2 & 3 \\ 0 & -4 \end{vmatrix} + (-1) \begin{vmatrix} -2 & 0 \\ 0 & 7 \end{vmatrix} = -23.$$

The volume is $|(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}| = 23$ units cubed. ■

EXERCISES 11.4

Cross Product Calculations

In Exercises 1–8, find the length and direction (when defined) of $\mathbf{u} \times \mathbf{v}$ and $\mathbf{v} \times \mathbf{u}$.

1. $\mathbf{u} = 2\mathbf{i} - 2\mathbf{j} - \mathbf{k}$, $\mathbf{v} = \mathbf{i} - \mathbf{k}$
2. $\mathbf{u} = 2\mathbf{i} + 3\mathbf{j}$, $\mathbf{v} = -\mathbf{i} + \mathbf{j}$
3. $\mathbf{u} = 2\mathbf{i} - 2\mathbf{j} + 4\mathbf{k}$, $\mathbf{v} = -\mathbf{i} + \mathbf{j} - 2\mathbf{k}$
4. $\mathbf{u} = \mathbf{i} + \mathbf{j} - \mathbf{k}$, $\mathbf{v} = \mathbf{0}$
5. $\mathbf{u} = 2\mathbf{i}$, $\mathbf{v} = -3\mathbf{j}$
6. $\mathbf{u} = \mathbf{i} \times \mathbf{j}$, $\mathbf{v} = \mathbf{j} \times \mathbf{k}$
7. $\mathbf{u} = -8\mathbf{i} - 2\mathbf{j} - 4\mathbf{k}$, $\mathbf{v} = 2\mathbf{i} + 2\mathbf{j} + \mathbf{k}$
8. $\mathbf{u} = \frac{3}{2}\mathbf{i} - \frac{1}{2}\mathbf{j} + \mathbf{k}$, $\mathbf{v} = \mathbf{i} + \mathbf{j} + 2\mathbf{k}$

In Exercises 9–14, sketch the coordinate axes and then include the vectors \mathbf{u} , \mathbf{v} , and $\mathbf{u} \times \mathbf{v}$ as vectors starting at the origin.

9. $\mathbf{u} = \mathbf{i}$, $\mathbf{v} = \mathbf{j}$
10. $\mathbf{u} = \mathbf{i} - \mathbf{k}$, $\mathbf{v} = \mathbf{j}$
11. $\mathbf{u} = \mathbf{i} - \mathbf{k}$, $\mathbf{v} = \mathbf{j} + \mathbf{k}$
12. $\mathbf{u} = 2\mathbf{i} - \mathbf{j}$, $\mathbf{v} = \mathbf{i} + 2\mathbf{j}$
13. $\mathbf{u} = \mathbf{i} + \mathbf{j}$, $\mathbf{v} = \mathbf{i} - \mathbf{j}$
14. $\mathbf{u} = \mathbf{j} + 2\mathbf{k}$, $\mathbf{v} = \mathbf{i}$

Triangles in Space

In Exercises 15–18,

- a. Find the area of the triangle determined by the points P , Q , and R .
 - b. Find a unit vector perpendicular to plane PQR .
15. $P(1, -1, 2)$, $Q(2, 0, -1)$, $R(0, 2, 1)$
 16. $P(1, 1, 1)$, $Q(2, 1, 3)$, $R(3, -1, 1)$
 17. $P(2, -2, 1)$, $Q(3, -1, 2)$, $R(3, -1, 1)$
 18. $P(-2, 2, 0)$, $Q(0, 1, -1)$, $R(-1, 2, -2)$

Triple Scalar Products

In Exercises 19–22, verify that

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = (\mathbf{v} \times \mathbf{w}) \cdot \mathbf{u} = (\mathbf{w} \times \mathbf{u}) \cdot \mathbf{v}$$

and find the volume of the parallelepiped (box) determined by \mathbf{u} , \mathbf{v} , and \mathbf{w} .

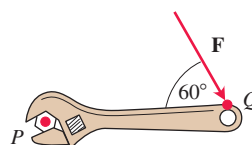

\mathbf{u}	\mathbf{v}	\mathbf{w}
19. $2\mathbf{i}$	$2\mathbf{j}$	$2\mathbf{k}$
20. $\mathbf{i} - \mathbf{j} + \mathbf{k}$	$2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$	$-\mathbf{i} + 2\mathbf{j} - \mathbf{k}$
21. $2\mathbf{i} + \mathbf{j}$	$2\mathbf{i} - \mathbf{j} + \mathbf{k}$	$\mathbf{i} + 2\mathbf{k}$
22. $\mathbf{i} + \mathbf{j} - 2\mathbf{k}$	$-\mathbf{i} - \mathbf{k}$	$2\mathbf{i} + 4\mathbf{j} - 2\mathbf{k}$

Theory and Examples

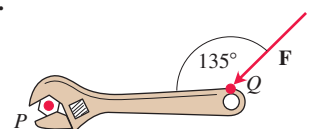

23. **Parallel and perpendicular vectors** Let $\mathbf{u} = 5\mathbf{i} - \mathbf{j} + \mathbf{k}$, $\mathbf{v} = \mathbf{j} - 5\mathbf{k}$, $\mathbf{w} = -15\mathbf{i} + 3\mathbf{j} - 3\mathbf{k}$. Which vectors, if any, are (a) perpendicular? (b) Parallel? Give reasons for your answers.
24. **Parallel and perpendicular vectors** Let $\mathbf{u} = \mathbf{i} + 2\mathbf{j} - \mathbf{k}$, $\mathbf{v} = -\mathbf{i} + \mathbf{j} + \mathbf{k}$, $\mathbf{w} = \mathbf{i} + \mathbf{k}$, $\mathbf{r} = -(\pi/2)\mathbf{i} - \pi\mathbf{j} + (\pi/2)\mathbf{k}$. Which vectors, if any, are (a) perpendicular? (b) Parallel? Give reasons for your answers.

In Exercises 25 and 26, find the magnitude of the torque exerted by \mathbf{F} on the bolt at P if $|\overline{PQ}| = 20$ cm and $|\mathbf{F}| = 15$ N. Answer in newton-meters.

25.

26.

27. Which of the following are *always true*, and which are *not always true*? Give reasons for your answers.
- $|\mathbf{u}| = \sqrt{\mathbf{u} \cdot \mathbf{u}}$
 - $\mathbf{u} \cdot \mathbf{u} = |\mathbf{u}|$
 - $\mathbf{u} \times \mathbf{0} = \mathbf{0} \times \mathbf{u} = \mathbf{0}$
 - $\mathbf{u} \times (-\mathbf{u}) = \mathbf{0}$
 - $\mathbf{u} \times \mathbf{v} = \mathbf{v} \times \mathbf{u}$
 - $\mathbf{u} \times (\mathbf{v} + \mathbf{w}) = \mathbf{u} \times \mathbf{v} + \mathbf{u} \times \mathbf{w}$
 - $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{v} = 0$
 - $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = \mathbf{u} \cdot (\mathbf{v} \times \mathbf{w})$
28. Which of the following are *always true*, and which are *not always true*? Give reasons for your answers.
- $\mathbf{u} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{u}$
 - $\mathbf{u} \times \mathbf{v} = -(\mathbf{v} \times \mathbf{u})$
 - $(-\mathbf{u}) \times \mathbf{v} = -(\mathbf{u} \times \mathbf{v})$
 - $(c\mathbf{u}) \cdot \mathbf{v} = \mathbf{u} \cdot (c\mathbf{v}) = c(\mathbf{u} \cdot \mathbf{v})$ (any number c)
 - $c(\mathbf{u} \times \mathbf{v}) = (c\mathbf{u}) \times \mathbf{v} = \mathbf{u} \times (c\mathbf{v})$ (any number c)
 - $\mathbf{u} \cdot \mathbf{u} = |\mathbf{u}|^2$
 - $(\mathbf{u} \times \mathbf{u}) \cdot \mathbf{u} = 0$
 - $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{u} = \mathbf{v} \cdot (\mathbf{u} \times \mathbf{v})$
29. Given nonzero vectors \mathbf{u} , \mathbf{v} , and \mathbf{w} , use dot product and cross product notation, as appropriate, to describe the following.
- The vector projection of \mathbf{u} onto \mathbf{v}
 - A vector orthogonal to \mathbf{u} and \mathbf{v}
 - A vector orthogonal to $\mathbf{u} \times \mathbf{v}$ and \mathbf{w}
 - The volume of the parallelepiped determined by \mathbf{u} , \mathbf{v} , and \mathbf{w}
 - A vector orthogonal to $\mathbf{u} \times \mathbf{v}$ and $\mathbf{u} \times \mathbf{w}$
 - A vector of length $|\mathbf{u}|$ in the direction of \mathbf{v}
30. Compute $(\mathbf{i} \times \mathbf{j}) \times \mathbf{j}$ and $\mathbf{i} \times (\mathbf{j} \times \mathbf{j})$. What can you conclude about the associativity of the cross product?
31. Let \mathbf{u} , \mathbf{v} , and \mathbf{w} be vectors. Which of the following make sense, and which do not? Give reasons for your answers.
- $(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w}$
 - $\mathbf{u} \times (\mathbf{v} \cdot \mathbf{w})$
 - $\mathbf{u} \times (\mathbf{v} \times \mathbf{w})$
 - $\mathbf{u} \cdot (\mathbf{v} \cdot \mathbf{w})$
32. **Cross products of three vectors** Show that except in degenerate cases, $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w}$ lies in the plane of \mathbf{u} and \mathbf{v} , whereas $\mathbf{u} \times (\mathbf{v} \times \mathbf{w})$ lies in the plane of \mathbf{v} and \mathbf{w} . What *are* the degenerate cases?
33. **Cancellation in cross products** If $\mathbf{u} \times \mathbf{v} = \mathbf{u} \times \mathbf{w}$ and $\mathbf{u} \neq \mathbf{0}$, then does $\mathbf{v} = \mathbf{w}$? Give reasons for your answer.
34. **Double cancellation** If $\mathbf{u} \neq \mathbf{0}$ and if $\mathbf{u} \times \mathbf{v} = \mathbf{u} \times \mathbf{w}$ and $\mathbf{u} \cdot \mathbf{v} = \mathbf{u} \cdot \mathbf{w}$, then does $\mathbf{v} = \mathbf{w}$? Give reasons for your answer.

Area of a Parallelogram

Find the areas of the parallelograms whose vertices are given in Exercises 35–40.

- $A(1, 0)$, $B(0, 1)$, $C(-1, 0)$, $D(0, -1)$
- $A(0, 0)$, $B(7, 3)$, $C(9, 8)$, $D(2, 5)$
- $A(-1, 2)$, $B(2, 0)$, $C(7, 1)$, $D(4, 3)$
- $A(-6, 0)$, $B(1, -4)$, $C(3, 1)$, $D(-4, 5)$
- $A(0, 0, 0)$, $B(3, 2, 4)$, $C(5, 1, 4)$, $D(2, -1, 0)$
- $A(1, 0, -1)$, $B(1, 7, 2)$, $C(2, 4, -1)$, $D(0, 3, 2)$

Area of a Triangle

Find the areas of the triangles whose vertices are given in Exercises 41–47.

- $A(0, 0)$, $B(-2, 3)$, $C(3, 1)$
- $A(-1, -1)$, $B(3, 3)$, $C(2, 1)$
- $A(-5, 3)$, $B(1, -2)$, $C(6, -2)$
- $A(-6, 0)$, $B(10, -5)$, $C(-2, 4)$
- $A(1, 0, 0)$, $B(0, 2, 0)$, $C(0, 0, -1)$
- $A(0, 0, 0)$, $B(-1, 1, -1)$, $C(3, 0, 3)$
- $A(1, -1, 1)$, $B(0, 1, 1)$, $C(1, 0, -1)$
- Find the volume of a parallelepiped with one of its eight vertices at $A(0, 0, 0)$ and three adjacent vertices at $B(1, 2, 0)$, $C(0, -3, 2)$, and $D(3, -4, 5)$.
- Triangle area** Find a 2×2 determinant formula for the area of the triangle in the xy -plane with vertices at $(0, 0)$, (a_1, a_2) , and (b_1, b_2) . Explain your work.
- Triangle area** Find a concise 3×3 determinant formula that gives the area of a triangle in the xy -plane having vertices (a_1, a_2) , (b_1, b_2) , and (c_1, c_2) .

Volume of a Tetrahedron

Using the methods of Section 6.1, where volume is computed by integrating cross-sectional area, it can be shown that the volume of a tetrahedron formed by three vectors is equal to $\frac{1}{6}$ the volume of the parallelepiped formed by the three vectors. Find the volumes of the tetrahedra whose vertices are given in Exercises 51–54.

- $A(0, 0, 0)$, $B(2, 0, 0)$, $C(0, 3, 0)$, $D(0, 0, 4)$
- $A(0, 0, 0)$, $B(1, 0, 2)$, $C(0, 2, 1)$, $D(3, 4, 0)$
- $A(1, -1, 0)$, $B(0, 2, -2)$, $C(-3, 0, 3)$, $D(0, 4, 4)$
- $A(-1, 2, 3)$, $B(2, 0, 1)$, $C(1, -3, 2)$, $D(-2, 1, -1)$

In Exercises 55–57, determine whether the given points are coplanar.

- $A(1, 1, 1)$, $B(-1, 0, 4)$, $C(0, 2, 1)$, $D(2, -2, 3)$
- $A(0, 0, 4)$, $B(6, 2, 0)$, $C(2, -1, 1)$, $D(-3, -4, 3)$
- $A(0, 1, 2)$, $B(-1, 1, 0)$, $C(2, 0, -1)$, $D(1, -1, 1)$

11.5 Lines and Planes in Space

This section shows how to use scalar and vector products to write equations for lines, line segments, and planes in space. We will use these representations throughout the rest of the text in studying the calculus of curves and surfaces in space.

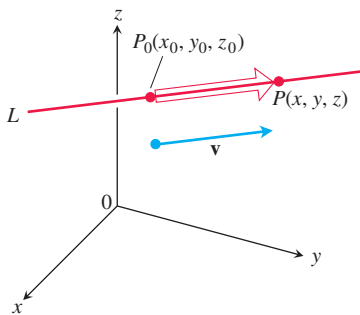

FIGURE 11.37 A point P lies on L through P_0 parallel to \mathbf{v} if and only if $\overrightarrow{P_0P}$ is a scalar multiple of \mathbf{v} .

Lines and Line Segments in Space

In the plane, a line is determined by a point and a number giving the slope of the line. In space a line is determined by a point and a *vector* giving the direction of the line.

Suppose that L is a line in space passing through a point $P_0(x_0, y_0, z_0)$ parallel to a vector $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$. Then L is the set of all points $P(x, y, z)$ for which $\overrightarrow{P_0P}$ is parallel to \mathbf{v} (Figure 11.37). Thus, $\overrightarrow{P_0P} = t\mathbf{v}$ for some scalar parameter t . The value of t depends on the location of the point P along the line, and the domain of t is $(-\infty, \infty)$. The expanded form of the equation $\overrightarrow{P_0P} = t\mathbf{v}$ is

$$(x - x_0)\mathbf{i} + (y - y_0)\mathbf{j} + (z - z_0)\mathbf{k} = t(v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}),$$

which can be rewritten as

$$x\mathbf{i} + y\mathbf{j} + z\mathbf{k} = x_0\mathbf{i} + y_0\mathbf{j} + z_0\mathbf{k} + t(v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}). \quad (1)$$

If $\mathbf{r}(t)$ is the position vector of a point $P(x, y, z)$ on the line and \mathbf{r}_0 is the position vector of the point $P_0(x_0, y_0, z_0)$, then Equation (1) gives the following vector form for the equation of a line in space.

Vector Equation for a Line

A vector equation for the line L through $P_0(x_0, y_0, z_0)$ parallel to a nonzero vector \mathbf{v} is

$$\mathbf{r}(t) = \mathbf{r}_0 + t\mathbf{v}, \quad -\infty < t < \infty, \quad (2)$$

where \mathbf{r} is the position vector of a point $P(x, y, z)$ on L and \mathbf{r}_0 is the position vector of $P_0(x_0, y_0, z_0)$.

Equating the corresponding components of the two sides of Equation (1) gives three scalar equations involving the parameter t :

$$x = x_0 + tv_1, \quad y = y_0 + tv_2, \quad z = z_0 + tv_3.$$

These equations give us the standard parametrization of the line for the parameter interval $-\infty < t < \infty$.

Parametric Equations for a Line

The standard parametrization of the line through $P_0(x_0, y_0, z_0)$ parallel to a nonzero vector $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ is

$$x = x_0 + tv_1, \quad y = y_0 + tv_2, \quad z = z_0 + tv_3, \quad -\infty < t < \infty. \quad (3)$$

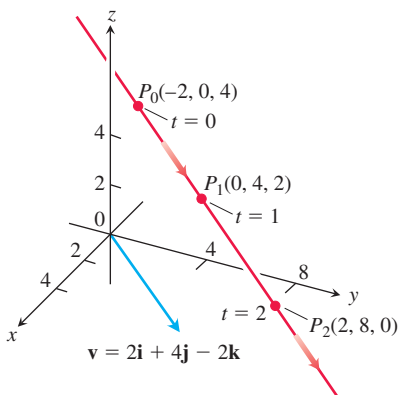

FIGURE 11.38 Selected points and parameter values on the line in Example 1. The arrows show the direction of increasing t .

EXAMPLE 1 Find parametric equations for the line through $(-2, 0, 4)$ parallel to $\mathbf{v} = 2\mathbf{i} + 4\mathbf{j} - 2\mathbf{k}$ (Figure 11.38).

Solution With $P_0(x_0, y_0, z_0)$ equal to $(-2, 0, 4)$ and $v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ equal to $2\mathbf{i} + 4\mathbf{j} - 2\mathbf{k}$, Equations (3) become

$$x = -2 + 2t, \quad y = 4t, \quad z = 4 - 2t. \quad \blacksquare$$

EXAMPLE 2 Find parametric equations for the line through $P(-3, 2, -3)$ and $Q(1, -1, 4)$.

Solution The vector

$$\overrightarrow{PQ} = (1 - (-3))\mathbf{i} + (-1 - 2)\mathbf{j} + (4 - (-3))\mathbf{k} = 4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$$

is parallel to the line, and Equations (3) with $(x_0, y_0, z_0) = (-3, 2, -3)$ give

$$x = -3 + 4t, \quad y = 2 - 3t, \quad z = -3 + 7t.$$

We could have chosen $Q(1, -1, 4)$ as the “base point” and written

$$x = 1 + 4t, \quad y = -1 - 3t, \quad z = 4 + 7t.$$

These equations serve as well as the first; they simply place you at a different point on the line for a given value of t . ■

Notice that parametrizations are not unique. Not only can the “base point” change, but so can the parameter. The equations $x = -3 + 4t^3$, $y = 2 - 3t^3$, and $z = -3 + 7t^3$ also parametrize the line in Example 2.

To parametrize a line segment joining two points, we first parametrize the line through the points. We then find the t -values for the endpoints and restrict t to lie in the closed interval bounded by these values. The line equations, together with this added restriction, parametrize the segment.

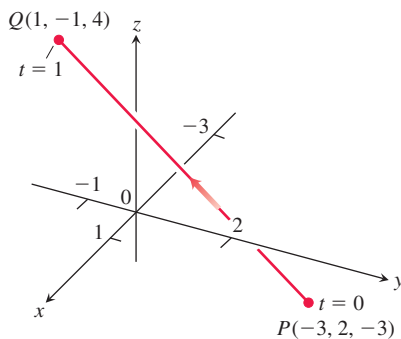

FIGURE 11.39 Example 3 derives a parametrization of line segment PQ . The arrow shows the direction of increasing t .

EXAMPLE 3 Parametrize the line segment joining the points $P(-3, 2, -3)$ and $Q(1, -1, 4)$ (Figure 11.39).

Solution We begin with equations for the line through P and Q , taking them, in this case, from Example 2:

$$x = -3 + 4t, \quad y = 2 - 3t, \quad z = -3 + 7t.$$

We observe that the point

$$(x, y, z) = (-3 + 4t, 2 - 3t, -3 + 7t)$$

on the line passes through $P(-3, 2, -3)$ at $t = 0$ and $Q(1, -1, 4)$ at $t = 1$. We add the restriction $0 \leq t \leq 1$ to parametrize the segment:

$$x = -3 + 4t, \quad y = 2 - 3t, \quad z = -3 + 7t, \quad 0 \leq t \leq 1. \quad \color{red}{\blacksquare}$$

The vector form (Equation (2)) for a line in space is more revealing if we think of a line as the path of a particle starting at position $P_0(x_0, y_0, z_0)$ and moving in the direction of vector \mathbf{v} . Rewriting Equation (2), we have

$$\begin{aligned} \mathbf{r}(t) &= \mathbf{r}_0 + t\mathbf{v} \\ &= \mathbf{r}_0 + t \underbrace{|\mathbf{v}|}_{\text{Speed}} \underbrace{\frac{\mathbf{v}}{|\mathbf{v}|}}_{\text{Direction}}. \end{aligned} \quad (4)$$

In other words, the position of the particle at time t is its initial position plus its distance moved (speed \times time) in the direction $\mathbf{v}/|\mathbf{v}|$ of its straight-line motion.

EXAMPLE 4 A helicopter is to fly directly from a helipad at the origin in the direction of the point $(1, 1, 1)$ at a speed of 60 m/s. What is the position of the helicopter after 10 s?

Solution We place the origin at the starting position (helipad) of the helicopter. Then the unit vector

$$\mathbf{u} = \frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k}$$

gives the flight direction of the helicopter. From Equation (4), the position of the helicopter at any time t is

$$\begin{aligned}\mathbf{r}(t) &= \mathbf{r}_0 + t(\text{speed}) \mathbf{u} \\ &= \mathbf{0} + t(60)\left(\frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k}\right) \\ &= 20\sqrt{3}t(\mathbf{i} + \mathbf{j} + \mathbf{k}).\end{aligned}$$

When $t = 10$ s,

$$\begin{aligned}\mathbf{r}(10) &= 200\sqrt{3}(\mathbf{i} + \mathbf{j} + \mathbf{k}) \\ &= \langle 200\sqrt{3}, 200\sqrt{3}, 200\sqrt{3} \rangle.\end{aligned}$$

After 10 s of flight from the origin toward $(1, 1, 1)$, the helicopter is located at the point $(200\sqrt{3}, 200\sqrt{3}, 200\sqrt{3})$ in space. It has traveled a distance of $(60 \text{ m/s})(10 \text{ s}) = 600$ m, which is the length of the vector $\mathbf{r}(10)$. ■

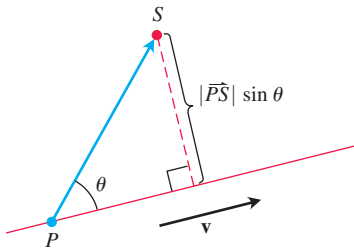

FIGURE 11.40 The distance from S to the line through P parallel to \mathbf{v} is $|\overline{PS}|\sin\theta$, where θ is the angle between \overline{PS} and \mathbf{v} .

The Distance from a Point to a Line in Space

To find the distance from a point S to a line that passes through a point P parallel to a vector \mathbf{v} , we find the absolute value of the scalar component of \overline{PS} in the direction of a vector normal to the line (Figure 11.40). In the notation of the figure, the absolute value of the scalar component is $|\overline{PS}|\sin\theta$, which is $\frac{|\overline{PS}|\|\mathbf{v}\|\sin\theta}{\|\mathbf{v}\|} = \frac{|\overline{PS} \times \mathbf{v}|}{\|\mathbf{v}\|}$.

Distance from a Point S to a Line Through P Parallel to \mathbf{v}

$$d = \frac{|\overline{PS} \times \mathbf{v}|}{\|\mathbf{v}\|} \quad (5)$$

EXAMPLE 5 Find the distance from the point $S(1, 1, 5)$ to the line

$$L: \quad x = 1 + t, \quad y = 3 - t, \quad z = 2t.$$

Solution We see from the equations for L that L passes through $P(1, 3, 0)$ parallel to $\mathbf{v} = \mathbf{i} - \mathbf{j} + 2\mathbf{k}$. With

$$\overline{PS} = (1 - 1)\mathbf{i} + (1 - 3)\mathbf{j} + (5 - 0)\mathbf{k} = -2\mathbf{j} + 5\mathbf{k}$$

and

$$\overline{PS} \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & -2 & 5 \\ 1 & -1 & 2 \end{vmatrix} = \mathbf{i} + 5\mathbf{j} + 2\mathbf{k},$$

Equation (5) gives

$$d = \frac{|\overline{PS} \times \mathbf{v}|}{\|\mathbf{v}\|} = \frac{\sqrt{1 + 25 + 4}}{\sqrt{1 + 1 + 4}} = \frac{\sqrt{30}}{\sqrt{6}} = \sqrt{5}. \quad \blacksquare$$

An Equation for a Plane in Space

A plane in space is determined by knowing a point on the plane and its “tilt” or orientation. This “tilt” is defined by specifying a vector that is perpendicular, or normal, to the plane.

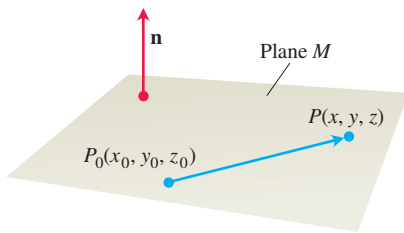

FIGURE 11.41 The standard equation for a plane in space is defined in terms of a vector normal to the plane: A point P lies in the plane through P_0 normal to \mathbf{n} if and only if $\mathbf{n} \cdot \overline{P_0P} = 0$.

Suppose that plane M passes through a point $P_0(x_0, y_0, z_0)$ and is normal to the nonzero vector $\mathbf{n} = A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$. A vector from P_0 to any point P on the plane is orthogonal to \mathbf{n} . Then M is the set of all points $P(x, y, z)$ for which $\overline{P_0P}$ is orthogonal to \mathbf{n} (Figure 11.41). Thus, the dot product $\mathbf{n} \cdot \overline{P_0P} = 0$. This equation is equivalent to

$$(A\mathbf{i} + B\mathbf{j} + C\mathbf{k}) \cdot [(x - x_0)\mathbf{i} + (y - y_0)\mathbf{j} + (z - z_0)\mathbf{k}] = 0,$$

so the plane M consists of the points (x, y, z) satisfying

$$A(x - x_0) + B(y - y_0) + C(z - z_0) = 0.$$

Equation for a Plane

The plane through $P_0(x_0, y_0, z_0)$ normal to a nonzero vector $\mathbf{n} = A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$ has

Vector equation: $\mathbf{n} \cdot \overline{P_0P} = 0$

Component equation: $A(x - x_0) + B(y - y_0) + C(z - z_0) = 0$

Component equation simplified: $Ax + By + Cz = D$, where

$$D = Ax_0 + By_0 + Cz_0$$

EXAMPLE 6 Find an equation for the plane through $P_0(-3, 0, 7)$ perpendicular to $\mathbf{n} = 5\mathbf{i} + 2\mathbf{j} - \mathbf{k}$.

Solution The component equation is

$$5(x - (-3)) + 2(y - 0) + (-1)(z - 7) = 0.$$

Simplifying, we obtain

$$5x + 15 + 2y - z + 7 = 0$$

$$5x + 2y - z = -22. \quad \blacksquare$$

Notice in Example 6 how the components of $\mathbf{n} = 5\mathbf{i} + 2\mathbf{j} - \mathbf{k}$ became the coefficients of x , y , and z in the equation $5x + 2y - z = -22$. The vector $\mathbf{n} = A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$ is normal to the plane $Ax + By + Cz = D$.

EXAMPLE 7 Find an equation for the plane through $A(0, 0, 1)$, $B(2, 0, 0)$, and $C(0, 3, 0)$.

Solution We find a vector normal to the plane and use it with one of the points (it does not matter which) to write an equation for the plane.

The cross product

$$\overline{AB} \times \overline{AC} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 0 & -1 \\ 0 & 3 & -1 \end{vmatrix} = 3\mathbf{i} + 2\mathbf{j} + 6\mathbf{k}$$

is normal to the plane. We substitute the components of this vector and the coordinates of $A(0, 0, 1)$ into the component form of the equation to obtain

$$3(x - 0) + 2(y - 0) + 6(z - 1) = 0$$

$$3x + 2y + 6z = 6. \quad \blacksquare$$

Lines of Intersection

Just as lines are parallel if and only if they have the same direction, two planes are **parallel** if and only if their normals are parallel, or $\mathbf{n}_1 = k\mathbf{n}_2$ for some scalar k . Two planes that are not parallel intersect in a line.

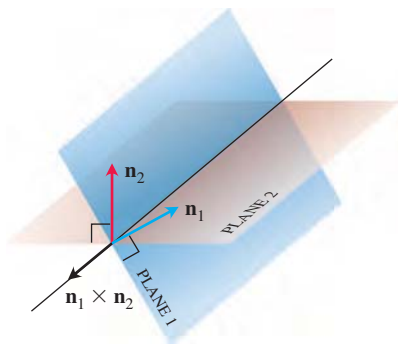

FIGURE 11.42 How the line of intersection of two planes is related to the planes' normal vectors (Example 8).

EXAMPLE 8 Find a vector parallel to the line of intersection of the planes $3x - 6y - 2z = 15$ and $2x + y - 2z = 5$.

Solution The line of intersection of two planes is perpendicular to both planes' normal vectors \mathbf{n}_1 and \mathbf{n}_2 (Figure 11.42) and therefore parallel to $\mathbf{n}_1 \times \mathbf{n}_2$. Turning this around, $\mathbf{n}_1 \times \mathbf{n}_2$ is a vector parallel to the planes' line of intersection. In our case,

$$\mathbf{n}_1 \times \mathbf{n}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & -6 & -2 \\ 2 & 1 & -2 \end{vmatrix} = 14\mathbf{i} + 2\mathbf{j} + 15\mathbf{k}.$$

Any nonzero scalar multiple of $\mathbf{n}_1 \times \mathbf{n}_2$ will do as well. ■

EXAMPLE 9 Find parametric equations for the line in which the planes $3x - 6y - 2z = 15$ and $2x + y - 2z = 5$ intersect.

Solution We find a vector parallel to the line and a point on the line and use Equations (3).

Example 8 identifies $\mathbf{v} = 14\mathbf{i} + 2\mathbf{j} + 15\mathbf{k}$ as a vector parallel to the line. To find a point on the line, we can take any point common to the two planes. Substituting $z = 0$ in the plane equations and solving for x and y simultaneously identifies one of these points as $(3, -1, 0)$. The line is

$$x = 3 + 14t, \quad y = -1 + 2t, \quad z = 15t.$$

The choice $z = 0$ is arbitrary, and we could have chosen $z = 1$ or $z = -1$ just as well. Or we could have let $x = 0$ and solved for y and z . The different choices would simply give different parametrizations of the same line. ■

Sometimes we want to know where a line and a plane intersect. For example, if we are looking at a flat plate and a line segment passes through it, we may be interested in knowing what portion of the line segment is hidden from our view by the plate. This application is used in computer graphics (Exercise 78).

EXAMPLE 10 Find the point where the line

$$x = \frac{8}{3} + 2t, \quad y = -2t, \quad z = 1 + t$$

intersects the plane $3x + 2y + 6z = 6$.

Solution The point

$$\left(\frac{8}{3} + 2t, -2t, 1 + t \right)$$

lies in the plane if its coordinates satisfy the equation of the plane—that is, if

$$\begin{aligned} 3\left(\frac{8}{3} + 2t\right) + 2(-2t) + 6(1 + t) &= 6 \\ 8 + 6t - 4t + 6 + 6t &= 6 \\ 8t &= -8 \\ t &= -1. \end{aligned}$$

The point of intersection is

$$(x, y, z)|_{t=-1} = \left(\frac{8}{3} - 2, 2, 1 - 1 \right) = \left(\frac{2}{3}, 2, 0 \right). \quad \blacksquare$$

The Distance from a Point to a Plane

If P is a point on a plane with a normal \mathbf{n} , then the distance from any point S to the plane is the length of the vector projection of \overline{PS} onto \mathbf{n} , as given in the following formula.

Distance from a Point S to a Plane Through a Point P with a Normal \mathbf{n}

$$d = \left| \overline{PS} \cdot \frac{\mathbf{n}}{|\mathbf{n}|} \right| \quad (6)$$

EXAMPLE 11 Find the distance from $S(1, 1, 3)$ to the plane $3x + 2y + 6z = 6$.

Solution We find a point P in the plane and calculate the length of the vector projection of \overline{PS} onto a vector \mathbf{n} normal to the plane (Figure 11.43). The coefficients in the equation $3x + 2y + 6z = 6$ give

$$\mathbf{n} = 3\mathbf{i} + 2\mathbf{j} + 6\mathbf{k}.$$

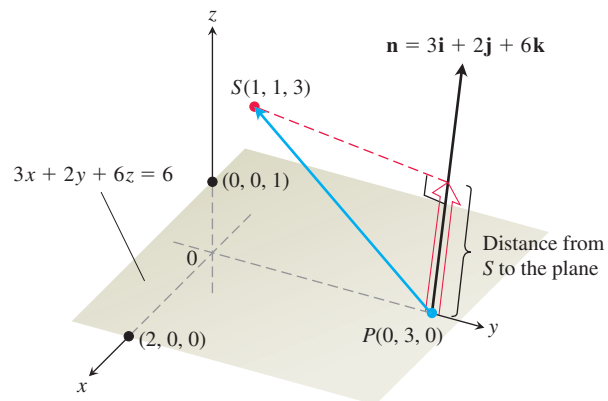

FIGURE 11.43 The distance from S to the plane is the length of the vector projection of \overline{PS} onto \mathbf{n} (Example 11).

The points on the plane easiest to find from the plane's equation are the intercepts. If we take P to be the y -intercept $(0, 3, 0)$, then

$$\overline{PS} = (1 - 0)\mathbf{i} + (1 - 3)\mathbf{j} + (3 - 0)\mathbf{k} = \mathbf{i} - 2\mathbf{j} + 3\mathbf{k},$$

$$|\mathbf{n}| = \sqrt{(3)^2 + (2)^2 + (6)^2} = \sqrt{49} = 7.$$

Therefore, the distance from S to the plane is

$$\begin{aligned} d &= \left| \overline{PS} \cdot \frac{\mathbf{n}}{|\mathbf{n}|} \right| && \text{Length of } \text{proj}_{\mathbf{n}} \overline{PS} \\ &= \left| (\mathbf{i} - 2\mathbf{j} + 3\mathbf{k}) \cdot \left(\frac{3}{7}\mathbf{i} + \frac{2}{7}\mathbf{j} + \frac{6}{7}\mathbf{k} \right) \right| \\ &= \left| \frac{3}{7} - \frac{4}{7} + \frac{18}{7} \right| = \frac{17}{7}. \end{aligned}$$

Angles Between Planes

The angle between two intersecting planes is defined to be the acute angle between their normal vectors (Figure 11.44).

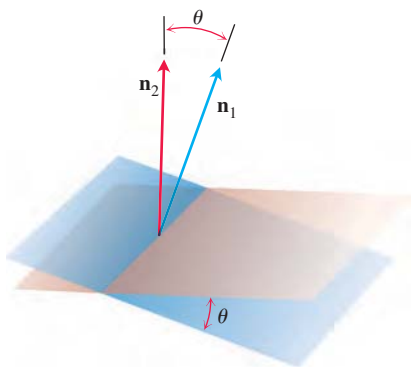

FIGURE 11.44 The angle between two planes is obtained from the angle between their normals.

EXAMPLE 11 Find the angle between the planes $3x - 6y - 2z = 15$ and $2x + y - 2z = 5$.

Solution The vectors

$$\mathbf{n}_1 = 3\mathbf{i} - 6\mathbf{j} - 2\mathbf{k}, \quad \mathbf{n}_2 = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$$

are normals to the planes. The angle between them is

$$\begin{aligned} \theta &= \arccos \left(\frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{\|\mathbf{n}_1\| \|\mathbf{n}_2\|} \right) \\ &= \arccos \left(\frac{4}{21} \right) \approx 1.38 \text{ radians.} \quad \text{About 79 degrees} \quad \blacksquare \end{aligned}$$

EXERCISES 11.5

Lines and Line Segments

Find parametric equations for the lines in Exercises 1–12.

- The line through the point $P(3, -4, -1)$ parallel to the vector $\mathbf{i} + \mathbf{j} + \mathbf{k}$
- The line through $P(1, 2, -1)$ and $Q(-1, 0, 1)$
- The line through $P(-2, 0, 3)$ and $Q(3, 5, -2)$
- The line through $P(1, 2, 0)$ and $Q(1, 1, -1)$
- The line through the origin parallel to the vector $2\mathbf{j} + \mathbf{k}$
- The line through the point $(3, -2, 1)$ parallel to the line $x = 1 + 2t, y = 2 - t, z = 3t$
- The line through $(1, 1, 1)$ parallel to the z -axis
- The line through $(2, 4, 5)$ perpendicular to the plane $3x + 7y - 5z = 21$
- The line through $(0, -7, 0)$ perpendicular to the plane $x + 2y + 2z = 13$
- The line through $(2, 3, 0)$ perpendicular to the vectors $\mathbf{u} = \mathbf{i} + 2\mathbf{j} + 3\mathbf{k}$ and $\mathbf{v} = 3\mathbf{i} + 4\mathbf{j} + 5\mathbf{k}$
- The x -axis
- The z -axis

Find parametrizations for the line segments joining the points in Exercises 13–20. Draw coordinate axes and sketch each segment, indicating the direction of increasing t for your parametrization.

- | | |
|------------------------------|-----------------------------|

Planes

Find equations for the planes in Exercises 21–26.

- The plane through $P_0(0, 2, -1)$ normal to $\mathbf{n} = 3\mathbf{i} - 2\mathbf{j} - \mathbf{k}$
- The plane through $(1, -1, 3)$ parallel to the plane $3x + y + z = 7$
- The plane through $(1, 1, -1), (2, 0, 2),$ and $(0, -2, 1)$
- The plane through $(2, 4, 5), (1, 5, 7),$ and $(-1, 6, 8)$

- The plane through $P_0(2, 4, 5)$ perpendicular to the line

$$x = 5 + t, \quad y = 1 + 3t, \quad z = 4t$$

- The plane through $A(1, -2, 1)$ perpendicular to the vector from the origin to A .
- Find the point of intersection of the lines $x = 2t + 1, y = 3t + 2, z = 4t + 3,$ and $x = s + 2, y = 2s + 4, z = -4s - 1,$ and then find the plane determined by these lines.
- Find the point of intersection of the lines $x = t, y = -t + 2, z = t + 1,$ and $x = 2s + 2, y = s + 3, z = 5s + 6,$ and then find the plane determined by these lines.

In Exercises 29 and 30, find the plane containing the intersecting lines.

- $L1: x = -1 + t, y = 2 + t, z = 1 - t; -\infty < t < \infty$
 $L2: x = 1 - 4s, y = 1 + 2s, z = 2 - 2s; -\infty < s < \infty$
- $L1: x = t, y = 3 - 3t, z = -2 - t; -\infty < t < \infty$
 $L2: x = 1 + s, y = 4 + s, z = -1 + s; -\infty < s < \infty$
- Find a plane through $P_0(2, 1, -1)$ and perpendicular to the line of intersection of the planes $2x + y - z = 3, x + 2y + z = 2.$
- Find a plane through the points $P_1(1, 2, 3),$ and $P_2(3, 2, 1)$ and perpendicular to the plane $4x - y + 2z = 7.$

Distances

In Exercises 33–38, find the distance from the point to the line.

- $(0, 0, 12); x = 4t, y = -2t, z = 2t$
- $(0, 0, 0); x = 5 + 3t, y = 5 + 4t, z = -3 - 5t$
- $(2, 1, 3); x = 2 + 2t, y = 1 + 6t, z = 3$
- $(2, 1, -1); x = 2t, y = 1 + 2t, z = 2t$
- $(3, -1, 4); x = 4 - t, y = 3 + 2t, z = -5 + 3t$
- $(-1, 4, 3); x = 10 + 4t, y = -3, z = 4t$

In Exercises 39–44, find the distance from the point to the plane.

- $(2, -3, 4), x + 2y + 2z = 13$
- $(0, 0, 0), 3x + 2y + 6z = 6$
- $(0, 1, 1), 4y + 3z = -12$

42. $(2, 2, 3)$, $2x + y + 2z = 4$
 43. $(0, -1, 0)$, $2x + y + 2z = 4$
 44. $(1, 0, -1)$, $-4x + y + z = 4$
 45. Find the distance from the plane $x + 2y + 6z = 1$ to the plane $x + 2y + 6z = 10$.
 46. Find the distance from the line $x = 2 + t$, $y = 1 + t$, $z = -(1/2) - (1/2)t$ to the plane $x + 2y + 6z = 10$.

Angles

In Exercises 47 and 48, find the angles between the planes.

47. $x + y = 1$, $2x + y - 2z = 2$
 48. $5x + y - z = 10$, $x - 2y + 3z = -1$

In Exercises 49 and 50, find the acute angles between the intersecting lines.

49. $x = t$, $y = 2t$, $z = -t$ and $x = 1 - t$, $y = 5 + t$, $z = 2t$
 50. $x = 2 + t$, $y = 4t + 2$, $z = 1 + t$ and $x = 3t - 2$, $y = -2$, $z = 2 - 2t$

In Exercises 51 and 52, find the acute angles between the lines and planes.

51. $x = 1 - t$, $y = 3t$, $z = 1 + t$; $2x - y + 3z = 6$
 52. $x = 2$, $y = 3 + 2t$, $z = 1 - 2t$; $x - y + z = 0$

T Use a calculator to find the acute angles between the planes in Exercises 53–56 to the nearest hundredth of a radian.

53. $2x + 2y + 2z = 3$, $2x - 2y - z = 5$
 54. $x + y + z = 1$, $z = 0$ (the xy -plane)
 55. $2x + 2y - z = 3$, $x + 2y + z = 2$
 56. $4y + 3z = -12$, $3x + 2y + 6z = 6$

Intersecting Lines and Planes

In Exercises 57–60, find the point in which the line meets the plane.

57. $x = 1 - t$, $y = 3t$, $z = 1 + t$; $2x - y + 3z = 6$
 58. $x = 2$, $y = 3 + 2t$, $z = -2 - 2t$; $6x + 3y - 4z = -12$
 59. $x = 1 + 2t$, $y = 1 + 5t$, $z = 3t$; $x + y + z = 2$
 60. $x = -1 + 3t$, $y = -2$, $z = 5t$; $2x - 3z = 7$

Find parametrizations for the lines in which the planes in Exercises 61–64 intersect.

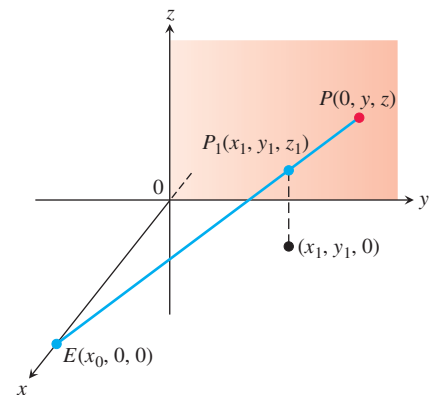

61. $x + y + z = 1$, $x + y = 2$
 62. $3x - 6y - 2z = 3$, $2x + y - 2z = 2$
 63. $x - 2y + 4z = 2$, $x + y - 2z = 5$
 64. $5x - 2y = 11$, $4y - 5z = -17$

Given two lines in space, either they are parallel, they intersect, or they are skew (lie in parallel planes). In Exercises 65 and 66, determine whether the lines, taken two at a time, are parallel, intersect, or are skew. If they intersect, find the point of intersection. Otherwise, find the distance between the two lines.

65. $L1: x = 3 + 2t$, $y = -1 + 4t$, $z = 2 - t$; $-\infty < t < \infty$
 $L2: x = 1 + 4s$, $y = 1 + 2s$, $z = -3 + 4s$; $-\infty < s < \infty$
 $L3: x = 3 + 2r$, $y = 2 + r$, $z = -2 + 2r$; $-\infty < r < \infty$
 66. $L1: x = 1 + 2t$, $y = -1 - t$, $z = 3t$; $-\infty < t < \infty$
 $L2: x = 2 - s$, $y = 3s$, $z = 1 + s$; $-\infty < s < \infty$
 $L3: x = 5 + 2r$, $y = 1 - r$, $z = 8 + 3r$; $-\infty < r < \infty$

Theory and Examples

67. Use Equations (3) to generate a parametrization of the line through $P(2, -4, 7)$ parallel to $\mathbf{v}_1 = 2\mathbf{i} - \mathbf{j} + 3\mathbf{k}$. Then generate another parametrization of the line using the point $P_2(-2, -2, 1)$ and the vector $\mathbf{v}_2 = -\mathbf{i} + (1/2)\mathbf{j} - (3/2)\mathbf{k}$.
 68. Use the component form to generate an equation for the plane through $P_1(4, 1, 5)$ normal to $\mathbf{n}_1 = \mathbf{i} - 2\mathbf{j} + \mathbf{k}$. Then generate another equation for the same plane using the point $P_2(3, -2, 0)$ and the normal vector $\mathbf{n}_2 = -\sqrt{2}\mathbf{i} + 2\sqrt{2}\mathbf{j} - \sqrt{2}\mathbf{k}$.
 69. Find the points in which the line $x = 1 + 2t$, $y = -1 - t$, $z = 3t$ meets the coordinate planes. Describe the reasoning behind your answer.
 70. Find equations for the line in the plane $z = 3$ that makes an angle of $\pi/6$ rad with \mathbf{i} and an angle of $\pi/3$ rad with \mathbf{j} . Describe the reasoning behind your answer.
 71. Is the line $x = 1 - 2t$, $y = 2 + 5t$, $z = -3t$ parallel to the plane $2x + y - z = 8$? Give reasons for your answer.
 72. How can you tell when two planes $A_1x + B_1y + C_1z = D_1$ and $A_2x + B_2y + C_2z = D_2$ are parallel? Perpendicular? Give reasons for your answer.
 73. Find two different planes whose intersection is the line $x = 1 + t$, $y = 2 - t$, $z = 3 + 2t$. Write equations for each plane in the form $Ax + By + Cz = D$.
 74. Find a plane through the origin that is perpendicular to the plane $M: 2x + 3y + z = 12$ in a right angle. How do you know that your plane is perpendicular to M ?
 75. The graph of $(x/a) + (y/b) + (z/c) = 1$ is a plane for any nonzero numbers a, b , and c . Which planes have an equation of this form?
 76. Suppose L_1 and L_2 are disjoint (nonintersecting) nonparallel lines. Is it possible for a nonzero vector to be perpendicular to both L_1 and L_2 ? Give reasons for your answer.
 77. **Perspective in computer graphics** In computer graphics and perspective drawing, we need to represent objects seen by the eye in space as images on a two-dimensional plane. Suppose that the eye is at $E(x_0, 0, 0)$ as shown here and that we want to represent a point $P_1(x_1, y_1, z_1)$ as a point on the yz -plane. We do this by projecting P_1 onto the plane with a ray from E . The point P_1 will be portrayed as the point $P(0, y, z)$. The problem for us as graphics designers is to find y and z given E and P_1 .
 a. Write a vector equation that holds between \overrightarrow{EP} and \overrightarrow{EP}_1 . Use the equation to express y and z in terms of x_0 , x_1 , y_1 , and z_1 .
 b. Test the formulas obtained for y and z in part (a) by investigating their behavior at $x_1 = 0$ and $x_1 = x_0$ and by seeing what happens as $x_0 \rightarrow \infty$. What do you find?

78. Hidden lines in computer graphics Here is another typical problem in computer graphics. Your eye is at $(4, 0, 0)$. You are looking at a triangular plate whose vertices are at $(1, 0, 1)$, $(1, 1, 0)$, and $(-2, 2, 2)$. The line segment from $(1, 0, 0)$ to $(0, 2, 2)$

passes through the plate. What portion of the line segment is hidden from your view by the plate? (This is an exercise in finding intersections of lines and planes.)

11.6 Cylinders and Quadric Surfaces

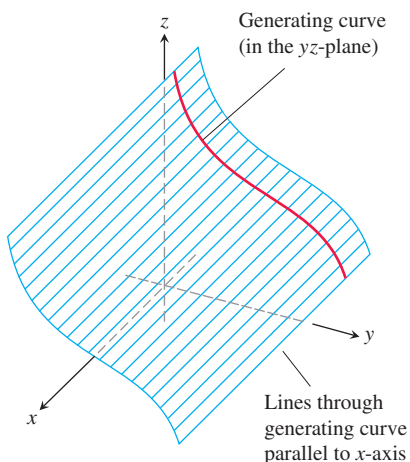

FIGURE 11.45 A cylinder and generating curve.

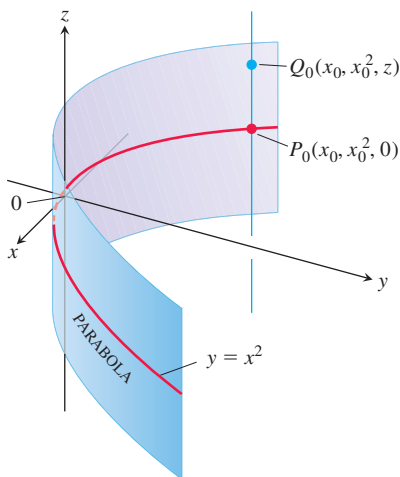

FIGURE 11.46 Every point of the cylinder in Example 1 has coordinates of the form (x_0, x_0^2, z) .

Up to now, we have studied two special types of surfaces: spheres and planes. In this section, we extend our inventory to include a variety of cylinders and quadric surfaces. Quadric surfaces are surfaces defined by second-degree equations in x , y , and z . Spheres are quadric surfaces, but there are others of equal interest that will be needed in Chapters 13–15.

Cylinders

Suppose we are given a plane in space that contains a curve, and in addition we are given a line that is not parallel to this plane. A **cylinder** is a surface that is generated by moving a line that is parallel to the given line along the curve, while keeping it parallel to the given line. The curve is called a **generating curve** for the cylinder (Figure 11.45 illustrates this when the given plane is the yz -plane and the given line is the x -axis). In solid geometry, where *cylinder* means *circular cylinder*, the generating curves are circles, but now we allow generating curves of any kind. The cylinder in our first example is generated by a parabola.

EXAMPLE 1 Find an equation for the cylinder made by the lines parallel to the z -axis that pass through the parabola $y = x^2$, $z = 0$ (Figure 11.46).

Solution The point $P_0(x_0, x_0^2, 0)$ lies on the parabola $y = x^2$ in the xy -plane. Then, for any value of z , the point $Q(x_0, x_0^2, z)$ lies on the cylinder because it lies on the line $x = x_0$, $y = x_0^2$ through P_0 parallel to the z -axis. Conversely, any point $Q(x_0, x_0^2, z)$ whose y -coordinate is the square of its x -coordinate lies on the cylinder because it lies on the line $x = x_0$, $y = x_0^2$ through P_0 parallel to the z -axis (Figure 11.46).

Regardless of the value of z , therefore, the points on the surface are the points whose coordinates satisfy the equation $y = x^2$. This makes $y = x^2$ an equation for the cylinder. ■

As Example 1 suggests, any curve $f(x, y) = c$ in the xy -plane generates a cylinder parallel to the z -axis whose equation is also $f(x, y) = c$. For instance, the equation $x^2 + y^2 = 1$ corresponds to the circular cylinder made by the lines parallel to the z -axis that pass through the circle $x^2 + y^2 = 1$ in the xy -plane.

In a similar way, any curve $g(x, z) = c$ in the xz -plane generates a cylinder parallel to the y -axis whose space equation is also $g(x, z) = c$. Any curve $h(y, z) = c$ generates a cylinder parallel to the x -axis whose space equation is also $h(y, z) = c$. The axis of a cylinder need not be parallel to a coordinate axis, however.

Quadric Surfaces

A **quadric surface** is the graph in space of a second-degree equation in x , y , and z . We first focus on quadric surfaces given by the equation

$$Ax^2 + By^2 + Cz^2 + Dz = E,$$

where A , B , C , D , and E are constants. The basic quadric surfaces are **ellipsoids**, **paraboloids**, **elliptical cones**, and **hyperboloids**. Spheres are special cases of ellipsoids. We present a few examples illustrating how to sketch a quadric surface, and then we give a summary table of graphs of the basic types.

EXAMPLE 2 The ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

(Figure 11.47) cuts the coordinate axes at $(\pm a, 0, 0)$, $(0, \pm b, 0)$, and $(0, 0, \pm c)$. It lies within the rectangular box defined by the inequalities $|x| \leq a$, $|y| \leq b$, and $|z| \leq c$. The surface is symmetric with respect to each of the coordinate planes because each variable in the defining equation is squared.

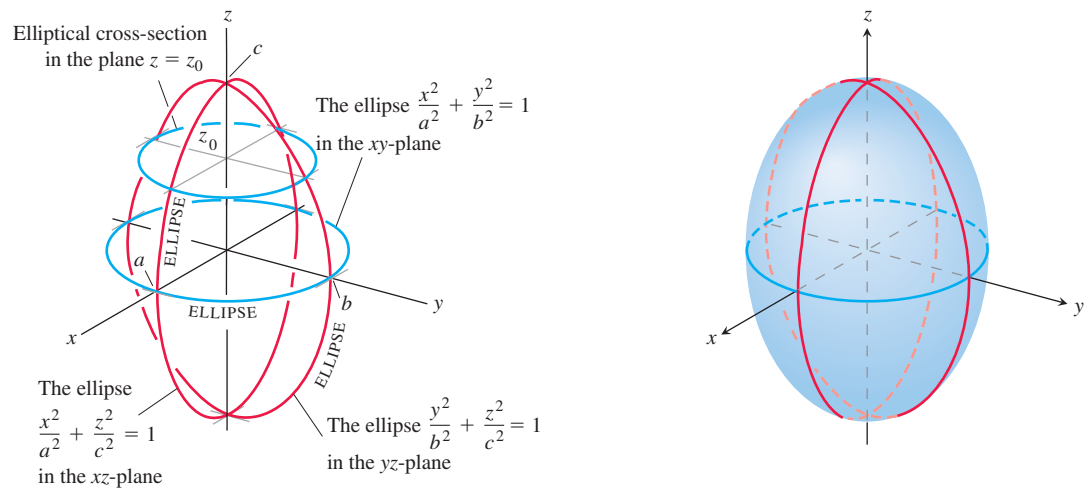

FIGURE 11.47 The ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ in Example 2 has elliptical cross-sections in each of the three coordinate planes.

The curves in which the three coordinate planes cut the surface are ellipses. For example,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad \text{when} \quad z = 0.$$

The curve cut from the surface by the plane $z = z_0$, $|z_0| < c$, is the ellipse

$$\frac{x^2}{a^2(1 - (z_0/c)^2)} + \frac{y^2}{b^2(1 - (z_0/c)^2)} = 1.$$

If any two of the semiaxes a , b , and c are equal, the surface is an **ellipsoid of revolution**. If all three are equal, the surface is a sphere. ■

EXAMPLE 3 The hyperbolic paraboloid

$$\frac{y^2}{b^2} - \frac{x^2}{a^2} = \frac{z}{c}, \quad c > 0$$

has symmetry with respect to the planes $x = 0$ and $y = 0$ (Figure 11.48). The cross-sections in these planes are

$$x = 0: \quad \text{the parabola } z = \frac{c}{b^2}y^2. \quad (1)$$

$$y = 0: \quad \text{the parabola } z = -\frac{c}{a^2}x^2. \quad (2)$$

In the plane $x = 0$, the parabola opens upward from the origin. The parabola in the plane $y = 0$ opens downward.

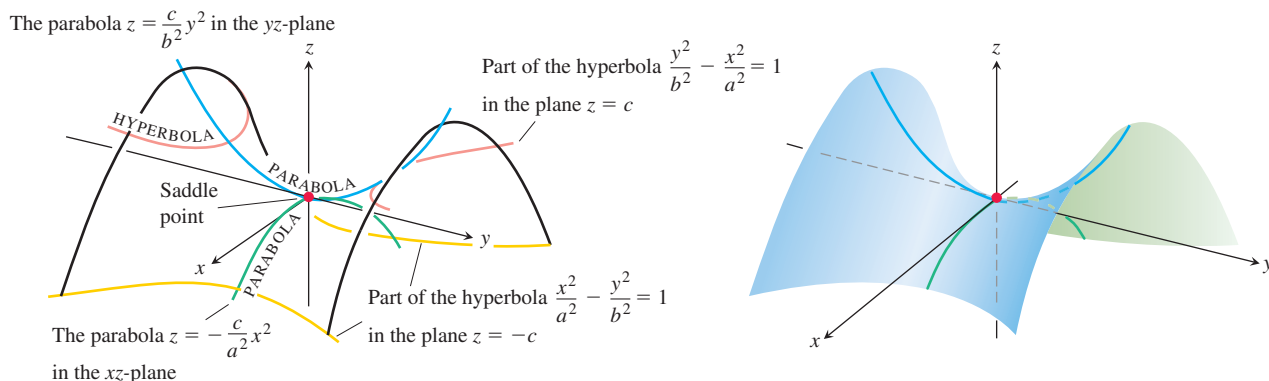

FIGURE 11.48 The hyperbolic paraboloid $(y^2/b^2) - (x^2/a^2) = z/c$, $c > 0$. The cross-sections in planes perpendicular to the z -axis above and below the xy -plane are hyperbolas. The cross-sections in planes perpendicular to the other axes are parabolas.

If we cut the surface by a plane $z = z_0 > 0$, the cross-section is a hyperbola,

$$\frac{y^2}{b^2} - \frac{x^2}{a^2} = \frac{z_0}{c},$$

with its focal axis parallel to the y -axis and its vertices on the parabola in Equation (1). If z_0 is negative, the focal axis is parallel to the x -axis and the vertices lie on the parabola in Equation (2).

Near the origin, the surface is shaped like a saddle or mountain pass. To a person traveling along the surface in the yz -plane the origin looks like a minimum. To a person traveling the xz -plane the origin looks like a maximum. Such a point is called a **saddle point** of a surface. We will say more about saddle points in Section 13.7. ■

Table 11.1 shows graphs of the six basic types of quadric surfaces. Each surface shown is symmetric with respect to the z -axis, but other coordinate axes can serve as well (with appropriate changes to the equation).

General Quadric Surfaces

The quadric surfaces we have considered have symmetries relative to the x -, y -, or z -axes. The general equation of second degree in three variables x , y , z is

$$Ax^2 + By^2 + Cz^2 + Dxy + Exz + Fyz + Gz + Hy + Iz + J = 0,$$

where $A, B, C, D, E, F, G, H, I$, and J are constants. This equation leads to surfaces similar to those in Table 11.1, but in general these surfaces might be translated and rotated relative to the x -, y -, and z -axes. Terms of the type Gx , Hy , or Iz in the above formula lead to translations, which can be seen by a process of completing the squares.

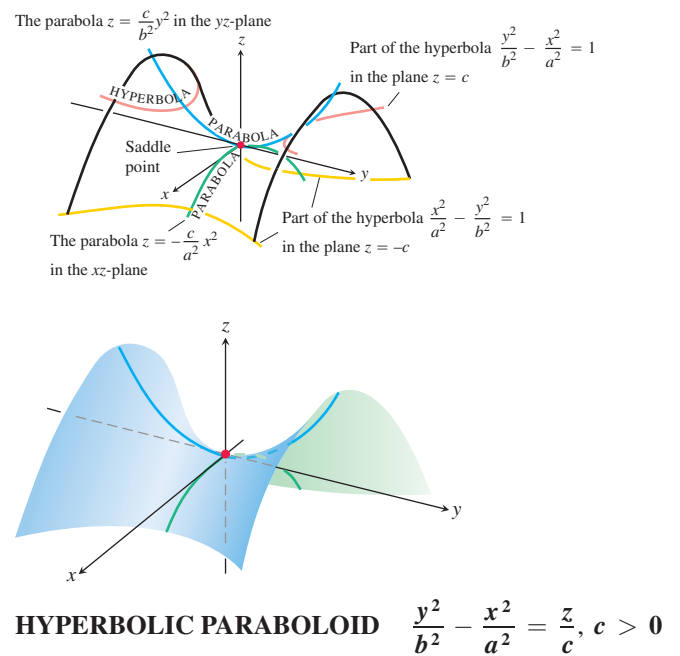

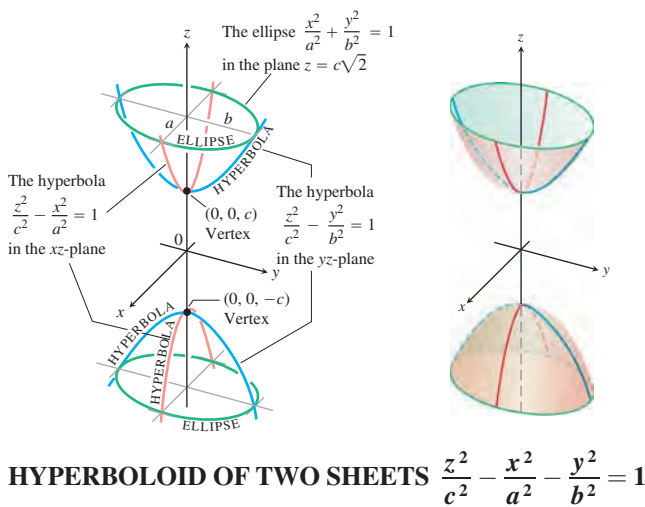

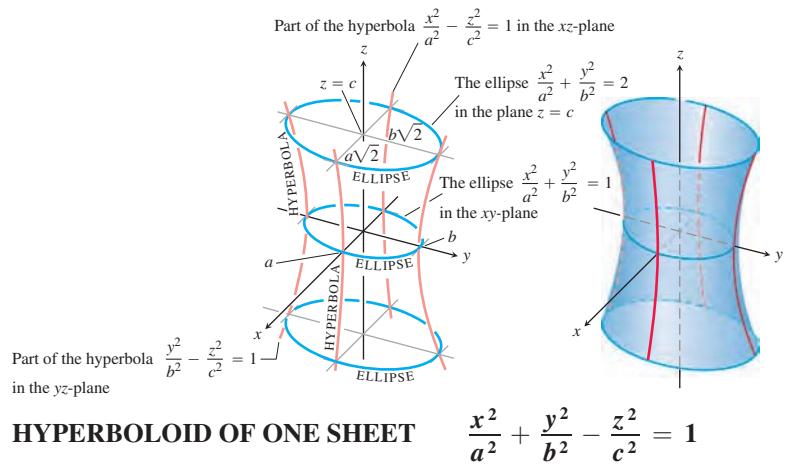

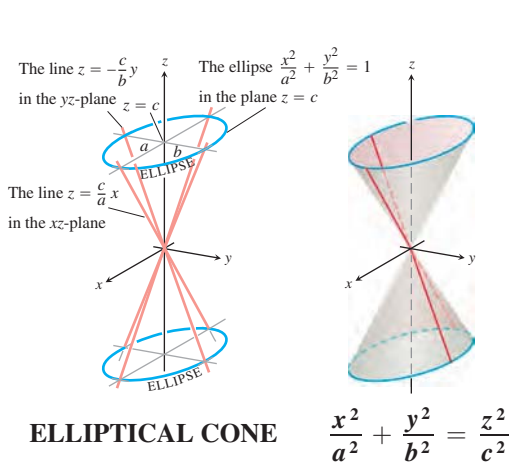

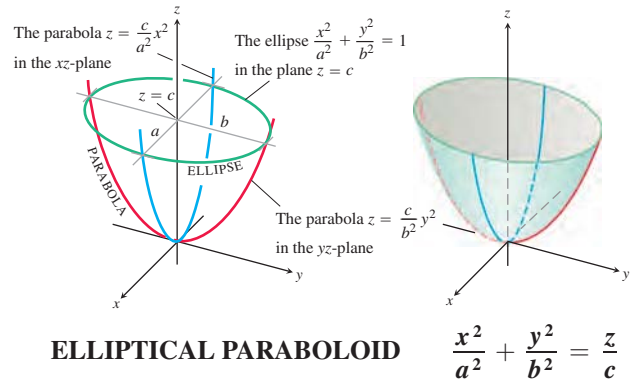

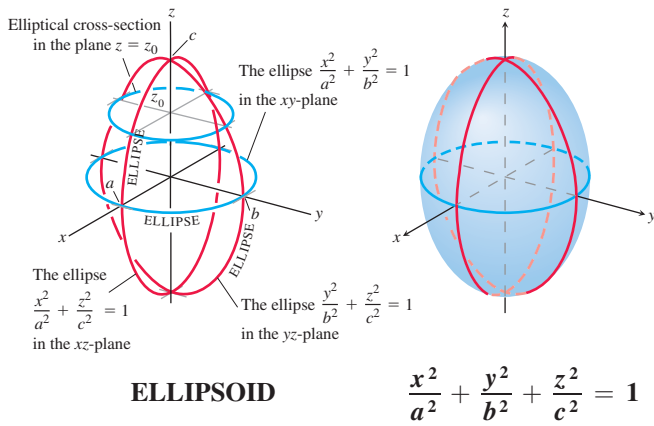

EXAMPLE 4 Identify the surface given by the equation

$$x^2 + y^2 + 4z^2 - 2x + 4y + 1 = 0.$$

Solution We complete the squares to simplify the expression:

$$\begin{aligned} x^2 + y^2 + 4z^2 - 2x + 4y + 1 &= (x - 1)^2 - 1 + (y + 2)^2 - 4 + 4z^2 + 1 \\ &= (x - 1)^2 + (y + 2)^2 + 4z^2 - 4. \end{aligned}$$

TABLE 11.1 Graphs of Quadric Surfaces

We can rewrite the original equation as

$$\frac{(x-1)^2}{4} + \frac{(y+2)^2}{4} + \frac{z^2}{1} = 1.$$

This is the equation of an ellipsoid whose three semiaxes have lengths 2, 2, and 1 and which is centered at the point $(1, -2, 0)$, as shown in Figure 11.49. ■

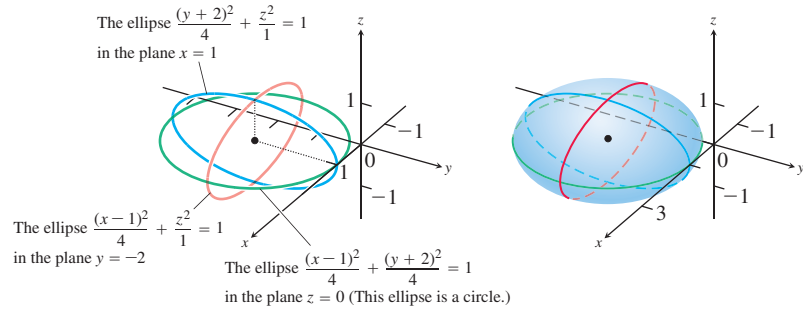

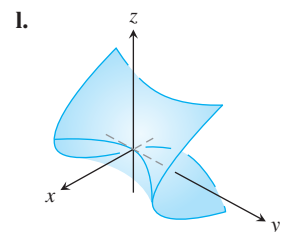

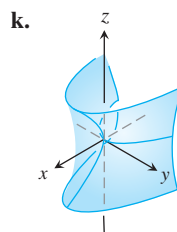

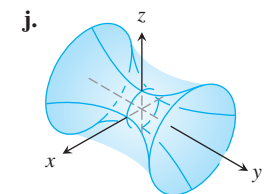

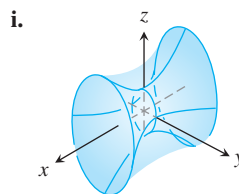

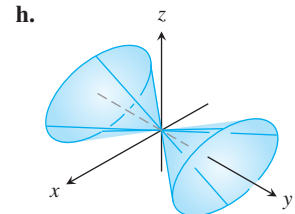

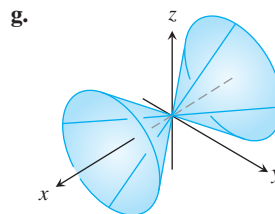

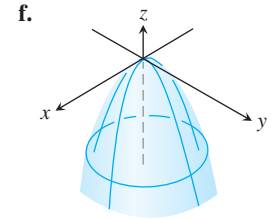

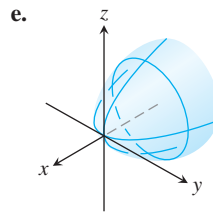

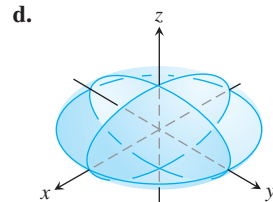

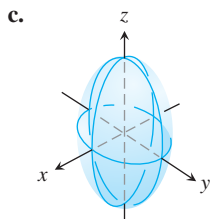

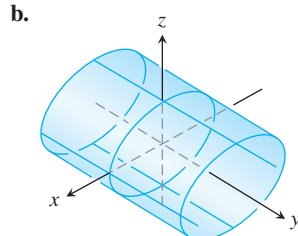

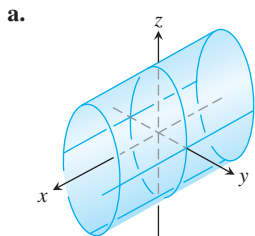

FIGURE 11.49 An ellipsoid centered at the point $(1, -2, 0)$.

EXERCISES 11.6

Matching Equations with Surfaces

In Exercises 1–12, match the equation with the surface it defines. Also, identify each surface by type (paraboloid, ellipsoid, etc.). The surfaces are labeled (a)–(l).

1. $x^2 + y^2 + 4z^2 = 10$
2. $z^2 + 4y^2 - 4x^2 = 4$
3. $9y^2 + z^2 = 16$
4. $y^2 + z^2 = x^2$
5. $x = y^2 - z^2$
6. $x = -y^2 - z^2$
7. $x^2 + 2z^2 = 8$
8. $z^2 + x^2 - y^2 = 1$
9. $x = z^2 - y^2$
10. $z = -4x^2 - y^2$
11. $x^2 + 4z^2 = y^2$
12. $9x^2 + 4y^2 + 2z^2 = 36$

Drawing

Sketch the surfaces in Exercises 13–44.

CYLINDERS

13. $x^2 + y^2 = 4$ 14. $z = y^2 - 1$
 15. $x^2 + 4z^2 = 16$ 16. $4x^2 + y^2 = 36$

ELLIPSOIDS

17. $9x^2 + y^2 + z^2 = 9$ 18. $4x^2 + 4y^2 + z^2 = 16$
 19. $4x^2 + 9y^2 + 4z^2 = 36$ 20. $9x^2 + 4y^2 + 36z^2 = 36$

PARABOLOIDS AND CONES

21. $z = x^2 + 4y^2$ 22. $z = 8 - x^2 - y^2$
 23. $x = 4 - 4y^2 - z^2$ 24. $y = 1 - x^2 - z^2$
 25. $x^2 + y^2 = z^2$ 26. $4x^2 + 9z^2 = 9y^2$

HYPERBOLOIDS

27. $x^2 + y^2 - z^2 = 1$ 28. $y^2 + z^2 - x^2 = 1$
 29. $z^2 - x^2 - y^2 = 1$ 30. $(y^2/4) - (x^2/4) - z^2 = 1$

HYPERBOLIC PARABOLOIDS

31. $y^2 - x^2 = z$ 32. $x^2 - y^2 = z$

ASSORTED

33. $z = 1 + y^2 - x^2$ 34. $4x^2 + 4y^2 = z^2$
 35. $y = -(x^2 + z^2)$ 36. $16x^2 + 4y^2 = 1$
 37. $x^2 + y^2 - z^2 = 4$ 38. $x^2 + z^2 = y$
 39. $x^2 + z^2 = 1$ 40. $16y^2 + 9z^2 = 4x^2$
 41. $z = -(x^2 + y^2)$ 42. $y^2 - x^2 - z^2 = 1$
 43. $4y^2 + z^2 - 4x^2 = 4$ 44. $x^2 + y^2 = z$

Theory and Examples

45. a. Express the area A of the cross-section cut from the ellipsoid

$$x^2 + \frac{y^2}{4} + \frac{z^2}{9} = 1$$

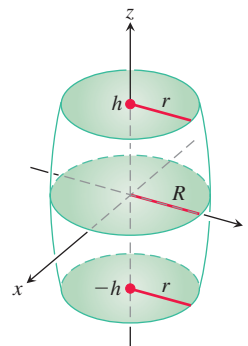

by the plane $z = c$ as a function of c . (The area of an ellipse with semiaxes a and b is πab .)

- b. Use slices perpendicular to the z -axis to find the volume of the ellipsoid in part (a).
 c. Now find the volume of the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Does your formula give the volume of a sphere of radius a if $a = b = c$?

46. The barrel shown here is shaped like an ellipsoid with equal pieces cut from the ends by planes perpendicular to the z -axis. The cross-sections perpendicular to the z -axis are circular. The barrel is $2h$ units high, its midsection radius is R , and its end radii are both r . Find a formula for the barrel's volume. Then check two things. First, suppose the sides of the barrel are straightened to turn the barrel into a cylinder of radius R and height $2h$. Does your formula give the cylinder's volume? Second, suppose $r = 0$ and $h = R$ so the barrel is a sphere. Does your formula give the sphere's volume?

47. Show that the volume of the segment cut from the paraboloid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = \frac{z}{c}$$

by the plane $z = h$ equals half the segment's base times its altitude.

48. a. Find the volume of the solid bounded by the hyperboloid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$$

and the planes $z = 0$ and $z = h$, $h > 0$.

- b. Express your answer in part (a) in terms of h and the areas A_0 and A_h of the regions cut by the hyperboloid from the planes $z = 0$ and $z = h$.
 c. Show that the volume in part (a) is also given by the formula

$$V = \frac{h}{6}(A_0 + 4A_m + A_h),$$

where A_m is the area of the region cut by the hyperboloid from the plane $z = h/2$.

Viewing Surfaces

- T Plot the surfaces in Exercises 49–52 over the indicated domains. If you can, rotate the surface into different viewing positions.

49. $z = y^2$, $-2 \leq x \leq 2$, $-0.5 \leq y \leq 2$
 50. $z = 1 - y^2$, $-2 \leq x \leq 2$, $-2 \leq y \leq 2$
 51. $z = x^2 + y^2$, $-3 \leq x \leq 3$, $-3 \leq y \leq 3$
 52. $z = x^2 + 2y^2$ over
 a. $-3 \leq x \leq 3$, $-3 \leq y \leq 3$
 b. $-1 \leq x \leq 1$, $-2 \leq y \leq 3$
 c. $-2 \leq x \leq 2$, $-2 \leq y \leq 2$
 d. $-2 \leq x \leq 2$, $-1 \leq y \leq 1$

COMPUTER EXPLORATIONS

Use a CAS to plot the surfaces in Exercises 53–58. Identify the type of quadric surface from your graph.

53. $\frac{x^2}{9} + \frac{y^2}{36} = 1 - \frac{z^2}{25}$ 54. $\frac{x^2}{9} - \frac{z^2}{9} = 1 - \frac{y^2}{16}$
 55. $5x^2 = z^2 - 3y^2$ 56. $\frac{y^2}{16} = 1 - \frac{x^2}{9} + z$
 57. $\frac{x^2}{9} - 1 = \frac{y^2}{16} + \frac{z^2}{2}$ 58. $y - \sqrt{4 - z^2} = 0$

CHAPTER 11 Questions to Guide Your Review

- When do directed line segments in the plane represent the same vector?
- How are vectors added and subtracted geometrically? How are they added and subtracted algebraically?
- How do you find a vector's magnitude and direction?
- If a vector is multiplied by a positive scalar, how is the result related to the original vector? What if the scalar is zero? Negative?
- Define the *dot product (scalar product)* of two vectors. Which algebraic laws are satisfied by dot products? Give examples. When is the dot product of two vectors equal to zero?
- What geometric interpretation does the dot product have? Give examples.
- What is the vector projection of a vector \mathbf{u} onto a vector \mathbf{v} ? Give an example of a useful application of a vector projection.
- Define the *cross product (vector product)* of two vectors. Which algebraic laws are satisfied by cross products, and which are not? Give examples. When is the cross product of two vectors equal to zero?
- What geometric or physical interpretations do cross products have? Give examples.
- What is the determinant formula for calculating the cross product of two vectors relative to the Cartesian \mathbf{i} , \mathbf{j} , \mathbf{k} -coordinate system? Use it in an example.
- How do you find equations for lines, line segments, and planes in space? Give examples. Can you express a line in space by a single equation? A plane?
- How do you find the distance from a point to a line in space? From a point to a plane? Give examples.
- What are box products? What significance do they have? How are they evaluated? Give an example.
- How do you find equations for spheres in space? Give examples.
- How do you find the intersection of two lines in space? A line and a plane? Two planes? Give examples.
- What is a cylinder? Give examples of equations that define cylinders in Cartesian coordinates.
- What are quadric surfaces? Give examples of different kinds of ellipsoids, paraboloids, cones, and hyperboloids (equations and sketches).

CHAPTER 11 Practice Exercises

Vector Calculations in Two Dimensions

In Exercises 1–4, let $\mathbf{u} = \langle -3, 4 \rangle$ and $\mathbf{v} = \langle 2, -5 \rangle$. Find (a) the component form of the vector and (b) its magnitude.

- $3\mathbf{u} - 4\mathbf{v}$
- $\mathbf{u} + \mathbf{v}$
- $-2\mathbf{u}$
- $5\mathbf{v}$

In Exercises 5–8, find the component form of the vector.

- The vector obtained by rotating $\langle 0, 1 \rangle$ through an angle of $2\pi/3$ radians
- The unit vector that makes an angle of $\pi/6$ radian with the positive x -axis
- The vector 2 units long in the direction $4\mathbf{i} - \mathbf{j}$
- The vector 5 units long in the direction opposite to the direction of $(3/5)\mathbf{i} + (4/5)\mathbf{j}$

Express the vectors in Exercises 9–12 in terms of their lengths and directions.

- $\sqrt{2}\mathbf{i} + \sqrt{2}\mathbf{j}$
- $-\mathbf{i} - \mathbf{j}$
- Velocity vector $\mathbf{v} = (-2 \sin t)\mathbf{i} + (2 \cos t)\mathbf{j}$ when $t = \pi/2$.
- Velocity vector $\mathbf{v} = (e^t \cos t - e^t \sin t)\mathbf{i} + (e^t \sin t + e^t \cos t)\mathbf{j}$ when $t = \ln 2$.

Vector Calculations in Three Dimensions

Express the vectors in Exercises 13 and 14 in terms of their lengths and directions.

- $2\mathbf{i} - 3\mathbf{j} + 6\mathbf{k}$
- $\mathbf{i} + 2\mathbf{j} - \mathbf{k}$
- Find a vector 2 units long in the direction of $\mathbf{v} = 4\mathbf{i} - \mathbf{j} + 4\mathbf{k}$.
- Find a vector 5 units long in the direction opposite to the direction of $\mathbf{v} = (3/5)\mathbf{i} + (4/5)\mathbf{k}$.

In Exercises 17 and 18, find $|\mathbf{v}|$, $|\mathbf{u}|$, $\mathbf{v} \cdot \mathbf{u}$, $\mathbf{u} \cdot \mathbf{v}$, $\mathbf{v} \times \mathbf{u}$, $\mathbf{u} \times \mathbf{v}$, $|\mathbf{v} \times \mathbf{u}|$, the angle between \mathbf{v} and \mathbf{u} , the scalar component of \mathbf{u} in the direction of \mathbf{v} , and the vector projection of \mathbf{u} onto \mathbf{v} .

- $\mathbf{v} = \mathbf{i} + \mathbf{j}$
 $\mathbf{u} = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$
- $\mathbf{v} = \mathbf{i} + \mathbf{j} + 2\mathbf{k}$
 $\mathbf{u} = -\mathbf{i} - \mathbf{k}$

In Exercises 19 and 20, find $\text{proj}_{\mathbf{v}} \mathbf{u}$.

- $\mathbf{v} = 2\mathbf{i} + \mathbf{j} - \mathbf{k}$
 $\mathbf{u} = \mathbf{i} + \mathbf{j} - 5\mathbf{k}$
- $\mathbf{u} = \mathbf{i} - 2\mathbf{j}$
 $\mathbf{v} = \mathbf{i} + \mathbf{j} + \mathbf{k}$

In Exercises 21 and 22, draw coordinate axes and then sketch \mathbf{u} , \mathbf{v} , and $\mathbf{u} \times \mathbf{v}$ as vectors at the origin.

- $\mathbf{u} = \mathbf{i}$, $\mathbf{v} = \mathbf{i} + \mathbf{j}$
- $\mathbf{u} = \mathbf{i} - \mathbf{j}$, $\mathbf{v} = \mathbf{i} + \mathbf{j}$
- If $|\mathbf{v}| = 2$, $|\mathbf{w}| = 3$, and the angle between \mathbf{v} and \mathbf{w} is $\pi/3$, find $|\mathbf{v} - 2\mathbf{w}|$.
- For what value or values of a will the vectors $\mathbf{u} = 2\mathbf{i} + 4\mathbf{j} - 5\mathbf{k}$ and $\mathbf{v} = -4\mathbf{i} - 8\mathbf{j} + a\mathbf{k}$ be parallel?

In Exercises 25 and 26, find (a) the area of the parallelogram determined by vectors \mathbf{u} and \mathbf{v} and (b) the volume of the parallelepiped determined by the vectors \mathbf{u} , \mathbf{v} , and \mathbf{w} .

25. $\mathbf{u} = \mathbf{i} + \mathbf{j} - \mathbf{k}$, $\mathbf{v} = 2\mathbf{i} + \mathbf{j} + \mathbf{k}$, $\mathbf{w} = -\mathbf{i} - 2\mathbf{j} + 3\mathbf{k}$

26. $\mathbf{u} = \mathbf{i} + \mathbf{j}$, $\mathbf{v} = \mathbf{j}$, $\mathbf{w} = \mathbf{i} + \mathbf{j} + \mathbf{k}$

Lines, Planes, and Distances

27. Suppose that \mathbf{n} is normal to a plane and that \mathbf{v} is parallel to the plane. Describe how you would find a vector \mathbf{n} that is both perpendicular to \mathbf{v} and parallel to the plane.

28. Find a vector in the plane parallel to the line $ax + by = c$.

In Exercises 29 and 30, find the distance from the point to the line.

29. $(2, 2, 0)$; $x = -t$, $y = t$, $z = -1 + t$

30. $(0, 4, 1)$; $x = 2 + t$, $y = 2 + t$, $z = t$

31. Parametrize the line that passes through the point $(1, 2, 3)$ parallel to the vector $\mathbf{v} = -3\mathbf{i} + 7\mathbf{k}$.

32. Parametrize the line segment joining the points $P(1, 2, 0)$ and $Q(1, 3, -1)$.

In Exercises 33 and 34, find the distance from the point to the plane.

33. $(6, 0, -6)$, $x - y = 4$

34. $(3, 0, 10)$, $2x + 3y + z = 2$

35. Find an equation for the plane that passes through the point $(3, -2, 1)$ normal to the vector $\mathbf{n} = 2\mathbf{i} + \mathbf{j} + \mathbf{k}$.

36. Find an equation for the plane that passes through the point $(-1, 6, 0)$ perpendicular to the line $x = -1 + t$, $y = 6 - 2t$, $z = 3t$.

In Exercises 37 and 38, find an equation for the plane through points P , Q , and R .

37. $P(1, -1, 2)$, $Q(2, 1, 3)$, $R(-1, 2, -1)$

38. $P(1, 0, 0)$, $Q(0, 1, 0)$, $R(0, 0, 1)$

39. Find the points in which the line $x = 1 + 2t$, $y = -1 - t$, $z = 3t$ meets the three coordinate planes.

40. Find the point in which the line through the origin perpendicular to the plane $2x - y - z = 4$ meets the plane $3x - 5y + 2z = 6$.

41. Find the acute angle between the planes $x = 7$ and $x + y + \sqrt{2}z = -3$.

42. Find the acute angle between the planes $x + y = 1$ and $y + z = 1$.

43. Find parametric equations for the line in which the planes $x + 2y + z = 1$ and $x - y + 2z = -8$ intersect.

44. Show that the line in which the planes

$$x + 2y - 2z = 5 \quad \text{and} \quad 5x - 2y - z = 0$$

intersect is parallel to the line

$$x = -3 + 2t, \quad y = 3t, \quad z = 1 + 4t.$$

45. The planes $3x + 6z = 1$ and $2x + 2y - z = 3$ intersect in a line.

a. Show that the planes are orthogonal.

b. Find equations for the line of intersection.

46. Find an equation for the plane that passes through the point $(1, 2, 3)$ parallel to $\mathbf{u} = 2\mathbf{i} + 3\mathbf{j} + \mathbf{k}$ and $\mathbf{v} = \mathbf{i} - \mathbf{j} + 2\mathbf{k}$.

47. Is $\mathbf{v} = 2\mathbf{i} - 4\mathbf{j} + \mathbf{k}$ related in any special way to the plane $2x + y = 5$? Give reasons for your answer.

48. The equation $\mathbf{n} \cdot \overrightarrow{P_0P} = 0$ represents the plane through P_0 normal to \mathbf{n} . What set does the inequality $\mathbf{n} \cdot \overrightarrow{P_0P} > 0$ represent?

49. Find the distance from the point $P(1, 4, 0)$ to the plane through $A(0, 0, 0)$, $B(2, 0, -1)$, and $C(2, -1, 0)$.

50. Find the distance from the point $(2, 2, 3)$ to the plane $2x + 3y + 5z = 0$.

51. Find a vector parallel to the plane $2x - y - z = 4$ and orthogonal to $\mathbf{i} + \mathbf{j} + \mathbf{k}$.

52. Find a unit vector orthogonal to \mathbf{A} in the plane of \mathbf{B} and \mathbf{C} if $\mathbf{A} = 2\mathbf{i} - \mathbf{j} + \mathbf{k}$, $\mathbf{B} = \mathbf{i} + 2\mathbf{j} + \mathbf{k}$, and $\mathbf{C} = \mathbf{i} + \mathbf{j} - 2\mathbf{k}$.

53. Find a vector of magnitude 2 parallel to the line of intersection of the planes $x + 2y + z - 1 = 0$ and $x - y + 2z + 7 = 0$.

54. Find the point in which the line through the origin perpendicular to the plane $2x - y - z = 4$ meets the plane $3x - 5y + 2z = 6$.

55. Find the point in which the line through $P(3, 2, 1)$ normal to the plane $2x - y + 2z = -2$ meets the plane.

56. What angle does the line of intersection of the planes $2x + y - z = 0$ and $x + y + 2z = 0$ make with the positive x -axis?

57. The line

$$L: x = 3 + 2t, \quad y = 2t, \quad z = t$$

intersects the plane $x + 3y - z = -4$ in a point P . Find the coordinates of P and find equations for the line in the plane through P perpendicular to L .

58. Show that for every real number k , the plane

$$x - 2y + z + 3 + k(2x - y - z + 1) = 0$$

contains the line of intersection of the planes

$$x - 2y + z + 3 = 0 \quad \text{and} \quad 2x - y - z + 1 = 0.$$

59. Find an equation for the plane through $A(-2, 0, -3)$ and $B(1, -2, 1)$ that lies parallel to the line through $C(-2, -13/5, 26/5)$ and $D(16/5, -13/5, 0)$.

60. Is the line $x = 1 + 2t$, $y = -2 + 3t$, $z = -5t$ related in any way to the plane $-4x - 6y + 10z = 9$? Give reasons for your answer.

61. Which of the following are equations for the plane through the points $P(1, 1, -1)$, $Q(3, 0, 2)$, and $R(-2, 1, 0)$?

a. $(2\mathbf{i} - 3\mathbf{j} + 3\mathbf{k}) \cdot ((x + 2)\mathbf{i} + (y - 1)\mathbf{j} + z\mathbf{k}) = 0$

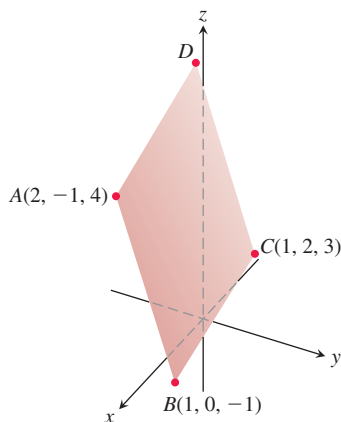

b. $x = 3 - t$, $y = -11t$, $z = 2 - 3t$

c. $(x + 2) + 11(y - 1) = 3z$

d. $(2\mathbf{i} - 3\mathbf{j} + 3\mathbf{k}) \times ((x + 2)\mathbf{i} + (y - 1)\mathbf{j} + z\mathbf{k}) = \mathbf{0}$

e. $(2\mathbf{i} - \mathbf{j} + 3\mathbf{k}) \times (-3\mathbf{i} + \mathbf{k}) \cdot ((x + 2)\mathbf{i} + (y - 1)\mathbf{j} + z\mathbf{k}) = 0$

62. The parallelogram shown here has vertices at $A(2, -1, 4)$, $B(1, 0, -1)$, $C(1, 2, 3)$, and D . Find

- the coordinates of D .
- the cosine of the interior angle at B .
- the vector projection of \overline{BA} onto \overline{BC} .
- the area of the parallelogram.
- an equation for the plane of the parallelogram.
- the areas of the orthogonal projections of the parallelogram on the three coordinate planes.

63. **Distance between skew lines** Find the distance between the line L_1 through the points $A(1, 0, -1)$ and $B(-1, 1, 0)$ and the line L_2 through the points $C(3, 1, -1)$ and $D(4, 5, -2)$. The distance is to be measured along the line perpendicular to the two lines. First find a vector \mathbf{n} perpendicular to both lines. Then project \overline{AC} onto \mathbf{n} .
64. (Continuation of Exercise 63.) Find the distance between the line through $A(4, 0, 2)$ and $B(2, 4, 1)$ and the line through $C(1, 3, 2)$ and $D(2, 2, 4)$.

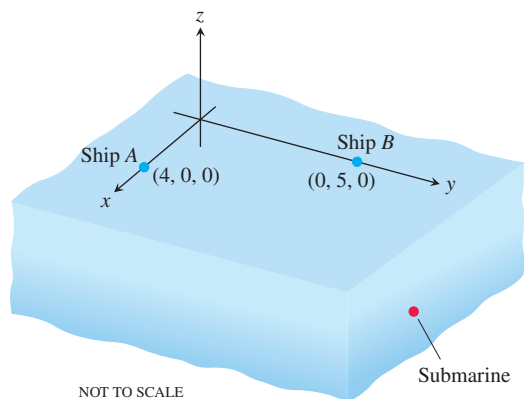

Quadric Surfaces

Identify and sketch the surfaces in Exercises 65–76.

- $x^2 + y^2 + z^2 = 4$
- $x^2 + (y - 1)^2 + z^2 = 1$
- $4x^2 + 4y^2 + z^2 = 4$
- $36x^2 + 9y^2 + 4z^2 = 36$
- $z = -(x^2 + y^2)$
- $y = -(x^2 + z^2)$
- $x^2 + y^2 = z^2$
- $x^2 + z^2 = y^2$
- $x^2 + y^2 - z^2 = 4$
- $4y^2 + z^2 - 4x^2 = 4$
- $y^2 - x^2 - z^2 = 1$
- $z^2 - x^2 - y^2 = 1$

CHAPTER 11 Additional and Advanced Exercises

1. **Submarine hunting** Two surface ships on maneuvers are trying to determine a submarine's course and speed to prepare for an aircraft intercept. As shown here, ship A is located at $(4, 0, 0)$, whereas ship B is located at $(0, 5, 0)$. All coordinates are given in thousands of meters. Ship A locates the submarine in the direction of the vector $2\mathbf{i} + 3\mathbf{j} - (1/3)\mathbf{k}$, and ship B locates it in the direction of the vector $18\mathbf{i} - 6\mathbf{j} - \mathbf{k}$. Four minutes ago, the submarine was located at $(2, -1, -1/3)$. The aircraft is due in 20 min. Assuming that the submarine moves in a straight line at a constant speed, to what position should the surface ships direct the aircraft?

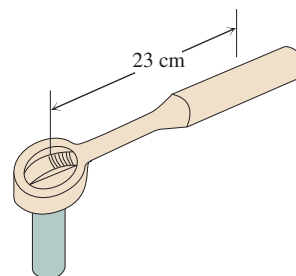

2. **A helicopter rescue** Two helicopters, H_1 and H_2 , are traveling together. At time $t = 0$, they separate and follow different straight-line paths given by

$$H_1: x = 6 + 40t, \quad y = -3 + 10t, \quad z = -3 + 2t$$

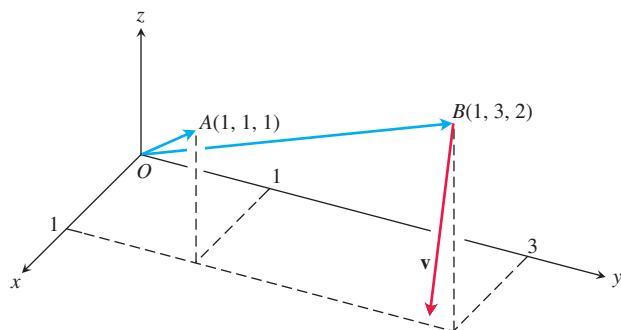

$$H_2: x = 6 + 110t, \quad y = -3 + 4t, \quad z = -3 + t.$$

Time t is measured in hours, and all coordinates are measured in kilometers. Due to system malfunctions, H_2 stops its flight at $(446, 13, 1)$ and, in a negligible amount of time, lands at $(446, 13, 0)$. Two hours later, H_1 is advised of this fact and heads toward H_2 at 150 km/h. How long will it take H_1 to reach H_2 ?

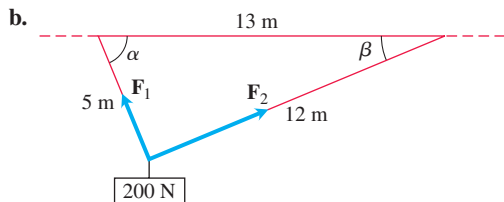

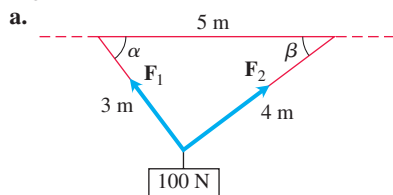

3. **Torque** The operator's manual for the Toro[®] 53-cm lawnmower says, "tighten the spark plug to 20.4 N · m." If you are installing the plug with a 26.5-cm socket wrench that places the center of your hand 23 cm from the axis of the spark plug, about how hard should you pull? Answer in newtons.

- 4. Rotating body** The line through the origin and the point $A(1, 1, 1)$ is the axis of rotation of a rigid body rotating with a constant angular speed of $3/2$ rad/s. The rotation appears to be clockwise when we look toward the origin from A . Find the velocity \mathbf{v} of the point of the body that is at the position $B(1, 3, 2)$.

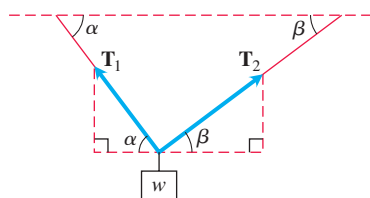

- 5.** Consider the weight suspended by two wires in each diagram. Find the magnitudes and components of vectors \mathbf{F}_1 and \mathbf{F}_2 , and angles α and β .

(Hint: This triangle is a right triangle.)

- 6.** Consider a weight of w N suspended by two wires in the diagram, where \mathbf{T}_1 and \mathbf{T}_2 are force vectors directed along the wires.

- a.** Find the vectors \mathbf{T}_1 and \mathbf{T}_2 and show that their magnitudes are

$$|\mathbf{T}_1| = \frac{w \cos \beta}{\sin(\alpha + \beta)}$$

and

$$|\mathbf{T}_2| = \frac{w \cos \alpha}{\sin(\alpha + \beta)}.$$

- b.** For a fixed β , determine the value of α that minimizes the magnitude $|\mathbf{T}_1|$.
c. For a fixed α , determine the value of β that minimizes the magnitude $|\mathbf{T}_2|$.

7. Determinants and planes

- a.** Show that

$$\begin{vmatrix} x_1 - x & y_1 - y & z_1 - z \\ x_2 - x & y_2 - y & z_2 - z \\ x_3 - x & y_3 - y & z_3 - z \end{vmatrix} = 0$$

is an equation for the plane through the three noncollinear points $P_1(x_1, y_1, z_1)$, $P_2(x_2, y_2, z_2)$, and $P_3(x_3, y_3, z_3)$.

- b.** What set of points in space is described by the equation

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0?$$

8. Determinants and lines Show that the lines

$$x = a_1s + b_1, \quad y = a_2s + b_2, \quad z = a_3s + b_3, \quad -\infty < s < \infty$$

and

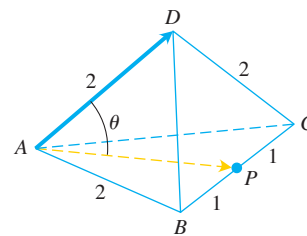

$$x = c_1t + d_1, \quad y = c_2t + d_2, \quad z = c_3t + d_3, \quad -\infty < t < \infty$$

intersect or are parallel if and only if

$$\begin{vmatrix} a_1 & c_1 & b_1 - d_1 \\ a_2 & c_2 & b_2 - d_2 \\ a_3 & c_3 & b_3 - d_3 \end{vmatrix} = 0.$$

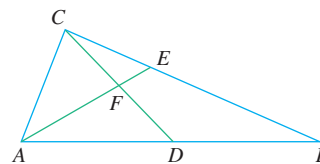

9. Consider a regular tetrahedron of side length 2.

- a.** Use vectors to find the angle θ formed by the base of the tetrahedron and any one of its other edges.

- b.** Use vectors to find the angle θ formed by any two adjacent faces of the tetrahedron. This angle is commonly referred to as a dihedral angle.

- 10.** In the figure here, D is the midpoint of side AB of triangle ABC , and E is one-third of the way between C and B . Use vectors to prove that F is the midpoint of line segment CD .

- 11.** Use vectors to show that the distance from $P_1(x_1, y_1)$ to the line $ax + by = c$ is

$$d = \frac{|ax_1 + by_1 - c|}{\sqrt{a^2 + b^2}}.$$

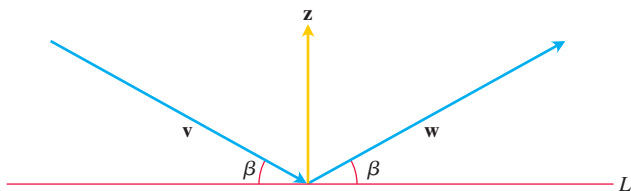

12. a. Use vectors to show that the distance from $P_1(x_1, y_1, z_1)$ to the plane $Ax + By + Cz = D$ is

$$d = \frac{|Ax_1 + By_1 + Cz_1 - D|}{\sqrt{A^2 + B^2 + C^2}}.$$

- b. Find an equation for the sphere that is tangent to the planes $x + y + z = 3$ and $x + y + z = 9$ if the planes $2x - y = 0$ and $3x - z = 0$ pass through the center of the sphere.
13. a. **Distance between parallel planes** Show that the distance between the parallel planes $Ax + By + Cz = D_1$ and $Ax + By + Cz = D_2$ is

$$d = \frac{|D_1 - D_2|}{|A\mathbf{i} + B\mathbf{j} + C\mathbf{k}|}.$$

- b. Find the distance between the planes $2x + 3y - z = 6$ and $2x + 3y - z = 12$.
- c. Find an equation for the plane parallel to the plane $2x - y + 2z = -4$ if the point $(3, 2, -1)$ is equidistant from the two planes.
- d. Write equations for the planes that lie parallel to, and 5 units away from, the plane $x - 2y + z = 3$.
14. Prove that four points $A, B, C,$ and D are coplanar (lie in a common plane) if and only if $\overrightarrow{AD} \cdot (\overrightarrow{AB} \times \overrightarrow{BC}) = 0$.
15. **The projection of a vector on a plane** Let P be a plane in space and let \mathbf{v} be a vector. The vector projection of \mathbf{v} onto the plane P , $\text{proj}_P \mathbf{v}$, can be defined informally as follows. Suppose the sun is shining so that its rays are normal to the plane P . Then $\text{proj}_P \mathbf{v}$ is the “shadow” of \mathbf{v} onto P . If P is the plane $x + 2y + 6z = 6$ and $\mathbf{v} = \mathbf{i} + \mathbf{j} + \mathbf{k}$, find $\text{proj}_P \mathbf{v}$.
16. The accompanying figure shows nonzero vectors $\mathbf{v}, \mathbf{w},$ and \mathbf{z} , with \mathbf{z} orthogonal to the line L , and \mathbf{v} and \mathbf{w} making equal angles β with L . Assuming $|\mathbf{v}| = |\mathbf{w}|$, find \mathbf{w} in terms of \mathbf{v} and \mathbf{z} .

17. **Triple vector products** The *triple vector products* $(\mathbf{u} \times \mathbf{v}) \times \mathbf{w}$ and $\mathbf{u} \times (\mathbf{v} \times \mathbf{w})$ are usually not equal, although the formulas for evaluating them from components are similar:

$$(\mathbf{u} \times \mathbf{v}) \times \mathbf{w} = (\mathbf{u} \cdot \mathbf{w})\mathbf{v} - (\mathbf{v} \cdot \mathbf{w})\mathbf{u}.$$

$$\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = (\mathbf{u} \cdot \mathbf{w})\mathbf{v} - (\mathbf{u} \cdot \mathbf{v})\mathbf{w}.$$

Verify each formula for the following vectors by evaluating its two sides and comparing the results.

\mathbf{u}	\mathbf{v}	\mathbf{w}
a. $2\mathbf{i}$	$2\mathbf{j}$	$2\mathbf{k}$
b. $\mathbf{i} - \mathbf{j} + \mathbf{k}$	$2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$	$-\mathbf{i} + 2\mathbf{j} - \mathbf{k}$
c. $2\mathbf{i} + \mathbf{j}$	$2\mathbf{i} - \mathbf{j} + \mathbf{k}$	$\mathbf{i} + 2\mathbf{k}$
d. $\mathbf{i} + \mathbf{j} - 2\mathbf{k}$	$-\mathbf{i} - \mathbf{k}$	$2\mathbf{i} + 4\mathbf{j} - 2\mathbf{k}$

18. **Cross and dot products** Show that if $\mathbf{u}, \mathbf{v}, \mathbf{w},$ and \mathbf{r} are any vectors, then

$$\mathbf{a.} \quad \mathbf{u} \times (\mathbf{v} \times \mathbf{w}) + \mathbf{v} \times (\mathbf{w} \times \mathbf{u}) + \mathbf{w} \times (\mathbf{u} \times \mathbf{v}) = \mathbf{0}$$

$$\mathbf{b.} \quad \mathbf{u} \times \mathbf{v} = (\mathbf{u} \cdot \mathbf{v} \times \mathbf{i})\mathbf{i} + (\mathbf{u} \cdot \mathbf{v} \times \mathbf{j})\mathbf{j} + (\mathbf{u} \cdot \mathbf{v} \times \mathbf{k})\mathbf{k}$$

$$\mathbf{c.} \quad (\mathbf{u} \times \mathbf{v}) \cdot (\mathbf{w} \times \mathbf{r}) = \begin{vmatrix} \mathbf{u} \cdot \mathbf{w} & \mathbf{v} \cdot \mathbf{w} \\ \mathbf{u} \cdot \mathbf{r} & \mathbf{v} \cdot \mathbf{r} \end{vmatrix}.$$

19. **Cross and dot products** Prove or disprove the formula

$$\mathbf{u} \times (\mathbf{u} \times (\mathbf{u} \times \mathbf{v})) \cdot \mathbf{w} = -|\mathbf{u}|^2 \mathbf{u} \cdot \mathbf{v} \times \mathbf{w}.$$

20. By forming the cross product of two appropriate vectors, derive the trigonometric identity

$$\sin(A - B) = \sin A \cos B - \cos A \sin B.$$

21. Use vectors to prove that

$$(a^2 + b^2)(c^2 + d^2) \geq (ac + bd)^2$$

for any four numbers $a, b, c,$ and d . (*Hint:* Let $\mathbf{u} = a\mathbf{i} + b\mathbf{j}$ and $\mathbf{v} = c\mathbf{i} + d\mathbf{j}$.)

22. **Dot multiplication is positive definite** Show that dot multiplication of vectors is *positive definite*; that is, show that $\mathbf{u} \cdot \mathbf{u} \geq 0$ for every vector \mathbf{u} and that $\mathbf{u} \cdot \mathbf{u} = 0$ if and only if $\mathbf{u} = \mathbf{0}$.

23. Show that $|\mathbf{u} + \mathbf{v}| \leq |\mathbf{u}| + |\mathbf{v}|$ for any vectors \mathbf{u} and \mathbf{v} .

24. Show that $\mathbf{w} = |\mathbf{v}|\mathbf{u} + |\mathbf{u}|\mathbf{v}$ bisects the angle between \mathbf{u} and \mathbf{v} .

25. Show that $|\mathbf{v}|\mathbf{u} + |\mathbf{u}|\mathbf{v}$ and $|\mathbf{v}|\mathbf{u} - |\mathbf{u}|\mathbf{v}$ are orthogonal.

CHAPTER 11 Technology Application Projects

Mathematica/Maple Projects

Projects can be found within MyLab Math.

Using Vectors to Represent Lines and Find Distances

Parts I and II: Learn the advantages of interpreting lines as vectors.

Part III: Use vectors to find the distance from a point to a line.

Putting a Scene in Three Dimensions onto a Two-Dimensional Canvas

Use the concept of planes in space to obtain a two-dimensional image.

Getting Started in Plotting in 3D

Part I: Use the vector definition of lines and planes to generate graphs and equations, and to compare different forms for the equations of a single line.

Part II: Plot functions that are defined implicitly.

12

Vector-Valued Functions and Motion in Space

OVERVIEW In this chapter we introduce the calculus of vector-valued functions. The domains of these functions are sets of real numbers, as before, but their ranges consist of vectors instead of scalars. When a vector-valued function changes, the change can occur in both magnitude and direction, so the derivative is itself a vector. The integral of a vector-valued function is also a vector. We use the calculus of these functions to describe the paths and motions of objects moving in a plane or in space, so their velocities and accelerations are given by vectors.

12.1 Curves in Space and Their Tangents

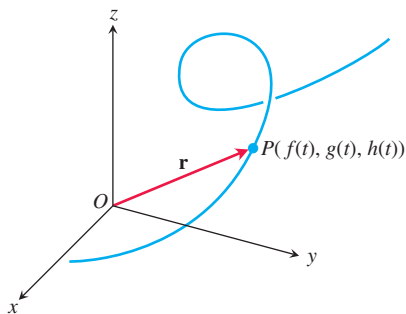

FIGURE 12.1 The position vector $\mathbf{r} = \overline{OP}$ of a particle moving through space is a function of time.

When a particle moves through space during a time interval I , we think of the particle's coordinates as functions defined on I :

$$x = f(t), \quad y = g(t), \quad z = h(t), \quad t \in I. \quad (1)$$

The points $(x, y, z) = (f(t), g(t), h(t))$, $t \in I$, make up the **curve** in space that we call the particle's **path**. The equations and interval in Equation (1) parametrize the curve.

A curve in space can also be represented in vector form. The vector

$$\mathbf{r}(t) = \overline{OP} = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k} \quad (2)$$

from the origin to the particle's position $P(f(t), g(t), h(t))$ at time t is the particle's position vector (Figure 12.1). The functions f , g , and h are the **component functions** (or components) of the position vector. We think of the particle's path as the curve traced by \mathbf{r} during the time interval I . Figure 12.2 displays several space curves generated by a computer graphing program.

Equation (2) defines \mathbf{r} as a vector function of the real variable t on the interval I . More generally, a **vector-valued function** or **vector function** on a domain set D is a rule that assigns a vector in space to each element in D . For now, the domains will be intervals of real numbers, and the graph of the function represents a curve in space. Vector functions on a domain in the plane or in space give rise to “vector fields,” which are important to the study of fluid flows, gravitational fields, and electromagnetic phenomena. We investigate vector fields and their applications in Chapter 15.

Real-valued functions are often called **scalar functions** to distinguish them from vector functions. The components of \mathbf{r} in Equation (2) are scalar functions of t . The domain of a vector-valued function is the common domain of its components.

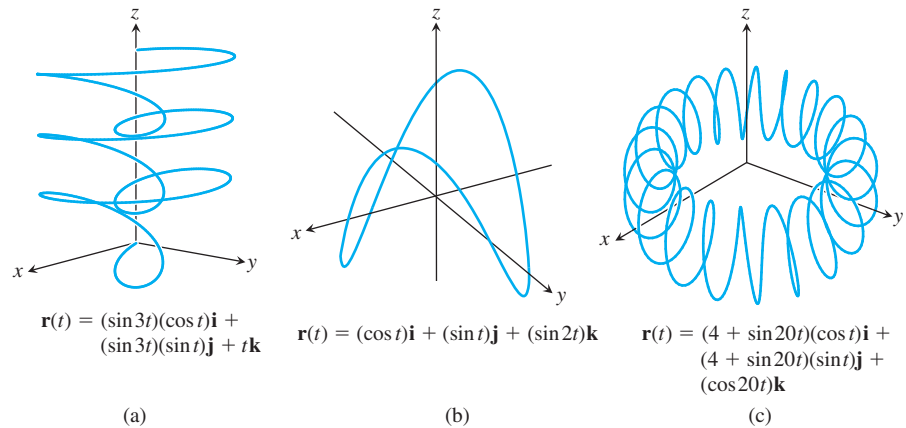

FIGURE 12.2 Space curves are defined by the position vectors $\mathbf{r}(t)$.

EXAMPLE 1 Graph the vector function

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}.$$

Solution This vector function $\mathbf{r}(t)$ is defined for all real values of t . The curve traced by \mathbf{r} winds around the circular cylinder $x^2 + y^2 = 1$ (Figure 12.3). The curve lies on the cylinder because the \mathbf{i} - and \mathbf{j} -components of \mathbf{r} , being the x - and y -coordinates of the tip of \mathbf{r} , satisfy the cylinder's equation:

$$x^2 + y^2 = (\cos t)^2 + (\sin t)^2 = 1.$$

The curve rises as the \mathbf{k} -component $z = t$ increases. Each time t increases by 2π , the curve completes one turn around the cylinder. The curve is called a **helix** (from an ancient Greek word for “spiral”). The equations

$$x = \cos t, \quad y = \sin t, \quad z = t$$

parametrize the helix. The domain is the largest set of points t for which all three equations are defined, or $-\infty < t < \infty$ for this example. Figure 12.4 shows more helices. ■

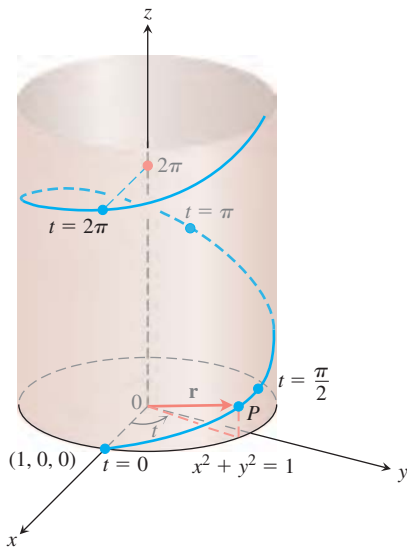

FIGURE 12.3 The helix $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$ (Example 1).

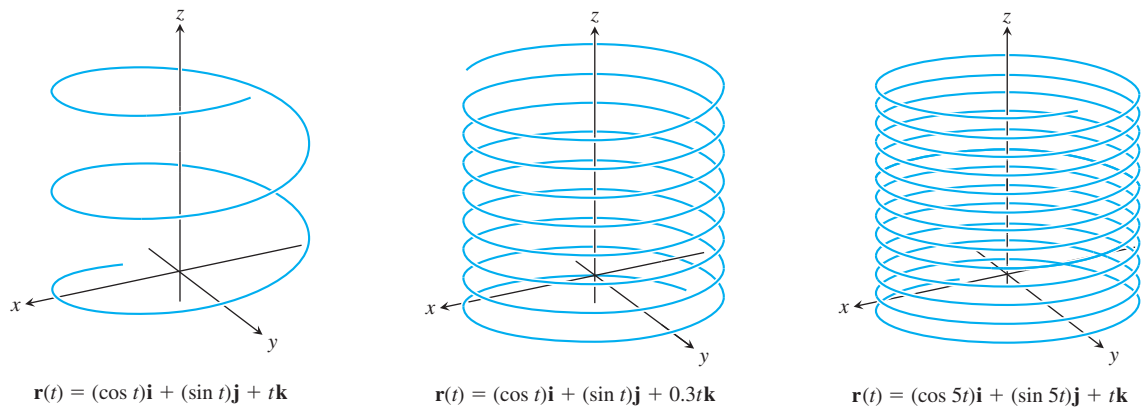

FIGURE 12.4 Helices spiral upward around a cylinder, like coiled springs.

Limits and Continuity

The way we define limits of vector-valued functions is similar to the way we define limits of real-valued functions.

DEFINITION Let $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ be a vector function with domain D , and let \mathbf{L} be a vector. We say that \mathbf{r} has **limit** \mathbf{L} as t approaches t_0 and write

$$\lim_{t \rightarrow t_0} \mathbf{r}(t) = \mathbf{L}$$

if, for every number $\varepsilon > 0$, there exists a corresponding number $\delta > 0$ such that, for all $t \in D$,

$$|\mathbf{r}(t) - \mathbf{L}| < \varepsilon \quad \text{whenever} \quad 0 < |t - t_0| < \delta.$$

If $\mathbf{L} = L_1\mathbf{i} + L_2\mathbf{j} + L_3\mathbf{k}$, then it can be shown that $\lim_{t \rightarrow t_0} \mathbf{r}(t) = \mathbf{L}$ precisely when

$$\lim_{t \rightarrow t_0} f(t) = L_1, \quad \lim_{t \rightarrow t_0} g(t) = L_2, \quad \text{and} \quad \lim_{t \rightarrow t_0} h(t) = L_3.$$

We omit the proof. The equation

$$\lim_{t \rightarrow t_0} \mathbf{r}(t) = \left(\lim_{t \rightarrow t_0} f(t) \right) \mathbf{i} + \left(\lim_{t \rightarrow t_0} g(t) \right) \mathbf{j} + \left(\lim_{t \rightarrow t_0} h(t) \right) \mathbf{k} \quad (3)$$

provides a practical way to calculate limits of vector functions.

EXAMPLE 2 If $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$, then

$$\begin{aligned} \lim_{t \rightarrow \pi/4} \mathbf{r}(t) &= \left(\lim_{t \rightarrow \pi/4} \cos t \right) \mathbf{i} + \left(\lim_{t \rightarrow \pi/4} \sin t \right) \mathbf{j} + \left(\lim_{t \rightarrow \pi/4} t \right) \mathbf{k} \\ &= \frac{\sqrt{2}}{2} \mathbf{i} + \frac{\sqrt{2}}{2} \mathbf{j} + \frac{\pi}{4} \mathbf{k}. \end{aligned}$$

We define continuity for vector functions the same way we define continuity for scalar functions defined over an interval.

DEFINITION A vector function $\mathbf{r}(t)$ is **continuous at a point** $t = t_0$ in its domain if $\lim_{t \rightarrow t_0} \mathbf{r}(t) = \mathbf{r}(t_0)$. The function is **continuous** if it is continuous at every point in its domain.

From Equation (3), we see that $\mathbf{r}(t)$ is continuous at $t = t_0$ if and only if each component function is continuous there (Exercise 45).

EXAMPLE 3

- (a) All the space curves shown in Figures 12.2 and 12.4 are continuous because their component functions are continuous at every value of t in $(-\infty, \infty)$.
 (b) The function

$$\mathbf{g}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + \lfloor t \rfloor \mathbf{k}$$

is discontinuous at every integer, because the greatest integer function $\lfloor t \rfloor$ is discontinuous at every integer. ■

Derivatives and Motion

Suppose that $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ is the position vector of a particle moving along a curve in space and that f , g , and h are differentiable functions of t . Then the difference between the particle's positions at time $t + \Delta t$ and time t is the vector

$$\Delta \mathbf{r} = \mathbf{r}(t + \Delta t) - \mathbf{r}(t)$$

To calculate the limit of a vector function, we find the limit of each component scalar function.

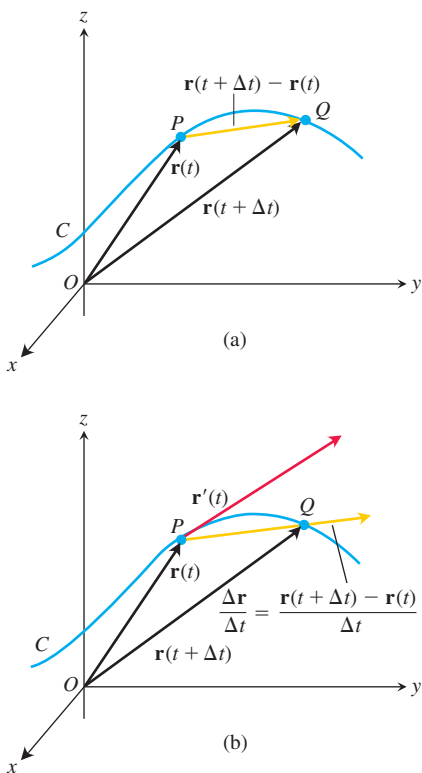

FIGURE 12.5 As $\Delta t \rightarrow 0$, the point Q approaches the point P along the curve C . In the limit, the vector $\overline{PQ}/\Delta t$ becomes the tangent vector $\mathbf{r}'(t)$.

(Figure 12.5a). In terms of components,

$$\begin{aligned}\Delta \mathbf{r} &= \mathbf{r}(t + \Delta t) - \mathbf{r}(t) \\ &= [f(t + \Delta t)\mathbf{i} + g(t + \Delta t)\mathbf{j} + h(t + \Delta t)\mathbf{k}] - [f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}] \\ &= [f(t + \Delta t) - f(t)]\mathbf{i} + [g(t + \Delta t) - g(t)]\mathbf{j} + [h(t + \Delta t) - h(t)]\mathbf{k}.\end{aligned}$$

As Δt approaches zero, three things seem to happen simultaneously. First, Q approaches P along the curve. Second, the secant line PQ seems to approach a limiting position tangent to the curve at P . Third, the quotient $\Delta \mathbf{r}/\Delta t$ (Figure 12.5b) approaches the limit

$$\begin{aligned}\lim_{\Delta t \rightarrow 0} \frac{\Delta \mathbf{r}}{\Delta t} &= \left[\lim_{\Delta t \rightarrow 0} \frac{f(t + \Delta t) - f(t)}{\Delta t} \right] \mathbf{i} + \left[\lim_{\Delta t \rightarrow 0} \frac{g(t + \Delta t) - g(t)}{\Delta t} \right] \mathbf{j} \\ &\quad + \left[\lim_{\Delta t \rightarrow 0} \frac{h(t + \Delta t) - h(t)}{\Delta t} \right] \mathbf{k} \\ &= \left[\frac{df}{dt} \right] \mathbf{i} + \left[\frac{dg}{dt} \right] \mathbf{j} + \left[\frac{dh}{dt} \right] \mathbf{k}.\end{aligned}$$

These observations lead us to the following definition.

DEFINITION The vector function $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ has a **derivative (is differentiable)** at t if f , g , and h have derivatives at t . The derivative is the vector function

$$\mathbf{r}'(t) = \frac{d\mathbf{r}}{dt} = \lim_{\Delta t \rightarrow 0} \frac{\mathbf{r}(t + \Delta t) - \mathbf{r}(t)}{\Delta t} = \frac{df}{dt} \mathbf{i} + \frac{dg}{dt} \mathbf{j} + \frac{dh}{dt} \mathbf{k}.$$

A vector function \mathbf{r} is **differentiable** if it is differentiable at every point of its domain.

The geometric significance of the definition of derivative is shown in Figure 12.5. The points P and Q have position vectors $\mathbf{r}(t)$ and $\mathbf{r}(t + \Delta t)$, and the vector \overline{PQ} is represented by $\mathbf{r}(t + \Delta t) - \mathbf{r}(t)$. For $\Delta t > 0$, the scalar multiple $(1/\Delta t)(\mathbf{r}(t + \Delta t) - \mathbf{r}(t))$ points in the same direction as the vector \overline{PQ} . As $\Delta t \rightarrow 0$, this vector approaches the vector $\mathbf{r}'(t)$, which is a vector tangent to the curve at P , as long as it is different from the zero vector $\mathbf{0}$ (Figure 12.5b).

The curve traced by \mathbf{r} is **smooth** if $d\mathbf{r}/dt$ is continuous and never $\mathbf{0}$, that is, if f , g , and h have continuous first derivatives that are not simultaneously 0. We require $d\mathbf{r}/dt \neq \mathbf{0}$ for a smooth curve to make sure the curve has a continuously turning tangent at each point. On a smooth curve, there are no sharp corners or cusps.

A curve that is made up of a finite number of smooth curves pieced together in a continuous fashion is called **piecewise smooth** (Figure 12.6).

Look once again at Figure 12.5. We drew the figure for Δt positive, so $\Delta \mathbf{r}$ points forward, in the direction of the motion. The vector $\Delta \mathbf{r}/\Delta t$, having the same direction as $\Delta \mathbf{r}$, points forward too. Had Δt been negative, $\Delta \mathbf{r}$ would have pointed backward, against the direction of motion. The quotient $\Delta \mathbf{r}/\Delta t$, however, being a negative scalar multiple of $\Delta \mathbf{r}$, would once again have pointed forward. No matter how $\Delta \mathbf{r}$ points, $\Delta \mathbf{r}/\Delta t$ points forward, and we expect the vector $d\mathbf{r}/dt = \lim_{\Delta t \rightarrow 0} \Delta \mathbf{r}/\Delta t$, when different from $\mathbf{0}$, to do the same.

This means that the derivative $d\mathbf{r}/dt$, which is the rate of change of position with respect to time, always points in the direction of motion. For a smooth curve, $d\mathbf{r}/dt$ is never zero; the particle does not stop or reverse direction.

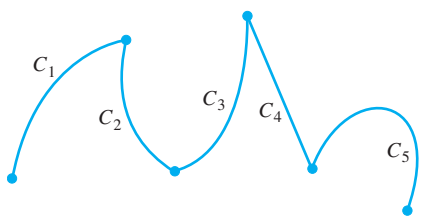

FIGURE 12.6 A piecewise smooth curve made up of five smooth curves connected end to end in a continuous fashion. The curve here is not smooth at the points joining the five smooth curves.

DEFINITIONS If \mathbf{r} is the position vector of a particle moving along a smooth curve in space, then

$$\mathbf{v}(t) = \frac{d\mathbf{r}}{dt}$$

is the particle's **velocity vector**. If \mathbf{v} is a nonzero vector, then it is tangent to the curve, and its direction is the **direction of motion**. The magnitude of \mathbf{v} is the particle's **speed**, and the derivative $\mathbf{a} = d\mathbf{v}/dt$, when it exists, is the particle's **acceleration vector**. In summary,

1. Velocity is the derivative of position: $\mathbf{v} = \frac{d\mathbf{r}}{dt}$.
2. Speed is the magnitude of velocity: $\text{Speed} = |\mathbf{v}|$.
3. Acceleration is the derivative of velocity: $\mathbf{a} = \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2}$.
4. The unit vector $\mathbf{v}/|\mathbf{v}|$ is the direction of motion at time t .

EXAMPLE 4 Find the velocity, speed, and acceleration of a particle whose motion in space is given by the position vector $\mathbf{r}(t) = 2 \cos t \mathbf{i} + 2 \sin t \mathbf{j} + 5 \cos^2 t \mathbf{k}$. Sketch the velocity vector $\mathbf{v}(7\pi/4)$.

Solution The velocity and acceleration vectors at time t are

$$\begin{aligned}\mathbf{v}(t) &= \mathbf{r}'(t) = -2 \sin t \mathbf{i} + 2 \cos t \mathbf{j} - 10 \cos t \sin t \mathbf{k} \\ &= -2 \sin t \mathbf{i} + 2 \cos t \mathbf{j} - 5 \sin 2t \mathbf{k}, \\ \mathbf{a}(t) &= \mathbf{r}''(t) = -2 \cos t \mathbf{i} - 2 \sin t \mathbf{j} - 10 \cos 2t \mathbf{k},\end{aligned}$$

and the speed is

$$|\mathbf{v}(t)| = \sqrt{(-2 \sin t)^2 + (2 \cos t)^2 + (-5 \sin 2t)^2} = \sqrt{4 + 25 \sin^2 2t}.$$

When $t = 7\pi/4$, we have

$$\mathbf{v}\left(\frac{7\pi}{4}\right) = \sqrt{2}\mathbf{i} + \sqrt{2}\mathbf{j} + 5\mathbf{k}, \quad \mathbf{a}\left(\frac{7\pi}{4}\right) = -\sqrt{2}\mathbf{i} + \sqrt{2}\mathbf{j}, \quad \left|\mathbf{v}\left(\frac{7\pi}{4}\right)\right| = \sqrt{29}.$$

A sketch of the curve of motion, and the velocity vector when $t = 7\pi/4$, can be seen in Figure 12.7. ■

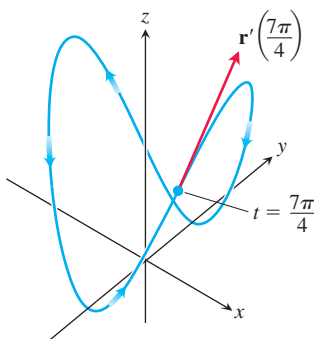

FIGURE 12.7 The curve and the velocity vector when $t = 7\pi/4$ for the motion given in Example 4.

We can express the velocity of a moving particle as the product of its speed and direction:

$$\text{Velocity} = |\mathbf{v}| \left(\frac{\mathbf{v}}{|\mathbf{v}|} \right) = (\text{speed})(\text{direction}).$$

Differentiation Rules

Because the derivatives of vector functions may be computed component by component, the rules for differentiating vector functions have the same form as the rules for differentiating scalar functions.

Differentiation Rules for Vector Functions

Let \mathbf{u} and \mathbf{v} be differentiable vector functions of t , \mathbf{C} a constant vector, c any scalar, and f any differentiable scalar function.

$$1. \text{ Constant Function Rule: } \frac{d}{dt} \mathbf{C} = \mathbf{0}$$

$$2. \text{ Scalar Multiple Rules: } \frac{d}{dt} [c\mathbf{u}(t)] = c\mathbf{u}'(t)$$

$$\frac{d}{dt} [f(t)\mathbf{u}(t)] = f'(t)\mathbf{u}(t) + f(t)\mathbf{u}'(t)$$

$$3. \text{ Sum Rule: } \frac{d}{dt} [\mathbf{u}(t) + \mathbf{v}(t)] = \mathbf{u}'(t) + \mathbf{v}'(t)$$

$$4. \text{ Difference Rule: } \frac{d}{dt} [\mathbf{u}(t) - \mathbf{v}(t)] = \mathbf{u}'(t) - \mathbf{v}'(t)$$

$$5. \text{ Dot Product Rule: } \frac{d}{dt} [\mathbf{u}(t) \cdot \mathbf{v}(t)] = \mathbf{u}'(t) \cdot \mathbf{v}(t) + \mathbf{u}(t) \cdot \mathbf{v}'(t)$$

$$6. \text{ Cross Product Rule: } \frac{d}{dt} [\mathbf{u}(t) \times \mathbf{v}(t)] = \mathbf{u}'(t) \times \mathbf{v}(t) + \mathbf{u}(t) \times \mathbf{v}'(t)$$

$$7. \text{ Chain Rule: } \frac{d}{dt} [\mathbf{u}(f(t))] = f'(t)\mathbf{u}'(f(t))$$

When you use the Cross Product Rule, remember to preserve the order of the factors. If \mathbf{u} comes first on the left side of the equation, it must also come first on the right, or the signs will be wrong.

We will prove the product rules and the Chain Rule but will leave the rules for constants, scalar multiples, sums, and differences as exercises.

Proof of the Dot Product Rule Suppose that

$$\mathbf{u} = u_1(t)\mathbf{i} + u_2(t)\mathbf{j} + u_3(t)\mathbf{k}$$

and

$$\mathbf{v} = v_1(t)\mathbf{i} + v_2(t)\mathbf{j} + v_3(t)\mathbf{k}.$$

Then

$$\begin{aligned} \frac{d}{dt}(\mathbf{u} \cdot \mathbf{v}) &= \frac{d}{dt}(u_1v_1 + u_2v_2 + u_3v_3) \\ &= \underbrace{u_1'v_1 + u_2'v_2 + u_3'v_3}_{\mathbf{u}' \cdot \mathbf{v}} + \underbrace{u_1v_1' + u_2v_2' + u_3v_3'}_{\mathbf{u} \cdot \mathbf{v}'} \end{aligned}$$

Proof of the Cross Product Rule We model the proof after the proof of the Product Rule for scalar functions. According to the definition of derivative,

$$\frac{d}{dt}(\mathbf{u} \times \mathbf{v}) = \lim_{h \rightarrow 0} \frac{\mathbf{u}(t+h) \times \mathbf{v}(t+h) - \mathbf{u}(t) \times \mathbf{v}(t)}{h}.$$

To change this fraction into an equivalent one that contains the difference quotients for the derivatives of \mathbf{u} and \mathbf{v} , we subtract and add $\mathbf{u}(t) \times \mathbf{v}(t+h)$ in the numerator. Then

$$\begin{aligned} \frac{d}{dt}(\mathbf{u} \times \mathbf{v}) &= \lim_{h \rightarrow 0} \frac{\mathbf{u}(t+h) \times \mathbf{v}(t+h) - \mathbf{u}(t) \times \mathbf{v}(t+h) + \mathbf{u}(t) \times \mathbf{v}(t+h) - \mathbf{u}(t) \times \mathbf{v}(t)}{h} \\ &= \lim_{h \rightarrow 0} \left[\frac{\mathbf{u}(t+h) - \mathbf{u}(t)}{h} \times \mathbf{v}(t+h) + \mathbf{u}(t) \times \frac{\mathbf{v}(t+h) - \mathbf{v}(t)}{h} \right] \\ &= \lim_{h \rightarrow 0} \frac{\mathbf{u}(t+h) - \mathbf{u}(t)}{h} \times \lim_{h \rightarrow 0} \mathbf{v}(t+h) + \lim_{h \rightarrow 0} \mathbf{u}(t) \times \lim_{h \rightarrow 0} \frac{\mathbf{v}(t+h) - \mathbf{v}(t)}{h}. \end{aligned}$$

The last of these equalities holds because the limit of the cross product of two vector functions is the cross product of their limits if the latter exist (Exercise 46). As h approaches zero, $\mathbf{v}(t+h)$ approaches $\mathbf{v}(t)$ because \mathbf{v} , being differentiable at t , is continuous at t (Exercise 47). The two fractions approach the values of $d\mathbf{u}/dt$ and $d\mathbf{v}/dt$ at t . In short,

$$\frac{d}{dt}(\mathbf{u} \times \mathbf{v}) = \left(\frac{d\mathbf{u}}{dt} \times \mathbf{v}\right) + \left(\mathbf{u} \times \frac{d\mathbf{v}}{dt}\right). \quad \blacksquare$$

Proof of the Chain Rule Suppose that $\mathbf{u}(s) = a(s)\mathbf{i} + b(s)\mathbf{j} + c(s)\mathbf{k}$ is a differentiable vector function of s and that $s = f(t)$ is a differentiable scalar function of t . Then a , b , and c are differentiable functions of t , and the Chain Rule for differentiable real-valued functions gives

$$\begin{aligned} \frac{d}{dt}[\mathbf{u}(s)] &= \frac{da}{dt}\mathbf{i} + \frac{db}{dt}\mathbf{j} + \frac{dc}{dt}\mathbf{k} \\ &= \frac{da}{ds}\frac{ds}{dt}\mathbf{i} + \frac{db}{ds}\frac{ds}{dt}\mathbf{j} + \frac{dc}{ds}\frac{ds}{dt}\mathbf{k} \\ &= \frac{ds}{dt}\left(\frac{da}{ds}\mathbf{i} + \frac{db}{ds}\mathbf{j} + \frac{dc}{ds}\mathbf{k}\right) \\ &= \frac{ds}{dt}\frac{d\mathbf{u}}{ds} \\ &= f'(t)\mathbf{u}'(f(t)). \end{aligned} \quad s = f(t) \quad \blacksquare$$

As an algebraic convenience, we sometimes write the product of a scalar c and a vector \mathbf{v} as $c\mathbf{v}$ instead of $c\mathbf{v}$. This permits us, for instance, to write the Chain Rule in a familiar form:

$$\frac{d\mathbf{u}}{dt} = \frac{d\mathbf{u}}{ds} \frac{ds}{dt},$$

where $s = f(t)$.

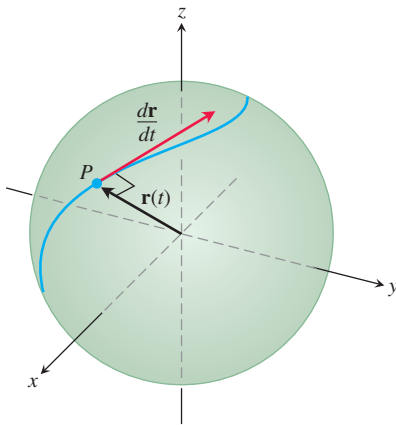

FIGURE 12.8 If a particle moves on a sphere in such a way that its position \mathbf{r} is a differentiable function of time, then $\mathbf{r} \cdot (d\mathbf{r}/dt) = 0$.

Vector Functions of Constant Length

When we track a particle moving on a sphere centered at the origin (Figure 12.8), the position vector has a constant length equal to the radius of the sphere. The velocity vector $d\mathbf{r}/dt$, tangent to the path of motion, is tangent to the sphere and hence perpendicular to \mathbf{r} . This is always the case for a differentiable vector function of constant length: The vector and its first derivative are orthogonal. By direct calculation,

$$\begin{aligned} \mathbf{r}(t) \cdot \mathbf{r}(t) &= |\mathbf{r}(t)|^2 = c^2 && |\mathbf{r}(t)| = c \text{ is constant.} \\ \frac{d}{dt}[\mathbf{r}(t) \cdot \mathbf{r}(t)] &= 0 && \text{Differentiate both sides.} \\ \mathbf{r}'(t) \cdot \mathbf{r}(t) + \mathbf{r}(t) \cdot \mathbf{r}'(t) &= 0 && \text{Rule 5 with } \mathbf{r}(t) = \mathbf{u}(t) = \mathbf{v}(t) \\ 2\mathbf{r}'(t) \cdot \mathbf{r}(t) &= 0. \end{aligned}$$

Thus the vectors $\mathbf{r}'(t)$ and $\mathbf{r}(t)$ are orthogonal because their dot product is 0. In summary, the following holds.

If \mathbf{r} is a differentiable vector function of t and the length of $\mathbf{r}(t)$ is constant, then

$$\mathbf{r} \cdot \frac{d\mathbf{r}}{dt} = 0. \quad (4)$$

We will use this observation repeatedly in Section 12.4. The converse is also true (see Exercise 41).

EXERCISES 12.1

In Exercises 1–4, find the given limits.

$$1. \lim_{t \rightarrow \pi} \left[\left(\sin \frac{t}{2} \right) \mathbf{i} + \left(\cos \frac{2}{3} t \right) \mathbf{j} + \left(\tan \frac{5}{4} t \right) \mathbf{k} \right]$$

$$2. \lim_{t \rightarrow -1} \left[t^3 \mathbf{i} + \left(\sin \frac{\pi}{2} t \right) \mathbf{j} + (\ln(t+2)) \mathbf{k} \right]$$

$$3. \lim_{t \rightarrow 1} \left[\left(\frac{t^2 - 1}{\ln t} \right) \mathbf{i} - \left(\frac{\sqrt{t} - 1}{1 - t} \right) \mathbf{j} + (\arctan t) \mathbf{k} \right]$$

$$4. \lim_{t \rightarrow 0} \left[\left(\frac{\sin t}{t} \right) \mathbf{i} + \left(\frac{\tan^2 t}{\sin 2t} \right) \mathbf{j} - \left(\frac{t^3 - 8}{t + 2} \right) \mathbf{k} \right]$$

Motion in the Plane

In Exercises 5–8, $\mathbf{r}(t)$ is the position of a particle in the xy -plane at time t . Find an equation in x and y whose graph is the path of the particle. Then find the particle's velocity and acceleration vectors at the given value of t .

$$5. \mathbf{r}(t) = (t+1)\mathbf{i} + (t^2 - 1)\mathbf{j}, \quad t = 1$$

$$6. \mathbf{r}(t) = \frac{t}{t+1}\mathbf{i} + \frac{1}{t}\mathbf{j}, \quad t = -\frac{1}{2}$$

$$7. \mathbf{r}(t) = e^t \mathbf{i} + \frac{2}{9} e^{2t} \mathbf{j}, \quad t = \ln 3$$

$$8. \mathbf{r}(t) = (\cos 2t)\mathbf{i} + (3 \sin 2t)\mathbf{j}, \quad t = 0$$

Exercises 9–12 give the position vectors of particles moving along various curves in the xy -plane. In each case, find the particle's velocity and acceleration vectors at the stated times and sketch them as vectors on the curve.

9. Motion on the circle $x^2 + y^2 = 1$

$$\mathbf{r}(t) = (\sin t)\mathbf{i} + (\cos t)\mathbf{j}; \quad t = \pi/4 \text{ and } \pi/2$$

10. Motion on the circle $x^2 + y^2 = 16$

$$\mathbf{r}(t) = \left(4 \cos \frac{t}{2} \right) \mathbf{i} + \left(4 \sin \frac{t}{2} \right) \mathbf{j}; \quad t = \pi \text{ and } 3\pi/2$$

11. Motion on the cycloid $x = t - \sin t$, $y = 1 - \cos t$

$$\mathbf{r}(t) = (t - \sin t)\mathbf{i} + (1 - \cos t)\mathbf{j}; \quad t = \pi \text{ and } 3\pi/2$$

12. Motion on the parabola $y = x^2 + 1$

$$\mathbf{r}(t) = t\mathbf{i} + (t^2 + 1)\mathbf{j}; \quad t = -1, 0, \text{ and } 1$$

Motion in Space

In Exercises 13–18, $\mathbf{r}(t)$ is the position of a particle in space at time t . Find the particle's velocity and acceleration vectors. Then find the particle's speed and direction of motion at the given value of t . Write the particle's velocity at that time as the product of its speed and direction.

$$13. \mathbf{r}(t) = (t+1)\mathbf{i} + (t^2 - 1)\mathbf{j} + 2t\mathbf{k}, \quad t = 1$$

$$14. \mathbf{r}(t) = (1+t)\mathbf{i} + \frac{t^2}{\sqrt{2}}\mathbf{j} + \frac{t^3}{3}\mathbf{k}, \quad t = 1$$

$$15. \mathbf{r}(t) = (2 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + 4t\mathbf{k}, \quad t = \pi/2$$

$$16. \mathbf{r}(t) = (\sec t)\mathbf{i} + (\tan t)\mathbf{j} + \frac{4}{3}t\mathbf{k}, \quad t = \pi/6$$

$$17. \mathbf{r}(t) = (2 \ln(t+1))\mathbf{i} + t^2\mathbf{j} + \frac{t^2}{2}\mathbf{k}, \quad t = 1$$

$$18. \mathbf{r}(t) = e^{-t}\mathbf{i} + (2 \cos 3t)\mathbf{j} + (2 \sin 3t)\mathbf{k}, \quad t = 0$$

In Exercises 19–22, $\mathbf{r}(t)$ is the position of a particle in space at time t . Find the angle between the velocity and acceleration vectors at time $t = 0$.

$$19. \mathbf{r}(t) = (3t+1)\mathbf{i} + \sqrt{3}t\mathbf{j} + t^2\mathbf{k}$$

$$20. \mathbf{r}(t) = \left(\frac{\sqrt{2}}{2}t \right) \mathbf{i} + \left(\frac{\sqrt{2}}{2}t - 16t^2 \right) \mathbf{j}$$

$$21. \mathbf{r}(t) = (\ln(t^2 + 1))\mathbf{i} + (\arctan t)\mathbf{j} + \sqrt{t^2 + 1}\mathbf{k}$$

$$22. \mathbf{r}(t) = \frac{4}{9}(1+t)^{3/2}\mathbf{i} + \frac{4}{9}(1-t)^{3/2}\mathbf{j} + \frac{1}{3}t\mathbf{k}$$

Tangents to Curves

As mentioned in the text, the **tangent line** to a smooth curve $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ at $t = t_0$ is the line that passes through the point $(f(t_0), g(t_0), h(t_0))$ parallel to $\mathbf{v}(t_0)$, the curve's velocity vector at t_0 . In Exercises 23–26, find parametric equations for the line that is tangent to the given curve at the given parameter value $t = t_0$.

$$23. \mathbf{r}(t) = (\sin t)\mathbf{i} + (t^2 - \cos t)\mathbf{j} + e^t\mathbf{k}, \quad t_0 = 0$$

$$24. \mathbf{r}(t) = t^2\mathbf{i} + (2t - 1)\mathbf{j} + t^3\mathbf{k}, \quad t_0 = 2$$

$$25. \mathbf{r}(t) = \ln t\mathbf{i} + \frac{t-1}{t+2}\mathbf{j} + t \ln t\mathbf{k}, \quad t_0 = 1$$

$$26. \mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (\sin 2t)\mathbf{k}, \quad t_0 = \frac{\pi}{2}$$

In Exercises 27–30, find the value(s) of t so that the tangent line to the given curve contains the given point.

$$27. \mathbf{r}(t) = t^2\mathbf{i} + (1+t)\mathbf{j} + (2t-3)\mathbf{k}; \quad (-8, 2, -1)$$

$$28. \mathbf{r}(t) = t\mathbf{i} + 3\mathbf{j} + \left(\frac{2}{3}t^{3/2} \right) \mathbf{k}; \quad (0, 3, -8/3)$$

$$29. \mathbf{r}(t) = 2t\mathbf{i} + t^2\mathbf{j} - t^2\mathbf{k}; \quad (0, -4, 4)$$

$$30. \mathbf{r}(t) = -t\mathbf{i} + t^2\mathbf{j} + (\ln t)\mathbf{k}; \quad (2, -5, -3)$$

In Exercises 31–36, $\mathbf{r}(t)$ is the position of a particle in space at time t . Match each position function with one of the graphs A–F.

$$31. \mathbf{r}(t) = (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} + t\mathbf{k}$$

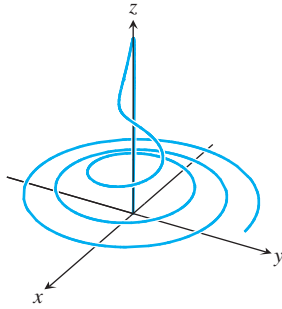

$$32. \mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (\sin 2t)\mathbf{k}$$

$$33. \mathbf{r}(t) = t^2\mathbf{i} + (t^2 + 1)\mathbf{j} + t^4\mathbf{k}$$

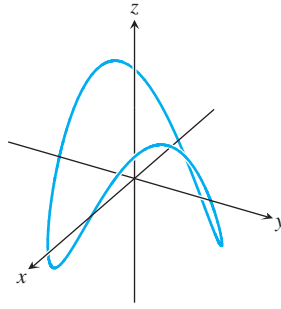

$$34. \mathbf{r}(t) = t\mathbf{i} + (\ln t)\mathbf{j} + (\sin t)\mathbf{k}$$

35. $\mathbf{r}(t) = t\mathbf{i} + (\cos t)\mathbf{j} + (\sin t)\mathbf{k}$

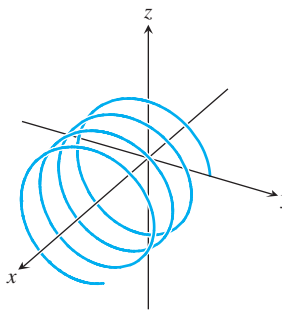

36. $\mathbf{r}(t) = (t \sin t)\mathbf{i} + (t \cos t)\mathbf{j} + \left(\frac{t}{t^2 + 1}\right)\mathbf{k}$

Theory and Examples

37. Motion along a circle Each of the following equations in parts (a)–(e) describes the motion of a particle having the same path, namely the unit circle $x^2 + y^2 = 1$. Although the path of each particle in parts (a)–(e) is the same, the behavior, or “dynamics,” of each particle is different. For each particle, answer the following questions.

- Does the particle have constant speed? If so, what is its constant speed?
- Is the particle’s acceleration vector always orthogonal to its velocity vector?
- Does the particle move clockwise or counterclockwise around the circle?
- Is the particle initially located at the point $(1, 0)$?

- $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}, \quad t \geq 0$
- $\mathbf{r}(t) = \cos(2t)\mathbf{i} + \sin(2t)\mathbf{j}, \quad t \geq 0$
- $\mathbf{r}(t) = \cos(t - \pi/2)\mathbf{i} + \sin(t - \pi/2)\mathbf{j}, \quad t \geq 0$
- $\mathbf{r}(t) = (\cos t)\mathbf{i} - (\sin t)\mathbf{j}, \quad t \geq 0$
- $\mathbf{r}(t) = \cos(t^2)\mathbf{i} + \sin(t^2)\mathbf{j}, \quad t \geq 0$

38. Motion along a circle Show that the vector-valued function

$$\mathbf{r}(t) = (2\mathbf{i} + 2\mathbf{j} + \mathbf{k}) + \cos t\left(\frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}\right) + \sin t\left(\frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k}\right)$$

describes the motion of a particle moving in the circle of radius 1 centered at the point $(2, 2, 1)$ and lying in the plane $x + y - 2z = 2$.

39. Motion along a parabola A particle moves along the top of the parabola $y^2 = 2x$ from left to right at a constant speed of 5 units per second. Find the velocity of the particle as it moves through the point $(2, 2)$.

40. Motion along a cycloid A particle moves in the xy -plane in such a way that its position at time t is

$$\mathbf{r}(t) = (t - \sin t)\mathbf{i} + (1 - \cos t)\mathbf{j}.$$

- T** **a.** Graph $\mathbf{r}(t)$. The resulting curve is a cycloid.
b. Find the maximum and minimum values of $|\mathbf{v}|$ and $|\mathbf{a}|$.
(Hint: Find the extreme values of $|\mathbf{v}|^2$ and $|\mathbf{a}|^2$ first, and take square roots later.)

41. Let \mathbf{r} be a differentiable vector function of t . Show that if $\mathbf{r} \cdot (d\mathbf{r}/dt) = 0$ for all t , then $|\mathbf{r}|$ is constant.

42. Derivatives of triple scalar products

a. Show that if \mathbf{u} , \mathbf{v} , and \mathbf{w} are differentiable vector functions of t , then

$$\frac{d}{dt}(\mathbf{u} \cdot \mathbf{v} \times \mathbf{w}) = \frac{d\mathbf{u}}{dt} \cdot \mathbf{v} \times \mathbf{w} + \mathbf{u} \cdot \frac{d\mathbf{v}}{dt} \times \mathbf{w} + \mathbf{u} \cdot \mathbf{v} \times \frac{d\mathbf{w}}{dt}.$$

b. Show that

$$\frac{d}{dt}\left(\mathbf{r} \cdot \frac{d\mathbf{r}}{dt} \times \frac{d^2\mathbf{r}}{dt^2}\right) = \mathbf{r} \cdot \left(\frac{d\mathbf{r}}{dt} \times \frac{d^3\mathbf{r}}{dt^3}\right).$$

(Hint: Differentiate on the left and look for vectors whose products are zero.)

- Prove the two Scalar Multiple Rules for vector functions.
- Prove the Sum and Difference Rules for vector functions.
- Component test for continuity at a point** Show that the vector function \mathbf{r} defined by $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ is continuous at $t = t_0$ if and only if f , g , and h are continuous at t_0 .
- Limits of cross products of vector functions** Suppose that $\mathbf{r}_1(t) = f_1(t)\mathbf{i} + f_2(t)\mathbf{j} + f_3(t)\mathbf{k}$, $\mathbf{r}_2(t) = g_1(t)\mathbf{i} + g_2(t)\mathbf{j} + g_3(t)\mathbf{k}$, $\lim_{t \rightarrow t_0} \mathbf{r}_1(t) = \mathbf{A}$, and $\lim_{t \rightarrow t_0} \mathbf{r}_2(t) = \mathbf{B}$. Use the determinant formula for cross products and the Limit Product Rule for scalar functions to show that

$$\lim_{t \rightarrow t_0} (\mathbf{r}_1(t) \times \mathbf{r}_2(t)) = \mathbf{A} \times \mathbf{B}.$$

47. Differentiable vector functions are continuous Show that if $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ is differentiable at $t = t_0$, then it is continuous at t_0 as well.

48. Constant Function Rule Prove that if \mathbf{u} is the vector function with the constant value \mathbf{C} , then $d\mathbf{u}/dt = \mathbf{0}$.

COMPUTER EXPLORATIONS

Use a CAS to perform the following steps in Exercises 49–52.

- Plot the space curve traced out by the position vector \mathbf{r} .
- Find the components of the velocity vector $d\mathbf{r}/dt$.
- Evaluate $d\mathbf{r}/dt$ at the given point t_0 and determine the equation of the tangent line to the curve at $\mathbf{r}(t_0)$.
- Plot the tangent line together with the curve over the given interval.

49. $\mathbf{r}(t) = (\sin t - t \cos t)\mathbf{i} + (\cos t + t \sin t)\mathbf{j} + t^2\mathbf{k}$,
 $0 \leq t \leq 6\pi$, $t_0 = 3\pi/2$

50. $\mathbf{r}(t) = \sqrt{2}t\mathbf{i} + e^t\mathbf{j} + e^{-t}\mathbf{k}$, $-2 \leq t \leq 3$, $t_0 = 1$

51. $\mathbf{r}(t) = (\sin 2t)\mathbf{i} + (\ln(1+t))\mathbf{j} + t\mathbf{k}$, $0 \leq t \leq 4\pi$,
 $t_0 = \pi/4$

52. $\mathbf{r}(t) = (\ln(t^2 + 2))\mathbf{i} + (\arctan 3t)\mathbf{j} + \sqrt{t^2 + 1}\mathbf{k}$,
 $-3 \leq t \leq 5$, $t_0 = 3$

In Exercises 53 and 54, you will explore graphically the behavior of the helix

$$\mathbf{r}(t) = (\cos at)\mathbf{i} + (\sin at)\mathbf{j} + btk$$

as you change the values of the constants a and b . Use a CAS to perform the steps in each exercise.

53. Set $b = 1$. Plot the helix $\mathbf{r}(t)$ together with the tangent line to the curve at $t = 3\pi/2$ for $a = 1, 2, 4$, and 6 over the interval $0 \leq t \leq 4\pi$. Describe in your own words what happens to the graph of the helix and the position of the tangent line as a increases through these positive values.

54. Set $a = 1$. Plot the helix $\mathbf{r}(t)$ together with the tangent line to the curve at $t = 3\pi/2$ for $b = 1/4, 1/2, 2$, and 4 over the interval $0 \leq t \leq 4\pi$. Describe in your own words what happens to the graph of the helix and the position of the tangent line as b increases through these positive values.

12.2 Integrals of Vector Functions; Projectile Motion

In this section we investigate integrals of vector functions and their application to motion along a path in space or in the plane.

Integrals of Vector Functions

A differentiable vector function $\mathbf{R}(t)$ is an **antiderivative** of a vector function $\mathbf{r}(t)$ on an interval I if $d\mathbf{R}/dt = \mathbf{r}$ at each point of I . If \mathbf{R} is an antiderivative of \mathbf{r} on I , it can be shown, working one component at a time, that every antiderivative of \mathbf{r} on I has the form $\mathbf{R} + \mathbf{C}$ for some constant vector \mathbf{C} (Exercise 45). The set of all antiderivatives of \mathbf{r} on I is the **indefinite integral** of \mathbf{r} on I .

DEFINITION The **indefinite integral** of \mathbf{r} with respect to t is the set of all antiderivatives of \mathbf{r} , denoted by

$$\int \mathbf{r}(t) dt.$$

The usual arithmetic rules for indefinite integrals apply.

EXAMPLE 1 To integrate a vector function, we integrate each of its components.

$$\int ((\cos t)\mathbf{i} + \mathbf{j} - 2t\mathbf{k}) dt = \left(\int \cos t dt \right)\mathbf{i} + \left(\int dt \right)\mathbf{j} - \left(\int 2t dt \right)\mathbf{k} \quad (1)$$

$$= (\sin t + C_1)\mathbf{i} + (t + C_2)\mathbf{j} - (t^2 + C_3)\mathbf{k} \quad (2)$$

$$= (\sin t)\mathbf{i} + t\mathbf{j} - t^2\mathbf{k} + \mathbf{C} \quad \mathbf{C} = C_1\mathbf{i} + C_2\mathbf{j} - C_3\mathbf{k}$$

As in the integration of scalar functions, we recommend that you skip the steps in Equations (1) and (2) and go directly to the final form. Find an antiderivative for each component and add a *constant vector* at the end. ■

Definite integrals of vector functions are best defined in terms of components. The definition is consistent with how we compute limits and derivatives of vector functions.

DEFINITION If the components of $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ are integrable over $[a, b]$, then so is \mathbf{r} , and the **definite integral** of \mathbf{r} from a to b is

$$\int_a^b \mathbf{r}(t) dt = \left(\int_a^b f(t) dt \right) \mathbf{i} + \left(\int_a^b g(t) dt \right) \mathbf{j} + \left(\int_a^b h(t) dt \right) \mathbf{k}.$$

EXAMPLE 2 As in Example 1, we integrate each component.

$$\begin{aligned} \int_0^\pi ((\cos t)\mathbf{i} + \mathbf{j} - 2t\mathbf{k}) dt &= \left(\int_0^\pi \cos t dt \right) \mathbf{i} + \left(\int_0^\pi dt \right) \mathbf{j} - \left(\int_0^\pi 2t dt \right) \mathbf{k} \\ &= \left[\sin t \right]_0^\pi \mathbf{i} + \left[t \right]_0^\pi \mathbf{j} - \left[t^2 \right]_0^\pi \mathbf{k} \\ &= [0 - 0] \mathbf{i} + [\pi - 0] \mathbf{j} - [\pi^2 - 0^2] \mathbf{k} \\ &= \pi \mathbf{j} - \pi^2 \mathbf{k} \end{aligned}$$

The Fundamental Theorem of Calculus for continuous vector functions says that

$$\int_a^b \mathbf{r}(t) dt = \mathbf{R}(t) \Big|_a^b = \mathbf{R}(b) - \mathbf{R}(a),$$

where \mathbf{R} is any antiderivative of \mathbf{r} , so that $\mathbf{R}'(t) = \mathbf{r}(t)$ (Exercise 46). Notice that an antiderivative of a vector function is also a vector function, whereas a definite integral of a vector function is a single constant vector.

EXAMPLE 3 Suppose we do not know the path of a hang glider, but only its acceleration vector $\mathbf{a}(t) = -(3 \cos t)\mathbf{i} - (3 \sin t)\mathbf{j} + 2\mathbf{k}$. We also know that initially (at time $t = 0$) the glider departed from the point $(4, 0, 0)$ with velocity $\mathbf{v}(0) = 3\mathbf{j}$. Find the glider's position as a function of t .

Solution Our goal is to find $\mathbf{r}(t)$ knowing

$$\text{The differential equation: } \mathbf{a} = \frac{d^2\mathbf{r}}{dt^2} = -(3 \cos t)\mathbf{i} - (3 \sin t)\mathbf{j} + 2\mathbf{k}$$

$$\text{The initial conditions: } \mathbf{v}(0) = 3\mathbf{j} \text{ and } \mathbf{r}(0) = 4\mathbf{i} + 0\mathbf{j} + 0\mathbf{k}.$$

Integrating both sides of the differential equation with respect to t gives

$$\mathbf{v}(t) = -(3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 2t\mathbf{k} + \mathbf{C}_1.$$

We use $\mathbf{v}(0) = 3\mathbf{j}$ to find \mathbf{C}_1 :

$$3\mathbf{j} = -(3 \sin 0)\mathbf{i} + (3 \cos 0)\mathbf{j} + (0)\mathbf{k} + \mathbf{C}_1$$

$$3\mathbf{j} = 3\mathbf{j} + \mathbf{C}_1$$

$$\mathbf{C}_1 = \mathbf{0}.$$

The glider's velocity as a function of time is

$$\frac{d\mathbf{r}}{dt} = \mathbf{v}(t) = -(3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 2t\mathbf{k}.$$

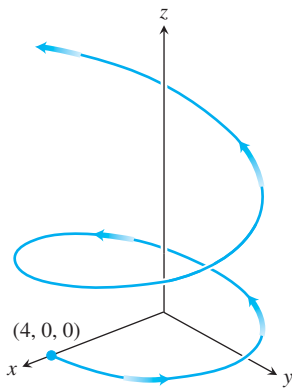

FIGURE 12.9 The path of the hang glider in Example 3. Although the path spirals around the z -axis, it is not a helix.

Integrating both sides of this last differential equation gives

$$\mathbf{r}(t) = (3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t^2\mathbf{k} + \mathbf{C}_2.$$

We then use the initial condition $\mathbf{r}(0) = 4\mathbf{i}$ to find \mathbf{C}_2 :

$$4\mathbf{i} = (3 \cos 0)\mathbf{i} + (3 \sin 0)\mathbf{j} + (0^2)\mathbf{k} + \mathbf{C}_2$$

$$4\mathbf{i} = 3\mathbf{i} + (0)\mathbf{j} + (0)\mathbf{k} + \mathbf{C}_2$$

$$\mathbf{C}_2 = \mathbf{i}.$$

The glider's position as a function of t is

$$\mathbf{r}(t) = (1 + 3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t^2\mathbf{k}.$$

This is the path of the glider shown in Figure 12.9. Although the path resembles that of a helix due to its spiraling nature around the z -axis, it is not a helix because of the way it is rising. (We say more about this in Section 12.5.) ■

The Vector and Parametric Equations for Ideal Projectile Motion

A classic example of integrating vector functions is the derivation of the equations for the motion of a projectile. In physics, projectile motion describes how an object fired at some angle from an initial position, and acted upon by only the force of gravity, moves in a vertical coordinate plane. In the classic example, we ignore the effects of any frictional drag on the object, which may vary with its speed and altitude, and also the fact that the force of gravity changes slightly with the projectile's changing height. In addition, we ignore the long-distance effects of Earth turning beneath the projectile, such as in a rocket launch or the firing of a projectile from a cannon. Ignoring these effects gives us a reasonable approximation of the motion in most cases.

To derive equations for projectile motion, we assume that the projectile behaves like a particle moving in a vertical coordinate plane and that the only force acting on the projectile during its flight is the constant force of gravity, which always points straight down. The magnitude of the gravitational acceleration g is approximately 9.8 m/s^2 at sea level. We assume that the projectile is launched from the origin at time $t = 0$ into the first quadrant with an initial velocity \mathbf{v}_0 (Figure 12.10). If \mathbf{v}_0 makes an angle α with the horizontal, then

$$\mathbf{v}_0 = (|\mathbf{v}_0| \cos \alpha)\mathbf{i} + (|\mathbf{v}_0| \sin \alpha)\mathbf{j}.$$

If we use the simpler notation v_0 for the initial speed $|\mathbf{v}_0|$, then

$$\mathbf{v}_0 = (v_0 \cos \alpha)\mathbf{i} + (v_0 \sin \alpha)\mathbf{j}. \quad (3)$$

The projectile's initial position is

$$\mathbf{r}_0 = 0\mathbf{i} + 0\mathbf{j} = 0. \quad (4)$$

Newton's second law of motion says that the force acting on the projectile is equal to the projectile's mass m times its acceleration, or $m(d^2\mathbf{r}/dt^2)$, if \mathbf{r} is the projectile's position vector and t is time. If the force is solely the gravitational force $-mg\mathbf{j}$, then

$$m \frac{d^2\mathbf{r}}{dt^2} = -mg\mathbf{j} \quad \text{and} \quad \frac{d^2\mathbf{r}}{dt^2} = -g\mathbf{j},$$

where g is the acceleration due to gravity. We find \mathbf{r} as a function of t by solving the following initial value problem.

$$\text{Differential equation:} \quad \frac{d^2\mathbf{r}}{dt^2} = -g\mathbf{j}$$

$$\text{Initial conditions:} \quad \mathbf{r} = \mathbf{r}_0 \quad \text{and} \quad \frac{d\mathbf{r}}{dt} = \mathbf{v}_0 \quad \text{when } t = 0$$

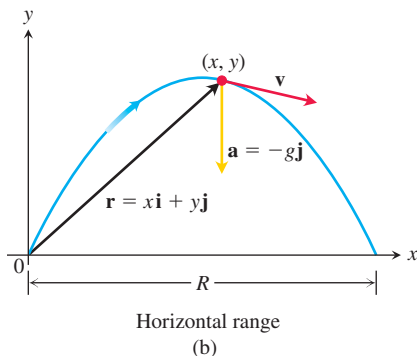

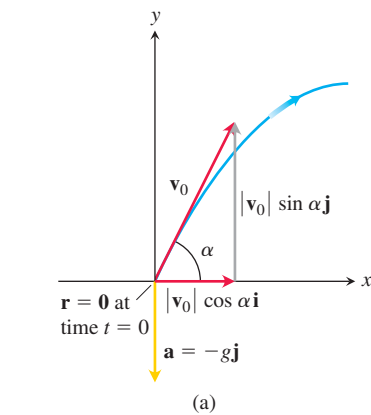

FIGURE 12.10 (a) Position, velocity, acceleration, and launch angle at $t = 0$. (b) Position, velocity, and acceleration at a later time t .

The first integration gives

$$\frac{d\mathbf{r}}{dt} = -(gt)\mathbf{j} + \mathbf{v}_0.$$

A second integration gives

$$\mathbf{r} = -\frac{1}{2}gt^2\mathbf{j} + \mathbf{v}_0t + \mathbf{r}_0.$$

Substituting the values of \mathbf{v}_0 and \mathbf{r}_0 from Equations (3) and (4) gives

$$\mathbf{r} = -\frac{1}{2}gt^2\mathbf{j} + \underbrace{(v_0 \cos \alpha)t\mathbf{i} + (v_0 \sin \alpha)t\mathbf{j}}_{\mathbf{v}_0t} + \mathbf{0}.$$

Collecting terms, we obtain the following.

Ideal Projectile Motion Equation

$$\mathbf{r} = (v_0 \cos \alpha)t\mathbf{i} + \left((v_0 \sin \alpha)t - \frac{1}{2}gt^2 \right)\mathbf{j}. \quad (5)$$

Equation (5) is the *vector equation* of the path for ideal projectile motion. The angle α is the projectile's **launch angle (firing angle, angle of elevation)**, and v_0 , as we said before, is the projectile's **initial speed**. The components of \mathbf{r} give the parametric equations

$$x = (v_0 \cos \alpha)t \quad \text{and} \quad y = (v_0 \sin \alpha)t - \frac{1}{2}gt^2, \quad (6)$$

where x is the distance downrange and y is the height of the projectile at time $t \geq 0$.

EXAMPLE 4 A projectile is fired from the origin over horizontal ground at an initial speed of 500 m/s and a launch angle of 60° . Where will the projectile be 10 s later?

Solution We use Equation (5) with $v_0 = 500$, $\alpha = 60^\circ$, $g = 9.8$, and $t = 10$ to find the projectile's components 10 s after firing.

$$\begin{aligned} \mathbf{r} &= (v_0 \cos \alpha)t\mathbf{i} + \left((v_0 \sin \alpha)t - \frac{1}{2}gt^2 \right)\mathbf{j} \\ &= (500)\left(\frac{1}{2}\right)(10)\mathbf{i} + \left((500)\left(\frac{\sqrt{3}}{2}\right)10 - \left(\frac{1}{2}\right)(9.8)(100) \right)\mathbf{j} \\ &\approx 2500\mathbf{i} + 3840\mathbf{j} \end{aligned}$$

Ten seconds after firing, the projectile is about 3840 m above ground and 2500 m downrange from the origin. ■

Ideal projectiles move along parabolas, as we now deduce from Equations (6). If we substitute $t = x/(v_0 \cos \alpha)$ from the first equation into the second, we obtain the Cartesian coordinate equation

$$y = -\left(\frac{g}{2v_0^2 \cos^2 \alpha} \right)x^2 + (\tan \alpha)x.$$

This equation has the form $y = ax^2 + bx$, so its graph is a parabola.

A projectile reaches its highest point when its vertical velocity component is zero. When fired over horizontal ground, the projectile lands when its vertical component equals zero in Equation (5), and the **range** R is the distance from the origin to the point of impact. We summarize the results here, which you are asked to verify in Exercise 31.

Height, Flight Time, and Range for Ideal Projectile Motion

For ideal projectile motion when an object is launched from the origin over a horizontal surface with initial speed v_0 and launch angle α :

$$\text{Maximum height: } y_{\max} = \frac{(v_0 \sin \alpha)^2}{2g}$$

$$\text{Flight time: } t = \frac{2v_0 \sin \alpha}{g}$$

$$\text{Range: } R = \frac{v_0^2}{g} \sin 2\alpha$$

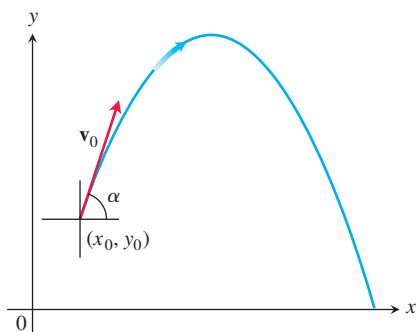

FIGURE 12.11 The path of a projectile fired from (x_0, y_0) with an initial velocity \mathbf{v}_0 at an angle of α degrees with the horizontal.

If we fire our ideal projectile from the point (x_0, y_0) instead of the origin (Figure 12.11), the position vector for the path of motion is

$$\mathbf{r} = (x_0 + (v_0 \cos \alpha)t)\mathbf{i} + \left(y_0 + (v_0 \sin \alpha)t - \frac{1}{2}gt^2\right)\mathbf{j}, \quad (7)$$

as you are asked to show in Exercise 33.

Projectile Motion with Wind Gusts

The next example shows how to account for another force acting on a projectile due to a gust of wind. We assume that the path of the baseball in Example 5 lies in a vertical plane.

EXAMPLE 5 A baseball is hit when it is 1 m above the ground. It leaves the bat with initial speed of 50 m/s, making an angle of 20° with the horizontal. At the instant the ball is hit, an instantaneous gust of wind blows in the horizontal direction directly opposite the direction the ball is taking toward the outfield, adding a component of $-2.5\mathbf{i}$ (m/s) to the ball's initial velocity ($2.5 \text{ m/s} = 9 \text{ km/h}$).

- Find a vector equation (position vector) for the path of the baseball.
- How high does the baseball go, and when does it reach maximum height?
- Assuming that the ball is not caught, find its range and flight time.

Solution

- Using Equation (3) and accounting for the gust of wind, the initial velocity of the baseball is

$$\begin{aligned} \mathbf{v}_0 &= (v_0 \cos \alpha)\mathbf{i} + (v_0 \sin \alpha)\mathbf{j} - 2.5\mathbf{i} \\ &= (50 \cos 20^\circ)\mathbf{i} + (50 \sin 20^\circ)\mathbf{j} - (2.5)\mathbf{i} \\ &= (50 \cos 20^\circ - 2.5)\mathbf{i} + (50 \sin 20^\circ)\mathbf{j}. \end{aligned}$$

The initial position is $\mathbf{r}_0 = 0\mathbf{i} + 1\mathbf{j}$. Integration of $d^2\mathbf{r}/dt^2 = -g\mathbf{j}$ gives

$$\frac{d\mathbf{r}}{dt} = -(gt)\mathbf{j} + \mathbf{v}_0.$$

A second integration gives

$$\mathbf{r} = -\frac{1}{2}gt^2\mathbf{j} + \mathbf{v}_0t + \mathbf{r}_0.$$

Substituting the values of \mathbf{v}_0 and \mathbf{r}_0 into the last equation gives the position vector of the baseball.

$$\begin{aligned}\mathbf{r} &= -\frac{1}{2}gt^2\mathbf{j} + \mathbf{v}_0t + \mathbf{r}_0 \\ &= -4.9t^2\mathbf{j} + (50 \cos 20^\circ - 2.5)t\mathbf{i} + (50 \sin 20^\circ)t\mathbf{j} + \mathbf{j} \\ &= (50 \cos 20^\circ - 2.5)t\mathbf{i} + (1 + (50 \sin 20^\circ)t - 4.9t^2)\mathbf{j}.\end{aligned}$$

(b) The baseball reaches its highest point when the vertical component of velocity is zero, or

$$\frac{dy}{dt} = 50 \sin 20^\circ - 9.8t = 0.$$

Solving for t we find

$$t = \frac{50 \sin 20^\circ}{9.8} \approx 1.75 \text{ s}.$$

Substituting this time into the vertical component for \mathbf{r} gives the maximum height

$$y_{\max} = 1 + (50 \sin 20^\circ)(1.75) - 4.9(1.75)^2 \approx 15.9 \text{ m}.$$

That is, the maximum height of the baseball is about 15.9 m, reached about 1.75 s after leaving the bat.

(c) To find when the baseball lands, we set the vertical component for \mathbf{r} equal to 0 and solve for t :

$$\begin{aligned}1 + (50 \sin 20^\circ)t - 4.9t^2 &= 0 \\ 1 + (17.1)t - 4.9t^2 &= 0.\end{aligned}$$

The solution values are about $t = 3.55$ s and $t = -0.06$ s. Substituting the positive time into the horizontal component for \mathbf{r} , we find the range

$$R = (50 \cos 20^\circ - 2.5)(3.55) \approx 157.8 \text{ m}.$$

Thus, the horizontal range is about 157.8 m, and the flight time is about 3.55 s. ■

In Exercises 41 and 42, we consider projectile motion when there is air resistance slowing down the flight.

EXERCISES 12.2

Integrating Vector-Valued Functions

Evaluate the integrals in Exercises 1–10.

$$1. \int_0^1 [t^3\mathbf{i} + 7\mathbf{j} + (t+1)\mathbf{k}] dt$$

$$2. \int_1^2 \left[(6-6t)\mathbf{i} + 3\sqrt{t}\mathbf{j} + \left(\frac{4}{t^2}\right)\mathbf{k} \right] dt$$

$$3. \int_{-\pi/4}^{\pi/4} [(\sin t)\mathbf{i} + (1 + \cos t)\mathbf{j} + (\sec^2 t)\mathbf{k}] dt$$

$$4. \int_0^{\pi/3} [(\sec t \tan t)\mathbf{i} + (\tan t)\mathbf{j} + (2 \sin t \cos t)\mathbf{k}] dt$$

$$5. \int_1^4 \left[\frac{1}{t}\mathbf{i} + \frac{1}{5-t}\mathbf{j} + \frac{1}{2t}\mathbf{k} \right] dt$$

$$6. \int_0^1 \left[\frac{2}{\sqrt{1-t^2}}\mathbf{i} + \frac{\sqrt{3}}{1+t^2}\mathbf{k} \right] dt$$

$$7. \int_0^1 [te^{t^2}\mathbf{i} + e^{-t}\mathbf{j} + \mathbf{k}] dt$$

$$8. \int_1^{\ln 3} [te^t\mathbf{i} + e^t\mathbf{j} + \ln t\mathbf{k}] dt$$

$$9. \int_0^{\pi/2} [\cos t\mathbf{i} - \sin 2t\mathbf{j} + \sin^2 t\mathbf{k}] dt$$

$$10. \int_0^{\pi/4} [\sec t\mathbf{i} + \tan^2 t\mathbf{j} - t \sin t\mathbf{k}] dt$$

Initial Value Problems

Solve the initial value problems in Exercises 11–20 for \mathbf{r} as a vector function of t .

11. Differential equation: $\frac{d\mathbf{r}}{dt} = -t\mathbf{i} - t\mathbf{j} - t\mathbf{k}$
Initial condition: $\mathbf{r}(0) = \mathbf{i} + 2\mathbf{j} + 3\mathbf{k}$
12. Differential equation: $\frac{d\mathbf{r}}{dt} = (180t)\mathbf{i} + (180t - 16t^2)\mathbf{j}$
Initial condition: $\mathbf{r}(0) = 100\mathbf{j}$
13. Differential equation: $\frac{d\mathbf{r}}{dt} = \frac{3}{2}(t+1)^{1/2}\mathbf{i} + e^{-t}\mathbf{j} + \frac{1}{t+1}\mathbf{k}$
Initial condition: $\mathbf{r}(0) = \mathbf{k}$
14. Differential equation: $\frac{d\mathbf{r}}{dt} = (t^3 + 4t)\mathbf{i} + t\mathbf{j} + 2t^2\mathbf{k}$
Initial condition: $\mathbf{r}(0) = \mathbf{i} + \mathbf{j}$
15. Differential equation:
 $\frac{d\mathbf{r}}{dt} = (\tan t)\mathbf{i} + \left(\cos\left(\frac{1}{2}t\right)\right)\mathbf{j} - (\sec 2t)\mathbf{k}, -\frac{\pi}{4} < t < \frac{\pi}{4}$
Initial condition: $\mathbf{r}(0) = 3\mathbf{i} - 2\mathbf{j} + \mathbf{k}$
16. Differential equation:
 $\frac{d\mathbf{r}}{dt} = \left(\frac{t}{t^2+2}\right)\mathbf{i} - \left(\frac{t^2+1}{t-2}\right)\mathbf{j} + \left(\frac{t^2+4}{t^2+3}\right)\mathbf{k}, t < 2$
Initial condition: $\mathbf{r}(0) = \mathbf{i} - \mathbf{j} + \mathbf{k}$
17. Differential equation: $\frac{d^2\mathbf{r}}{dt^2} = -32\mathbf{k}$
Initial conditions: $\mathbf{r}(0) = 100\mathbf{k}$ and $\left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = 8\mathbf{i} + 8\mathbf{j}$
18. Differential equation: $\frac{d^2\mathbf{r}}{dt^2} = -(\mathbf{i} + \mathbf{j} + \mathbf{k})$
Initial conditions: $\mathbf{r}(0) = 10\mathbf{i} + 10\mathbf{j} + 10\mathbf{k}$ and $\left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = \mathbf{0}$
19. Differential equation: $\frac{d^2\mathbf{r}}{dt^2} = e^t\mathbf{i} - e^{-t}\mathbf{j} + 4e^{2t}\mathbf{k}$
Initial conditions: $\mathbf{r}(0) = 3\mathbf{i} + \mathbf{j} + 2\mathbf{k}$ and $\left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = -\mathbf{i} + 4\mathbf{j}$
20. Differential equation:
 $\frac{d^2\mathbf{r}}{dt^2} = (\sin t)\mathbf{i} - (\cos t)\mathbf{j} + (4 \sin t \cos t)\mathbf{k}$
Initial conditions: $\mathbf{r}(0) = \mathbf{i} - \mathbf{k}$ and $\left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = \mathbf{i}$

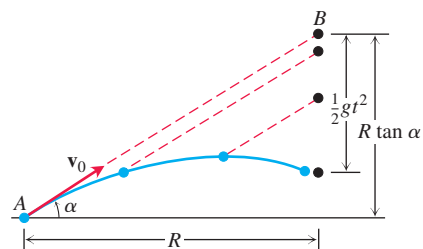

Motion Along a Straight Line

21. At time $t = 0$, a particle is located at the point $(1, 2, 3)$. It travels in a straight line to the point $(4, 1, 4)$, has speed 2 at $(1, 2, 3)$, and has constant acceleration $3\mathbf{i} - \mathbf{j} + \mathbf{k}$. Find an equation for the position vector $\mathbf{r}(t)$ of the particle at time t .
22. A particle traveling in a straight line is located at the point $(1, -1, 2)$ and has speed 2 at time $t = 0$. The particle moves toward the point $(3, 0, 3)$ with constant acceleration $2\mathbf{i} + \mathbf{j} + \mathbf{k}$. Find its position vector $\mathbf{r}(t)$ at time t .

Projectile Motion

Projectile flights in Exercises 23–40 are to be treated as ideal unless stated otherwise. All launch angles are assumed to be measured from the horizontal. All projectiles are assumed to be launched from the origin over a horizontal surface unless stated otherwise. For some exercises, a calculator may be helpful.

23. **Travel time** A projectile is fired at a speed of 840 m/s at an angle of 60° . How long will it take to get 21 km downrange?
24. **Range and height versus speed**
- Show that doubling a projectile's initial speed at a given launch angle multiplies its range by 4.
 - By about what percentage should you increase the initial speed to double the height and range?
25. **Flight time and height** A projectile is fired with an initial speed of 500 m/s at an angle of elevation of 45° .
- When and how far away will the projectile strike?
 - How high overhead will the projectile be when it is 5 km downrange?
 - What is the greatest height reached by the projectile?
26. **Throwing a baseball** A baseball is thrown from the stands 9.8 m above the field at an angle of 30° up from the horizontal. When and how far away will the ball strike the ground if its initial speed is 9.8 m/s?
27. **Firing golf balls** A spring gun at ground level fires a golf ball at an angle of 45° . The ball lands 10 m away.
- What was the ball's initial speed?
 - For the same initial speed, find the two firing angles that make the range 6 m.
28. **Beaming electrons** An electron in a cathode-ray tube (CRT) is beamed horizontally at a speed of 5×10^6 m/s toward the face of the tube 40 cm away. About how far will the electron drop before it hits?
29. **Equal-range firing angles** What two angles of elevation will enable a projectile to reach a target 16 km downrange on the same level as the gun if the projectile's initial speed is 400 m/s?
30. **Finding muzzle speed** Find the muzzle speed of a gun whose maximum range is 24.5 km.
31. Verify the results given in the text (following Example 4) for the maximum height, flight time, and range for ideal projectile motion.
32. **Colliding marbles** The accompanying figure shows an experiment with two marbles. Marble A was launched toward marble B with launch angle α and initial speed v_0 . At the same instant, marble B was released to fall from rest at $R \tan \alpha$ units directly above a spot R units downrange from A. The marbles were found to collide regardless of the value of v_0 . Was this mere coincidence, or must this happen? Give reasons for your answer.

- 33. Firing from (x_0, y_0)** Derive the equations

$$x = x_0 + (v_0 \cos \alpha)t,$$

$$y = y_0 + (v_0 \sin \alpha)t - \frac{1}{2}gt^2$$

(see Equation (7) in the text) by solving the following initial value problem for a vector \mathbf{r} in the plane.

Differential equation: $\frac{d^2\mathbf{r}}{dt^2} = -g\mathbf{j}$

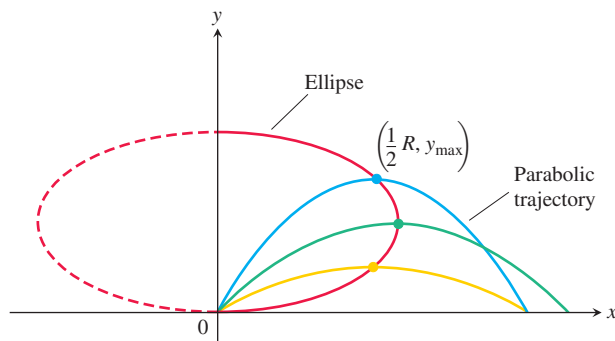

Initial conditions: $\mathbf{r}(0) = x_0\mathbf{i} + y_0\mathbf{j}$

$$\frac{d\mathbf{r}}{dt}(0) = (v_0 \cos \alpha)\mathbf{i} + (v_0 \sin \alpha)\mathbf{j}$$

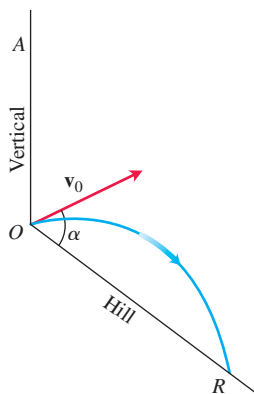

- 34. Where trajectories crest** For a projectile fired from the ground at launch angle α with initial speed v_0 , consider α as a variable and v_0 as a fixed constant. For each α , $0 < \alpha < \pi/2$, we obtain a parabolic trajectory as shown in the accompanying figure. Show that the points in the plane that give the maximum heights of these parabolic trajectories all lie on the ellipse

$$x^2 + 4\left(y - \frac{v_0^2}{4g}\right)^2 = \frac{v_0^4}{4g^2},$$

where $x \geq 0$.

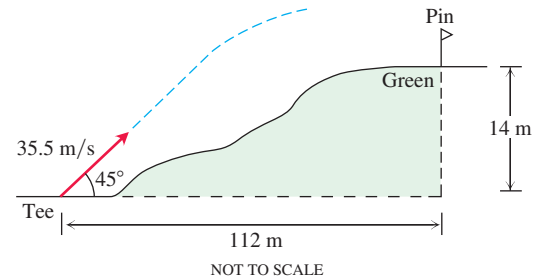

- 35. Launching downhill** An ideal projectile is launched straight down an inclined plane as shown in the accompanying figure.
- Show that the greatest downhill range is achieved when the initial velocity vector bisects angle AOR .
 - If the projectile were fired uphill instead of down, what launch angle would maximize its range? Give reasons for your answer.

- 36. Elevated green** A golf ball is hit with an initial speed of 35.5 m/s at an angle of elevation of 45° from the tee to a green

that is elevated 14 m above the tee as shown in the diagram. Assuming that the pin, 112 m downrange, does not get in the way, where will the ball land in relation to the pin?

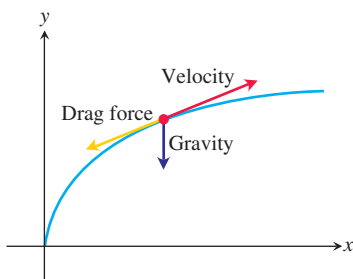

- 37. Volleyball** A volleyball is hit when it is 1.3 m above the ground and 4 m from a 2-m-high net. It leaves the point of impact with an initial velocity of 12 m/s at an angle of 27° and slips by the opposing team untouched.
- Find a vector equation for the path of the volleyball.
 - How high does the volleyball go, and when does it reach maximum height?
 - Find its range and flight time.
 - When is the volleyball 2.3 m above the ground? How far (ground distance) is the volleyball from where it will land?
 - Suppose that the net is raised to 2.5 m. Does this change things? Explain.
- 38. Shot put** In Moscow in 1987, Natalya Lisouskaya set a women's world record by putting a 4 kg shot 22.63 m. Assuming that she launched the shot at a 40° angle to the horizontal from 2 m above the ground, what was the shot's initial speed?
- 39.** A child throws a ball with an initial speed of 18 m/s at an angle of elevation of 60° toward a tall building that is 7 m from the child. If the child's hand is 1.6 m from the ground, show that the ball hits the building, and find the height above the ground of the point where the ball hits the building.
- 40. Hitting a baseball under a wind gust** A baseball is hit when it is 0.8 m above the ground. It leaves the bat with an initial velocity of 40 m/s at a launch angle of 23° . At the instant the ball is hit, an instantaneous gust of wind blows against the ball, adding a component of $-4\mathbf{i}$ (m/s) to the ball's initial velocity. A 5-m-high fence lies 90 m from home plate in the direction of the flight.
- Find a vector equation for the path of the baseball.
 - How high does the baseball go, and when does it reach maximum height?
 - Find the range and flight time of the baseball, assuming that the ball is not caught.
 - When is the baseball 6 m high? How far (ground distance) is the baseball from home plate at that height?
 - Has the batter hit a home run? Explain.

Projectile Motion with Linear Drag

The main force affecting the motion of a projectile, other than gravity, is air resistance. This slowing down force is **drag force**, and it acts in a direction *opposite* to the velocity of the projectile (see accompanying figure). For projectiles moving through the air at relatively low speeds,

however, the drag force is (very nearly) proportional to the speed (to the first power) and so is called **linear**.

41. Linear drag Derive the equations

$$x = \frac{v_0}{k}(1 - e^{-kt})\cos \alpha$$

$$y = \frac{v_0}{k}(1 - e^{-kt})(\sin \alpha) + \frac{g}{k^2}(1 - kt - e^{-kt})$$

by solving the following initial value problem for a vector \mathbf{r} in the plane.

Differential equation: $\frac{d^2\mathbf{r}}{dt^2} = -g\mathbf{j} - k\mathbf{v} = -g\mathbf{j} - k\frac{d\mathbf{r}}{dt}$

Initial conditions: $\mathbf{r}(0) = \mathbf{0}$

$$\left.\frac{d\mathbf{r}}{dt}\right|_{t=0} = \mathbf{v}_0 = (v_0 \cos \alpha)\mathbf{i} + (v_0 \sin \alpha)\mathbf{j}$$

The **drag coefficient** k is a positive constant representing resistance due to air density, v_0 and α are the projectile's initial speed and launch angle, and g is the acceleration of gravity.

42. Hitting a baseball with linear drag Consider the baseball problem in Example 5 when there is linear drag (see Exercise 41). Assume a drag coefficient $k = 0.12$, but no gust of wind.

- From Exercise 41, find a vector form for the path of the baseball.
- How high does the baseball go, and when does it reach maximum height?
- Find the range and flight time of the baseball.
- When is the baseball 9 m high? How far (ground distance) is the baseball from home plate at that height?
- A 3-m-high outfield fence is 115 m from home plate in the direction of the flight of the baseball. The outfielder can jump and catch any ball up to 3.3 m off the ground to stop it from going over the fence. Has the batter hit a home run?

Theory and Examples

43. Establish the following properties of integrable vector functions.

a. The *Constant Scalar Multiple Rule*:

$$\int_a^b k\mathbf{r}(t) dt = k \int_a^b \mathbf{r}(t) dt \quad (\text{any scalar } k)$$

The *Rule for Negatives*,

$$\int_a^b (-\mathbf{r}(t)) dt = -\int_a^b \mathbf{r}(t) dt,$$

is obtained by taking $k = -1$.

b. The *Sum and Difference Rules*:

$$\int_a^b (\mathbf{r}_1(t) \pm \mathbf{r}_2(t)) dt = \int_a^b \mathbf{r}_1(t) dt \pm \int_a^b \mathbf{r}_2(t) dt$$

c. The *Constant Vector Multiple Rules*:

$$\int_a^b \mathbf{C} \cdot \mathbf{r}(t) dt = \mathbf{C} \cdot \int_a^b \mathbf{r}(t) dt \quad (\text{any constant vector } \mathbf{C})$$

and

$$\int_a^b \mathbf{C} \times \mathbf{r}(t) dt = \mathbf{C} \times \int_a^b \mathbf{r}(t) dt \quad (\text{any constant vector } \mathbf{C})$$

44. Products of scalar and vector functions Suppose that the scalar function $u(t)$ and the vector function $\mathbf{r}(t)$ are both defined for $a \leq t \leq b$.

- Show that $u\mathbf{r}$ is continuous on $[a, b]$ if u and \mathbf{r} are continuous on $[a, b]$.
- If u and \mathbf{r} are both differentiable on $[a, b]$, show that $u\mathbf{r}$ is differentiable on $[a, b]$ and that

$$\frac{d}{dt}(u\mathbf{r}) = u\frac{d\mathbf{r}}{dt} + \frac{du}{dt}\mathbf{r}.$$

45. Antiderivatives of vector functions

- Use Corollary 2 of the Mean Value Theorem for scalar functions to show that if two vector functions $\mathbf{R}_1(t)$ and $\mathbf{R}_2(t)$ have identical derivatives on an interval I , then the functions differ by a constant vector value throughout I .
- Use the result in part (a) to show that if $\mathbf{R}(t)$ is any antiderivative of $\mathbf{r}(t)$ on I , then any other antiderivative of \mathbf{r} on I equals $\mathbf{R}(t) + \mathbf{C}$ for some constant vector \mathbf{C} .

46. The Fundamental Theorem of Calculus The Fundamental Theorem of Calculus for scalar functions of a real variable holds for vector functions of a real variable as well. Prove this by using the theorem for scalar functions to show first that if a vector function $\mathbf{r}(t)$ is continuous for $a \leq t \leq b$, then

$$\frac{d}{dt} \int_a^t \mathbf{r}(\tau) d\tau = \mathbf{r}(t)$$

at every point t of (a, b) . Then use the conclusion in part (b) of Exercise 45 to show that if \mathbf{R} is any antiderivative of \mathbf{r} on $[a, b]$, then

$$\int_a^b \mathbf{r}(t) dt = \mathbf{R}(b) - \mathbf{R}(a).$$

47. Hitting a baseball with linear drag under a wind gust

Consider again the baseball problem in Example 5. This time, assume a drag coefficient of 0.08 and an instantaneous gust of wind that adds a component of $-5\mathbf{i}$ (m/s) to the initial velocity at the instant the baseball is hit.

- Find a vector equation for the path of the baseball.
- How high does the baseball go, and when does it reach maximum height?
- Find the range and flight time of the baseball.
- When is the baseball 10 m high? How far (ground distance) is the baseball from home plate at that height?
- A 6-m-high outfield fence is 120 m from home plate in the direction of the flight of the baseball. Has the batter hit a home run? If "yes," what change in the horizontal component of the ball's initial velocity would have kept the ball in the park? If "no," what change would have allowed it to be a home run?

48. Height versus time Show that a projectile attains three-quarters of its maximum height in half the time it takes to reach the maximum height.

12.3 Arc Length in Space

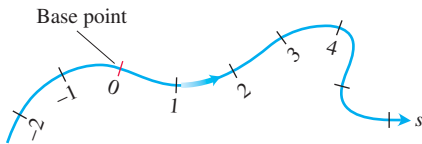

FIGURE 12.12 Smooth curves can be scaled like number lines, the coordinate of each point being its directed distance along the curve from a preselected base point.

In this and the next two sections, we study the mathematical features of a curve's shape that describe the sharpness of its turning and its twisting.

Arc Length Along a Space Curve

One of the features of smooth space and plane curves is that they have a measurable length. This enables us to locate points along these curves by giving their directed distance s along the curve from some base point, the way we locate points on coordinate axes by giving their directed distance from the origin (Figure 12.12). This is what we did for plane curves in Section 10.2.

To measure distance along a smooth curve in space, we add a z -term to the formula we use for curves in the plane.

DEFINITION The **length** of a smooth curve $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$, $a \leq t \leq b$, that is traced exactly once as t increases from $t = a$ to $t = b$ is

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} dt. \quad (1)$$

Just as for plane curves, we can calculate the length of a curve in space from any convenient parametrization that meets the stated conditions. We omit the proof.

The square root in Equation (1) is $|\mathbf{v}|$, the length of a velocity vector $d\mathbf{r}/dt$. This enables us to write the formula for length a shorter way.

Arc Length Formula

$$L = \int_a^b |\mathbf{v}| dt \quad (2)$$

EXAMPLE 1 A glider is soaring upward along the helix

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}.$$

How long is the glider's path from $t = 0$ to $t = 2\pi$?

Solution The path segment during this time corresponds to one full turn of the helix (Figure 12.13). The length of this portion of the curve is

$$\begin{aligned} L &= \int_0^{2\pi} |\mathbf{v}| dt = \int_0^{2\pi} \sqrt{(-\sin t)^2 + (\cos t)^2 + (1)^2} dt \\ &= \int_0^{2\pi} \sqrt{2} dt = 2\pi\sqrt{2} \text{ units of length.} \end{aligned}$$

This is $\sqrt{2}$ times the circumference of the circle in the xy -plane over which the helix stands. ■

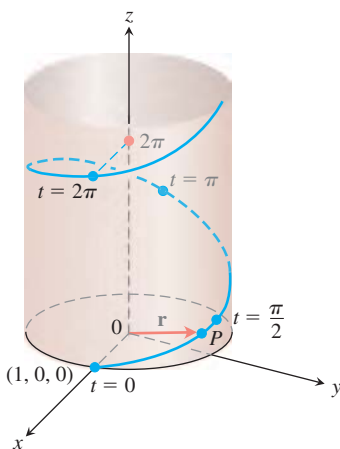

FIGURE 12.13 The helix in Example 1, $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$.

If we choose a base point $P(t_0)$ on a smooth curve C parametrized by t , each value of t determines a point $P(t) = (x(t), y(t), z(t))$ on C and a "directed distance"

$$s(t) = \int_{t_0}^t |\mathbf{v}(\tau)| d\tau,$$

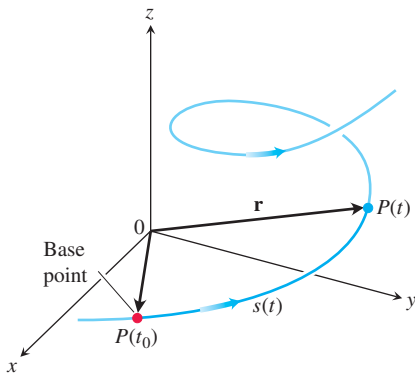

FIGURE 12.14 The directed distance along the curve from $P(t_0)$ to any point $P(t)$ is $s(t) = \int_{t_0}^t |\mathbf{v}(\tau)| d\tau$.

τ is the Greek letter tau (rhymes with “now”)

measured along C from the base point (Figure 12.14). This is the arc length function we defined in Section 10.2 for plane curves that have no z -component. If $t > t_0$, $s(t)$ is the distance along the curve from $P(t_0)$ to $P(t)$. If $t < t_0$, $s(t)$ is the negative of the distance. Each value of s determines a point on C , and this parametrizes C with respect to s . We call s an **arc length parameter** for the curve. The parameter’s value increases in the direction of increasing t . We will see that the arc length parameter is particularly effective for investigating the turning and twisting nature of a space curve.

Arc Length Parameter with Base Point $P(t_0)$

$$s(t) = \int_{t_0}^t \sqrt{[x'(\tau)]^2 + [y'(\tau)]^2 + [z'(\tau)]^2} d\tau = \int_{t_0}^t |\mathbf{v}(\tau)| d\tau \quad (3)$$

We use the Greek letter τ (“tau”) as the variable of integration in Equation (3) because the letter t is already in use as the upper limit.

If a curve $\mathbf{r}(t)$ is already given in terms of some parameter t , and $s(t)$ is the arc length function given by Equation (3), then we may be able to solve for t as a function of s : $t = t(s)$. Then the curve can be reparametrized in terms of s by substituting for t : $\mathbf{r} = \mathbf{r}(t(s))$. The new parametrization identifies a point on the curve with its directed distance along the curve from the base point.

EXAMPLE 2 This is an example for which we can actually find the arc length parametrization of a curve. If $t_0 = 0$, then the arc length parameter along the helix

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$$

from t_0 to t is

$$\begin{aligned} s(t) &= \int_{t_0}^t |\mathbf{v}(\tau)| d\tau && \text{Eq. (3)} \\ &= \int_0^t \sqrt{2} d\tau && \text{Value from Example 1} \\ &= \sqrt{2}t. \end{aligned}$$

Solving this equation for t gives $t = s/\sqrt{2}$. Substituting into the position vector \mathbf{r} gives the following arc length parametrization for the helix:

$$\mathbf{r}(t(s)) = \left(\cos \frac{s}{\sqrt{2}}\right)\mathbf{i} + \left(\sin \frac{s}{\sqrt{2}}\right)\mathbf{j} + \frac{s}{\sqrt{2}}\mathbf{k}. \quad \blacksquare$$

Unlike the case that appears in Example 2, the arc length parametrization is generally difficult to find analytically for a curve already given in terms of some other parameter t . Fortunately, however, we rarely need an exact formula for $s(t)$ or its inverse $t(s)$.

HISTORICAL BIOGRAPHY

Josiah Willard Gibbs
(1839–1903)

Gibbs, born in Connecticut, USA, taught at Yale as a professor of mathematics. He made contributions to thermodynamics, electromagnetics, and statistical mechanics. For his foundational work, Gibbs is known as the father of vector analysis.

Speed on a Smooth Curve

Since the derivatives beneath the radical in Equation (3) are continuous (the curve is smooth), the Fundamental Theorem of Calculus tells us that s is a differentiable function of t with derivative

$$\frac{ds}{dt} = |\mathbf{v}(t)|. \quad (4)$$

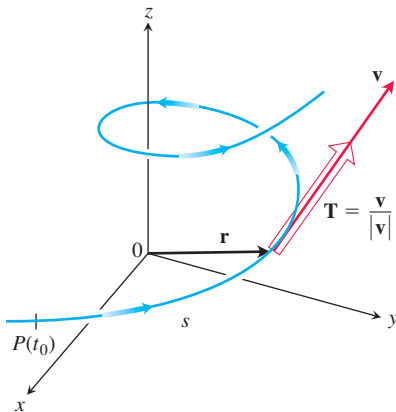

FIGURE 12.15 We find the unit tangent vector \mathbf{T} by dividing \mathbf{v} by its length $|\mathbf{v}|$.

Although the base point $P(t_0)$ plays a role in defining s in Equation (3), it plays no role in Equation (4). The rate at which a moving particle covers distance along its path is independent of how far away it is from the base point. Equation (4) says that this rate is the magnitude of \mathbf{v} .

Notice that $ds/dt > 0$ since, by definition, $|\mathbf{v}|$ is never zero for a smooth curve. We see once again that s is an increasing function of t .

Unit Tangent Vector

On a smooth curve, we already know that the velocity vector $\mathbf{v} = d\mathbf{r}/dt$ is tangent to the curve $\mathbf{r}(t)$ and that the vector

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|}$$

is therefore a unit vector tangent to the curve, called the **unit tangent vector** (Figure 12.15). The unit tangent vector \mathbf{T} for a smooth curve is a differentiable function of t whenever \mathbf{v} is a differentiable function of t . As we will see in Section 12.5, \mathbf{T} is one of three unit vectors in a traveling reference frame that is used to describe the motion of objects traveling in three dimensions.

EXAMPLE 3 Find the unit tangent vector of the curve

$$\mathbf{r}(t) = (1 + 3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t^2\mathbf{k}$$

representing the path of the glider in Example 3, Section 12.2.

Solution In that example, we found

$$\mathbf{v} = \frac{d\mathbf{r}}{dt} = -(3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 2t\mathbf{k}$$

and

$$|\mathbf{v}| = \sqrt{9 + 4t^2}.$$

Thus,

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|} = -\frac{3 \sin t}{\sqrt{9 + 4t^2}}\mathbf{i} + \frac{3 \cos t}{\sqrt{9 + 4t^2}}\mathbf{j} + \frac{2t}{\sqrt{9 + 4t^2}}\mathbf{k}. \quad \blacksquare$$

For the counterclockwise motion

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$$

around the unit circle, we see that

$$\mathbf{v} = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j}$$

is already a unit vector, so $\mathbf{T} = \mathbf{v}$ and \mathbf{T} is orthogonal to \mathbf{r} (Figure 12.16).

The velocity vector is the change in the position vector \mathbf{r} with respect to time t , but how does the position vector change with respect to arc length? More precisely, what is the derivative $d\mathbf{r}/ds$? Since $ds/dt > 0$ for the curves we are considering, s is one-to-one and has an inverse that gives t as a differentiable function of s (Section 3.8). The derivative of the inverse is

$$\frac{dt}{ds} = \frac{1}{ds/dt} = \frac{1}{|\mathbf{v}|}.$$

This makes \mathbf{r} a differentiable function of s whose derivative can be calculated with the Chain Rule to be

$$\frac{d\mathbf{r}}{ds} = \frac{d\mathbf{r}}{dt} \frac{dt}{ds} = \mathbf{v} \frac{1}{|\mathbf{v}|} = \frac{\mathbf{v}}{|\mathbf{v}|} = \mathbf{T}. \quad (5)$$

This equation says that $d\mathbf{r}/ds$ is the unit tangent vector in the direction of the velocity vector \mathbf{v} (Figure 12.15).

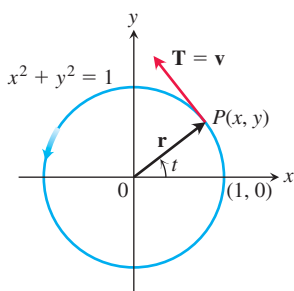

FIGURE 12.16 Counterclockwise motion around the unit circle.

EXERCISES 12.3

Finding Tangent Vectors and Lengths

In Exercises 1–8, find the curve's unit tangent vector. Also, find the length of the indicated portion of the curve.

- $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{j} + \sqrt{5}t\mathbf{k}, \quad 0 \leq t \leq \pi$
 - $\mathbf{r}(t) = (6 \sin 2t)\mathbf{i} + (6 \cos 2t)\mathbf{j} + 5t\mathbf{k}, \quad 0 \leq t \leq \pi$
 - $\mathbf{r}(t) = t\mathbf{i} + (2/3)t^{3/2}\mathbf{k}, \quad 0 \leq t \leq 8$
 - $\mathbf{r}(t) = (2 + t)\mathbf{i} - (t + 1)\mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq 3$
 - $\mathbf{r}(t) = (\cos^3 t)\mathbf{j} + (\sin^3 t)\mathbf{k}, \quad 0 \leq t \leq \pi/2$
 - $\mathbf{r}(t) = 6t^3\mathbf{i} - 2t^3\mathbf{j} - 3t^3\mathbf{k}, \quad 1 \leq t \leq 2$
 - $\mathbf{r}(t) = (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} + (2\sqrt{2}/3)t^{3/2}\mathbf{k}, \quad 0 \leq t \leq \pi$
 - $\mathbf{r}(t) = (t \sin t + \cos t)\mathbf{i} + (t \cos t - \sin t)\mathbf{j}, \quad \sqrt{2} \leq t \leq 2$
9. Find the point on the curve

$$\mathbf{r}(t) = (5 \sin t)\mathbf{i} + (5 \cos t)\mathbf{j} + 12t\mathbf{k}$$

at a distance 26π units along the curve from the point $(0, 5, 0)$ in the direction corresponding to increasing t values.

10. Find the point on the curve

$$\mathbf{r}(t) = (12 \sin t)\mathbf{i} - (12 \cos t)\mathbf{j} + 5t\mathbf{k}$$

at a distance 13π units along the curve from the point $(0, -12, 0)$ in the direction corresponding to decreasing t values.

Arc Length Parameter

In Exercises 11–14, find the arc length parameter along the curve from the point where $t = 0$ by evaluating the integral

$$s(t) = \int_0^t |\mathbf{v}(\tau)| d\tau$$

from Equation (3). Then use the formula for $s(t)$ to find the length of the indicated portion of the curve.

- $\mathbf{r}(t) = (4 \cos t)\mathbf{i} + (4 \sin t)\mathbf{j} + 3t\mathbf{k}, \quad 0 \leq t \leq \pi/2$
- $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}, \quad \pi/2 \leq t \leq \pi$
- $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + e^t \mathbf{k}, \quad -\ln 4 \leq t \leq 0$
- $\mathbf{r}(t) = (1 + 2t)\mathbf{i} + (1 + 3t)\mathbf{j} + (6 - 6t)\mathbf{k}, \quad -1 \leq t \leq 0$

Theory and Examples

15. **Arc length** Find the length of the curve

$$\mathbf{r}(t) = (\sqrt{2}t)\mathbf{i} + (\sqrt{2}t)\mathbf{j} + (1 - t^2)\mathbf{k}$$

from $(0, 0, 1)$ to $(\sqrt{2}, \sqrt{2}, 0)$.

16. **Length of helix** The length $2\pi\sqrt{2}$ of the turn of the helix in Example 1 is also the length of the diagonal of a square 2π units on a side. Show how to obtain this square by cutting away and flattening a portion of the cylinder around which the helix winds.

17. **Ellipse**

- Show that the curve $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (1 - \cos t)\mathbf{k}, \quad 0 \leq t \leq 2\pi$, is an ellipse by showing that it is the intersection of a right circular cylinder and a plane. Find equations for the cylinder and plane.
- Sketch the ellipse on the cylinder. Add to your sketch the unit tangent vectors at $t = 0, \pi/2, \pi$, and $3\pi/2$.

- Show that the acceleration vector always lies parallel to the plane (orthogonal to a vector normal to the plane). Thus, if you draw the acceleration as a vector attached to the ellipse, it will lie in the plane of the ellipse. Add the acceleration vectors for $t = 0, \pi/2, \pi$, and $3\pi/2$ to your sketch.
- Write an integral for the length of the ellipse. Do not try to evaluate the integral; it is nonelementary.

- T** e. **Numerical integrator** Estimate the length of the ellipse to two decimal places.

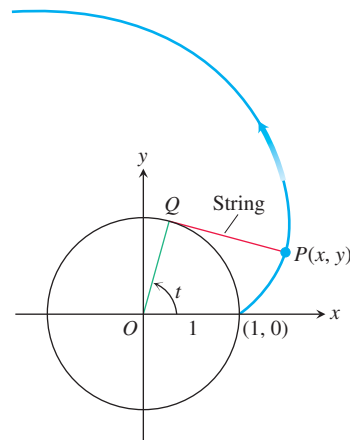

18. **Length is independent of parametrization** To illustrate that the length of a smooth space curve does not depend on the parametrization you use to compute it, calculate the length of one turn of the helix in Example 1 with the following parametrizations.

- $\mathbf{r}(t) = (\cos 4t)\mathbf{i} + (\sin 4t)\mathbf{j} + 4t\mathbf{k}, \quad 0 \leq t \leq \pi/2$
- $\mathbf{r}(t) = [\cos(t/2)]\mathbf{i} + [\sin(t/2)]\mathbf{j} + (t/2)\mathbf{k}, \quad 0 \leq t \leq 4\pi$
- $\mathbf{r}(t) = (\cos t)\mathbf{i} - (\sin t)\mathbf{j} - t\mathbf{k}, \quad -2\pi \leq t \leq 0$

19. **The involute of a circle** If a string wound around a fixed circle is unwound while held taut in the plane of the circle, its end P traces an *involute* of the circle. In the accompanying figure, the circle in question is the circle $x^2 + y^2 = 1$ and the tracing point starts at $(1, 0)$. The unwound portion of the string is tangent to the circle at Q , and t is the radian measure of the angle from the positive x -axis to segment OQ . Derive the parametric equations

$$x = \cos t + t \sin t, \quad y = \sin t - t \cos t, \quad t > 0$$

of the point $P(x, y)$ for the involute.

- (Continuation of Exercise 19.) Find the unit tangent vector to the involute of the circle at the point $P(x, y)$.
- Distance along a line** Show that if \mathbf{u} is a unit vector, then the arc length parameter along the line $\mathbf{r}(t) = P_0 + t\mathbf{u}$ from the point $P_0(x_0, y_0, z_0)$ where $t = 0$, is t itself.
- Use Simpson's Rule with $n = 10$ to approximate the length of arc of $\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + t^3\mathbf{k}$ from the origin to the point $(2, 4, 8)$.

12.4 Curvature and Normal Vectors of a Curve

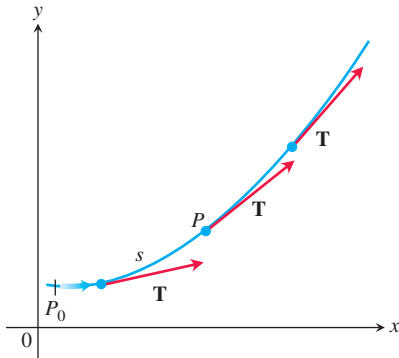

FIGURE 12.17 As P moves along the curve in the direction of increasing arc length, the unit tangent vector turns. The value of $|d\mathbf{T}/ds|$ at P is called the *curvature* of the curve at P .

In this section we study how a curve turns or bends. To gain perspective, we look first at curves in the coordinate plane. Then we consider curves in space.

Curvature of a Plane Curve

As a particle moves along a smooth curve in the plane, $\mathbf{T} = d\mathbf{r}/ds$ turns as the curve bends. Since \mathbf{T} is a unit vector, its length remains constant and only its direction changes as the particle moves along the curve. The rate at which \mathbf{T} turns per unit of length along the curve is called the *curvature* (Figure 12.17). The traditional symbol for the curvature function is the Greek letter κ (“kappa”).

DEFINITION If \mathbf{T} is the unit tangent vector of a smooth curve in the plane, then the **curvature** function of the curve is

$$\kappa = \left| \frac{d\mathbf{T}}{ds} \right|.$$

If $|d\mathbf{T}/ds|$ is large, \mathbf{T} turns sharply as the particle passes through P , and the curvature at P is large. If $|d\mathbf{T}/ds|$ is close to zero, \mathbf{T} turns more slowly, and the curvature at P is smaller.

If a smooth curve $\mathbf{r}(t)$ is already given in terms of some parameter t other than the arc length parameter s , we can calculate the curvature as

$$\begin{aligned} \kappa &= \left| \frac{d\mathbf{T}}{ds} \right| = \left| \frac{d\mathbf{T}}{dt} \frac{dt}{ds} \right| && \text{Chain Rule} \\ &= \frac{1}{|ds/dt|} \left| \frac{d\mathbf{T}}{dt} \right| \\ &= \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right|. && \frac{ds}{dt} = |\mathbf{v}| \end{aligned}$$

κ is the Greek letter kappa.

Formula for Calculating Curvature

If $\mathbf{r}(t)$ is a smooth curve in the plane, then the curvature is the scalar function

$$\kappa = \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right|, \quad (1)$$

where $\mathbf{T} = \mathbf{v}/|\mathbf{v}|$ is the unit tangent vector.

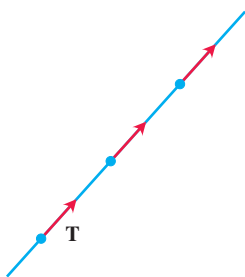

FIGURE 12.18 Along a straight line, \mathbf{T} always points in the same direction. The curvature, $|d\mathbf{T}/ds|$, is zero (Example 1).

Testing the definition, we see in Examples 1 and 2 below that the curvature is constant for straight lines and circles.

EXAMPLE 1 A straight line is parametrized by $\mathbf{r}(t) = \mathbf{C} + t\mathbf{v}$ for constant vectors \mathbf{C} and \mathbf{v} . Thus, $\mathbf{r}'(t) = \mathbf{v}$, and the unit tangent vector $\mathbf{T} = \mathbf{v}/|\mathbf{v}|$ is a constant vector that always points in the same direction and has derivative $\mathbf{0}$ (Figure 12.18). It follows that, for any value of the parameter t , the curvature of the straight line is zero:

$$\kappa = \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right| = \frac{1}{|\mathbf{v}|} |\mathbf{0}| = 0. \quad \blacksquare$$

EXAMPLE 2 Here we find the curvature of a circle. We begin with the parametrization

$$\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}$$

of a circle of radius a . Then

$$\mathbf{v} = \frac{d\mathbf{r}}{dt} = -(a \sin t)\mathbf{i} + (a \cos t)\mathbf{j}$$

$$|\mathbf{v}| = \sqrt{(-a \sin t)^2 + (a \cos t)^2} = \sqrt{a^2} = |a| = a. \quad \text{Since } a > 0, |a| = a.$$

From this we find

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|} = -(\sin t)\mathbf{i} + (\cos t)\mathbf{j}$$

$$\frac{d\mathbf{T}}{dt} = -(\cos t)\mathbf{i} - (\sin t)\mathbf{j}$$

$$\left| \frac{d\mathbf{T}}{dt} \right| = \sqrt{\cos^2 t + \sin^2 t} = 1.$$

Hence, for any value of the parameter t , the curvature of the circle is

$$\kappa = \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right| = \frac{1}{a}(1) = \frac{1}{a} = \frac{1}{\text{radius}}. \quad \blacksquare$$

Among the vectors orthogonal to the unit tangent vector \mathbf{T} , there is one of particular significance because it points in the direction in which the curve is turning. Since \mathbf{T} has constant length (because its length is always 1), the derivative $d\mathbf{T}/ds$ is orthogonal to \mathbf{T} (Equation 4, Section 12.1). Therefore, if we divide $d\mathbf{T}/ds$ by its length κ , we obtain a *unit* vector \mathbf{N} orthogonal to \mathbf{T} (Figure 12.19).

DEFINITION At a point where $\kappa \neq 0$, the **principal unit normal** vector for a smooth curve in the plane is

$$\mathbf{N} = \frac{1}{\kappa} \frac{d\mathbf{T}}{ds}.$$

The vector $d\mathbf{T}/ds$ points in the direction in which \mathbf{T} turns as the curve bends. Therefore, if we face in the direction of increasing arc length, the vector $d\mathbf{T}/ds$ points toward the right if \mathbf{T} turns clockwise and toward the left if \mathbf{T} turns counterclockwise. In other words, the principal normal vector \mathbf{N} will point toward the concave side of the curve (Figure 12.19).

If a smooth curve $\mathbf{r}(t)$ is already given in terms of some parameter t other than the arc length parameter s , we can use the Chain Rule to calculate \mathbf{N} directly:

$$\begin{aligned} \mathbf{N} &= \frac{d\mathbf{T}/ds}{|d\mathbf{T}/ds|} \\ &= \frac{(d\mathbf{T}/dt)(dt/ds)}{|d\mathbf{T}/dt| |dt/ds|} \\ &= \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|}. \end{aligned} \quad \frac{dt}{ds} = \frac{1}{ds/dt} > 0 \text{ cancels.}$$

This formula enables us to find \mathbf{N} without having to find κ and s first.

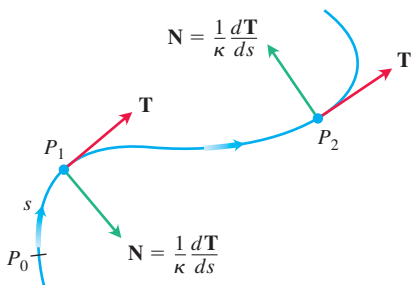

FIGURE 12.19 The vector $d\mathbf{T}/ds$, normal to the curve, always points in the direction in which \mathbf{T} is turning. The unit normal vector \mathbf{N} is the direction of $d\mathbf{T}/ds$.

Formula for Calculating \mathbf{N}

If $\mathbf{r}(t)$ is a smooth curve in the plane, then the principal unit normal is

$$\mathbf{N} = \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|}, \quad (2)$$

where $\mathbf{T} = \mathbf{v}/|\mathbf{v}|$ is the unit tangent vector.

EXAMPLE 3 Find \mathbf{T} and \mathbf{N} for the circular motion

$$\mathbf{r}(t) = (\cos 2t)\mathbf{i} + (\sin 2t)\mathbf{j}.$$

Solution We first find \mathbf{T} :

$$\mathbf{v} = -(2 \sin 2t)\mathbf{i} + (2 \cos 2t)\mathbf{j}$$

$$|\mathbf{v}| = \sqrt{4 \sin^2 2t + 4 \cos^2 2t} = 2$$

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|} = -(\sin 2t)\mathbf{i} + (\cos 2t)\mathbf{j}.$$

From this we find

$$\frac{d\mathbf{T}}{dt} = -(2 \cos 2t)\mathbf{i} - (2 \sin 2t)\mathbf{j}$$

$$\left| \frac{d\mathbf{T}}{dt} \right| = \sqrt{4 \cos^2 2t + 4 \sin^2 2t} = 2$$

and

$$\mathbf{N} = \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|} = -(\cos 2t)\mathbf{i} - (\sin 2t)\mathbf{j}. \quad \text{Eq. (2)}$$

Notice that $\mathbf{T} \cdot \mathbf{N} = 0$, verifying that \mathbf{N} is orthogonal to \mathbf{T} . Notice too, that for the circular motion here, \mathbf{N} points from $\mathbf{r}(t)$ toward the circle's center at the origin. ■

Circle of Curvature for Plane Curves

The **circle of curvature** or **osculating circle** at a point P on a plane curve where $\kappa \neq 0$ is the circle in the plane of the curve that

1. is tangent to the curve at P (has the same tangent line the curve has)
2. has the same curvature the curve has at P
3. has center that lies toward the concave or inner side of the curve (as in Figure 12.20).

The **radius of curvature** of the curve at P is the radius of the circle of curvature, which, according to Example 2, is

$$\text{Radius of curvature} = \rho = \frac{1}{\kappa}.$$

To find ρ , we find κ and take the reciprocal. The **center of curvature** of the curve at P is the center of the circle of curvature.

EXAMPLE 4 Find and graph the osculating circle of the parabola $y = x^2$ at the origin.

Solution We parametrize the parabola using the parameter $t = x$ (Section 10.1, Example 5):

$$\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j}.$$

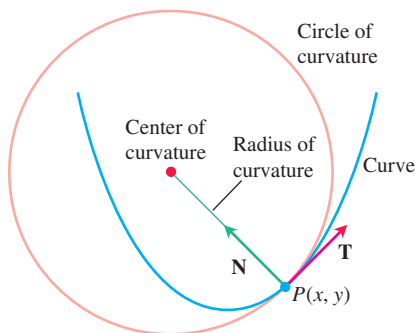

FIGURE 12.20 The center of the osculating circle at $P(x, y)$ lies toward the inner side of the curve.

First we find the curvature of the parabola at the origin, using Equation (1):

$$\mathbf{v} = \frac{d\mathbf{r}}{dt} = \mathbf{i} + 2t\mathbf{j}$$

$$|\mathbf{v}| = \sqrt{1 + 4t^2}$$

so that

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|} = (1 + 4t^2)^{-1/2} \mathbf{i} + 2t(1 + 4t^2)^{-1/2} \mathbf{j}.$$

From this we find

$$\frac{d\mathbf{T}}{dt} = -4t(1 + 4t^2)^{-3/2} \mathbf{i} + [2(1 + 4t^2)^{-1/2} - 8t^2(1 + 4t^2)^{-3/2}] \mathbf{j}.$$

At the origin, $t = 0$, so the curvature is

$$\begin{aligned} \kappa(0) &= \frac{1}{|\mathbf{v}(0)|} \left| \frac{d\mathbf{T}}{dt}(0) \right| && \text{Eq. (1)} \\ &= \frac{1}{\sqrt{1}} |0\mathbf{i} + 2\mathbf{j}| \\ &= (1)\sqrt{0^2 + 2^2} = 2. \end{aligned}$$

Therefore, the radius of curvature is $1/\kappa = 1/2$. At the origin we have $t = 0$ and $\mathbf{T} = \mathbf{i}$, so $\mathbf{N} = \mathbf{j}$. Thus the center of the circle is $(0, 1/2)$. The equation of the osculating circle is

$$(x - 0)^2 + \left(y - \frac{1}{2}\right)^2 = \left(\frac{1}{2}\right)^2.$$

You can see from Figure 12.21 that the osculating circle is a better approximation to the parabola at the origin than is the tangent line approximation $y = 0$. ■

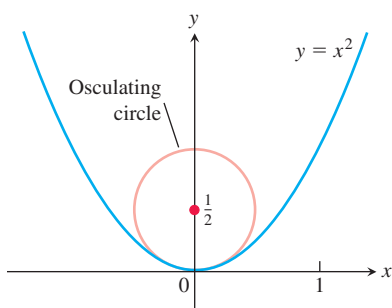

FIGURE 12.21 The osculating circle for the parabola $y = x^2$ at the origin (Example 4).

Curvature and Normal Vectors for Space Curves

If a smooth curve in space is specified by the position vector $\mathbf{r}(t)$ as a function of some parameter t , and if s is the arc length parameter of the curve, then the unit tangent vector \mathbf{T} is $d\mathbf{r}/ds = \mathbf{v}/|\mathbf{v}|$. The **curvature** in space is then defined to be

$$\kappa = \left| \frac{d\mathbf{T}}{ds} \right| = \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right| \quad (3)$$

just as for plane curves. The vector $d\mathbf{T}/ds$ is orthogonal to \mathbf{T} , and we define the **principal unit normal** to be

$$\mathbf{N} = \frac{1}{\kappa} \frac{d\mathbf{T}}{ds} = \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|}. \quad (4)$$

EXAMPLE 5 Find the curvature for the helix (Figure 12.22)

$$\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j} + bt\mathbf{k}, \quad a, b \geq 0, \quad a^2 + b^2 \neq 0.$$

Solution We calculate \mathbf{T} from the velocity vector \mathbf{v} :

$$\begin{aligned} \mathbf{v} &= -(a \sin t)\mathbf{i} + (a \cos t)\mathbf{j} + b\mathbf{k} \\ |\mathbf{v}| &= \sqrt{a^2 \sin^2 t + a^2 \cos^2 t + b^2} = \sqrt{a^2 + b^2} \\ \mathbf{T} &= \frac{\mathbf{v}}{|\mathbf{v}|} = \frac{1}{\sqrt{a^2 + b^2}} [-(a \sin t)\mathbf{i} + (a \cos t)\mathbf{j} + b\mathbf{k}]. \end{aligned}$$

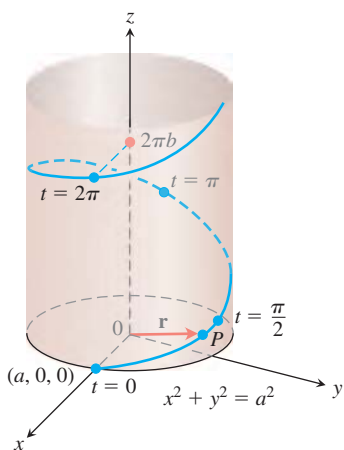

FIGURE 12.22 The helix

$\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j} + bt\mathbf{k}$, drawn with a and b positive and $t \geq 0$ (Example 5).

Then we use Equation (3):

$$\begin{aligned}\kappa &= \frac{1}{|\mathbf{v}|} \left| \frac{d\mathbf{T}}{dt} \right| \\ &= \frac{1}{\sqrt{a^2 + b^2}} \left| \frac{1}{\sqrt{a^2 + b^2}} [-(a \cos t)\mathbf{i} - (a \sin t)\mathbf{j}] \right| \\ &= \frac{a}{a^2 + b^2} |-(\cos t)\mathbf{i} - (\sin t)\mathbf{j}| \\ &= \frac{a}{a^2 + b^2} \sqrt{(\cos t)^2 + (\sin t)^2} = \frac{a}{a^2 + b^2}.\end{aligned}$$

From this equation, we see that increasing b for a fixed a decreases the curvature. Decreasing a for a fixed b eventually decreases the curvature as well.

If $b = 0$, the helix reduces to a circle of radius a , and its curvature reduces to $1/a$, as it should. If $a = 0$, the helix becomes the z -axis, and its curvature reduces to 0, again as it should. ■

EXAMPLE 6 Find \mathbf{N} for the helix in Example 5 and describe how the vector is pointing.

Solution We have

$$\frac{d\mathbf{T}}{dt} = -\frac{1}{\sqrt{a^2 + b^2}} [(a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}] \quad \text{Example 5}$$

$$\left| \frac{d\mathbf{T}}{dt} \right| = \frac{1}{\sqrt{a^2 + b^2}} \sqrt{a^2 \cos^2 t + a^2 \sin^2 t} = \frac{a}{\sqrt{a^2 + b^2}}$$

$$\mathbf{N} = \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|} \quad \text{Eq. (4)}$$

$$\begin{aligned}&= -\frac{\sqrt{a^2 + b^2}}{a} \cdot \frac{1}{\sqrt{a^2 + b^2}} [(a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}] \\ &= -(\cos t)\mathbf{i} - (\sin t)\mathbf{j}.\end{aligned}$$

Thus, \mathbf{N} is parallel to the xy -plane and always points toward the z -axis. ■

EXERCISES 12.4

Plane Curves

Find \mathbf{T} , \mathbf{N} , and κ for the plane curves in Exercises 1–4.

- $\mathbf{r}(t) = t\mathbf{i} + (\ln \cos t)\mathbf{j}$, $-\pi/2 < t < \pi/2$
- $\mathbf{r}(t) = (\ln \sec t)\mathbf{i} + t\mathbf{j}$, $-\pi/2 < t < \pi/2$
- $\mathbf{r}(t) = (2t + 3)\mathbf{i} + (5 - t^2)\mathbf{j}$
- $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}$, $t > 0$

5. A formula for the curvature of the graph of a function in the xy -plane

- a. The graph $y = f(x)$ in the xy -plane automatically has the parametrization $x = x$, $y = f(x)$, and the vector formula $\mathbf{r}(x) = x\mathbf{i} + f(x)\mathbf{j}$. Use this formula to show that if f is a twice-differentiable function of x , then

$$\kappa(x) = \frac{|f''(x)|}{[1 + (f'(x))^2]^{3/2}}.$$

- b. Use the formula for κ in part (a) to find the curvature of $y = \ln(\cos x)$, $-\pi/2 < x < \pi/2$. Compare your answer with the answer in Exercise 1.
- c. Show that the curvature is zero at a point of inflection.

6. A formula for the curvature of a parametrized plane curve

- a. Show that the curvature of a smooth curve $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j}$ defined by twice-differentiable functions $x = f(t)$ and $y = g(t)$ is given by the formula

$$\kappa = \frac{|x'y'' - y'x''|}{[(x')^2 + (y')^2]^{3/2}}.$$

Apply this formula to find the curvatures of the following curves.

- b. $\mathbf{r}(t) = t\mathbf{i} + (\ln \sin t)\mathbf{j}$, $0 < t < \pi$
- c. $\mathbf{r}(t) = [\arctan(\sinh t)]\mathbf{i} + (\ln \cosh t)\mathbf{j}$

7. Normals to plane curves

- a. Show that $\mathbf{n}(t) = -g'(t)\mathbf{i} + f'(t)\mathbf{j}$ and $-\mathbf{n}(t) = g'(t)\mathbf{i} - f'(t)\mathbf{j}$ are both normal to the curve $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j}$ at the point $(f(t), g(t))$.

To obtain \mathbf{N} for a particular plane curve, we can choose the one of \mathbf{n} or $-\mathbf{n}$ from part (a) that points toward the concave side of the curve, and make it into a unit vector. (See Figure 12.19.) Apply this method to find \mathbf{N} for the following curves.

b. $\mathbf{r}(t) = t\mathbf{i} + e^{2t}\mathbf{j}$

c. $\mathbf{r}(t) = \sqrt{4-t^2}\mathbf{i} + t\mathbf{j}, \quad -2 \leq t \leq 2$

8. (Continuation of Exercise 7)

a. Use the method of Exercise 7 to find \mathbf{N} for the curve

$\mathbf{r}(t) = t\mathbf{i} + (1/3)t^3\mathbf{j}$ when $t < 0$; when $t > 0$.

b. Calculate \mathbf{N} for $t \neq 0$ directly from \mathbf{T} using Equation (4) for the curve in part (a). Does \mathbf{N} exist at $t = 0$? Graph the curve and explain what is happening to \mathbf{N} as t passes from negative to positive values.**Space Curves**Find \mathbf{T} , \mathbf{N} , and κ for the space curves in Exercises 9–16.

9. $\mathbf{r}(t) = (3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 4t\mathbf{k}$

10. $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j} + 3t\mathbf{k}$

11. $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + 2t\mathbf{k}$

12. $\mathbf{r}(t) = (6 \sin 2t)\mathbf{i} + (6 \cos 2t)\mathbf{j} + 5t\mathbf{k}$

13. $\mathbf{r}(t) = (t^3/3)\mathbf{i} + (t^2/2)\mathbf{j} + t\mathbf{k}, \quad t > 0$

14. $\mathbf{r}(t) = (\cos^3 t)\mathbf{j} + (\sin^3 t)\mathbf{k}, \quad 0 < t < \pi/2$

15. $\mathbf{r}(t) = t\mathbf{i} + (a \cosh(t/a))\mathbf{k}, \quad a > 0$

16. $\mathbf{r}(t) = (\cosh t)\mathbf{i} - (\sinh t)\mathbf{j} + t\mathbf{k}$

More on Curvature17. Show that the parabola $y = ax^2$, $a \neq 0$, has its largest curvature at its vertex and has no minimum curvature. (Note: Since the curvature of a curve remains the same if the curve is translated or rotated, this result is true for any parabola.)18. Show that the ellipse $x = a \cos t$, $y = b \sin t$, $a > b > 0$, has its largest curvature on its major axis and its smallest curvature on its minor axis. (The same is true for any ellipse.)19. **Maximizing the curvature of a helix** In Example 5, we found the curvature of the helix $\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j} + bt\mathbf{k}$ ($a, b \geq 0$) to be $\kappa = a/(a^2 + b^2)$. What is the largest value κ can have for a given value of b ? Give reasons for your answer.20. **Total curvature** We find the **total curvature** of the portion of a smooth curve that runs from $s = s_0$ to $s = s_1 > s_0$ by integrating κ from s_0 to s_1 . If the curve has some other parameter, say t , then the total curvature is

$$K = \int_{s_0}^{s_1} \kappa \, ds = \int_{t_0}^{t_1} \kappa \frac{ds}{dt} dt = \int_{t_0}^{t_1} \kappa |\mathbf{v}| dt,$$

where t_0 and t_1 correspond to s_0 and s_1 . Find the total curvatures ofa. The portion of the helix $\mathbf{r}(t) = (3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + t\mathbf{k}$, $0 \leq t \leq 4\pi$.b. The parabola $y = x^2$, $-\infty < x < \infty$.21. Find an equation for the circle of curvature of the curve $\mathbf{r}(t) = t\mathbf{i} + (\sin t)\mathbf{j}$ at the point $(\pi/2, 1)$. (The curve parametrizes the graph of $y = \sin x$ in the xy -plane.)22. Find an equation for the circle of curvature of the curve $\mathbf{r}(t) = (2 \ln t)\mathbf{i} - [t + (1/t)]\mathbf{j}$, $e^{-2} \leq t \leq e^2$, at the point $(0, -2)$, where $t = 1$.**T** The formula

$$\kappa(x) = \frac{|f''(x)|}{[1 + (f'(x))^2]^{3/2}},$$

derived in Exercise 5, expresses the curvature $\kappa(x)$ of a twice-differentiable plane curve $y = f(x)$ as a function of x . Find the curvature function of each of the curves in Exercises 23–26. Then graph $f(x)$ together with $\kappa(x)$ over the given interval. You will find some surprises.

23. $y = x^2$, $-2 \leq x \leq 2$

24. $y = x^4/4$, $-2 \leq x \leq 2$

25. $y = \sin x$, $0 \leq x \leq 2\pi$

26. $y = e^x$, $-1 \leq x \leq 2$

In Exercises 27 and 28, determine the maximum curvature for the graph of each function.

27. $f(x) = \ln x$

28. $f(x) = \frac{x}{x+1}$ for $x > -1$

29. **Osculating circle** Show that the center of the osculating circle for the parabola $y = x^2$ at the point (a, a^2) is located at $(-4a^3, 3a^2 + \frac{1}{2})$.30. **Osculating circle** Find a parametrization of the osculating circle for the parabola $y = x^2$ when $x = 1$.**COMPUTER EXPLORATIONS**In Exercises 31–38 you will use a CAS to explore the osculating circle at a point P on a plane curve where $\kappa \neq 0$. Use a CAS to perform the following steps:

a. Plot the plane curve given in parametric or function form over the specified interval to see what it looks like.

b. Calculate the curvature κ of the curve at the given value t_0 using the appropriate formula from Exercise 5 or 6. Use the parametrization $x = t$ and $y = f(t)$ if the curve is given as a function $y = f(x)$.c. Find the unit normal vector \mathbf{N} at t_0 . Notice that the signs of the components of \mathbf{N} depend on whether the unit tangent vector \mathbf{T} is turning clockwise or counterclockwise at $t = t_0$. (See Exercise 7.)d. If $\mathbf{C} = a\mathbf{i} + b\mathbf{j}$ is the vector from the origin to the center (a, b) of the osculating circle, find the center \mathbf{C} from the vector equation

$$\mathbf{C} = \mathbf{r}(t_0) + \frac{1}{\kappa(t_0)}\mathbf{N}(t_0).$$

The point $P(x_0, y_0)$ on the curve is given by the position vector $\mathbf{r}(t_0)$.e. Plot implicitly the equation $(x - a)^2 + (y - b)^2 = 1/\kappa^2$ of the osculating circle. Then plot the curve and osculating circle together. You may need to experiment with the size of the viewing window, but be sure the axes are equally scaled.

31. $\mathbf{r}(t) = (3 \cos t)\mathbf{i} + (5 \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$, $t_0 = \pi/4$

32. $\mathbf{r}(t) = (\cos^3 t)\mathbf{i} + (\sin^3 t)\mathbf{j}$, $0 \leq t \leq 2\pi$, $t_0 = \pi/4$

33. $\mathbf{r}(t) = t^2\mathbf{i} + (t^3 - 3t)\mathbf{j}$, $-4 \leq t \leq 4$, $t_0 = 3/5$

34. $\mathbf{r}(t) = (t^3 - 2t^2 - t)\mathbf{i} + \frac{3t}{\sqrt{1+t^2}}\mathbf{j}$, $-2 \leq t \leq 5$, $t_0 = 1$

35. $\mathbf{r}(t) = (2t - \sin t)\mathbf{i} + (2 - 2 \cos t)\mathbf{j}$, $0 \leq t \leq 3\pi$, $t_0 = 3\pi/2$

36. $\mathbf{r}(t) = (e^{-t} \cos t)\mathbf{i} + (e^{-t} \sin t)\mathbf{j}$, $0 \leq t \leq 6\pi$, $t_0 = \pi/4$

37. $y = x^2 - x$, $-2 \leq x \leq 5$, $x_0 = 1$

38. $y = x(1-x)^{2/5}$, $-1 \leq x \leq 2$, $x_0 = 1/2$

12.5 Tangential and Normal Components of Acceleration

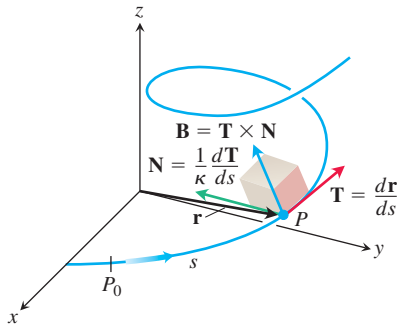

FIGURE 12.23 The TNB frame of mutually orthogonal unit vectors traveling along a curve in space.

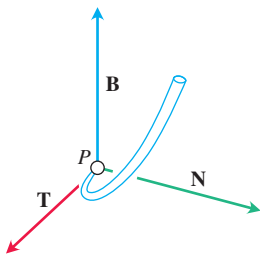

FIGURE 12.24 The vectors \mathbf{T} , \mathbf{N} , and \mathbf{B} (in that order) make a right-handed frame of mutually orthogonal unit vectors in space.

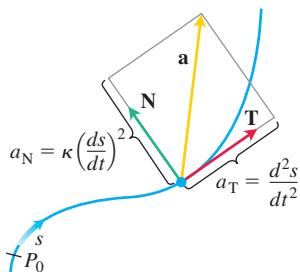

FIGURE 12.25 The tangential and normal components of acceleration. The acceleration \mathbf{a} always lies in the plane of \mathbf{T} and \mathbf{N} and is orthogonal to \mathbf{B} .

If you are flying in an airplane that is traveling along a curve in space, the Cartesian \mathbf{i} , \mathbf{j} , and \mathbf{k} coordinate system for representing the vectors describing your motion may not be very relevant to you. Vectors that are likely to be more important are those representing your forward direction (the unit tangent vector \mathbf{T}) and the direction in which your path is turning (the unit normal vector \mathbf{N}), along with a third unit vector perpendicular to the other two. Expressing the acceleration vector along the curve as a linear combination of these three mutually orthogonal unit vectors traveling with the motion (Figure 12.23) can reveal much about the nature of your path and your motion along it.

The TNB Frame

The **binormal vector** of a curve in space is $\mathbf{B} = \mathbf{T} \times \mathbf{N}$, which is a unit vector that is orthogonal to both \mathbf{T} and \mathbf{N} (Figure 12.24). Together \mathbf{T} , \mathbf{N} , and \mathbf{B} define a moving right-handed vector frame that plays a significant role in analyzing the paths of particles moving through space. It is called the **Frenet** (“fre-nay”) **frame** (after Jean-Frédéric Frenet, 1816–1900), or the **TNB frame**.

Tangential and Normal Components of Acceleration

When an object is accelerated by gravity, brakes, or rocket motors, we often need to know how much of the acceleration acts in the direction of motion, which is the direction of the tangent vector \mathbf{T} . We can calculate this using the Chain Rule to rewrite \mathbf{v} as

$$\mathbf{v} = \frac{d\mathbf{r}}{dt} = \frac{d\mathbf{r}}{ds} \frac{ds}{dt} = \mathbf{T} \frac{ds}{dt}.$$

Then we differentiate both ends of this string of equalities to get

$$\begin{aligned} \mathbf{a} &= \frac{d\mathbf{v}}{dt} = \frac{d}{dt} \left(\mathbf{T} \frac{ds}{dt} \right) = \frac{d^2s}{dt^2} \mathbf{T} + \frac{ds}{dt} \frac{d\mathbf{T}}{dt} \\ &= \frac{d^2s}{dt^2} \mathbf{T} + \frac{ds}{dt} \left(\frac{d\mathbf{T}}{ds} \frac{ds}{dt} \right) = \frac{d^2s}{dt^2} \mathbf{T} + \frac{ds}{dt} \left(\kappa \mathbf{N} \frac{ds}{dt} \right) \quad \frac{d\mathbf{T}}{ds} = \kappa \mathbf{N} \\ &= \frac{d^2s}{dt^2} \mathbf{T} + \kappa \left(\frac{ds}{dt} \right)^2 \mathbf{N}. \end{aligned}$$

DEFINITION If the acceleration vector is written as

$$\mathbf{a} = a_T \mathbf{T} + a_N \mathbf{N}, \quad (1)$$

then

$$a_T = \frac{d^2s}{dt^2} = \frac{d}{dt} |\mathbf{v}| \quad \text{and} \quad a_N = \kappa \left(\frac{ds}{dt} \right)^2 = \kappa |\mathbf{v}|^2 \quad (2)$$

are the **tangential** and the **normal** scalar components of acceleration.

Notice that the binormal vector \mathbf{B} does not appear in Equation (1). No matter how the path of the moving object we are watching may appear to twist and turn in space, the acceleration \mathbf{a} always lies in the plane of \mathbf{T} and \mathbf{N} and therefore is orthogonal to \mathbf{B} . The equation also tells us exactly how much of the acceleration takes place tangent to the motion (d^2s/dt^2) and how much takes place normal to the motion $[\kappa(ds/dt)^2]$ (Figure 12.25).

What information can we discover from Equations (2)? By definition, acceleration \mathbf{a} is the rate of change of velocity \mathbf{v} , and in general, both the length and direction of \mathbf{v} change as an object moves along its path. The tangential component of acceleration a_T measures

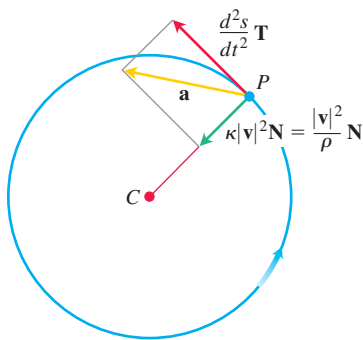

FIGURE 12.26 The tangential and normal components of the acceleration of an object that is speeding up as it moves counterclockwise around a circle of radius ρ .

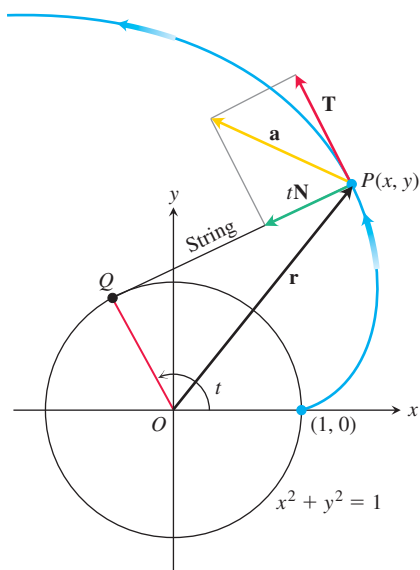

FIGURE 12.27 The tangential and normal components of the acceleration of the motion $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}$, for $t > 0$. If a string wound around a fixed circle is unwound while held taut in the plane of the circle, its end P traces an involute of the circle (Example 1).

the rate of change of the *length* of \mathbf{v} (that is, the change in the speed). The normal component of acceleration a_N is proportional to the rate of change of the *direction* of \mathbf{v} .

Notice that the normal scalar component of the acceleration is the curvature times the *square* of the speed. This explains why you have to hold on when your car makes a sharp (large κ), high-speed (large $|\mathbf{v}|$) turn. If you double the speed of your car, you will experience four times the normal component of acceleration for the same curvature.

If an object moves in a circle at a constant speed, d^2s/dt^2 is zero and all the acceleration points along \mathbf{N} toward the circle's center. If the object is speeding up or slowing down, \mathbf{a} has a positive or negative tangential component (Figure 12.26).

To calculate a_N , we usually use the formula $a_N = \sqrt{|\mathbf{a}|^2 - a_T^2}$, which comes from solving the equation $|\mathbf{a}|^2 = \mathbf{a} \cdot \mathbf{a} = a_T^2 + a_N^2$ for a_N (which, unlike the tangential component, cannot be negative). With this formula, we can find a_N without having to calculate κ first.

Formula for Calculating the Normal Component of Acceleration

$$a_N = \sqrt{|\mathbf{a}|^2 - a_T^2} \quad (3)$$

EXAMPLE 1 Without finding \mathbf{T} and \mathbf{N} , write the acceleration of the motion

$$\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}, \quad t > 0$$

in the form $\mathbf{a} = a_T\mathbf{T} + a_N\mathbf{N}$. (The path of the motion is the involute of the circle in Figure 12.27. See also Section 12.3, Exercise 19.)

Solution We use the first of Equations (2) to find a_T :

$$\begin{aligned} \mathbf{v} &= \frac{d\mathbf{r}}{dt} = (-\sin t + \sin t + t \cos t)\mathbf{i} + (\cos t - \cos t + t \sin t)\mathbf{j} \\ &= (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} \end{aligned}$$

$$|\mathbf{v}| = \sqrt{t^2 \cos^2 t + t^2 \sin^2 t} = \sqrt{t^2} = |t| = t \quad t > 0$$

$$a_T = \frac{d}{dt}|\mathbf{v}| = \frac{d}{dt}(t) = 1. \quad \text{Eq. (2)}$$

Knowing a_T , we use Equation (3) to find a_N :

$$\mathbf{a} = (\cos t - t \sin t)\mathbf{i} + (\sin t + t \cos t)\mathbf{j}$$

$$|\mathbf{a}|^2 = t^2 + 1$$

After some algebra

$$\begin{aligned} a_N &= \sqrt{|\mathbf{a}|^2 - a_T^2} \\ &= \sqrt{(t^2 + 1) - (1)} = \sqrt{t^2} = t. \end{aligned}$$

We then use Equation (1) to write

$$\mathbf{a} = a_T\mathbf{T} + a_N\mathbf{N} = (1)\mathbf{T} + (t)\mathbf{N} = \mathbf{T} + t\mathbf{N}. \quad \blacksquare$$

Torsion

How does $d\mathbf{B}/ds$ behave in relation to \mathbf{T} , \mathbf{N} , and \mathbf{B} ? From the rule for differentiating a cross product in Section 12.1, we have

$$\frac{d\mathbf{B}}{ds} = \frac{d(\mathbf{T} \times \mathbf{N})}{ds} = \frac{d\mathbf{T}}{ds} \times \mathbf{N} + \mathbf{T} \times \frac{d\mathbf{N}}{ds}.$$

Since \mathbf{N} is the direction of $d\mathbf{T}/ds$, $(d\mathbf{T}/ds) \times \mathbf{N} = \mathbf{0}$ and

$$\frac{d\mathbf{B}}{ds} = \mathbf{0} + \mathbf{T} \times \frac{d\mathbf{N}}{ds} = \mathbf{T} \times \frac{d\mathbf{N}}{ds}.$$

From this we see that $d\mathbf{B}/ds$ is orthogonal to \mathbf{T} , since a cross product is orthogonal to its factors.

Since $d\mathbf{B}/ds$ is also orthogonal to \mathbf{B} (the latter has constant length), it follows that $d\mathbf{B}/ds$ is orthogonal to the plane of \mathbf{B} and \mathbf{T} . In other words, $d\mathbf{B}/ds$ is parallel to \mathbf{N} , so $d\mathbf{B}/ds$ is a scalar multiple of \mathbf{N} . In symbols,

$$\frac{d\mathbf{B}}{ds} = -\tau\mathbf{N}.$$

The negative sign in this equation is traditional. The scalar τ is called the *torsion* along the curve. Notice that

$$\frac{d\mathbf{B}}{ds} \cdot \mathbf{N} = -\tau\mathbf{N} \cdot \mathbf{N} = -\tau(1) = -\tau.$$

We use this equation for our next definition.

DEFINITION Let $\mathbf{B} = \mathbf{T} \times \mathbf{N}$. The **torsion** function of a smooth curve is

$$\tau = -\frac{d\mathbf{B}}{ds} \cdot \mathbf{N}. \quad (4)$$

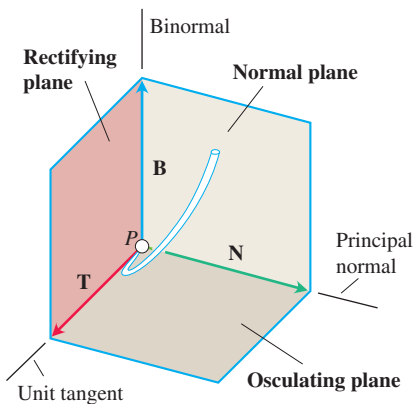

FIGURE 12.28 The names of the three planes determined by \mathbf{T} , \mathbf{N} , and \mathbf{B} .

Unlike the curvature κ , which is never negative, the torsion τ may be positive, negative, or zero.

The three planes determined by \mathbf{T} , \mathbf{N} , and \mathbf{B} are named and shown in Figure 12.28. The curvature $\kappa = |d\mathbf{T}/ds|$ can be thought of as the rate at which the normal plane turns as the point P moves along its path. Similarly, the torsion $\tau = -(d\mathbf{B}/ds) \cdot \mathbf{N}$ is the rate at which the osculating plane turns about \mathbf{T} as P moves along the curve. Torsion measures how the curve twists.

Look at Figure 12.29. If P is a train climbing up a curved track, the rate at which the headlight turns from side to side per unit distance is the curvature of the track. The rate at which the engine tends to twist out of the plane formed by \mathbf{T} and \mathbf{N} is the torsion. It can be shown that a space curve is a helix if and only if it has constant nonzero curvature and constant nonzero torsion.

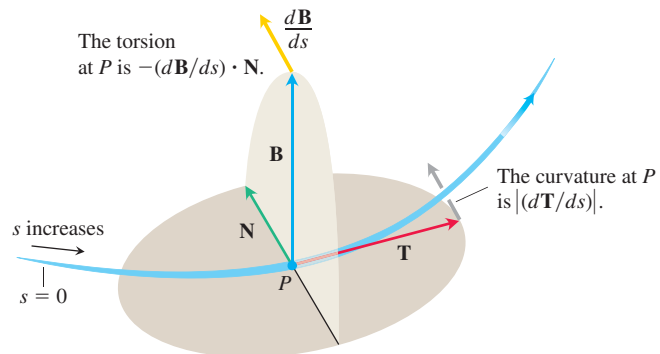

FIGURE 12.29 Every moving body travels with a **TNB** frame that characterizes the geometry of its path of motion.

Formulas for Computing Curvature and Torsion

We now give easy-to-use formulas for computing the curvature and torsion of a smooth curve. From Equations (1) and (2), we have

$$\begin{aligned}\mathbf{v} \times \mathbf{a} &= \left(\frac{ds}{dt} \mathbf{T}\right) \times \left[\frac{d^2s}{dt^2} \mathbf{T} + \kappa \left(\frac{ds}{dt}\right)^2 \mathbf{N}\right] && \mathbf{v} = dr/dt = (ds/dt)\mathbf{T} \\ &= \left(\frac{ds}{dt} \frac{d^2s}{dt^2}\right) (\mathbf{T} \times \mathbf{T}) + \kappa \left(\frac{ds}{dt}\right)^3 (\mathbf{T} \times \mathbf{N}) \\ &= \kappa \left(\frac{ds}{dt}\right)^3 \mathbf{B}. && \begin{array}{l} \mathbf{T} \times \mathbf{T} = \mathbf{0} \text{ and} \\ \mathbf{T} \times \mathbf{N} = \mathbf{B} \end{array}\end{aligned}$$

It follows that

$$|\mathbf{v} \times \mathbf{a}| = \kappa \left|\frac{ds}{dt}\right|^3 |\mathbf{B}| = \kappa |\mathbf{v}|^3. \quad \frac{ds}{dt} = |\mathbf{v}| \quad \text{and} \quad |\mathbf{B}| = 1$$

Solving for κ gives the following formula.

Vector Formula for Curvature

$$\kappa = \frac{|\mathbf{v} \times \mathbf{a}|}{|\mathbf{v}|^3} \quad (5)$$

Equation (5) calculates the curvature, a geometric property of the curve, from the velocity and acceleration of any vector representation of the curve in which $|\mathbf{v}|$ is different from zero. From any formula for motion along a curve, no matter how variable the motion may be (as long as \mathbf{v} is never zero), we can calculate a geometric property of the curve that seems to have nothing to do with the way the curve is parametrically defined.

The most widely used formula for torsion, derived in more advanced texts, is given in a determinant form.

Formula for Torsion

$$\tau = \frac{\begin{vmatrix} \dot{x} & \dot{y} & \dot{z} \\ \ddot{x} & \ddot{y} & \ddot{z} \\ \dddot{x} & \dddot{y} & \dddot{z} \end{vmatrix}}{|\mathbf{v} \times \mathbf{a}|^2} \quad (\text{if } \mathbf{v} \times \mathbf{a} \neq \mathbf{0}) \quad (6)$$

Newton's Dot Notation for Derivatives

The dots in Equation (6) denote differentiation with respect to t , one derivative for each dot. Thus, \dot{x} ("x dot") means dx/dt , \ddot{x} ("x double dot") means d^2x/dt^2 , and \dddot{x} ("x triple dot") means d^3x/dt^3 . Similarly, $\dot{y} = dy/dt$, and so on.

This formula calculates the torsion directly from the derivatives of the component functions $x = f(t)$, $y = g(t)$, $z = h(t)$ that make up \mathbf{r} . The determinant's first row comes from \mathbf{v} , the second row comes from \mathbf{a} , and the third row comes from $\dot{\mathbf{a}} = d\mathbf{a}/dt$. This formula for torsion is traditionally written using Newton's dot notation for derivatives.

EXAMPLE 2 Use Equations (5) and (6) to find the curvature κ and torsion τ for the helix

$$\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j} + btk, \quad a, b \geq 0, \quad a^2 + b^2 \neq 0.$$

Solution We calculate the curvature with Equation (5):

$$\begin{aligned}\mathbf{v} &= -(a \sin t)\mathbf{i} + (a \cos t)\mathbf{j} + b\mathbf{k} \\ \mathbf{a} &= -(a \cos t)\mathbf{i} - (a \sin t)\mathbf{j} \\ \mathbf{v} \times \mathbf{a} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -a \sin t & a \cos t & b \\ -a \cos t & -a \sin t & 0 \end{vmatrix} \\ &= (ab \sin t)\mathbf{i} - (ab \cos t)\mathbf{j} + a^2\mathbf{k} \\ \kappa &= \frac{|\mathbf{v} \times \mathbf{a}|}{|\mathbf{v}|^3} = \frac{\sqrt{a^2b^2 + a^4}}{(a^2 + b^2)^{3/2}} = \frac{a\sqrt{a^2 + b^2}}{(a^2 + b^2)^{3/2}} = \frac{a}{a^2 + b^2}. \quad (7)\end{aligned}$$

Notice that Equation (7) agrees with the result in Example 5 in Section 12.4, where we calculated the curvature directly from its definition.

To evaluate Equation (6) for the torsion, we find the entries in the determinant by differentiating \mathbf{r} with respect to t . We already have \mathbf{v} and \mathbf{a} , and

$$\dot{\mathbf{a}} = \frac{d\mathbf{a}}{dt} = (a \sin t)\mathbf{i} - (a \cos t)\mathbf{j}.$$

Hence,

$$\begin{aligned}\tau &= \frac{\begin{vmatrix} \dot{x} & \dot{y} & \dot{z} \\ \ddot{x} & \ddot{y} & \ddot{z} \\ \ddot{\ddot{x}} & \ddot{\ddot{y}} & \ddot{\ddot{z}} \end{vmatrix}}{|\mathbf{v} \times \mathbf{a}|^2} = \frac{\begin{vmatrix} -a \sin t & a \cos t & b \\ -a \cos t & -a \sin t & 0 \\ a \sin t & -a \cos t & 0 \end{vmatrix}}{(a\sqrt{a^2 + b^2})^2} && \text{Value of } |\mathbf{v} \times \mathbf{a}| \text{ from Eq. (7)} \\ &= \frac{b(a^2 \cos^2 t + a^2 \sin^2 t)}{a^2(a^2 + b^2)} \\ &= \frac{b}{a^2 + b^2}.\end{aligned}$$

From this last equation we see that the torsion of a helix about a circular cylinder is constant. In fact, constant curvature and constant torsion characterize the helix among all curves in space. ■

Computation Formulas for Curves in Space

Unit tangent vector:

$$\mathbf{T} = \frac{\mathbf{v}}{|\mathbf{v}|}$$

Principal unit normal vector:

$$\mathbf{N} = \frac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|}$$

Binormal vector:

$$\mathbf{B} = \mathbf{T} \times \mathbf{N}$$

Curvature:

$$\kappa = \left| \frac{d\mathbf{T}}{ds} \right| = \frac{|\mathbf{v} \times \mathbf{a}|}{|\mathbf{v}|^3}$$

Torsion:

$$\tau = -\frac{d\mathbf{B}}{ds} \cdot \mathbf{N} = \frac{\begin{vmatrix} \dot{x} & \dot{y} & \dot{z} \\ \ddot{x} & \ddot{y} & \ddot{z} \\ \ddot{\ddot{x}} & \ddot{\ddot{y}} & \ddot{\ddot{z}} \end{vmatrix}}{|\mathbf{v} \times \mathbf{a}|^2}$$

Tangential and normal scalar components of acceleration:

$$\mathbf{a} = a_T \mathbf{T} + a_N \mathbf{N}$$

$$a_T = \frac{d}{dt} |\mathbf{v}|$$

$$a_N = \kappa |\mathbf{v}|^2 = \sqrt{|\mathbf{a}|^2 - a_T^2}$$

EXERCISES 12.5

Finding Tangential and Normal Components

In Exercises 1–4, write \mathbf{a} in the form $\mathbf{a} = a_T \mathbf{T} + a_N \mathbf{N}$ without finding \mathbf{T} and \mathbf{N} .

- $\mathbf{r}(t) = (2t + 3)\mathbf{i} + (t^2 - 1)\mathbf{j}$
- $\mathbf{r}(t) = 3t^2\mathbf{i} + 2t^3\mathbf{j}$
- $\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j} + bt\mathbf{k}$
- $\mathbf{r}(t) = (1 + 3t)\mathbf{i} + (t - 2)\mathbf{j} - 3t\mathbf{k}$

In Exercises 5–10, write \mathbf{a} in the form $\mathbf{a} = a_T \mathbf{T} + a_N \mathbf{N}$ at the given value of t without finding \mathbf{T} and \mathbf{N} .

- $\mathbf{r}(t) = e^t\mathbf{i} + e^{-t}\mathbf{j}, \quad t = 0$
- $\mathbf{r}(t) = \cos(t^2)\mathbf{i} + \sin(t^2)\mathbf{j}, \quad t = \frac{1}{2}\sqrt{\pi}$
- $\mathbf{r}(t) = (t + 1)\mathbf{i} + 2t\mathbf{j} + t^2\mathbf{k}, \quad t = 1$
- $\mathbf{r}(t) = (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} + t^2\mathbf{k}, \quad t = 0$
- $\mathbf{r}(t) = t^2\mathbf{i} + (t + (1/3)t^3)\mathbf{j} + (t - (1/3)t^3)\mathbf{k}, \quad t = 0$
- $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + \sqrt{2}e^t\mathbf{k}, \quad t = 0$

Finding the TNB Frame

In Exercises 11 and 12, find \mathbf{r} , \mathbf{T} , \mathbf{N} , and \mathbf{B} at the given value of t . Then find equations for the osculating, normal, and rectifying planes at that value of t .

- $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} - \mathbf{k}, \quad t = \pi/4$
- $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}, \quad t = 0$

In Exercises 9–16 of Section 12.4, you found \mathbf{T} , \mathbf{N} , and κ . Now, in the following Exercises 13–20, find \mathbf{B} and τ for these space curves.

- $\mathbf{r}(t) = (3 \sin t)\mathbf{i} + (3 \cos t)\mathbf{j} + 4t\mathbf{k}$
- $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j} + 3\mathbf{k}$
- $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + 2\mathbf{k}$
- $\mathbf{r}(t) = (6 \sin 2t)\mathbf{i} + (6 \cos 2t)\mathbf{j} + 5t\mathbf{k}$
- $\mathbf{r}(t) = (t^3/3)\mathbf{i} + (t^2/2)\mathbf{j} + \mathbf{k}, \quad t > 0$
- $\mathbf{r}(t) = (\cos^3 t)\mathbf{j} + (\sin^3 t)\mathbf{k}, \quad 0 < t < \pi/2$
- $\mathbf{r}(t) = t\mathbf{i} + (a \cosh(t/a))\mathbf{k}, \quad a > 0$
- $\mathbf{r}(t) = (\cosh t)\mathbf{i} - (\sinh t)\mathbf{j} + t\mathbf{k}$

Physical Applications

- The speedometer on your car reads a steady 35 km/h. Could you be accelerating? Explain.
- Can anything be said about the acceleration of a particle that is moving at a constant speed? Give reasons for your answer.
- Can anything be said about the speed of a particle whose acceleration is always orthogonal to its velocity? Give reasons for your answer.
- An object of mass m travels along the parabola $y = x^2$ with a constant speed of 10 units/s. What is the force on the object due to its acceleration at $(0, 0)$? at $(2^{1/2}, 2)$? Write your answers in terms of \mathbf{i} and \mathbf{j} . (Remember Newton's law, $\mathbf{F} = m\mathbf{a}$.)

Theory and Examples

25. Show that κ and τ are both zero for the line

$$\mathbf{r}(t) = (x_0 + At)\mathbf{i} + (y_0 + Bt)\mathbf{j} + (z_0 + Ct)\mathbf{k}.$$

26. Show that a moving particle will move in a straight line if the normal component of its acceleration is zero.
27. **A sometime shortcut to curvature** If you already know $|a_N|$ and $|\mathbf{v}|$, then the formula $a_N = \kappa|\mathbf{v}|^2$ gives a convenient way to find the curvature. Use it to find the curvature and radius of curvature of the curve

$$\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}, \quad t > 0.$$

(Take a_N and $|\mathbf{v}|$ from Example 1.)

28. What can be said about the torsion of a smooth plane curve $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j}$? Give reasons for your answer.
29. **Differentiable curves with zero torsion lie in planes** That a sufficiently differentiable curve with zero torsion lies in a plane is a special case of the fact that a particle whose velocity remains perpendicular to a fixed vector \mathbf{C} moves in a plane perpendicular to \mathbf{C} . This, in turn, can be viewed as the following result.

Suppose $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}$ is twice differentiable for all t in an interval $[a, b]$, that $\mathbf{r} = 0$ when $t = a$, and that $\mathbf{v} \cdot \mathbf{k} = 0$ for all t in $[a, b]$. Show that $h(t) = 0$ for all t in $[a, b]$. (Hint: Start with $\mathbf{a} = d^2\mathbf{r}/dt^2$ and apply the initial conditions in reverse order.)

30. **A formula that calculates τ from \mathbf{B} and \mathbf{v}** If we start with the definition $\tau = -(d\mathbf{B}/ds) \cdot \mathbf{N}$ and apply the Chain Rule to rewrite $d\mathbf{B}/ds$ as

$$\frac{d\mathbf{B}}{ds} = \frac{d\mathbf{B}}{dt} \frac{dt}{ds} = \frac{d\mathbf{B}}{dt} \frac{1}{|\mathbf{v}|},$$

we arrive at the formula

$$\tau = -\frac{1}{|\mathbf{v}|} \left(\frac{d\mathbf{B}}{dt} \cdot \mathbf{N} \right).$$

Use the formula to find the torsion of the helix in Example 2.

COMPUTER EXPLORATIONS

Rounding the answers to four decimal places, use a CAS to find \mathbf{v} , \mathbf{a} , speed, \mathbf{T} , \mathbf{N} , \mathbf{B} , κ , τ , and the tangential and normal components of acceleration for the curves in Exercises 31–34 at the given values of t .

- $\mathbf{r}(t) = (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} + t\mathbf{k}, \quad t = \sqrt{3}$
- $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + e^t\mathbf{k}, \quad t = \ln 2$
- $\mathbf{r}(t) = (t - \sin t)\mathbf{i} + (1 - \cos t)\mathbf{j} + \sqrt{-t}\mathbf{k}, \quad t = -3\pi$
- $\mathbf{r}(t) = (3t - t^2)\mathbf{i} + (3t^2)\mathbf{j} + (3t + t^3)\mathbf{k}, \quad t = 1$

12.6 Velocity and Acceleration in Polar Coordinates

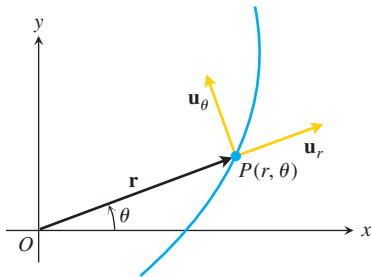

FIGURE 12.30 The length of \mathbf{r} is the positive polar coordinate r of the point P . Thus \mathbf{u}_r , which is $\mathbf{r}/|\mathbf{r}|$, is also \mathbf{r}/r . Equations (1) express \mathbf{u}_r and \mathbf{u}_θ in terms of \mathbf{i} and \mathbf{j} .

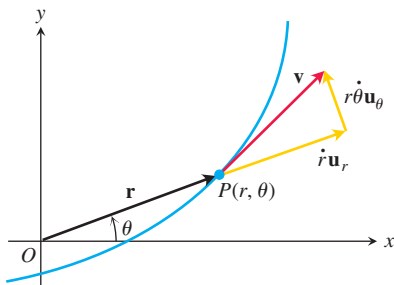

FIGURE 12.31 In polar coordinates, the velocity vector is $\mathbf{v} = \dot{r}\mathbf{u}_r + r\dot{\theta}\mathbf{u}_\theta$.

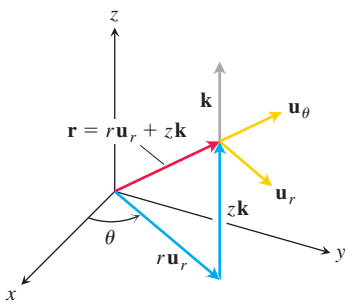

FIGURE 12.32 Position vector and basic unit vectors in cylindrical coordinates. Notice that $|\mathbf{r}| \neq r$ if $z \neq 0$ since $|\mathbf{r}| = \sqrt{r^2 + z^2}$.

In this section we derive equations for velocity and acceleration in polar coordinates. These equations are useful for calculating the paths of planets and satellites in space, and we use them to examine Kepler's three laws of planetary motion.

Motion in Polar and Cylindrical Coordinates

When a particle at $P(r, \theta)$ moves along a curve in the polar coordinate plane, we express its position, velocity, and acceleration in terms of the moving unit vectors

$$\mathbf{u}_r = (\cos \theta)\mathbf{i} + (\sin \theta)\mathbf{j}, \quad \mathbf{u}_\theta = -(\sin \theta)\mathbf{i} + (\cos \theta)\mathbf{j}, \quad (1)$$

shown in Figure 12.30. The vector \mathbf{u}_r points along the position vector \overline{OP} , so $\mathbf{r} = r\mathbf{u}_r$. The vector \mathbf{u}_θ , orthogonal to \mathbf{u}_r , points in the direction of increasing θ .

We find from Equations (1) that

$$\frac{d\mathbf{u}_r}{d\theta} = -(\sin \theta)\mathbf{i} + (\cos \theta)\mathbf{j} = \mathbf{u}_\theta$$

$$\frac{d\mathbf{u}_\theta}{d\theta} = -(\cos \theta)\mathbf{i} - (\sin \theta)\mathbf{j} = -\mathbf{u}_r.$$

We next differentiate \mathbf{u}_r and \mathbf{u}_θ with respect to t to find how they change with time. The Chain Rule gives

$$\dot{\mathbf{u}}_r = \frac{d\mathbf{u}_r}{d\theta}\dot{\theta} = \dot{\theta}\mathbf{u}_\theta, \quad \dot{\mathbf{u}}_\theta = \frac{d\mathbf{u}_\theta}{d\theta}\dot{\theta} = -\dot{\theta}\mathbf{u}_r. \quad (2)$$

Hence, we can express the velocity vector in terms of \mathbf{u}_r and \mathbf{u}_θ as

$$\mathbf{v} = \dot{\mathbf{r}} = \frac{d}{dt}(r\mathbf{u}_r) = \dot{r}\mathbf{u}_r + r\dot{\mathbf{u}}_r = \dot{r}\mathbf{u}_r + r\dot{\theta}\mathbf{u}_\theta.$$

See Figure 12.31. As in the previous section, we use Newton's dot notation for time derivatives to keep the formulas as simple as we can: $\dot{\mathbf{u}}_r$ means $d\mathbf{u}_r/dt$, $\dot{\theta}$ means $d\theta/dt$, and so on.

The acceleration is

$$\mathbf{a} = \dot{\mathbf{v}} = (\ddot{r}\mathbf{u}_r + \dot{r}\dot{\mathbf{u}}_r) + (\dot{r}\dot{\theta}\mathbf{u}_\theta + r\ddot{\theta}\mathbf{u}_\theta + r\dot{\theta}\dot{\mathbf{u}}_\theta).$$

When Equations (2) are used to evaluate $\dot{\mathbf{u}}_r$ and $\dot{\mathbf{u}}_\theta$ and the components are separated, the equation for acceleration in terms of \mathbf{u}_r and \mathbf{u}_θ becomes

$$\mathbf{a} = (\ddot{r} - r\dot{\theta}^2)\mathbf{u}_r + (r\ddot{\theta} + 2\dot{r}\dot{\theta})\mathbf{u}_\theta.$$

To extend these equations of motion to space, we add $z\mathbf{k}$ to the right-hand side of the equation $\mathbf{r} = r\mathbf{u}_r$. Then, in these *cylindrical coordinates*, we have

Position:	$\mathbf{r} = r\mathbf{u}_r + z\mathbf{k}$	
Velocity:	$\mathbf{v} = \dot{r}\mathbf{u}_r + r\dot{\theta}\mathbf{u}_\theta + \dot{z}\mathbf{k}$	(3)
Acceleration:	$\mathbf{a} = (\ddot{r} - r\dot{\theta}^2)\mathbf{u}_r + (r\ddot{\theta} + 2\dot{r}\dot{\theta})\mathbf{u}_\theta + \ddot{z}\mathbf{k}$	

The vectors \mathbf{u}_r , \mathbf{u}_θ , and \mathbf{k} make a right-handed frame (Figure 12.32) in which

$$\mathbf{u}_r \times \mathbf{u}_\theta = \mathbf{k}, \quad \mathbf{u}_\theta \times \mathbf{k} = \mathbf{u}_r, \quad \mathbf{k} \times \mathbf{u}_r = \mathbf{u}_\theta.$$

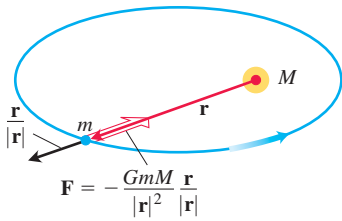

FIGURE 12.33 The force of gravity is directed along the line joining the centers of mass.

Planets Move in Planes

Newton's law of gravitation says that if \mathbf{r} is the radius vector from the center of a sun of mass M to the center of a planet of mass m , then the force \mathbf{F} of the gravitational attraction between the planet and sun is

$$\mathbf{F} = -\frac{GmM}{|\mathbf{r}|^2} \frac{\mathbf{r}}{|\mathbf{r}|}$$

(Figure 12.33). The number G is the **universal gravitational constant**. If we measure mass in kilograms, force in newtons, and distance in meters, G is about $6.6738 \times 10^{-11} \text{ Nm}^2 \text{ kg}^{-2}$.

Combining the gravitation law with Newton's second law, $\mathbf{F} = m\ddot{\mathbf{r}}$, for the force acting on the planet gives

$$m\ddot{\mathbf{r}} = -\frac{GmM}{|\mathbf{r}|^2} \frac{\mathbf{r}}{|\mathbf{r}|},$$

$$\ddot{\mathbf{r}} = -\frac{GM}{|\mathbf{r}|^2} \frac{\mathbf{r}}{|\mathbf{r}|}.$$

The planet is therefore accelerated toward the sun's center of mass at all times.

Since $\ddot{\mathbf{r}}$ is a scalar multiple of \mathbf{r} , we have

$$\mathbf{r} \times \ddot{\mathbf{r}} = \mathbf{0}.$$

From this last equation,

$$\frac{d}{dt}(\mathbf{r} \times \dot{\mathbf{r}}) = \underbrace{\dot{\mathbf{r}} \times \dot{\mathbf{r}}}_0 + \mathbf{r} \times \ddot{\mathbf{r}} = \mathbf{r} \times \ddot{\mathbf{r}} = \mathbf{0}.$$

It follows that

$$\mathbf{r} \times \dot{\mathbf{r}} = \mathbf{C} \tag{4}$$

for some constant vector \mathbf{C} .

Equation (4) tells us that \mathbf{r} and $\dot{\mathbf{r}}$ always lie in a plane perpendicular to \mathbf{C} . Hence, the planet moves in a fixed plane through the center of mass of its sun (Figure 12.34). We next see how Kepler's laws describe the motion in a precise way.

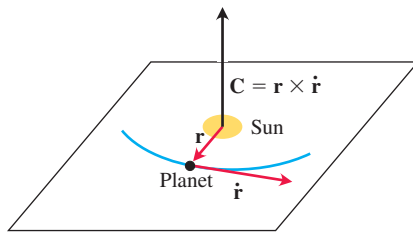

FIGURE 12.34 A planet that obeys Newton's laws of gravitation and motion travels in the plane through its sun's center of mass perpendicular to $\mathbf{C} = \mathbf{r} \times \dot{\mathbf{r}}$.

Kepler's First Law (Ellipse Law)

Kepler's first law says that a planet's path is an ellipse with its sun at one focus. The eccentricity of the ellipse is

$$e = \frac{r_0 v_0^2}{GM} - 1, \tag{5}$$

and the polar equation (see Section 10.7 Equation (5)) is

$$r = \frac{(1+e)r_0}{1+e \cos \theta}. \tag{6}$$

Here v_0 is the speed when the planet is positioned at its minimum distance r_0 from the sun. We omit the lengthy proof. The sun's mass M is $1.99 \times 10^{30} \text{ kg}$.

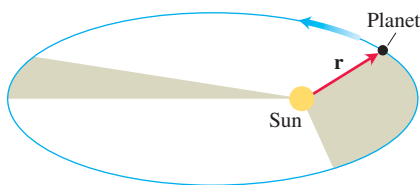

FIGURE 12.35 The line joining a planet to its sun sweeps over equal areas in equal times.

Kepler's Second Law (Equal Area Law)

Kepler's second law says that the radius vector from the sun to a planet (the vector \mathbf{r} in our model) sweeps out equal areas in equal times, as displayed in Figure 12.35. In that figure, we assume the plane of the planet is the xy -plane, so the unit vector in the direction of \mathbf{C} is \mathbf{k} .

We introduce polar coordinates in the plane, choosing as initial line $\theta = 0$, the direction \mathbf{r} when $|\mathbf{r}| = r$ is a minimum value. Then at $t = 0$, we have $r(0) = r_0$ being a minimum so,

$$\dot{r}|_{t=0} = \left. \frac{dr}{dt} \right|_{t=0} = 0 \quad \text{and} \quad v_0 = |\mathbf{v}|_{t=0} = [r\dot{\theta}]_{t=0}. \quad \text{Eq. (3), } \dot{z} = 0$$

To derive Kepler's second law, we use Equation (3) to evaluate the cross product $\mathbf{C} = \mathbf{r} \times \dot{\mathbf{r}}$ from Equation (4):

$$\begin{aligned} \mathbf{C} &= \mathbf{r} \times \dot{\mathbf{r}} = \mathbf{r} \times \mathbf{v} \\ &= r\mathbf{u}_r \times (\dot{r}\mathbf{u}_r + r\dot{\theta}\mathbf{u}_\theta) && \text{Eq. (3), } \dot{z} = 0 \\ &= r\dot{r}(\underbrace{\mathbf{u}_r \times \mathbf{u}_r}_0) + r(r\dot{\theta})(\underbrace{\mathbf{u}_r \times \mathbf{u}_\theta}_\mathbf{k}) \\ &= r(r\dot{\theta})\mathbf{k}. \end{aligned} \quad (7)$$

Setting t equal to zero shows that

$$\mathbf{C} = [r(r\dot{\theta})]_{t=0} \mathbf{k} = r_0 v_0 \mathbf{k}.$$

Substituting this value for \mathbf{C} in Equation (7) gives

$$r_0 v_0 \mathbf{k} = r^2 \dot{\theta} \mathbf{k}, \quad \text{or} \quad r^2 \dot{\theta} = r_0 v_0.$$

This is where the area comes in. The area differential in polar coordinates is

$$dA = \frac{1}{2} r^2 d\theta$$

(Section 10.5). Accordingly, dA/dt has the constant value

$$\frac{dA}{dt} = \frac{1}{2} r^2 \dot{\theta} = \frac{1}{2} r_0 v_0. \quad (8)$$

So dA/dt is constant, giving Kepler's second law.

HISTORICAL BIOGRAPHY

Johannes Kepler (1571–1630)

The German astronomer, mathematician, and physicist Johannes Kepler was the first scientist to demand physical explanations of celestial phenomena. His three laws of planetary motion, the results of a lifetime of work, changed astronomy and played a crucial role in the development of Newtonian physics and calculus.

To know more, visit the companion Website.

Kepler's Third Law (Time–Distance Law)

The time T it takes a planet to go around its sun once is the planet's **orbital period**. Kepler's *third law* says that T and the orbit's semimajor axis a are related by the equation

$$\frac{T^2}{a^3} = \frac{4\pi^2}{GM}.$$

Since the right-hand side of this equation is constant within a given solar system, the ratio of T^2 to a^3 is the same for every planet in the system.

Here is a partial derivation of Kepler's third law. The area enclosed by the planet's elliptical orbit is calculated as follows:

$$\begin{aligned} \text{Area} &= \int_0^T dA \\ &= \int_0^T \frac{1}{2} r_0 v_0 dt && \text{Eq. (8)} \\ &= \frac{1}{2} T r_0 v_0. \end{aligned}$$

If b is the semiminor axis, the area of the ellipse is πab , so

$$T = \frac{2\pi ab}{r_0 v_0} = \frac{2\pi a^2}{r_0 v_0} \sqrt{1 - e^2}. \quad \text{For any ellipse, } b = a\sqrt{1 - e^2}. \quad (9)$$

It remains only to express a and e in terms of r_0 , v_0 , G , and M . Equation (5) does this for e . For a , we observe that setting θ equal to π in Equation (6) gives

$$r_{\max} = r_0 \frac{1 + e}{1 - e}.$$

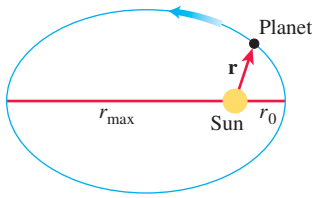

FIGURE 12.36 The length of the major axis of the ellipse is $2a = r_0 + r_{\max}$.

Hence, from Figure 12.36,

$$2a = r_0 + r_{\max} = \frac{2r_0}{1 - e} = \frac{2r_0 GM}{2GM - r_0 v_0^2}. \quad (10)$$

Squaring both sides of Equation (9) and substituting the results of Equations (5) and (10) produce Kepler's third law (Exercise 11).

EXERCISES 12.6

In Exercises 1–7, find the velocity and acceleration vectors in terms of \mathbf{u}_r and \mathbf{u}_θ .

1. $r = \theta$ and $\frac{d\theta}{dt} = 2$

2. $r = \frac{1}{\theta}$ and $\frac{d\theta}{dt} = t^2$

3. $r = a(1 - \cos \theta)$ and $\frac{d\theta}{dt} = 3$

4. $r = a \sin 2\theta$ and $\frac{d\theta}{dt} = 2t$

5. $r = e^{a\theta}$ and $\frac{d\theta}{dt} = 2$

6. $r = a(1 + \sin t)$ and $\theta = 1 - e^{-t}$

7. $r = 2 \cos 4t$ and $\theta = 2t$

8. **Type of orbit** For what values of v_0 in Equation (5) is the orbit in Equation (6) a circle? An ellipse? A parabola? A hyperbola?

9. **Circular orbits** Show that a planet in a circular orbit moves with a constant speed. (*Hint:* This is a consequence of one of Kepler's laws.)

10. Suppose that \mathbf{r} is the position vector of a particle moving along a plane curve and dA/dt is the rate at which the vector sweeps out area. Without introducing coordinates, and assuming the necessary derivatives exist, give a geometric argument based on increments and limits for the validity of the equation

$$\frac{dA}{dt} = \frac{1}{2} |\mathbf{r} \times \dot{\mathbf{r}}|.$$

11. **Kepler's third law** Complete the derivation of Kepler's third law (the part following Equation (10)).

12. Do the data in the accompanying table support Kepler's third law? Give reasons for your answer.

Planet	Semimajor axis a (10^{10} m)	Period T (years)
Mercury	5.79	0.241
Venus	10.81	0.615
Mars	22.78	1.881
Saturn	142.70	29.457

13. **Earth's major axis** Estimate the length of the major axis of Earth's orbit if its orbital period is 365.256 days.

14. Estimate the length of the major axis of the orbit of Uranus if its orbital period is 84 years.

15. The eccentricity of Earth's orbit is $e = 0.0167$, so the orbit is nearly circular, with radius approximately 150×10^6 km. Find, in units of km^2/s , the rate dA/dt satisfying Kepler's second law.

16. **Jupiter's orbital period** Estimate the orbital period of Jupiter, assuming that $a = 77.8 \times 10^{10}$ m.

17. **Mass of Jupiter** Io is one of the moons of Jupiter. It has a semi-major axis of 0.042×10^{10} m and an orbital period of 1.769 days. Use these data to estimate the mass of Jupiter.

18. **Distance from Earth to the moon** The period of the moon's rotation around Earth is 2.36055×10^6 s. Estimate the distance to the moon.

CHAPTER 12 Questions to Guide Your Review

- State the rules for differentiating and integrating vector functions. Give examples.
- How do you define and calculate the velocity, speed, direction of motion, and acceleration of a body moving along a sufficiently differentiable space curve? Give an example.
- What is special about the derivatives of vector functions of constant length? Give an example.
- What are the vector and parametric equations for ideal projectile motion? How do you find a projectile's maximum height, flight time, and range? Give examples.

- How do you define and calculate the length of a segment of a smooth space curve? Give an example. What mathematical assumptions are involved in the definition?
- How do you measure distance along a smooth curve in space from a preselected base point? Give an example.
- What is a differentiable curve's unit tangent vector? Give an example.
- Define curvature, circle of curvature (osculating circle), center of curvature, and radius of curvature for twice-differentiable curves in the plane. Give examples. What curves have zero curvature? Constant curvature?

9. What is a plane curve's principal normal vector? When is it defined? Which way does it point? Give an example.
10. How do you define \mathbf{N} and κ for curves in space? How are these quantities related? Give examples.
11. What is a curve's binormal vector? Give an example. How is this vector related to the curve's torsion? Give an example.

12. What formulas are available for writing a moving object's acceleration as a sum of its tangential and normal components? Give an example. Why might one want to write the acceleration this way? What if the object moves at a constant speed? At a constant speed around a circle?
13. State Kepler's laws.

CHAPTER 12 Practice Exercises

Motion in the Plane

In Exercises 1 and 2, graph the curves and sketch their velocity and acceleration vectors at the given values of t . Then write \mathbf{a} in the form $\mathbf{a} = a_T \mathbf{T} + a_N \mathbf{N}$ without finding \mathbf{T} and \mathbf{N} , and find the value of κ at the given values of t .

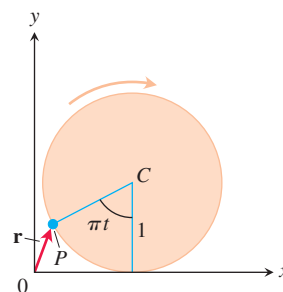

1. $\mathbf{r}(t) = (4 \cos t)\mathbf{i} + (\sqrt{2} \sin t)\mathbf{j}$, $t = 0$ and $\pi/4$
2. $\mathbf{r}(t) = (\sqrt{3} \sec t)\mathbf{i} + (\sqrt{3} \tan t)\mathbf{j}$, $t = 0$
3. The position of a particle in the plane at time t is

$$\mathbf{r} = \frac{1}{\sqrt{1+t^2}}\mathbf{i} + \frac{t}{\sqrt{1+t^2}}\mathbf{j}.$$

Find the particle's highest speed.

4. Suppose $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j}$. Show that the angle between \mathbf{r} and \mathbf{a} never changes. What is the angle?
5. **Finding curvature** At point P , the velocity and acceleration of a particle moving in the plane are $\mathbf{v} = 3\mathbf{i} + 4\mathbf{j}$ and $\mathbf{a} = 5\mathbf{i} + 15\mathbf{j}$. Find the curvature of the particle's path at P .
6. Find the point on the curve $y = e^x$ where the curvature is greatest.
7. A particle moves around the unit circle in the xy -plane. Its position at time t is $\mathbf{r} = x\mathbf{i} + y\mathbf{j}$, where x and y are differentiable functions of t . Find dy/dt if $\mathbf{v} \cdot \mathbf{i} = y$. Is the motion clockwise or counterclockwise?
8. You send a message through a pneumatic tube that follows the curve $9y = x^3$ (distance in meters). At the point $(3, 3)$, $\mathbf{v} \cdot \mathbf{i} = 4$ and $\mathbf{a} \cdot \mathbf{i} = -2$. Find the values of $\mathbf{v} \cdot \mathbf{j}$ and $\mathbf{a} \cdot \mathbf{j}$ at $(3, 3)$.
9. **Characterizing circular motion** A particle moves in the plane so that its velocity and position vectors are always orthogonal. Show that the particle moves in a circle centered at the origin.
10. **Speed along a cycloid** A circular wheel with radius 1 m and center C rolls to the right along the x -axis at a half-turn per second. (See the accompanying figure.) At time t seconds, the position vector of the point P on the wheel's circumference is

$$\mathbf{r} = (\pi t - \sin \pi t)\mathbf{i} + (1 - \cos \pi t)\mathbf{j}.$$
 - a. Sketch the curve traced by P during the interval $0 \leq t \leq 3$.
 - b. Find \mathbf{v} and \mathbf{a} at $t = 0, 1, 2,$ and 3 and add these vectors to your sketch.
 - c. At any given time, what is the forward speed of the topmost point of the wheel? Of C ?

Projectile Motion

11. **Shot put** A shot leaves the thrower's hand 2 m above the ground at a 45° angle at 14 m/s. Where is it 3 s later?
12. **Javelin** A javelin leaves the thrower's hand 2.5 m above the ground at a 45° angle at 24 m/s. How high does it go?
13. A golf ball is hit with an initial speed v_0 at an angle α to the horizontal from a point that lies at the foot of a straight-sided hill that is inclined at an angle ϕ to the horizontal, where

$$0 < \phi < \alpha < \frac{\pi}{2}.$$

Show that the ball lands at a distance

$$\frac{2v_0^2 \cos \alpha}{g \cos^2 \phi} \sin(\alpha - \phi),$$

measured up the face of the hill. Hence, show that the greatest range that can be achieved for a given v_0 occurs when $\alpha = (\phi/2) + (\pi/4)$, that is, when the initial velocity vector bisects the angle between the vertical and the hill.

- T** 14. **Javelin** In Potsdam in 1988, Petra Felke of (then) East Germany set a women's world record by throwing a javelin 80 m.
- a. Assuming that Felke launched the javelin at a 40° angle to the horizontal 2 m above the ground, what was the javelin's initial speed?
 - b. How high did the javelin go?

Motion in Space

Find the lengths of the curves in Exercises 15 and 16.

15. $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{j} + t^2\mathbf{k}$, $0 \leq t \leq \pi/4$
16. $\mathbf{r}(t) = (3 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + 2t^{3/2}\mathbf{k}$, $0 \leq t \leq 3$

In Exercises 17–20, find \mathbf{T} , \mathbf{N} , \mathbf{B} , κ , and τ at the given value of t .

17. $\mathbf{r}(t) = \frac{4}{9}(1+t)^{3/2}\mathbf{i} + \frac{4}{9}(1-t)^{3/2}\mathbf{j} + \frac{1}{3}t\mathbf{k}$, $t = 0$

18. $\mathbf{r}(t) = (e^t \sin 2t)\mathbf{i} + (e^t \cos 2t)\mathbf{j} + 2e^t\mathbf{k}$, $t = 0$

19. $\mathbf{r}(t) = t\mathbf{i} + \frac{1}{2}e^{2t}\mathbf{j}$, $t = \ln 2$

20. $\mathbf{r}(t) = (3 \cosh 2t)\mathbf{i} + (3 \sinh 2t)\mathbf{j} + 6t\mathbf{k}$, $t = \ln 2$

In Exercises 21 and 22, write \mathbf{a} in the form $\mathbf{a} = a_T\mathbf{T} + a_N\mathbf{N}$ at $t = 0$ without finding \mathbf{T} and \mathbf{N} .

21. $\mathbf{r}(t) = (2 + 3t + 3t^2)\mathbf{i} + (4t + 4t^2)\mathbf{j} - (6 \cos t)\mathbf{k}$

22. $\mathbf{r}(t) = (2 + t)\mathbf{i} + (t + 2t^2)\mathbf{j} + (1 + t^2)\mathbf{k}$

23. Find \mathbf{T} , \mathbf{N} , \mathbf{B} , κ , and τ as functions of t if

$$\mathbf{r}(t) = (\sin t)\mathbf{i} + (\sqrt{2} \cos t)\mathbf{j} + (\sin t)\mathbf{k}.$$

24. At what times in the interval $0 \leq t \leq \pi$ are the velocity and acceleration vectors of the motion $\mathbf{r}(t) = \mathbf{i} + (5 \cos t)\mathbf{j} + (3 \sin t)\mathbf{k}$ orthogonal?

25. The position of a particle moving in space at time $t \geq 0$ is

$$\mathbf{r}(t) = 2\mathbf{i} + \left(4 \sin \frac{t}{2}\right)\mathbf{j} + \left(3 - \frac{t}{\pi}\right)\mathbf{k}.$$

Find the first time \mathbf{r} is orthogonal to the vector $\mathbf{i} - \mathbf{j}$.

26. Find equations for the osculating, normal, and rectifying planes of the curve $\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + t^3\mathbf{k}$ at the point $(1, 1, 1)$.

27. Find parametric equations for the line that is tangent to the curve $\mathbf{r}(t) = e^t\mathbf{i} + (\sin t)\mathbf{j} + \ln(1-t)\mathbf{k}$ at $t = 0$.

28. Find parametric equations for the line that is tangent to the helix $\mathbf{r}(t) = (\sqrt{2} \cos t)\mathbf{i} + (\sqrt{2} \sin t)\mathbf{j} + t\mathbf{k}$ at the point where $t = \pi/4$.

Theory and Examples

29. **Synchronous curves** By eliminating α from the ideal projectile equations

$$x = (v_0 \cos \alpha)t, \quad y = (v_0 \sin \alpha)t - \frac{1}{2}gt^2,$$

show that $x^2 + (y + gt^2/2)^2 = v_0^2 t^2$. This shows that projectiles launched simultaneously from the origin at the same initial speed will, at any given instant, all lie on the circle of radius $v_0 t$ centered at $(0, -gt^2/2)$, regardless of their launch angle. These circles are the *synchronous curves* of the launching.

30. **Radius of curvature** Show that the radius of curvature of a twice-differentiable plane curve $\mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j}$ is given by the formula

$$\rho = \frac{\dot{x}^2 + \dot{y}^2}{\sqrt{\ddot{x}^2 + \ddot{y}^2 - \ddot{s}^2}}, \quad \text{where } \ddot{s} = \frac{d}{dt} \sqrt{\dot{x}^2 + \dot{y}^2}.$$

31. **An alternative definition of curvature in the plane** An alternative definition gives the curvature of a sufficiently differentiable plane curve to be $|d\phi/ds|$, where ϕ is the angle between \mathbf{T} and \mathbf{i}

(Figure 12.37a). Figure 12.37b shows the distance s measured counterclockwise around the circle $x^2 + y^2 = a^2$ from the point $(a, 0)$ to a point P , along with the angle ϕ at P . Calculate the circle's curvature using the alternative definition. (*Hint:* $\phi = \theta + \pi/2$.)

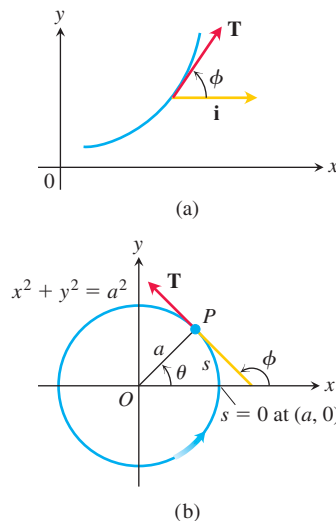

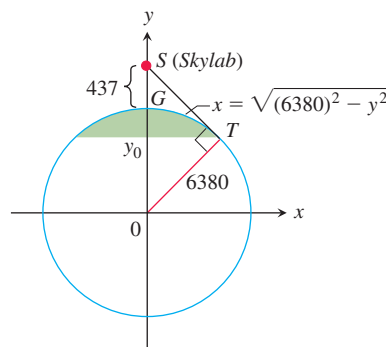

FIGURE 12.37 Figures for Exercise 31.

32. **The view from Skylab 4** What percentage of Earth's surface area could the astronauts see when *Skylab 4* was at its apogee height, 437 km above the surface? To find out, model the visible surface as the surface generated by revolving the circular arc GT , shown here, about the y -axis. Then carry out these steps:

1. Use similar triangles in the figure to show that $y_0/6380 = 6380/(6380 + 437)$. Solve for y_0 .
2. To four significant digits, calculate the visible area as

$$VA = \int_{y_0}^{6380} 2\pi x \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy.$$

3. Express the result as a percentage of Earth's surface area.

CHAPTER 12 Additional and Advanced Exercises

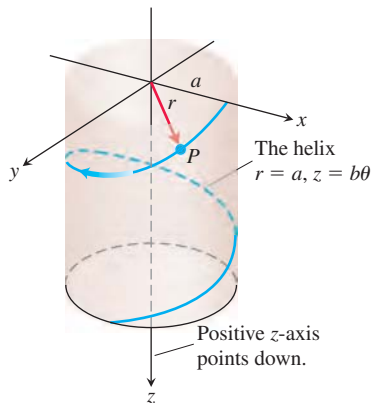

Applications

1. A frictionless particle P , starting from rest at time $t = 0$ at the point $(a, 0, 0)$, slides down the helix

$$\mathbf{r}(\theta) = (a \cos \theta)\mathbf{i} + (a \sin \theta)\mathbf{j} + b\theta\mathbf{k} \quad (a, b > 0)$$

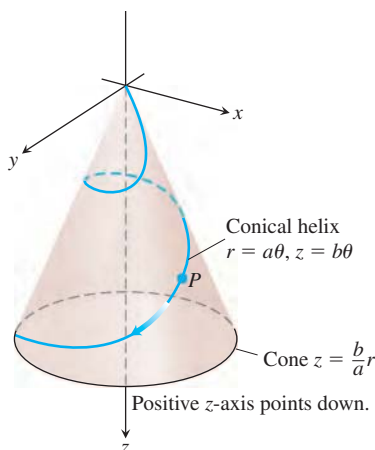

under the influence of gravity, as in the accompanying figure. The θ in this equation is the cylindrical coordinate θ , and the helix is the curve $r = a$, $z = b\theta$, $\theta \geq 0$, in cylindrical coordinates. We assume θ to be a differentiable function of t for the motion. The law of conservation of energy tells us that the particle's speed after it has fallen straight down a distance z is $\sqrt{2gz}$, where g is the constant acceleration of gravity.

- Find the angular velocity $d\theta/dt$ when $\theta = 2\pi$.
- Express the particle's θ - and z -coordinates as functions of t .
- Express the tangential and normal components of the velocity $d\mathbf{r}/dt$ and acceleration $d^2\mathbf{r}/dt^2$ as functions of t . Does the acceleration have any nonzero component in the direction of the binormal vector \mathbf{B} ?

2. Suppose the curve in Exercise 1 is replaced by the conical helix $r = a\theta$, $z = b\theta$ shown in the accompanying figure.

- Express the angular velocity $d\theta/dt$ as a function of θ .
- Express the distance the particle travels along the helix as a function of θ .

Motion in Polar and Cylindrical Coordinates

3. Deduce from the orbit equation

$$r = \frac{(1+e)r_0}{1+e \cos \theta}$$

that a planet is closest to its sun when $\theta = 0$, and show that $r = r_0$ at that time.

- T** 4. **A Kepler equation** The problem of locating a planet in its orbit at a given time and date eventually leads to solving “Kepler” equations of the form

$$f(x) = x - 1 - \frac{1}{2}\sin x = 0.$$

- Show that this particular equation has a solution between $x = 0$ and $x = 2$.
 - With your computer or calculator in radian mode, use Newton's method to find the solution to as many places as you can.
5. In Section 12.6, we found the velocity of a particle moving in the plane to be

$$\mathbf{v} = \dot{x}\mathbf{i} + \dot{y}\mathbf{j} = \dot{r}\mathbf{u}_r + r\dot{\theta}\mathbf{u}_\theta.$$

- Express \dot{x} and \dot{y} in terms of \dot{r} and $r\dot{\theta}$ by evaluating the dot products $\mathbf{v} \cdot \mathbf{i}$ and $\mathbf{v} \cdot \mathbf{j}$.
 - Express \dot{r} and $r\dot{\theta}$ in terms of \dot{x} and \dot{y} by evaluating the dot products $\mathbf{v} \cdot \mathbf{u}_r$ and $\mathbf{v} \cdot \mathbf{u}_\theta$.
6. Express the curvature of a twice-differentiable curve $r = f(\theta)$ in the polar coordinate plane in terms of f and its derivatives.
7. A slender rod through the origin of the polar coordinate plane rotates (in the plane) about the origin at the rate of 3 rad/min. A beetle starting from the point $(2, 0)$ crawls along the rod toward the origin at the rate of 1 cm/min.

- Find the beetle's acceleration and velocity in polar form when it is halfway to (1 cm from) the origin.

- T** b. To the nearest millimeter, what will be the length of the path the beetle has traveled by the time it reaches the origin?

8. Arc length in cylindrical coordinates

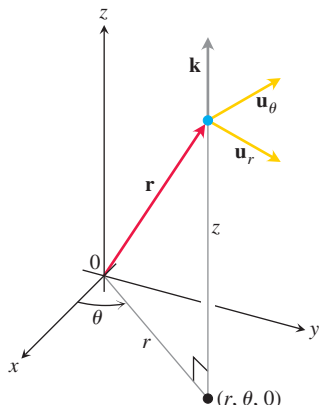

- Show that when you express $ds^2 = dx^2 + dy^2 + dz^2$ in terms of cylindrical coordinates, you get $ds^2 = dr^2 + r^2d\theta^2 + dz^2$.
- Interpret this result geometrically in terms of the edges and a diagonal of a box. Sketch the box.
- Use the result in part (a) to find the length of the curve $r = e^\theta$, $z = e^\theta$, $0 \leq \theta \leq \ln 8$.

9. Unit vectors for position and motion in cylindrical coordinates

When the position of a particle moving in space is given in cylindrical coordinates, the unit vectors we use to describe its position and motion are

$$\mathbf{u}_r = (\cos \theta)\mathbf{i} + (\sin \theta)\mathbf{j}, \quad \mathbf{u}_\theta = -(\sin \theta)\mathbf{i} + (\cos \theta)\mathbf{j}.$$

and \mathbf{k} (see accompanying figure). The particle's position vector is then $\mathbf{r} = r\mathbf{u}_r + z\mathbf{k}$, where r is the positive polar distance coordinate of the particle's position.

- a. Show that \mathbf{u}_r , \mathbf{u}_θ , and \mathbf{k} , in this order, form a right-handed frame of unit vectors.

- b. Show that

$$\frac{d\mathbf{u}_r}{d\theta} = \mathbf{u}_\theta \quad \text{and} \quad \frac{d\mathbf{u}_\theta}{d\theta} = -\mathbf{u}_r.$$

- c. Assuming that the necessary derivatives with respect to t exist, express $\mathbf{v} = \dot{\mathbf{r}}$ and $\mathbf{a} = \ddot{\mathbf{r}}$ in terms of \mathbf{u}_r , \mathbf{u}_θ , \mathbf{k} , \dot{r} , and $\dot{\theta}$.

- d. **Conservation of angular momentum** Let $\mathbf{r}(t)$ denote the position in space of a moving object at time t . Suppose the force acting on the object at time t is

$$\mathbf{F}(t) = -\frac{c}{|\mathbf{r}(t)|^3} \mathbf{r}(t),$$

where c is a constant. In physics the **angular momentum** of an object at time t is defined to be $\mathbf{L}(t) = \mathbf{r}(t) \times m\mathbf{v}(t)$, where m is the mass of the object and $\mathbf{v}(t)$ is the velocity. Prove that angular momentum is a conserved quantity; that is, prove that $\mathbf{L}(t)$ is a constant vector, independent of time. Remember Newton's law $\mathbf{F} = m\mathbf{a}$. (This is a calculus problem, not a physics problem.)

CHAPTER 12 Technology Application Projects

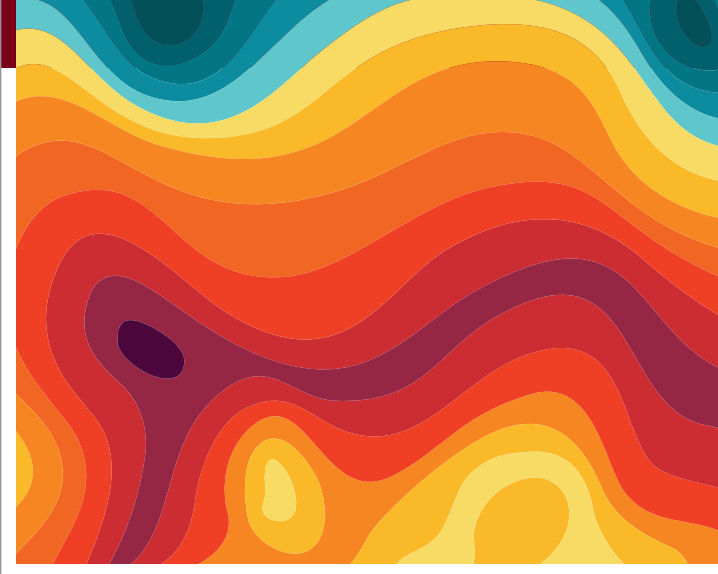

Mathematica/Maple Projects

Projects can be found within MyLab Math.

- **Radar Tracking of a Moving Object**
Visualize position, velocity, and acceleration vectors to analyze motion.
- **Parametric and Polar Equations with a Figure Skater**
Visualize position, velocity, and acceleration vectors to analyze motion.
- **Moving in Three Dimensions**
Compute distance traveled, speed, curvature, and torsion for motion along a space curve. Visualize and compute the tangential, normal, and binormal vectors associated with motion along a space curve.

13

Partial Derivatives

OVERVIEW The volume of a right circular cylinder is a function $V = \pi r^2 h$ of its radius and its height, so it is a function $V(r, h)$ of two variables r and h . The speed of sound through seawater is primarily a function of salinity S and temperature T . The monthly payment on a home mortgage is a function of the principal borrowed P , the interest rate i , and the term t of the loan. These are examples of functions that depend on more than one independent variable. In this chapter we extend the ideas of single-variable differential calculus to functions of several variables.

13.1 Functions of Several Variables

Real-valued functions of several independent real variables are defined analogously to functions of a single variable. Points in the domain are now ordered pairs (or triples, quadruples, n -tuples) of real numbers, and values in the range are real numbers.

DEFINITIONS Suppose D is a set of n -tuples of real numbers (x_1, x_2, \dots, x_n) . A **real-valued function** f on D is a rule that assigns a real number

$$w = f(x_1, x_2, \dots, x_n)$$

to each element in D . The set D is the function's **domain**. The set of w -values taken on by f is the function's **range**. The symbol w is the **dependent variable** of f , and f is said to be a function of the n **independent variables** x_1 to x_n . We also call the x_j 's the function's **input variables** and call w the function's **output variable**.

If f is a function of two independent variables, we usually call the independent variables x and y and the dependent variable z , and we picture the domain of f as a region in the xy -plane (Figure 13.1). If f is a function of three independent variables, we call the independent variables x , y , and z and the dependent variable w , and we picture the domain as a region in space.

In applications, we tend to use letters that remind us of what the variables stand for. To say that the volume of a right circular cylinder is a function of its radius and height, we might write $V = f(r, h)$. To be more specific, we might replace the notation $f(r, h)$ by the formula that calculates the value of V from the values of r and h , and write $V = \pi r^2 h$. In either case, r and h would be the independent variables and V the dependent variable of the function.

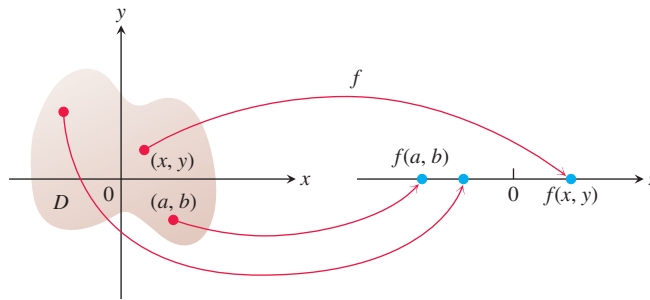

FIGURE 13.1 An arrow diagram for the function $z = f(x, y)$.

As usual, we evaluate functions defined by formulas by substituting the values of the independent variables in the formula and calculating the corresponding value of the dependent variable. For example, the value of $f(x, y, z) = \sqrt{x^2 + y^2 + z^2}$ at the point $(3, 0, 4)$ is

$$f(3, 0, 4) = \sqrt{(3)^2 + (0)^2 + (4)^2} = \sqrt{25} = 5.$$

Domains and Ranges

In defining a function of more than one variable, we follow the usual practice of excluding inputs that lead to complex numbers or division by zero. If $f(x, y) = \sqrt{y - x^2}$, then y cannot be less than x^2 . If $f(x, y) = 1/(xy)$, then xy cannot be zero. The domain of a function is assumed to be the largest set for which the defining rule generates real numbers, unless the domain is otherwise specified explicitly. The range consists of the set of output values for the dependent variable.

EXAMPLE 1

(a) These are functions of two variables. Note the restrictions that apply to their domains in order to obtain a real value for the dependent variable z .

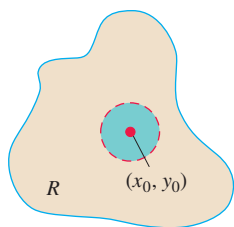

Function	Domain	Range
$z = \sqrt{y - x^2}$	$y \geq x^2$	$[0, \infty)$
$z = \frac{1}{xy}$	$xy \neq 0$	$(-\infty, 0) \cup (0, \infty)$
$z = \sin xy$	Entire plane	$[-1, 1]$

(b) These are functions of three variables with restrictions on some of their domains.

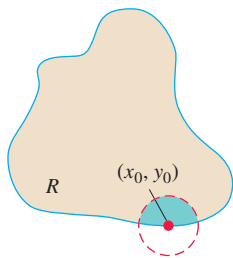

Function	Domain	Range
$w = \sqrt{x^2 + y^2 + z^2}$	Entire space	$[0, \infty)$
$w = \frac{1}{x^2 + y^2 + z^2}$	$(x, y, z) \neq (0, 0, 0)$	$(0, \infty)$
$w = xy \ln z$	Half-space $z > 0$	$(-\infty, \infty)$

Functions of Two Variables

On the real line, closed intervals $[a, b]$ include their boundary points while open intervals (a, b) do not. Intervals such as $[a, b)$, which includes only one of its two boundary points, are neither open nor closed. Regions in the plane can also be open, closed, or neither.

(a) Interior point

(b) Boundary point

FIGURE 13.2 Interior points and boundary points of a plane region R . An interior point is necessarily a point of R . A boundary point of R need not belong to R .

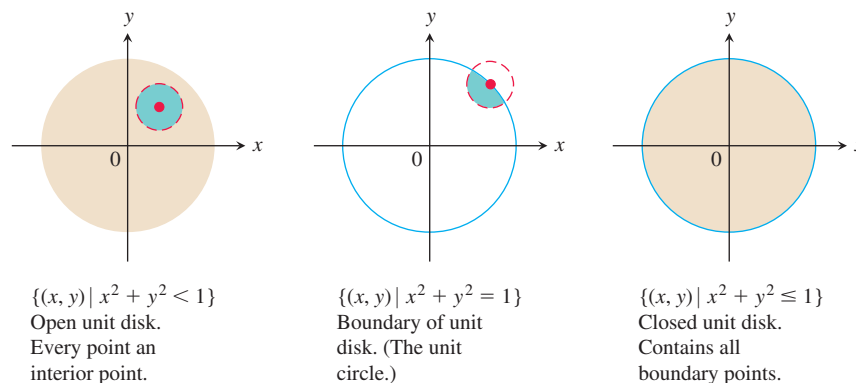

FIGURE 13.3 Interior points and boundary points of the unit disk in the plane.

As with a half-open interval of real numbers $[a, b)$, some regions in the plane are neither open nor closed. If you start with the open disk in Figure 13.3 and add to it some, but not all, of its boundary points, the resulting set is neither open nor closed. The boundary points that *are* there keep the set from being open. The absence of the remaining boundary points keeps the set from being closed. Two interesting examples are the empty set and the entire plane. The empty set has no interior points and no boundary points. This implies that the empty set is open (because it does not contain points that are not interior points), and at the same time it is closed (because there are no boundary points that it fails to contain). The entire xy -plane is also both open and closed: open because every point in the plane is an interior point, and closed because it has no boundary points. The empty set and the entire plane are the only subsets of the plane that are both open and closed. Other sets may be open, or closed, or neither.

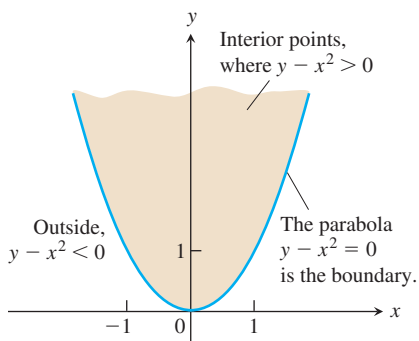

FIGURE 13.4 The domain of $f(x, y)$ in Example 2 consists of the shaded region and its bounding parabola.

DEFINITIONS A region in the plane is **bounded** if it lies inside a disk of finite radius. A region is **unbounded** if it is not bounded.

Examples of *bounded* sets in the plane include line segments, triangles, interiors of triangles, rectangles, circles, and disks. Examples of *unbounded* sets in the plane include lines, coordinate axes, the graphs of functions defined on infinite intervals, quadrants, half-planes, and the plane itself.

EXAMPLE 2 Describe the domain of the function $f(x, y) = \sqrt{y - x^2}$.

Solution Since f is defined only where $y - x^2 \geq 0$, the domain is the closed, unbounded region shown in Figure 13.4. The parabola $y = x^2$ is the boundary of the domain. The points above the parabola make up the domain's interior. ■

Graphs, Level Curves, and Contours of Functions of Two Variables

There are two standard ways to picture the values of a function $f(x, y)$. One is to draw and label curves in the domain on which f has a constant value. The other is to sketch the surface $z = f(x, y)$ in space.

DEFINITIONS The set of points in the plane where a function $f(x, y)$ has a constant value $f(x, y) = c$ is called a **level curve** of f . The set of all points $(x, y, f(x, y))$ in space, for (x, y) in the domain of f , is called the **graph** of f .

The graph of f is often called the **surface** $z = f(x, y)$.

EXAMPLE 3 Graph $f(x, y) = 100 - x^2 - y^2$ and plot the level curves $f(x, y) = 0$, $f(x, y) = 51$, and $f(x, y) = 75$ in the domain of f in the plane.

Solution The domain of f is the entire xy -plane, and the range of f is the set of real numbers less than or equal to 100. The graph is the paraboloid $z = 100 - x^2 - y^2$, the positive portion of which is shown in Figure 13.5.

The level curve $f(x, y) = 0$ is the set of points in the xy -plane at which

$$f(x, y) = 100 - x^2 - y^2 = 0, \quad \text{or} \quad x^2 + y^2 = 100,$$

which is the circle of radius 10 centered at the origin. Similarly, the level curves $f(x, y) = 51$ and $f(x, y) = 75$ (Figure 13.5) are the circles

$$f(x, y) = 100 - x^2 - y^2 = 51, \quad \text{or} \quad x^2 + y^2 = 49$$

$$f(x, y) = 100 - x^2 - y^2 = 75, \quad \text{or} \quad x^2 + y^2 = 25.$$

The level curve $f(x, y) = 100$ consists of the origin alone. (It is still a level curve.)

If $x^2 + y^2 > 100$, then the values of $f(x, y)$ are negative. For example, the circle $x^2 + y^2 = 144$, which is the circle centered at the origin with radius 12, gives the constant value $f(x, y) = -44$ and is a level curve of f . ■

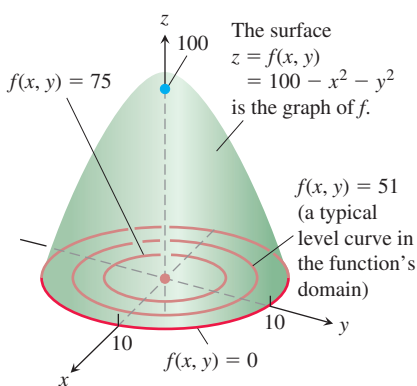

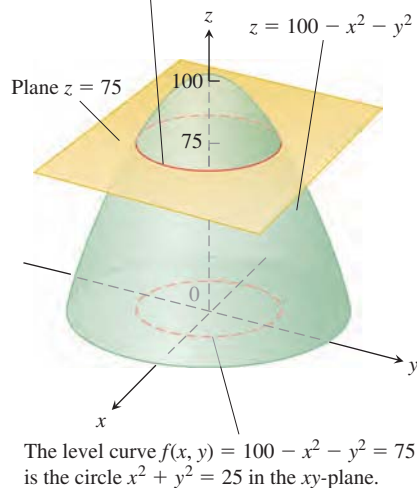

FIGURE 13.5 The graph and selected level curves of the function $f(x, y)$ in Example 3. The level curves lie in the xy -plane, which is the domain of the function $f(x, y)$.

The contour curve $f(x, y) = 100 - x^2 - y^2 = 75$ is the circle $x^2 + y^2 = 25$ in the plane $z = 75$.

The level curve $f(x, y) = 100 - x^2 - y^2 = 75$ is the circle $x^2 + y^2 = 25$ in the xy -plane.

FIGURE 13.6 A plane $z = c$ parallel to the xy -plane intersecting a surface $z = f(x, y)$ produces a contour curve.

The curve in space in which the plane $z = c$ cuts a surface $z = f(x, y)$ is made up of the points that represent the function value $f(x, y) = c$. It is called the **contour curve** $f(x, y) = c$ to distinguish it from the level curve $f(x, y) = c$ in the domain of f . Figure 13.6 shows the contour curve $f(x, y) = 75$ on the surface $z = 100 - x^2 - y^2$ defined by the function $f(x, y) = 100 - x^2 - y^2$. The contour curve lies directly above the circle $x^2 + y^2 = 25$, which is the level curve $f(x, y) = 75$ in the function's domain.

The distinction between level curves and contour curves is often overlooked, and it is common to call both types of curves by the same name, relying on context to make it clear which type of curve is meant. On most maps, for example, the curves that represent constant elevation (height above sea level) are called contours, not level curves (Figure 13.7).

Functions of Three Variables

In the plane, the points where a function of two independent variables has a constant value $f(x, y) = c$ make a curve in the function's domain. In space, the points where a function of three independent variables has a constant value $f(x, y, z) = c$ make a surface in the function's domain.

DEFINITION The set of points (x, y, z) in space where a function of three independent variables has a constant value $f(x, y, z) = c$ is called a **level surface** of f .

FIGURE 13.7 Contours on Mt. Washington in New Hampshire.
(Source: United States Geological Survey)

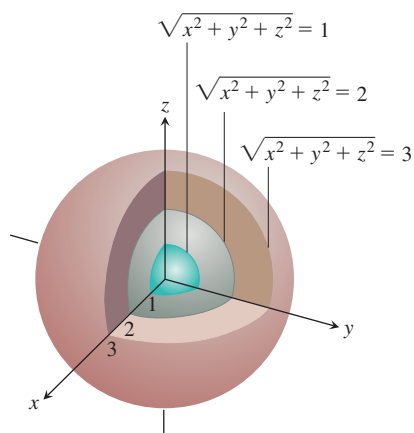

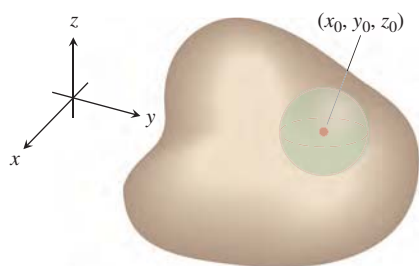

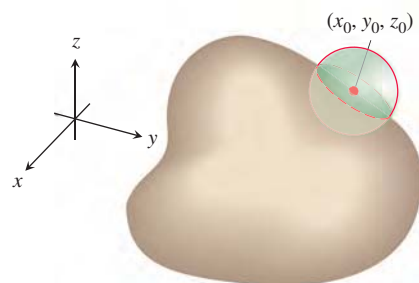

FIGURE 13.8 The level surfaces of $f(x, y, z) = \sqrt{x^2 + y^2 + z^2}$ are concentric spheres (Example 4).

(a) Interior point

(b) Boundary point

FIGURE 13.9 Interior points and boundary points of a region in space. As with regions in the plane, a boundary point need not belong to the space region R .

Since the graphs of functions of three variables consist of points $(x, y, z, f(x, y, z))$ lying in a four-dimensional space, we cannot sketch them effectively in our three-dimensional frame of reference. We can see how the function behaves, however, by looking at its three-dimensional level surfaces.

EXAMPLE 4 Describe the level surfaces of the function

$$f(x, y, z) = \sqrt{x^2 + y^2 + z^2}.$$

Solution The value of f is the distance from the origin to the point (x, y, z) . Each level surface $\sqrt{x^2 + y^2 + z^2} = c$, $c > 0$, is a sphere of radius c centered at the origin. Figure 13.8 shows a cutaway view of three of these spheres. The level surface $\sqrt{x^2 + y^2 + z^2} = 0$ consists of the origin alone.

We are not graphing the function here; we are looking at level surfaces in the function's domain. The level surfaces show how the function's values change as we move through its domain. If we remain on a sphere of radius c centered at the origin, the function maintains a constant value, namely c . If we move from a point on one sphere to a point on another, the function's value changes. It increases if we move away from the origin and decreases if we move toward the origin. The way the values change depends on the direction we take. The dependence of change on direction is important. We return to it in Section 13.5. ■

The definitions of interior, boundary, open, closed, bounded, and unbounded for regions in space are similar to those for regions in the plane. To accommodate the extra dimension, we use solid balls of positive radius instead of disks.

DEFINITIONS A point (x_0, y_0, z_0) in a region R in space is an **interior point** of R if it is the center of a solid ball that lies entirely in R (Figure 13.9a). A point (x_0, y_0, z_0) is a **boundary point** of R if every solid ball centered at (x_0, y_0, z_0) contains points that lie outside of R as well as points that lie inside R (Figure 13.9b). The **interior** of R is the set of interior points of R . The **boundary** of R is the set of boundary points of R .

A region is **open** if it consists entirely of interior points. A region is **closed** if it contains its entire boundary.

A region is **bounded** if it lies inside a solid ball of finite radius; otherwise, the region is **unbounded**.

Examples of *open* sets in space include the interior of a sphere, the open half-space $z > 0$, the first octant (where x , y , and z are all positive), and space itself. Examples of *closed* sets in space include lines, planes, and the closed half-space $z \geq 0$. A solid sphere

with part of its boundary removed or a solid cube with a missing face, edge, or corner point is *neither open nor closed*.

Functions of more than three independent variables are also important. For example, a model that measures temperature in the atmosphere may depend not only on the location of the point $P(x, y, z)$ in space, but also on the time t when it is measured, so we would write $T = f(x, y, z, t)$.

Computer Graphing

Three-dimensional graphing software makes it possible to graph functions of two variables. We can often get information more quickly from a graph than from a formula, since the surfaces reveal increasing and decreasing behavior, and high points or low points.

EXAMPLE 5 The temperature w beneath the Earth's surface is a function of the depth x beneath the surface and the time t of the year. If we measure x in meters and t as the number of days elapsed from the expected date of the yearly highest surface temperature, we can model the variation in temperature with the function

$$w = \cos(1.7 \times 10^{-2}t - 0.6x)e^{-0.6x}.$$

(The temperature at 0 m is scaled to vary from +1 to -1, so that the variation at x meters can be interpreted as a fraction of the variation at the surface.)

Figure 13.10 shows a graph of the function. At a depth of 5 m, the variation (change in vertical amplitude in the figure) is about 5% of the surface variation. At 8 m, there is almost no variation during the year.

The graph also shows that the temperature 5 m below the surface is about half a year out of phase with the surface temperature. When the temperature is lowest on the surface (late January, say), it is at its highest 5 m below. Five meters below the ground, the seasons are reversed. ■

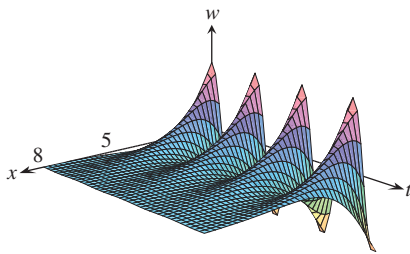

FIGURE 13.10 This graph shows the seasonal variation of the temperature below ground as a fraction of surface temperature (Example 5).

Figure 13.11 shows computer-generated graphs of a number of functions of two variables together with their level curves.

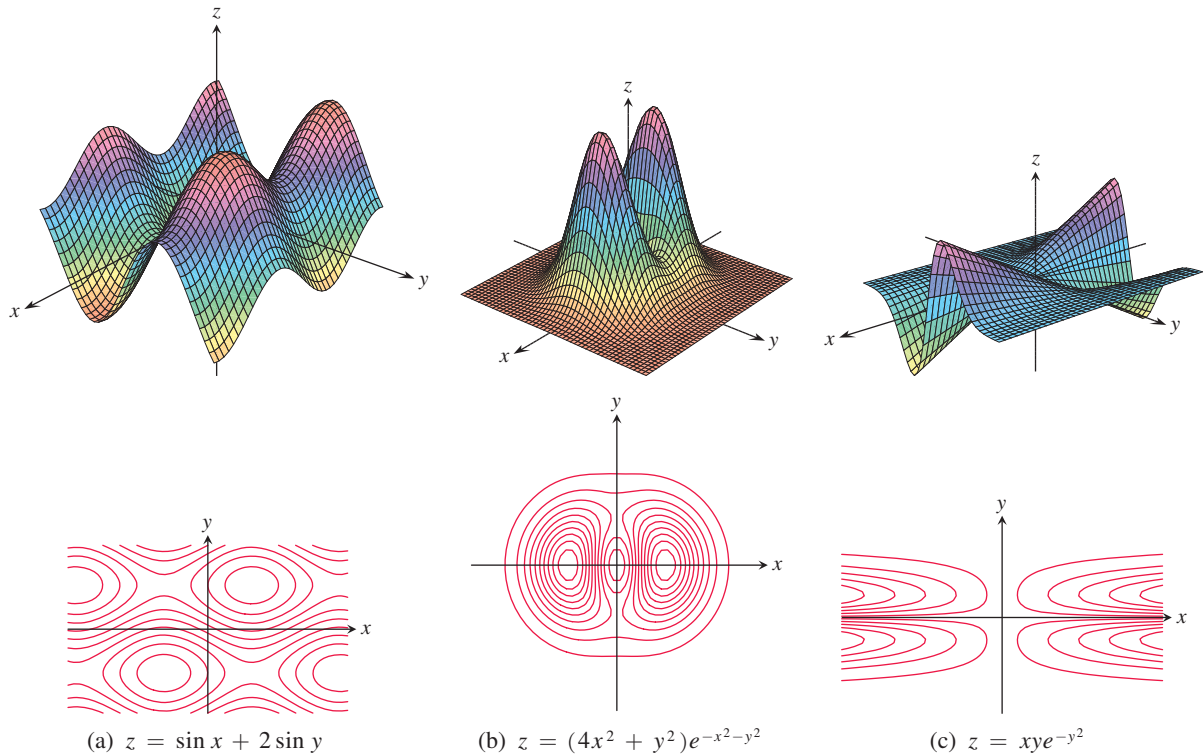

FIGURE 13.11 Computer-generated graphs and level curves of typical functions of two variables.

EXERCISES 13.1

Domain, Range, and Level Curves

In Exercises 1–4, find the specific function values.

- $f(x, y) = x^2 + xy^3$
 - $f(0, 0)$
 - $f(-1, 1)$
 - $f(2, 3)$
 - $f(-3, -2)$
- $f(x, y) = \sin(xy)$
 - $f\left(2, \frac{\pi}{6}\right)$
 - $f\left(-3, \frac{\pi}{12}\right)$
 - $f\left(\pi, \frac{1}{4}\right)$
 - $f\left(-\frac{\pi}{2}, -7\right)$
- $f(x, y, z) = \frac{x - y}{y^2 + z^2}$
 - $f(3, -1, 2)$
 - $f\left(1, \frac{1}{2}, -\frac{1}{4}\right)$
 - $f\left(0, -\frac{1}{3}, 0\right)$
 - $f(2, 2, 100)$
- $f(x, y, z) = \sqrt{49 - x^2 - y^2 - z^2}$
 - $f(0, 0, 0)$
 - $f(2, -3, 6)$
 - $f(-1, 2, 3)$
 - $f\left(\frac{4}{\sqrt{2}}, \frac{5}{\sqrt{2}}, \frac{6}{\sqrt{2}}\right)$

In Exercises 5–12, find and sketch the domain for each function.

- $f(x, y) = \sqrt{y - x - 2}$
- $f(x, y) = \ln(x^2 + y^2 - 4)$
- $f(x, y) = \frac{(x - 1)(y + 2)}{(y - x)(y - x^3)}$
- $f(x, y) = \frac{\sin(xy)}{x^2 + y^2 - 25}$
- $f(x, y) = \cos^{-1}(y - x^2)$
- $f(x, y) = \ln(xy + x - y - 1)$
- $f(x, y) = \sqrt{(x^2 - 4)(y^2 - 9)}$
- $f(x, y) = \frac{1}{\ln(4 - x^2 - y^2)}$

In Exercises 13–16, find and sketch the level curves $f(x, y) = c$ on the same set of coordinate axes for the given values of c . We refer to these level curves as a contour map.

- $f(x, y) = x + y - 1$, $c = -3, -2, -1, 0, 1, 2, 3$
- $f(x, y) = x^2 + y^2$, $c = 0, 1, 4, 9, 16, 25$
- $f(x, y) = xy$, $c = -9, -4, -1, 0, 1, 4, 9$
- $f(x, y) = \sqrt{25 - x^2 - y^2}$, $c = 0, 1, 2, 3, 4$

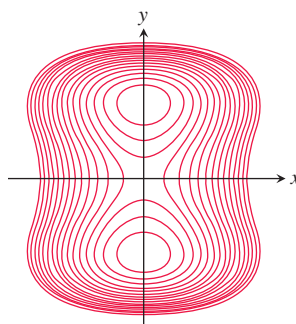

In Exercises 17–30, (a) find the function's domain, (b) find the function's range, (c) describe the function's level curves, (d) find the boundary of the function's domain, (e) determine whether the domain is an open region, a closed region, or neither, and (f) decide whether the domain is bounded or unbounded.

- $f(x, y) = y - x$
- $f(x, y) = \sqrt{y - x}$
- $f(x, y) = 4x^2 + 9y^2$
- $f(x, y) = x^2 - y^2$
- $f(x, y) = xy$
- $f(x, y) = y/x^2$
- $f(x, y) = \frac{1}{\sqrt{16 - x^2 - y^2}}$
- $f(x, y) = \sqrt{9 - x^2 - y^2}$
- $f(x, y) = \ln(x^2 + y^2)$
- $f(x, y) = e^{-(x^2 + y^2)}$
- $f(x, y) = \sin^{-1}(y - x)$
- $f(x, y) = \tan^{-1}\left(\frac{y}{x}\right)$
- $f(x, y) = \ln(x^2 + y^2 - 1)$
- $f(x, y) = \ln(9 - x^2 - y^2)$

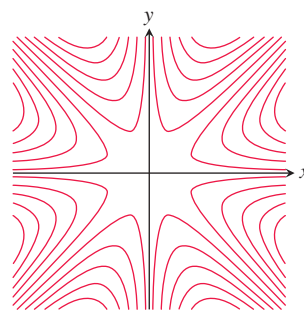

Matching Surfaces with Level Curves

Exercises 31–36 show level curves for six functions. The graphs of these functions are given on the next page (items a–f), as are their equations (items g–l). Match each set of level curves with the appropriate graph and the appropriate equation.

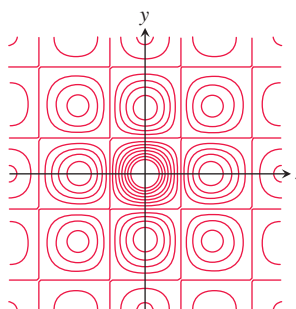

31.

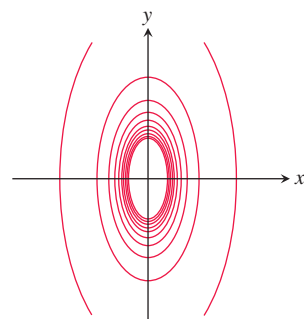

32.

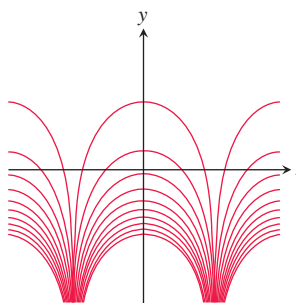

33.

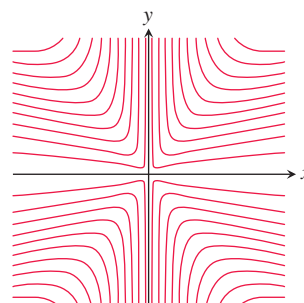

34.

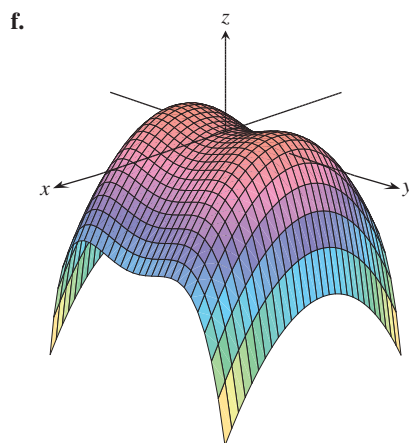

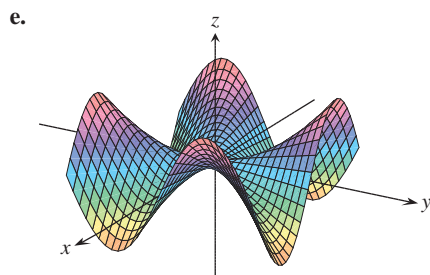

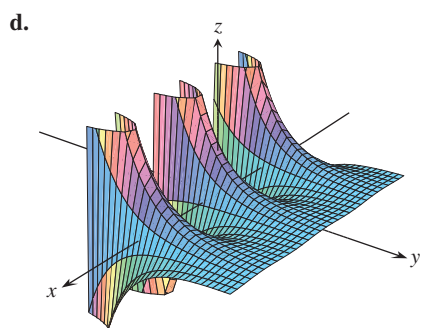

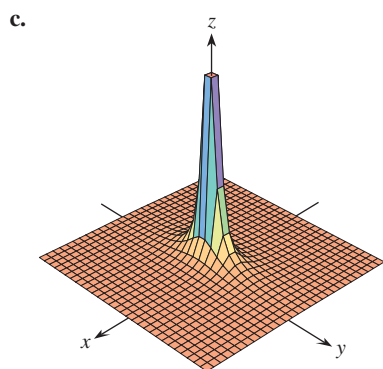

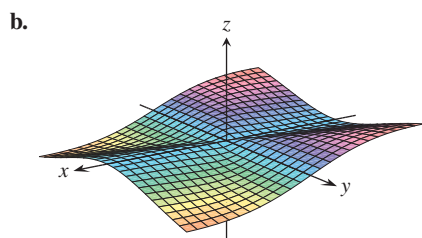

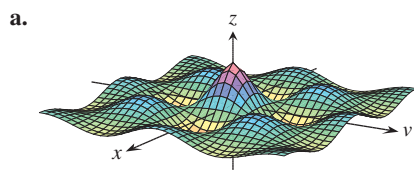

35.

36.

g. $z = -\frac{xy^2}{x^2 + y^2}$

h. $z = y^2 - y^4 - x^2$

i. $z = (\cos x)(\cos y)e^{-\sqrt{x^2+y^2}/4}$

j. $z = e^{-y} \cos x$

k. $z = \frac{1}{4x^2 + y^2}$

l. $z = \frac{xy(x^2 - y^2)}{x^2 + y^2}$

Functions of Two Variables

Display the values of the functions in Exercises 37–48 in two ways: (a) by sketching the surface $z = f(x, y)$ and (b) by drawing an assortment of level curves in the function's domain. Label each level curve with its function value.

37. $f(x, y) = y^2$

38. $f(x, y) = \sqrt{x}$

39. $f(x, y) = x^2 + y^2$

40. $f(x, y) = \sqrt{x^2 + y^2}$

41. $f(x, y) = x^2 - y$

42. $f(x, y) = 4 - x^2 - y^2$

43. $f(x, y) = 4x^2 + y^2$

44. $f(x, y) = 6 - 2x - 3y$

45. $f(x, y) = 1 - |y|$

46. $f(x, y) = 1 - |x| - |y|$

47. $f(x, y) = \sqrt{x^2 + y^2} + 4$

48. $f(x, y) = \sqrt{x^2 + y^2} - 4$

Finding Level Curves

In Exercises 49–52, find an equation for, and sketch the graph of, the level curve of the function $f(x, y)$ that passes through the given point.

49. $f(x, y) = 16 - x^2 - y^2$, $(2\sqrt{2}, \sqrt{2})$

50. $f(x, y) = \sqrt{x^2 - 1}$, $(1, 0)$

51. $f(x, y) = \sqrt{x + y^2 - 3}$, $(3, -1)$

52. $f(x, y) = \frac{2y - x}{x + y + 1}$, $(-1, 1)$

Sketching Level Surfaces

In Exercises 53–60, sketch a typical level surface for the function.

53. $f(x, y, z) = x^2 + y^2 + z^2$

54. $f(x, y, z) = \ln(x^2 + y^2 + z^2)$

55. $f(x, y, z) = x + z$

56. $f(x, y, z) = z$

57. $f(x, y, z) = x^2 + y^2$

58. $f(x, y, z) = y^2 + z^2$

59. $f(x, y, z) = z - x^2 - y^2$

60. $f(x, y, z) = (x^2/25) + (y^2/16) + (z^2/9)$

Finding Level Surfaces

In Exercises 61–64, find an equation for the level surface of the function through the given point.

61. $f(x, y, z) = \sqrt{x - y} - \ln z$, $(3, -1, 1)$

62. $f(x, y, z) = \ln(x^2 + y + z^2), \quad (-1, 2, 1)$

63. $g(x, y, z) = \sqrt{x^2 + y^2 + z^2}, \quad (1, -1, \sqrt{2})$

64. $g(x, y, z) = \frac{x - y + z}{2x + y - z}, \quad (1, 0, -2)$

In Exercises 65–68, find and sketch the domain of f . Then find an equation for the level curve or surface of the function passing through the given point.

65. $f(x, y) = \sum_{n=0}^{\infty} \left(\frac{x}{y}\right)^n, \quad (1, 2)$

66. $g(x, y, z) = \sum_{n=0}^{\infty} \frac{(x+y)^n}{n!z^n}, \quad (\ln 4, \ln 9, 2)$

67. $f(x, y) = \int_x^y \frac{d\theta}{\sqrt{1-\theta^2}}, \quad (0, 1)$

68. $g(x, y, z) = \int_x^y \frac{dt}{1+t^2} + \int_0^z \frac{d\theta}{\sqrt{4-\theta^2}}, \quad (0, 1, \sqrt{3})$

COMPUTER EXPLORATIONS

Use a CAS to perform the following steps for each of the functions in Exercises 69–72.

a. Plot the surface over the given rectangle.

b. Plot several level curves in the rectangle.

c. Plot the level curve of f through the given point.

69. $f(x, y) = x \sin \frac{y}{2} + y \sin 2x, \quad 0 \leq x \leq 5\pi, \quad 0 \leq y \leq 5\pi,$
 $P(3\pi, 3\pi)$

70. $f(x, y) = (\sin x)(\cos y)e^{\sqrt{x^2+y^2}/8}, \quad 0 \leq x \leq 5\pi,$
 $0 \leq y \leq 5\pi, \quad P(4\pi, 4\pi)$

71. $f(x, y) = \sin(x + 2 \cos y), \quad -2\pi \leq x \leq 2\pi,$
 $-2\pi \leq y \leq 2\pi, \quad P(\pi, \pi)$

72. $f(x, y) = e^{(x^{0.1}-y)} \sin(x^2 + y^2), \quad 0 \leq x \leq 2\pi,$
 $-2\pi \leq y \leq \pi, \quad P(\pi, -\pi)$

Use a CAS to plot the implicitly defined level surfaces in Exercises 73–76.

73. $4 \ln(x^2 + y^2 + z^2) = 1$ 74. $x^2 + z^2 = 1$

75. $x + y^2 - 3z^2 = 1$

76. $\sin\left(\frac{x}{2}\right) - (\cos y)\sqrt{x^2 + z^2} = 2$

Parametrized Surfaces Just as you describe curves in the plane parametrically with a pair of equations $x = f(t)$, $y = g(t)$ defined on some parameter interval I , you can sometimes describe surfaces in space with a triple of equations $x = f(u, v)$, $y = g(u, v)$, $z = h(u, v)$ defined on some parameter rectangle $a \leq u \leq b$, $c \leq v \leq d$. Many computer algebra systems permit you to plot such surfaces in *parametric mode*. (Parametrized surfaces are discussed in detail in Section 15.5.) Use a CAS to plot the surfaces in Exercises 77–80. Also plot several level curves in the xy -plane.

77. $x = u \cos v, \quad y = u \sin v, \quad z = u, \quad 0 \leq u \leq 2,$
 $0 \leq v \leq 2\pi$

78. $x = u \cos v, \quad y = u \sin v, \quad z = v, \quad 0 \leq u \leq 2,$
 $0 \leq v \leq 2\pi$

79. $x = (2 + \cos u) \cos v, \quad y = (2 + \cos u) \sin v, \quad z = \sin u,$
 $0 \leq u \leq 2\pi, \quad 0 \leq v \leq 2\pi$

80. $x = 2 \cos u \cos v, \quad y = 2 \cos u \sin v, \quad z = 2 \sin u,$
 $0 \leq u \leq 2\pi, \quad 0 \leq v \leq \pi$

13.2 Limits and Continuity in Higher Dimensions

In this section we develop limits and continuity for multivariable functions. The theory is similar to that developed for single-variable functions, but since we now have more than one independent variable, there is additional complexity that requires some new ideas.

Limits for Functions of Two Variables

If the values of $f(x, y)$ lie arbitrarily close to a fixed real number L for all points (x, y) sufficiently close to a point (x_0, y_0) , we say that f approaches the limit L as (x, y) approaches (x_0, y_0) . This is similar to the informal definition for the limit of a function of a single variable. Notice, however, that when (x_0, y_0) lies in the interior of f 's domain, (x, y) can approach (x_0, y_0) from any direction, not just from the left or the right. For the limit to exist, the same limiting value must be obtained whatever direction of approach is taken. We illustrate this issue in several examples following the definition.

DEFINITION Suppose that every open circular disk centered at (x_0, y_0) contains a point in the domain of f other than (x_0, y_0) itself. We say that a function $f(x, y)$ approaches the **limit** L as (x, y) approaches (x_0, y_0) , and write

$$\lim_{(x,y) \rightarrow (x_0,y_0)} f(x, y) = L,$$

if, for every number $\varepsilon > 0$, there exists a corresponding number $\delta > 0$ such that for all (x, y) in the domain of f ,

$$|f(x, y) - L| < \varepsilon \quad \text{whenever} \quad 0 < \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta.$$

The definition of limit says that the distance between $f(x, y)$ and L becomes arbitrarily small whenever the distance from (x, y) to (x_0, y_0) is made sufficiently small (but not 0). The definition applies to interior points (x_0, y_0) as well as boundary points of the domain of f , although a boundary point need not lie within the domain. The points (x, y) that approach (x_0, y_0) are always taken to be in the domain of f . See Figure 13.12.

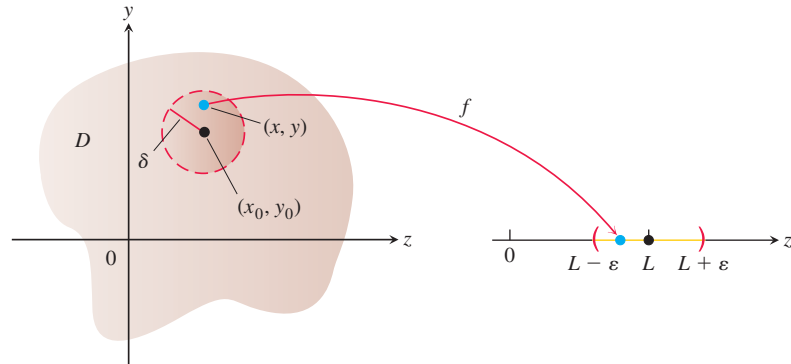

FIGURE 13.12 In the limit definition, δ is the radius of a disk centered at (x_0, y_0) . For all points (x, y) within this disk, the function values $f(x, y)$ lie inside the corresponding interval $(L - \epsilon, L + \epsilon)$.

As for functions of a single variable, it can be shown that

$$\lim_{(x, y) \rightarrow (x_0, y_0)} x = x_0 \quad (1)$$

$$\lim_{(x, y) \rightarrow (x_0, y_0)} y = y_0 \quad (2)$$

$$\lim_{(x, y) \rightarrow (x_0, y_0)} k = k \quad (\text{any number } k). \quad (3)$$

For example, in the first limit statement above, $f(x, y) = x$ and $L = x_0$. Using the definition of limit, suppose that $\epsilon > 0$ is chosen. If we let δ equal this ϵ , we see that if

$$0 < \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta = \epsilon,$$

then

$$\begin{aligned} \sqrt{(x - x_0)^2} &< \epsilon && (x - x_0)^2 \leq (x - x_0)^2 + (y - y_0)^2 \\ |x - x_0| &< \epsilon && \sqrt{a^2} = |a| \\ |f(x, y) - x_0| &< \epsilon && x = f(x, y) \end{aligned}$$

That is,

$$|f(x, y) - x_0| < \epsilon \quad \text{whenever} \quad 0 < \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta.$$

So a δ has been found satisfying the requirement of the definition, and therefore we have proved that

$$\lim_{(x, y) \rightarrow (x_0, y_0)} f(x, y) = \lim_{(x, y) \rightarrow (x_0, y_0)} x = x_0.$$

Equation (1) is a special case of the more general formula

$$\lim_{(x, y) \rightarrow (x_0, y_0)} g(x) = \lim_{x \rightarrow x_0} g(x), \quad (4)$$

according to which, if $f(x, y)$ can be expressed as a function g of a single variable x , then $\lim_{(x, y) \rightarrow (x_0, y_0)} f(x, y)$ depends only on what happens to g as x approaches x_0 . Similarly, the following formula generalizes Equation (2):

$$\lim_{(x, y) \rightarrow (x_0, y_0)} h(y) = \lim_{y \rightarrow y_0} h(y) \quad (5)$$

As with single-variable functions, the limit of the sum of two functions is the sum of their limits (when they both exist), with similar results for the limits of the differences, constant multiples, products, quotients, powers, and roots. These facts are summarized in Theorem 1.

THEOREM 1—Properties of Limits of Functions of Two Variables

The following rules hold if L , M , and k are real numbers and

$$\lim_{(x,y) \rightarrow (x_0,y_0)} f(x,y) = L \quad \text{and} \quad \lim_{(x,y) \rightarrow (x_0,y_0)} g(x,y) = M.$$

1. *Sum Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} [f(x,y) + g(x,y)] = L + M$
2. *Difference Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} [f(x,y) - g(x,y)] = L - M$
3. *Constant Multiple Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} kf(x,y) = kL$ (any number k)
4. *Product Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} [f(x,y) \cdot g(x,y)] = L \cdot M$
5. *Quotient Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} \frac{f(x,y)}{g(x,y)} = \frac{L}{M}$, $M \neq 0$
6. *Power Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} [f(x,y)]^n = L^n$, n a positive integer
7. *Root Rule:* $\lim_{(x,y) \rightarrow (x_0,y_0)} \sqrt[n]{f(x,y)} = \sqrt[n]{L} = L^{1/n}$,
 n a positive integer, and if n is even,
we assume that $L > 0$.
8. *Composition Rule:* If $h(z)$ is continuous at $z = L$, then
 $\lim_{(x,y) \rightarrow (x_0,y_0)} h(f(x,y)) = h(L)$.

Although we will not prove Theorem 1 here, we give an informal discussion of why it is true. If (x, y) is sufficiently close to (x_0, y_0) , then $f(x, y)$ is close to L and $g(x, y)$ is close to M (from the informal interpretation of limits). It is then reasonable that $f(x, y) + g(x, y)$ is close to $L + M$; $f(x, y) - g(x, y)$ is close to $L - M$; $kf(x, y)$ is close to kL ; $f(x, y)g(x, y)$ is close to LM ; and $f(x, y)/g(x, y)$ is close to L/M if $M \neq 0$. Similarly, powers and roots of f are close to those of L , and a continuous function h composed with f has a value close to its value $h(L)$ when applied to L .

When we apply Theorem 1 and Equations (1)–(3) to polynomials and rational functions, we obtain the useful result that the limits of these functions as $(x, y) \rightarrow (x_0, y_0)$ can be calculated by evaluating the functions at (x_0, y_0) . The only requirement is that the rational functions be defined at (x_0, y_0) .

EXAMPLE 1 In this example, we combine Equations (1)–(5) with the results in Theorem 1 to calculate the limits.

$$(a) \quad \lim_{(x,y) \rightarrow (0,1)} \frac{x - xy + 3}{x^2y + 5xy - y^3} = \frac{0 - (0)(1) + 3}{(0)^2(1) + 5(0)(1) - (1)^3} = -3$$

$$(b) \quad \begin{aligned} \lim_{(x,y) \rightarrow (3,-4)} \sqrt{x^2 + y^2} &= \sqrt{\lim_{(x,y) \rightarrow (3,-4)} (x^2 + y^2)} && \text{Rule 7} \\ &= \sqrt{3^2 + (-4)^2} && \text{Rules 1 and 6 and Eq. (1) and (2)} \\ &= \sqrt{25} = 5 \end{aligned}$$

$$(c) \quad \begin{aligned} \lim_{(x,y) \rightarrow (\pi/2, 0)} \left(\frac{x}{\sin x} - \frac{\sin y}{y} \right) &= \lim_{(x,y) \rightarrow (\pi/2, 0)} \frac{x}{\sin x} - \lim_{(x,y) \rightarrow (\pi/2, 0)} \frac{\sin y}{y} && \text{Rule 2} \\ &= \lim_{x \rightarrow \pi/2} \frac{x}{\sin x} - \lim_{y \rightarrow 0} \frac{\sin y}{y} && \text{Eq. (4) and (5)} \\ &= \frac{\pi}{2} - 1 && \text{Theorem 6, Section 2.4} \quad \blacksquare \end{aligned}$$

EXAMPLE 2 Find $\lim_{(x,y) \rightarrow (0,0)} \frac{x^2 - xy}{\sqrt{x} - \sqrt{y}}$.

Solution Since the denominator $\sqrt{x} - \sqrt{y}$ approaches 0 as $(x, y) \rightarrow (0, 0)$, we cannot use the Quotient Rule from Theorem 1. If we multiply numerator and denominator by $\sqrt{x} + \sqrt{y}$, however, we produce an equivalent fraction whose limit we *can* find:

$$\begin{aligned} \lim_{(x,y) \rightarrow (0,0)} \frac{x^2 - xy}{\sqrt{x} - \sqrt{y}} &= \lim_{(x,y) \rightarrow (0,0)} \frac{(x^2 - xy)(\sqrt{x} + \sqrt{y})}{(\sqrt{x} - \sqrt{y})(\sqrt{x} + \sqrt{y})} && \text{Multiply by a form equal to 1.} \\ &= \lim_{(x,y) \rightarrow (0,0)} \frac{x(x - y)(\sqrt{x} + \sqrt{y})}{x - y} && \text{Algebra} \\ &= \lim_{(x,y) \rightarrow (0,0)} x(\sqrt{x} + \sqrt{y}) && \text{Cancel the nonzero factor } (x - y). \\ &= \left(\lim_{(x,y) \rightarrow (0,0)} x \right) \left[\left(\lim_{(x,y) \rightarrow (0,0)} \sqrt{x} \right) + \left(\lim_{(x,y) \rightarrow (0,0)} \sqrt{y} \right) \right] && \text{Rules 4 and 1} \\ &= \left(\lim_{(x,y) \rightarrow (0,0)} x \right) \left[\sqrt{\lim_{(x,y) \rightarrow (0,0)} x} + \sqrt{\lim_{(x,y) \rightarrow (0,0)} y} \right] && \text{Rule 7} \\ &= (0) [\sqrt{0} + \sqrt{0}] = 0 && \text{Eq. (1) and (2)} \end{aligned}$$

We can cancel the factor $(x - y)$ because the path $y = x$ (where we would have $x - y = 0$) is *not* in the domain of the function

$$f(x, y) = \frac{x^2 - xy}{\sqrt{x} - \sqrt{y}}. \quad \blacksquare$$

EXAMPLE 3 Find $\lim_{(x,y) \rightarrow (0,0)} \frac{4xy^2}{x^2 + y^2}$ if it exists.

Solution We first observe that along the line $x = 0$, the function always has value 0 when $y \neq 0$. Likewise, along the line $y = 0$, the function has value 0 provided $x \neq 0$. So if the limit does exist as (x, y) approaches $(0, 0)$, the value of the limit must be 0 (see Figure 13.13). To see whether this is true, we apply the definition of limit.

Let $\varepsilon > 0$ be given, but arbitrary. We want to find a $\delta > 0$ such that

$$\left| \frac{4xy^2}{x^2 + y^2} - 0 \right| < \varepsilon \quad \text{whenever} \quad 0 < \sqrt{x^2 + y^2} < \delta$$

or

$$\frac{4|x|y^2}{x^2 + y^2} < \varepsilon \quad \text{whenever} \quad 0 < \sqrt{x^2 + y^2} < \delta.$$

Since $y^2 \leq x^2 + y^2$, we have that

$$\frac{4|x|y^2}{x^2 + y^2} \leq 4|x| = 4\sqrt{x^2} \leq 4\sqrt{x^2 + y^2}. \quad \frac{y^2}{x^2 + y^2} \leq 1$$

So if we choose $\delta = \varepsilon/4$ and let $0 < \sqrt{x^2 + y^2} < \delta$, we get

$$\left| \frac{4xy^2}{x^2 + y^2} - 0 \right| \leq 4\sqrt{x^2 + y^2} < 4\delta = 4\left(\frac{\varepsilon}{4}\right) = \varepsilon.$$

It follows from the definition that

$$\lim_{(x,y) \rightarrow (0,0)} \frac{4xy^2}{x^2 + y^2} = 0. \quad \blacksquare$$

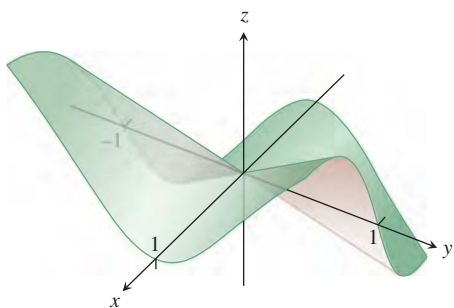

FIGURE 13.13 The surface graph suggests that the limit of the function in Example 3 must be 0, if it exists.

EXAMPLE 4 If $f(x, y) = \frac{y}{x}$, does $\lim_{(x,y) \rightarrow (0,0)} f(x, y)$ exist?

Solution The domain of f does not include the y -axis, so we do not consider any points (x, y) where $x = 0$ in the approach toward the origin $(0, 0)$. Along the x -axis, the value of the function is $f(x, 0) = 0$ for all $x \neq 0$. So if the limit does exist as $(x, y) \rightarrow (0, 0)$, the value of the limit must be $L = 0$. On the other hand, along the line $y = x$, the value of the function is $f(x, x) = x/x = 1$ for all $x \neq 0$. That is, the function f approaches the value 1 along the line $y = x$. This means that for every disk of radius δ centered at $(0, 0)$, the disk will contain points $(x, 0)$ on the x -axis where the value of the function is 0, and also points (x, x) along the line $y = x$ where the value of the function is 1. So no matter how small we choose δ as the radius of the disk in Figure 13.12, there will be points within the disk for which the function values differ by 1. Therefore, the limit cannot exist because we can take ε to be any number less than 1 in the limit definition and deny that $L = 0$ or 1, or any other real number. The limit does not exist because we have different limiting values along different paths approaching the point $(0, 0)$. ■

Continuity

As with functions of a single variable, continuity is defined in terms of limits.

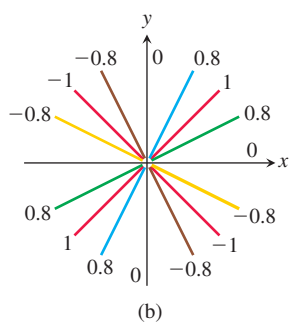

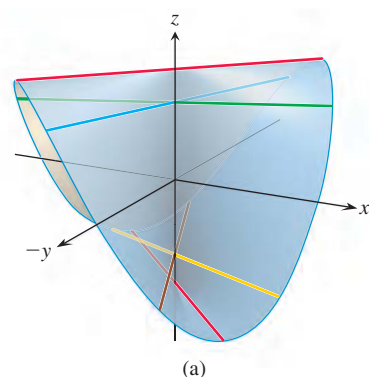

FIGURE 13.14 (a) The graph of

$$f(x, y) = \begin{cases} \frac{2xy}{x^2 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0). \end{cases}$$

The function is continuous at every point except the origin. (b) The value of f along each line $y = mx$, $x \neq 0$, is constant but varies with m (Example 5).

DEFINITION Suppose that every open circular disk centered at (x_0, y_0) contains a point in the domain of f other than (x_0, y_0) itself. Then a function $f(x, y)$ is **continuous at the point (x_0, y_0)** if

1. f is defined at (x_0, y_0) ,
2. $\lim_{(x,y) \rightarrow (x_0,y_0)} f(x, y)$ exists, and
3. $\lim_{(x,y) \rightarrow (x_0,y_0)} f(x, y) = f(x_0, y_0)$.

A function is **continuous** if it is continuous at every point of its domain.

As with the definition of limit, the definition of continuity applies at boundary points as well as interior points of the domain of f .

A consequence of Theorem 1 is that algebraic combinations of continuous functions are continuous at every point at which all the functions involved are defined. This means that sums, differences, constant multiples, products, quotients, and powers of continuous functions are continuous where defined. In particular, polynomials and rational functions of two variables are continuous at every point at which they are defined.

EXAMPLE 5 Show that

$$f(x, y) = \begin{cases} \frac{2xy}{x^2 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0). \end{cases}$$

is continuous at every point except the origin (Figure 13.14).

Solution The function f is continuous at every point (x, y) except $(0, 0)$ because its values at points other than $(0, 0)$ are given by a rational function of x and y , and therefore at those points the limiting value is simply obtained by substituting the values of x and y into that rational expression.

At $(0, 0)$, the value of f is defined, but f has no limit as $(x, y) \rightarrow (0, 0)$. The reason is that different paths of approach to the origin can lead to different results, as we now see.

For every value of m , the function f has a constant value on the “punctured” line $y = mx, x \neq 0$, because

$$f(x, y) \Big|_{y=mx} = \frac{2xy}{x^2 + y^2} \Big|_{y=mx} = \frac{2x(mx)}{x^2 + (mx)^2} = \frac{2mx^2}{x^2 + m^2x^2} = \frac{2m}{1 + m^2}.$$

Therefore, f has this number as its limit as (x, y) approaches $(0, 0)$ along the line:

$$\lim_{\substack{(x, y) \rightarrow (0, 0) \\ \text{along } y=mx}} f(x, y) = \lim_{(x, y) \rightarrow (0, 0)} \left[f(x, y) \Big|_{y=mx} \right] = \frac{2m}{1 + m^2}.$$

This limit changes with each value of the slope m . There is therefore no single number we may call the limit of f as (x, y) approaches the origin. The limit fails to exist, and the function is not continuous at the origin. ■

Examples 4 and 5 illustrate an important point about limits of functions of two or more variables. For a limit to exist at a point, the limit must be the same along every approach path. This result is analogous to the single-variable case where both the left- and right-sided limits had to have the same value. For functions of two or more variables, if we ever find paths with different limits, we know the function has no limit at the point they approach.

Two-Path Test for Nonexistence of a Limit

If a function $f(x, y)$ has different limits along two different paths in the domain of f as (x, y) approaches (x_0, y_0) , then $\lim_{(x, y) \rightarrow (x_0, y_0)} f(x, y)$ does not exist.

EXAMPLE 6 Show that the function

$$f(x, y) = \frac{2x^2y}{x^4 + y^2}$$

(Figure 13.15) has no limit as (x, y) approaches $(0, 0)$.

Solution As (x, y) approaches $(0, 0)$, both the numerator and the denominator approach 0, which gives the indeterminate form $0/0$. We examine the values of f along parabolic curves that end at $(0, 0)$. Along the curve $y = kx^2, x \neq 0$, the function has the constant value

$$f(x, y) \Big|_{y=kx^2} = \frac{2x^2y}{x^4 + y^2} \Big|_{y=kx^2} = \frac{2x^2(kx^2)}{x^4 + (kx^2)^2} = \frac{2kx^4}{x^4 + k^2x^4} = \frac{2k}{1 + k^2}.$$

Therefore,

$$\lim_{\substack{(x, y) \rightarrow (0, 0) \\ \text{along } y=kx^2}} f(x, y) = \lim_{(x, y) \rightarrow (0, 0)} \left[f(x, y) \Big|_{y=kx^2} \right] = \frac{2k}{1 + k^2}.$$

This limit varies with the path of approach. If (x, y) approaches $(0, 0)$ along the parabola $y = x^2$, for instance, $k = 1$ and the limit is 1. If (x, y) approaches $(0, 0)$ along the x -axis, $k = 0$ and the limit is 0. By the two-path test, f has no limit as (x, y) approaches $(0, 0)$. ■

It can be shown that the function in Example 6 has limit 0 along every straight line path $y = mx$ (Exercise 57). This implies the following observation:

Having the same limit along all straight lines approaching (x_0, y_0) does not imply that a limit exists at (x_0, y_0) .

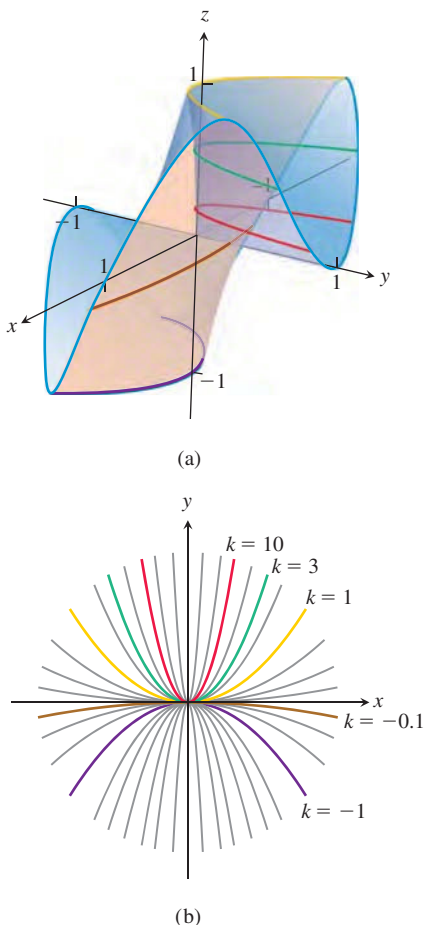

FIGURE 13.15 (a) The graph of $f(x, y) = 2x^2y/(x^4 + y^2)$. (b) Along each path $y = kx^2, x \neq 0$, the value of f is constant, but varies with k (Example 6).

Whenever it is correctly defined, the composition of continuous functions is also continuous. The only requirement is that each function be continuous where it is applied. The proof, omitted here, is similar to that for functions of a single variable (Theorem 9 in Section 2.6).

Continuity of Compositions

If f is continuous at (x_0, y_0) and g is a single-variable function continuous at $f(x_0, y_0)$, then the composition $h = g \circ f$ defined by $h(x, y) = g(f(x, y))$ is also continuous at (x_0, y_0) .

For example, the composite functions

$$e^{x-y}, \quad \cos \frac{xy}{x^2 + 1}, \quad \ln(1 + x^2y^2)$$

are continuous at every point (x, y) .

Functions of More Than Two Variables

The definitions of limit and continuity for functions of two variables and the conclusions about limits and continuity for sums, products, quotients, powers, and compositions all extend to functions of three or more variables. Functions like

$$\ln(x + y + z) \quad \text{and} \quad \frac{y \sin z}{x - 1}$$

are continuous throughout their domains, and limits like

$$\lim_{P \rightarrow (1, 0, -1)} \frac{e^{x+z}}{z^2 + \cos \sqrt{xy}} = \frac{e^{1-1}}{(-1)^2 + \cos 0} = \frac{1}{2},$$

where P denotes the point (x, y, z) , may be found by direct substitution.

Extreme Values of Continuous Functions on Closed, Bounded Sets

The Extreme Value Theorem (Theorem 1, Section 4.1) states that a function of a single variable that is continuous at every point of a closed, bounded interval $[a, b]$ takes on an absolute maximum value and an absolute minimum value at least once in $[a, b]$. The same holds true of a function $z = f(x, y)$ that is continuous on a closed, bounded set R in the plane (like a line segment, a disk, or a filled-in triangle). The function takes on an absolute maximum value at some point in R and an absolute minimum value at some point in R . The function may take on a maximum or minimum value more than once over R .

Similar results hold for functions of three or more variables. A continuous function $w = f(x, y, z)$ must take on absolute maximum and minimum values on any closed, bounded set (such as a solid ball or cube, spherical shell, or rectangular solid) on which it is defined. We will learn how to find these extreme values in Section 13.7.

EXERCISES 13.2

Limits with Two Variables

Find the limits in Exercises 1–12.

1. $\lim_{(x,y) \rightarrow (0,0)} \frac{3x^2 - y^2 + 5}{x^2 + y^2 + 2}$

2. $\lim_{(x,y) \rightarrow (0,4)} \frac{x}{\sqrt{y}}$

3. $\lim_{(x,y) \rightarrow (3,4)} \sqrt{x^2 + y^2 - 1}$

4. $\lim_{(x,y) \rightarrow (2,-3)} \left(\frac{1}{x} + \frac{1}{y} \right)^2$

5. $\lim_{(x,y) \rightarrow (0, \pi/4)} \sec x \tan y$

6. $\lim_{(x,y) \rightarrow (0,0)} \cos \frac{x^2 + y^3}{x + y + 1}$

$$7. \lim_{(x,y) \rightarrow (0, \ln 2)} e^{x-y}$$

$$8. \lim_{(x,y) \rightarrow (1,1)} \ln|1 + x^2 y^2|$$

$$9. \lim_{(x,y) \rightarrow (0,0)} \frac{e^y \sin x}{x}$$

$$10. \lim_{(x,y) \rightarrow (1/27, \pi^3)} \cos \sqrt[3]{xy}$$

$$11. \lim_{(x,y) \rightarrow (1, \pi/6)} \frac{x \sin y}{x^2 + 1}$$

$$12. \lim_{(x,y) \rightarrow (\pi/2, 0)} \frac{\cos y + 1}{y - \sin x}$$

Limits of Quotients

Find the limits in Exercises 13–24 by rewriting the fractions first.

$$13. \lim_{\substack{(x,y) \rightarrow (1,1) \\ x \neq y}} \frac{x^2 - 2xy + y^2}{x - y}$$

$$14. \lim_{\substack{(x,y) \rightarrow (1,1) \\ x \neq y}} \frac{x^2 - y^2}{x - y}$$

$$15. \lim_{\substack{(x,y) \rightarrow (1,1) \\ x \neq 1}} \frac{xy - y - 2x + 2}{x - 1}$$

$$16. \lim_{\substack{(x,y) \rightarrow (2,-4) \\ x \neq -4, x \neq x^2}} \frac{y + 4}{x^2 y - xy + 4x^2 - 4x}$$

$$17. \lim_{(x,y) \rightarrow (0,0)} \frac{x - y + 2\sqrt{x} - 2\sqrt{y}}{\sqrt{x} - \sqrt{y}}$$

$$18. \lim_{\substack{(x,y) \rightarrow (2,2) \\ x+y=4}} \frac{x + y - 4}{\sqrt{x} + y - 2}$$

$$19. \lim_{\substack{(x,y) \rightarrow (2,0) \\ 2x-y=4}} \frac{\sqrt{2x-y} - 2}{2x - y - 4}$$

$$20. \lim_{\substack{(x,y) \rightarrow (4,3) \\ x=y+1}} \frac{\sqrt{x} - \sqrt{y+1}}{x - y - 1}$$

$$21. \lim_{(x,y) \rightarrow (0,0)} \frac{\sin(x^2 + y^2)}{x^2 + y^2}$$

$$22. \lim_{(x,y) \rightarrow (0,0)} \frac{1 - \cos(xy)}{xy}$$

$$23. \lim_{(x,y) \rightarrow (1,-1)} \frac{x^3 + y^3}{x + y}$$

$$24. \lim_{(x,y) \rightarrow (2,2)} \frac{x - y}{x^4 - y^4}$$

Limits with Three Variables

Find the limits in Exercises 25–30.

$$25. \lim_{P \rightarrow (1,3,4)} \left(\frac{1}{x} + \frac{1}{y} + \frac{1}{z} \right)$$

$$26. \lim_{P \rightarrow (1,-1,-1)} \frac{2xy + yz}{x^2 + z^2}$$

$$27. \lim_{P \rightarrow (\pi, \pi, 0)} (\sin^2 x + \cos^2 y + \sec^2 z)$$

$$28. \lim_{P \rightarrow (-1/4, \pi/2, 2)} \tan^{-1} xyz$$

$$29. \lim_{P \rightarrow (\pi, 0, 3)} ze^{-2y} \cos 2x$$

$$30. \lim_{P \rightarrow (2,-3,6)} \ln \sqrt{x^2 + y^2 + z^2}$$

Continuity for Two Variables

At what points (x, y) in the plane are the functions in Exercises 31–34 continuous?

$$31. \text{ a. } f(x, y) = \sin(x + y) \quad \text{ b. } f(x, y) = \ln(x^2 + y^2)$$

$$32. \text{ a. } f(x, y) = \frac{x + y}{x - y} \quad \text{ b. } f(x, y) = \frac{y}{x^2 + 1}$$

$$33. \text{ a. } g(x, y) = \sin \frac{1}{xy} \quad \text{ b. } g(x, y) = \frac{x + y}{2 + \cos x}$$

$$34. \text{ a. } g(x, y) = \frac{x^2 + y^2}{x^2 - 3x + 2} \quad \text{ b. } g(x, y) = \frac{1}{x^2 - y}$$

Continuity for Three Variables

At what points (x, y, z) in space are the functions in Exercises 35–40 continuous?

$$35. \text{ a. } f(x, y, z) = x^2 + y^2 - 2z^2$$

$$\text{ b. } f(x, y, z) = \sqrt{x^2 + y^2 - 1}$$

$$36. \text{ a. } f(x, y, z) = \ln xyz \quad \text{ b. } f(x, y, z) = e^{x+y} \cos z$$

$$37. \text{ a. } h(x, y, z) = xy \sin \frac{1}{z} \quad \text{ b. } h(x, y, z) = \frac{1}{x^2 + z^2 - 1}$$

$$38. \text{ a. } h(x, y, z) = \frac{1}{|y| + |z|} \quad \text{ b. } h(x, y, z) = \frac{1}{|xy| + |z|}$$

$$39. \text{ a. } h(x, y, z) = \ln(z - x^2 - y^2 - 1)$$

$$\text{ b. } h(x, y, z) = \frac{1}{z - \sqrt{x^2 + y^2}}$$

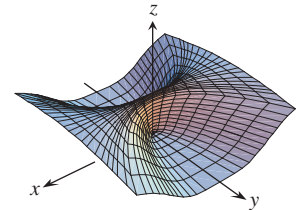

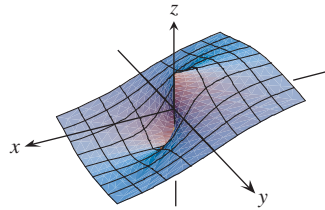

$$40. \text{ a. } h(x, y, z) = \sqrt{4 - x^2 - y^2 - z^2}$$

$$\text{ b. } h(x, y, z) = \frac{1}{4 - \sqrt{x^2 + y^2 + z^2} - 9}$$

No Limit Exists at the Origin

By considering different paths of approach, show that the functions in Exercises 41–48 have no limit as $(x, y) \rightarrow (0, 0)$.

$$41. f(x, y) = -\frac{x}{\sqrt{x^2 + y^2}} \quad 42. f(x, y) = \frac{x^4}{x^4 + y^2}$$

$$43. f(x, y) = \frac{x^4 - y^2}{x^4 + y^2} \quad 44. f(x, y) = \frac{xy}{|xy|}$$

$$45. g(x, y) = \frac{x - y}{x + y} \quad 46. g(x, y) = \frac{x^2 - y}{x - y}$$

$$47. h(x, y) = \frac{x^2 + y}{y} \quad 48. h(x, y) = \frac{x^2 y}{x^4 + y^2}$$

Theory and Examples

In Exercises 49–54, show that the limits do not exist.

$$49. \lim_{(x,y) \rightarrow (1,1)} \frac{xy^2 - 1}{y - 1}$$

$$50. \lim_{(x,y) \rightarrow (1,-1)} \frac{xy + 1}{x^2 - y^2}$$

$$51. \lim_{(x,y) \rightarrow (0,1)} \frac{x \ln y}{x^2 + (\ln y)^2}$$

$$52. \lim_{(x,y) \rightarrow (1,0)} \frac{xe^y - 1}{xe^y - 1 + y}$$

$$53. \lim_{(x,y) \rightarrow (0,0)} \frac{y + \sin x}{x + \sin y}$$

$$54. \lim_{(x,y) \rightarrow (1,1)} \frac{\tan y - y \tan x}{y - x}$$

$$55. \text{ Let } f(x, y) = \begin{cases} 1, & y \geq x^4 \\ 1, & y \leq 0 \\ 0, & \text{otherwise.} \end{cases}$$

Find each of the following limits, or explain that the limit does not exist.

$$\text{a. } \lim_{(x,y) \rightarrow (0,1)} f(x, y)$$

$$\text{b. } \lim_{(x,y) \rightarrow (2,3)} f(x, y)$$

$$\text{c. } \lim_{(x,y) \rightarrow (0,0)} f(x, y)$$

$$56. \text{ Let } f(x, y) = \begin{cases} x^2, & x \geq 0 \\ x^3, & x < 0. \end{cases}$$

Find the following limits.

$$\text{a. } \lim_{(x,y) \rightarrow (3,-2)} f(x, y)$$

$$\text{b. } \lim_{(x,y) \rightarrow (-2,1)} f(x, y)$$

$$\text{c. } \lim_{(x,y) \rightarrow (0,0)} f(x, y)$$

57. Show that the function in Example 6 has limit 0 along every straight line approaching (0, 0).

58. If $f(x_0, y_0) = 3$, what can you say about

$$\lim_{(x,y) \rightarrow (x_0, y_0)} f(x, y)$$

if f is continuous at (x_0, y_0) ? If f is not continuous at (x_0, y_0) ? Give reasons for your answers.

The Sandwich Theorem for functions of two variables states that if $g(x, y) \leq f(x, y) \leq h(x, y)$ for all $(x, y) \neq (x_0, y_0)$ in a disk centered at (x_0, y_0) and if g and h have the same finite limit L as $(x, y) \rightarrow (x_0, y_0)$, then

$$\lim_{(x,y) \rightarrow (x_0, y_0)} f(x, y) = L.$$

Use this result to support your answers to the questions in Exercises 59–62.

59. Does knowing that

$$1 - \frac{x^2 y^2}{3} < \frac{\tan^{-1} xy}{xy} < 1$$

tell you anything about

$$\lim_{(x,y) \rightarrow (0,0)} \frac{\tan^{-1} xy}{xy}?$$

Give reasons for your answer.

60. Does knowing that

$$2|xy| - \frac{x^2 y^2}{6} < 4 - 4 \cos \sqrt{|xy|} < 2|xy|$$

tell you anything about

$$\lim_{(x,y) \rightarrow (0,0)} \frac{4 - 4 \cos \sqrt{|xy|}}{|xy|}?$$

Give reasons for your answer.

61. Does knowing that $|\sin(1/x)| \leq 1$ tell you anything about

$$\lim_{(x,y) \rightarrow (0,0)} y \sin \frac{1}{x}?$$

Give reasons for your answer.

62. Does knowing that $|\cos(1/y)| \leq 1$ tell you anything about

$$\lim_{(x,y) \rightarrow (0,0)} x \cos \frac{1}{y}?$$

Give reasons for your answer.

63. (Continuation of Example 5.)

a. Reread Example 5. Then substitute $m = \tan \theta$ into the formula

$$f(x, y) \Big|_{y=mx} = \frac{2m}{1+m^2}$$

and simplify the result to show how the value of f varies with the line's angle of inclination.

b. Use the formula you obtained in part (a) to show that the limit of f as $(x, y) \rightarrow (0, 0)$ along the line $y = mx$ varies from -1 to 1 , depending on the angle of approach.

64. **Continuous extension** Define $f(0, 0)$ in a way that extends

$$f(x, y) = xy \frac{x^2 - y^2}{x^2 + y^2}$$

to be continuous at the origin.

Changing Variables to Polar Coordinates

If you cannot make any headway with $\lim_{(x,y) \rightarrow (0,0)} f(x, y)$ in rectangular coordinates, try changing to polar coordinates. Substitute $x = r \cos \theta$, $y = r \sin \theta$, and investigate the limit of the resulting expression as $r \rightarrow 0$. In other words, try to decide whether there exists a number L satisfying the following criterion:

Given $\varepsilon > 0$, there exists a $\delta > 0$ such that for all r and θ ,

$$|r| < \delta \Rightarrow |f(r, \theta) - L| < \varepsilon. \quad (1)$$

If such an L exists, then

$$\lim_{(x,y) \rightarrow (0,0)} f(x, y) = \lim_{r \rightarrow 0} f(r \cos \theta, r \sin \theta) = L.$$

For instance,

$$\lim_{(x,y) \rightarrow (0,0)} \frac{x^3}{x^2 + y^2} = \lim_{r \rightarrow 0} \frac{r^3 \cos^3 \theta}{r^2} = \lim_{r \rightarrow 0} r \cos^3 \theta = 0.$$

To verify the last of these equalities, we need to show that Equation (1) is satisfied with $f(r, \theta) = r \cos^3 \theta$ and $L = 0$. That is, we need to show that given any $\varepsilon > 0$, there exists a $\delta > 0$ such that for all r and θ ,

$$|r| < \delta \Rightarrow |r \cos^3 \theta - 0| < \varepsilon.$$

Since

$$|r \cos^3 \theta| = |r| |\cos^3 \theta| \leq |r| \cdot 1 = |r|,$$

the implication holds for all r and θ if we take $\delta = \varepsilon$.

In contrast,

$$\frac{x^2}{x^2 + y^2} = \frac{r^2 \cos^2 \theta}{r^2} = \cos^2 \theta$$

takes on all values from 0 to 1 regardless of how small $|r|$ is, so that

$\lim_{(x,y) \rightarrow (0,0)} x^2/(x^2 + y^2)$ does not exist.

In each of these instances, the existence or nonexistence of the limit as $r \rightarrow 0$ is fairly clear. Shifting to polar coordinates does not always help, however, and may even tempt us to false conclusions. For example, the limit may exist along every straight line (or ray) $\theta = \text{constant}$ and yet fail to exist in the broader sense. Example 5 illustrates this point. In polar coordinates, $f(x, y) = (2x^2y)/(x^4 + y^2)$ becomes

$$f(r \cos \theta, r \sin \theta) = \frac{r \cos \theta \sin 2\theta}{r^2 \cos^4 \theta + \sin^2 \theta}$$

for $r \neq 0$. If we hold θ constant and let $r \rightarrow 0$, the limit is 0. On the path $y = x^2$, however, we have $r \sin \theta = r^2 \cos^2 \theta$ and

$$\begin{aligned} f(r \cos \theta, r \sin \theta) &= \frac{r \cos \theta \sin 2\theta}{r^2 \cos^4 \theta + (r \cos^2 \theta)^2} \\ &= \frac{2r \cos^2 \theta \sin \theta}{2r^2 \cos^4 \theta} = \frac{r \sin \theta}{r^2 \cos^2 \theta} = 1. \end{aligned}$$

In Exercises 65–70, find the limit of f as $(x, y) \rightarrow (0, 0)$ or show that the limit does not exist.

$$65. f(x, y) = \frac{x^3 - xy^2}{x^2 + y^2} \quad 66. f(x, y) = \cos\left(\frac{x^3 - y^3}{x^2 + y^2}\right)$$

$$67. f(x, y) = \frac{y^2}{x^2 + y^2} \quad 68. f(x, y) = \frac{2x}{x^2 + x + y^2}$$

$$69. f(x, y) = \tan^{-1}\left(\frac{|x| + |y|}{x^2 + y^2}\right)$$

$$70. f(x, y) = \frac{x^2 - y^2}{x^2 + y^2}$$

In Exercises 71 and 72, define $f(0, 0)$ in a way that extends f to be continuous at the origin.

$$71. f(x, y) = \ln\left(\frac{3x^2 - x^2y^2 + 3y^2}{x^2 + y^2}\right)$$

$$72. f(x, y) = \frac{3x^2y}{x^2 + y^2}$$

Using the Limit Definition

Each of Exercises 73–78 gives a function $f(x, y)$ and a positive number ε . In each exercise, show that there exists a $\delta > 0$ such that for all (x, y) ,

$$\sqrt{x^2 + y^2} < \delta \Rightarrow |f(x, y) - f(0, 0)| < \varepsilon.$$

$$73. f(x, y) = x^2 + y^2, \quad \varepsilon = 0.01$$

$$74. f(x, y) = y/(x^2 + 1), \quad \varepsilon = 0.05$$

$$75. f(x, y) = (x + y)/(x^2 + 1), \quad \varepsilon = 0.01$$

$$76. f(x, y) = (x + y)/(2 + \cos x), \quad \varepsilon = 0.02$$

$$77. f(x, y) = \frac{xy^2}{x^2 + y^2} \quad \text{and} \quad f(0, 0) = 0, \quad \varepsilon = 0.04$$

$$78. f(x, y) = \frac{x^3 + y^4}{x^2 + y^2} \quad \text{and} \quad f(0, 0) = 0, \quad \varepsilon = 0.02$$

Each of Exercises 79–82 gives a function $f(x, y, z)$ and a positive number ε . In each exercise, show that there exists a $\delta > 0$ such that for all (x, y, z) ,

$$\sqrt{x^2 + y^2 + z^2} < \delta \Rightarrow |f(x, y, z) - f(0, 0, 0)| < \varepsilon.$$

$$79. f(x, y, z) = x^2 + y^2 + z^2, \quad \varepsilon = 0.015$$

$$80. f(x, y, z) = xyz, \quad \varepsilon = 0.008$$

$$81. f(x, y, z) = \frac{x + y + z}{x^2 + y^2 + z^2 + 1}, \quad \varepsilon = 0.015$$

$$82. f(x, y, z) = \tan^2 x + \tan^2 y + \tan^2 z, \quad \varepsilon = 0.03$$

83. Show that $f(x, y, z) = x + y - z$ is continuous at every point (x_0, y_0, z_0) .

84. Show that $f(x, y, z) = x^2 + y^2 + z^2$ is continuous at the origin.

13.3 Partial Derivatives

The calculus of several variables is similar to single-variable calculus applied to several variables, one at a time. When we hold all but one of the independent variables of a function constant and differentiate with respect to that one variable, we get a “partial” derivative. This section shows how partial derivatives are defined and interpreted geometrically, and how to calculate them by applying the familiar rules for differentiating functions of a single variable. The idea of *differentiability* for functions of several variables requires more than the existence of the partial derivatives, because a point can be approached from many different directions. However, we will see that differentiable functions of several variables behave similarly to differentiable single-variable functions. In particular, they are continuous and can be well approximated by linear functions.

Partial Derivatives of a Function of Two Variables

If (x_0, y_0) is a point in the domain of a function $f(x, y)$, the vertical plane $y = y_0$ will cut the surface $z = f(x, y)$ in the curve $z = f(x, y_0)$ (Figure 13.16). This curve is the graph

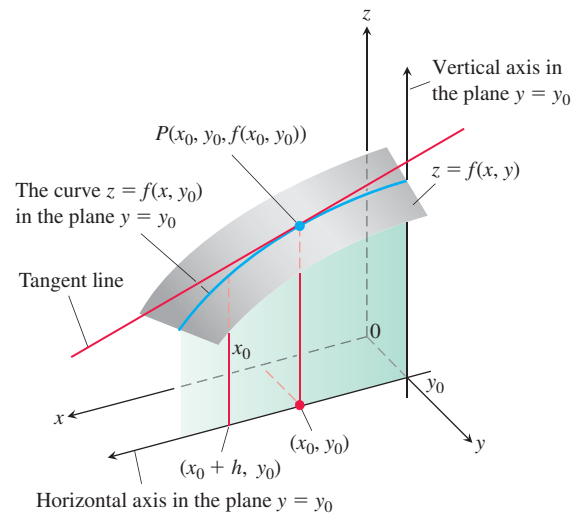

FIGURE 13.16 The intersection of the plane $y = y_0$ with the surface $z = f(x, y)$, viewed from above the first quadrant of the xy -plane.

of the function $z = f(x, y_0)$ in the plane $y = y_0$. The horizontal coordinate in this plane is x ; the vertical coordinate is z . The y -value is held constant at y_0 , so y is not a variable.

We define the partial derivative of f with respect to x at the point (x_0, y_0) as the ordinary derivative of $f(x, y_0)$ with respect to x at the point $x = x_0$. To distinguish partial derivatives from ordinary derivatives, we use the symbol ∂ rather than the d previously used. In the definition, h represents a real number, positive or negative.

DEFINITION The **partial derivative of $f(x, y)$ with respect to x at the point (x_0, y_0)** is

$$\left. \frac{\partial f}{\partial x} \right|_{(x_0, y_0)} = \lim_{h \rightarrow 0} \frac{f(x_0 + h, y_0) - f(x_0, y_0)}{h},$$

provided the limit exists.

The partial derivative of $f(x, y)$ with respect to x at the point (x_0, y_0) is the same as the ordinary derivative of $f(x, y_0)$ at the point x_0 :

$$\left. \frac{\partial f}{\partial x} \right|_{(x_0, y_0)} = \left. \frac{d}{dx} f(x, y_0) \right|_{x=x_0}.$$

A variety of notations are used to denote the partial derivative at a point (x_0, y_0) , including

$$\frac{\partial f}{\partial x}(x_0, y_0), \quad f_x(x_0, y_0), \quad \text{and} \quad \left. \frac{\partial z}{\partial x} \right|_{(x_0, y_0)}.$$

When we do not specify a specific point (x_0, y_0) at which the partial derivative is being evaluated, then the partial derivative becomes a *function* whose domain is the points where the partial derivative exists. Notations for this function include

$$\frac{\partial f}{\partial x}, \quad f_x, \quad \text{and} \quad \frac{\partial z}{\partial x}.$$

The slope of the curve $z = f(x, y_0)$ at the point $P(x_0, y_0, f(x_0, y_0))$ in the plane $y = y_0$ is the value of the partial derivative of f with respect to x at (x_0, y_0) . (In Figure 13.16 this slope is negative.) The tangent line to the curve at P is the line in the plane $y = y_0$ that passes through P with this slope. The partial derivative $\partial f/\partial x$ at (x_0, y_0) gives the rate of change of f with respect to x when y is held fixed at the value y_0 .

The definition of the partial derivative of $f(x, y)$ with respect to y at a point (x_0, y_0) is similar to the definition of the partial derivative of f with respect to x . We hold x fixed at the value x_0 and take the ordinary derivative of $f(x_0, y)$ with respect to y at y_0 .

DEFINITION The partial derivative of $f(x, y)$ with respect to y at the point (x_0, y_0) is

$$\left. \frac{\partial f}{\partial y} \right|_{(x_0, y_0)} = \left. \frac{d}{dy} f(x_0, y) \right|_{y=y_0} = \lim_{h \rightarrow 0} \frac{f(x_0, y_0 + h) - f(x_0, y_0)}{h},$$

provided the limit exists.

The slope of the curve $z = f(x_0, y)$ at the point $P(x_0, y_0, f(x_0, y_0))$ in the vertical plane $x = x_0$ (Figure 13.17) is the partial derivative of f with respect to y at (x_0, y_0) . The tangent line to the curve at P is the line in the plane $x = x_0$ that passes through P with this slope. The partial derivative gives the rate of change of f with respect to y at (x_0, y_0) when x is held fixed at the value x_0 .

The partial derivative with respect to y is denoted the same way as the partial derivative with respect to x :

$$\left. \frac{\partial f}{\partial y} \right|_{(x_0, y_0)}, \quad f_y(x_0, y_0), \quad \frac{\partial f}{\partial y}, \quad f_y.$$

Notice that we now have two tangent lines associated with the surface $z = f(x, y)$ at the point $P(x_0, y_0, f(x_0, y_0))$ (Figure 13.18). Is the plane they determine tangent to the surface at P ? We will see that it is for the *differentiable* functions defined at the end of this section, and we will learn how to find the tangent plane in Section 13.6. First we have to better understand partial derivatives.

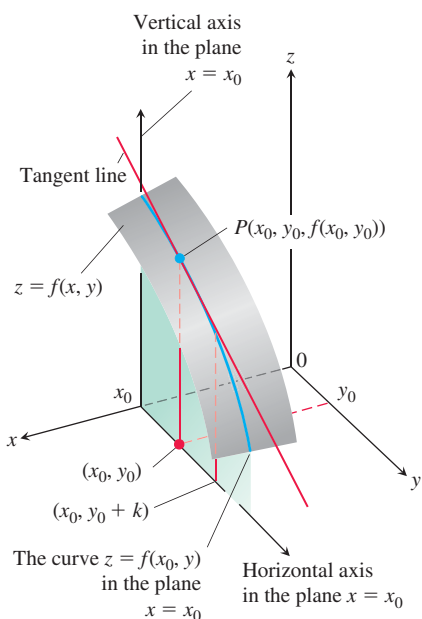

FIGURE 13.17 The intersection of the plane $x = x_0$ with the surface $z = f(x, y)$, viewed from above the first quadrant of the xy -plane.

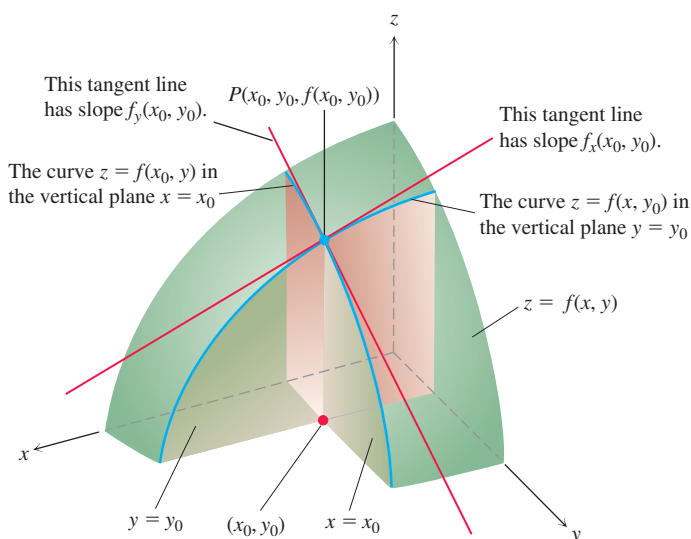

FIGURE 13.18 Figures 13.16 and 13.17 combined. The tangent lines at the point $(x_0, y_0, f(x_0, y_0))$ determine a plane that, in this picture at least, appears to be tangent to the surface.

Calculations

The definitions of $\partial f/\partial x$ and $\partial f/\partial y$ give us two different ways of differentiating f at a point: with respect to x in the usual way while treating y as a constant, and with respect to y in the usual way while treating x as a constant. As the following examples show, the values of these partial derivatives are usually different at a given point (x_0, y_0) .

EXAMPLE 1 Find the values of $\partial f/\partial x$ and $\partial f/\partial y$ at the point $(4, -5)$ if

$$f(x, y) = x^2 + 3xy + y - 1.$$

Solution To find $\partial f/\partial x$, we treat y as a constant and differentiate with respect to x :

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}(x^2 + 3xy + y - 1) = 2x + 3 \cdot 1 \cdot y + 0 - 0 = 2x + 3y.$$

The value of $\partial f/\partial x$ at $(4, -5)$ is $2(4) + 3(-5) = -7$.

To find $\partial f/\partial y$, we treat x as a constant and differentiate with respect to y :

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}(x^2 + 3xy + y - 1) = 0 + 3 \cdot x \cdot 1 + 1 - 0 = 3x + 1.$$

The value of $\partial f/\partial y$ at $(4, -5)$ is $3(4) + 1 = 13$. ■

EXAMPLE 2 Find $\partial f/\partial y$ as a function if $f(x, y) = y \sin xy$.

Solution We treat x as a constant and f as a product of y and $\sin xy$:

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(y \sin xy) = y \frac{\partial}{\partial y} \sin xy + (\sin xy) \frac{\partial}{\partial y}(y) \\ &= (y \cos xy) \frac{\partial}{\partial y}(xy) + \sin xy = xy \cos xy + \sin xy. \end{aligned}$$
 ■

EXAMPLE 3 Find f_x and f_y as functions if

$$f(x, y) = \frac{2y}{y + \cos x}.$$

Solution We treat f as a quotient. With y held constant, we use the quotient rule to get

$$\begin{aligned} f_x &= \frac{\partial}{\partial x} \left(\frac{2y}{y + \cos x} \right) = \frac{(y + \cos x) \frac{\partial}{\partial x}(2y) - 2y \frac{\partial}{\partial x}(y + \cos x)}{(y + \cos x)^2} \\ &= \frac{(y + \cos x)(0) - 2y(-\sin x)}{(y + \cos x)^2} = \frac{2y \sin x}{(y + \cos x)^2}. \end{aligned}$$

With x held constant and again applying the quotient rule, we get

$$\begin{aligned} f_y &= \frac{\partial}{\partial y} \left(\frac{2y}{y + \cos x} \right) = \frac{(y + \cos x) \frac{\partial}{\partial y}(2y) - 2y \frac{\partial}{\partial y}(y + \cos x)}{(y + \cos x)^2} \\ &= \frac{(y + \cos x)(2) - 2y(1)}{(y + \cos x)^2} = \frac{2 \cos x}{(y + \cos x)^2}. \end{aligned}$$
 ■

Implicit differentiation works for partial derivatives the way it works for ordinary derivatives, as the next example illustrates.

EXAMPLE 4 Find $\partial z/\partial x$ assuming that the equation

$$yz - \ln z = x + y$$

defines z as a function of the two independent variables x and y and the partial derivative exists.

Solution We differentiate both sides of the equation with respect to x , holding y constant and treating z as a differentiable function of x :

$$\begin{aligned} \frac{\partial}{\partial x}(yz) - \frac{\partial}{\partial x} \ln z &= \frac{\partial x}{\partial x} + \frac{\partial y}{\partial x} \\ y \frac{\partial z}{\partial x} - \frac{1}{z} \frac{\partial z}{\partial x} &= 1 + 0 && \text{With } y \text{ constant, } \frac{\partial}{\partial x}(yz) = y \frac{\partial z}{\partial x}. \\ \left(y - \frac{1}{z}\right) \frac{\partial z}{\partial x} &= 1 \\ \frac{\partial z}{\partial x} &= \frac{z}{yz - 1}. \end{aligned}$$

EXAMPLE 5 The plane $x = 1$ intersects the paraboloid $z = x^2 + y^2$ in a parabola. Find the slope of the tangent line to the parabola at $(1, 2, 5)$ (Figure 13.19).

Solution The parabola lies in a plane parallel to the yz -plane, and the slope is the value of the partial derivative $\partial z/\partial y$ at $(1, 2)$:

$$\left. \frac{\partial z}{\partial y} \right|_{(1,2)} = \left. \frac{\partial}{\partial y}(x^2 + y^2) \right|_{(1,2)} = 2y \Big|_{(1,2)} = 2(2) = 4.$$

As a check, we can treat the parabola as the graph of the single-variable function $z = (1)^2 + y^2 = 1 + y^2$ in the plane $x = 1$ and ask for the slope at $y = 2$. The slope, calculated now as an ordinary derivative, is

$$\left. \frac{dz}{dy} \right|_{y=2} = \left. \frac{d}{dy}(1 + y^2) \right|_{y=2} = 2y \Big|_{y=2} = 4.$$

Functions of More Than Two Variables

The definitions of the partial derivatives of functions of more than two independent variables are similar to the definitions for functions of two variables. They are ordinary derivatives with respect to one variable, taken while the other independent variables are held constant.

EXAMPLE 6 If x , y , and z are independent variables and

$$f(x, y, z) = x \sin(y + 3z),$$

then

$$\begin{aligned} \frac{\partial f}{\partial z} &= \frac{\partial}{\partial z}[x \sin(y + 3z)] = x \frac{\partial}{\partial z} \sin(y + 3z) && x \text{ held constant} \\ &= x \cos(y + 3z) \frac{\partial}{\partial z}(y + 3z) && \text{Chain rule} \\ &= 3x \cos(y + 3z). && y \text{ held constant} \end{aligned}$$

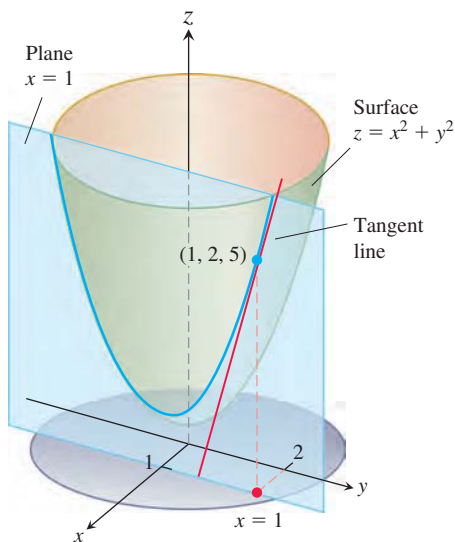

FIGURE 13.19 The tangent line to the curve of intersection of the plane $x = 1$ and the surface $z = x^2 + y^2$ at the point $(1, 2, 5)$ (Example 5).

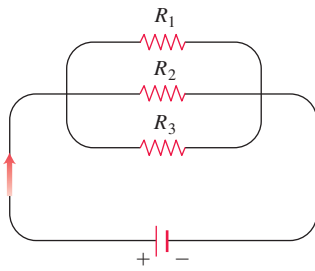

FIGURE 13.20 Resistors arranged this way are said to be connected in parallel (Example 7). Each resistor lets a portion of the current through. Their equivalent resistance R is calculated with the formula

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}.$$

EXAMPLE 7 If resistors of R_1 , R_2 , and R_3 ohms are connected in parallel to make an R -ohm resistor, the value of R can be found from the equation

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$$

(Figure 13.20). Find the value of $\partial R/\partial R_2$ when $R_1 = 30$, $R_2 = 45$, and $R_3 = 90$ ohms.

Solution To find $\partial R/\partial R_2$, we treat R_1 and R_3 as constants and, using implicit differentiation, differentiate both sides of the equation with respect to R_2 :

$$\begin{aligned} \frac{\partial}{\partial R_2} \left(\frac{1}{R} \right) &= \frac{\partial}{\partial R_2} \left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \right) \\ -\frac{1}{R^2} \frac{\partial R}{\partial R_2} &= 0 - \frac{1}{R_2^2} + 0 \\ \frac{\partial R}{\partial R_2} &= \frac{R^2}{R_2^2} = \left(\frac{R}{R_2} \right)^2. \end{aligned}$$

When $R_1 = 30$, $R_2 = 45$, and $R_3 = 90$,

$$\frac{1}{R} = \frac{1}{30} + \frac{1}{45} + \frac{1}{90} = \frac{3 + 2 + 1}{90} = \frac{6}{90} = \frac{1}{15},$$

so $R = 15$ and

$$\frac{\partial R}{\partial R_2} = \left(\frac{15}{45} \right)^2 = \left(\frac{1}{3} \right)^2 = \frac{1}{9}.$$

Thus at the given values, a small change in the resistance R_2 leads to a change in R about one-ninth as large. ■

Partial Derivatives and Continuity

A function $f(x, y)$ can have partial derivatives with respect to both x and y at a point without the function being continuous there. This is different from functions of a single variable, where the existence of a derivative implies continuity. If the partial derivatives of $f(x, y)$ exist and are continuous throughout a disk centered at (x_0, y_0) , however, then f is continuous at (x_0, y_0) , as we see at the end of this section.

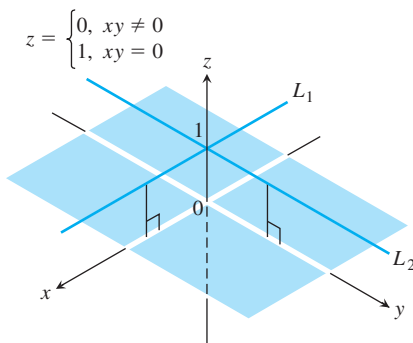

FIGURE 13.21 The graph of

$$f(x, y) = \begin{cases} 0, & xy \neq 0 \\ 1, & xy = 0 \end{cases}$$

consists of the lines L_1 and L_2 (lying 1 unit above the xy -plane) and the four open quadrants of the xy -plane. The function has partial derivatives at the origin but is not continuous there (Example 8).

EXAMPLE 8 Let

$$f(x, y) = \begin{cases} 0, & xy \neq 0 \\ 1, & xy = 0 \end{cases}$$

(Figure 13.21).

- Find the limit of f as (x, y) approaches $(0, 0)$ along the line $y = x$.
- Find the limit of f as (x, y) approaches $(0, 0)$ along the line $y = 0$.
- Prove that f is not continuous at the origin.
- Show that both partial derivatives $\partial f/\partial x$ and $\partial f/\partial y$ exist at the origin.

Solution

- (a) Since $f(x, y)$ is zero at every point on the line $y = x$ (except at the origin), we have

$$\lim_{(x,y) \rightarrow (0,0)} f(x, y) \Big|_{y=x} = \lim_{(x,y) \rightarrow (0,0)} 0 = 0.$$

- (b) Since $f(x, y)$ takes the constant value 1 at every point on the line $y = 0$, we have

$$\lim_{(x,y) \rightarrow (0,0)} f(x, y) \Big|_{y=0} = \lim_{(x,y) \rightarrow (0,0)} 1 = 1.$$

- (c) By the two-path test, f has no limit as (x, y) approaches $(0, 0)$. Consequently, f is not continuous at $(0, 0)$.
- (d) To find $\partial f/\partial x$ at $(0, 0)$, we hold y fixed at $y = 0$. Then $f(x, y) = 1$ for all x , and the graph of f is the line L_1 in Figure 13.21. The slope of this line at any x is $\partial f/\partial x = 0$. In particular, $\partial f/\partial x = 0$ at $(0, 0)$. Similarly, $\partial f/\partial y$ is the slope of line L_2 at any y , so $\partial f/\partial y = 0$ at $(0, 0)$. ■

What Example 8 suggests is that we need a stronger requirement for differentiability in higher dimensions than the mere existence of the partial derivatives. We define differentiability for functions of two variables (which is somewhat more complicated than for single-variable functions) at the end of this section and then revisit the connection to continuity.

Second-Order Partial Derivatives

When we differentiate a function $f(x, y)$ twice, we produce its second-order derivatives. These derivatives are usually denoted by

$$\frac{\partial^2 f}{\partial x^2} \text{ or } f_{xx}, \quad \frac{\partial^2 f}{\partial y^2} \text{ or } f_{yy},$$

$$\frac{\partial^2 f}{\partial x \partial y} \text{ or } f_{yx}, \quad \text{and} \quad \frac{\partial^2 f}{\partial y \partial x} \text{ or } f_{xy}.$$

The defining equations are

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right), \quad \frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right),$$

and so on. Notice the order in which the mixed partial derivatives are taken:

$$\frac{\partial^2 f}{\partial x \partial y} \quad \text{Differentiate first with respect to } y, \text{ then with respect to } x.$$

$$f_{yx} = (f_y)_x \quad \text{Means the same thing}$$

HISTORICAL BIOGRAPHY

Pierre-Simon Laplace
(1749–1827)

Mathematician and astronomer, Laplace was born in Normandy, France. He was among the most influential scientists of his time and was called the Newton of France for contributions to the understanding of the solar system's stability. Laplace also generalized the laws of mechanics for their application to the motion and properties of the heavenly bodies.

EXAMPLE 9 If $f(x, y) = x \cos y + ye^x$, find the second-order derivatives

$$\frac{\partial^2 f}{\partial x^2}, \quad \frac{\partial^2 f}{\partial y \partial x}, \quad \frac{\partial^2 f}{\partial y^2}, \quad \text{and} \quad \frac{\partial^2 f}{\partial x \partial y}.$$

Solution The first step is to calculate both first partial derivatives.

$$\frac{\partial f}{\partial x} = \frac{\partial}{\partial x}(x \cos y + ye^x) = \cos y + ye^x$$

$$\frac{\partial f}{\partial y} = \frac{\partial}{\partial y}(x \cos y + ye^x) = -x \sin y + e^x$$

Now we find both partial derivatives of each first partial:

$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} \right) = -\sin y + e^x$$

$$\frac{\partial^2 f}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial y} \right) = -\sin y + e^x$$

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} \right) = ye^x$$

$$\frac{\partial^2 f}{\partial y^2} = \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial y} \right) = -x \cos y. \quad \blacksquare$$

The Mixed Derivative Theorem

You may have noticed that the “mixed” second-order partial derivatives

$$\frac{\partial^2 f}{\partial y \partial x} \quad \text{and} \quad \frac{\partial^2 f}{\partial x \partial y}$$

in Example 9 are equal. This is not a coincidence. They must be equal whenever f , f_x , f_y , f_{xy} , and f_{yx} are continuous, as stated in the following theorem. However, the mixed derivatives can be different when the continuity conditions are not satisfied (see Exercise 82).

THEOREM 2—The Mixed Derivative Theorem

If $f(x, y)$ and its partial derivatives f_x , f_y , f_{xy} , and f_{yx} are defined throughout an open region containing a point (a, b) and are all continuous at (a, b) , then

$$f_{xy}(a, b) = f_{yx}(a, b).$$

Theorem 2 is also known as Clairaut's Theorem, after the French mathematician Alexis Clairaut, who discovered it. A proof is given in Appendix A.10. Theorem 2 says that to calculate a mixed second-order derivative, we may differentiate in either order, provided the continuity conditions are satisfied. This ability to proceed in different order sometimes simplifies our calculations.

EXAMPLE 10 Find $\frac{\partial^2 w}{\partial x \partial y}$ if

$$w = xy + \frac{e^y}{y^2 + 1}.$$

Solution The symbol $\partial^2 w / \partial x \partial y$ tells us to differentiate first with respect to y and then with respect to x . However, if we interchange the order of differentiation and differentiate first with respect to x , we get the answer more quickly. In two steps,

$$\frac{\partial w}{\partial x} = y \quad \text{and} \quad \frac{\partial^2 w}{\partial y \partial x} = 1.$$

If we differentiate first with respect to y , we obtain $\partial^2 w / \partial x \partial y = 1$ as well, but with more work. We can differentiate in either order because the conditions of Theorem 2 hold for w at all points (x_0, y_0) . ■

Partial Derivatives of Still Higher Order

Although we will deal mostly with first- and second-order partial derivatives, because these appear the most frequently in applications, there is no theoretical limit to how many times we can differentiate a function as long as the derivatives involved exist. Thus, we get third- and fourth-order derivatives denoted by symbols like

$$\frac{\partial^3 f}{\partial x \partial y^2} = f_{yyx},$$

$$\frac{\partial^4 f}{\partial x^2 \partial y^2} = f_{yyxx},$$

and so on. As with second-order derivatives, the order of differentiation is immaterial as long as all the derivatives through the order in question are continuous.

EXAMPLE 11 Find f_{yxyz} if $f(x, y, z) = 1 - 2xy^2z + x^2y$.

Solution We first differentiate with respect to the variable y , then x , then y again, and finally with respect to z :

$$f_y = -4xyz + x^2$$

$$f_{yx} = -4yz + 2x$$

$$f_{yxy} = -4z$$

$$f_{yxyz} = -4.$$

HISTORICAL BIOGRAPHY

Alexis Clairaut (1713–1765)

Alexis Clairaut was a mathematical genius, who was called to visit the Academy of Sciences in Paris when he was only 12 years old. In a study published in 1743, the Clairaut proposition postulates in a simple way the dependency of the geometrical flattening ratio on the relationship between the gravity and the centrifugal force.

Differentiability

The concept of differentiability for functions of several variables is more complicated than for single-variable functions, because a point in the domain can be approached from many directions and along any path, not just from the left or from the right. The existence of both partial derivatives at a point (x_0, y_0) is not by itself even enough to show continuity at (x_0, y_0) , as we saw in Example 8. The differentiability of f is instead based on the idea that a linear function gives a good model of a differentiable function near a point.

In Section 3.11, we saw that a differentiable function f can be approximated near a point x_0 by its linearization,

$$L(x) = f(x_0) + f'(x_0)(x - x_0).$$

This formula allows us to find a linear function L , a function whose graph is a straight line, such that L closely approximates f near x_0 . This can be done whenever f is differentiable, even when f itself is described by a very complicated formula. Approximations are much more useful and meaningful when they are accompanied by information on their accuracy. In Section 3.11, Equation (1), we saw that a differentiable function f satisfies

$$f(x) - f(x_0) = f'(x_0)(x - x_0) + \varepsilon(x - x_0),$$

where $\varepsilon \rightarrow 0$ as $x \rightarrow x_0$. Framed in terms of approximating f by L , this becomes

$$f(x) - L(x) = \varepsilon(x - x_0), \quad (1)$$

where again $\varepsilon \rightarrow 0$ as $x \rightarrow x_0$.

Rather than being a consequence of the definition, the differentiability for a function of two variables $f(x, y)$ is defined to mean that f can be approximated by a linear function. The approximating linear function $L(x, y)$ for $f(x, y)$ near the point (x_0, y_0) takes the form

$$L(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0),$$

and the graph of L is a plane, called the *tangent plane*, that approximates the graph of f near (x_0, y_0) . Notice that $L(x_0, y_0) = f(x_0, y_0)$, so the functions L and f coincide at (x_0, y_0) . Moreover the partial derivatives of L and f are also equal at (x_0, y_0) . We will study tangent planes in detail in Section 13.6.

We now specify how closely f is approximated by L at (x_0, y_0) . Extending the formula for single variable functions in Equation (1), we require that the difference between f and L satisfies

$$f(x, y) - L(x, y) = \varepsilon_1(x - x_0) + \varepsilon_2(y - y_0), \quad (2)$$

where both $\varepsilon_1 \rightarrow 0$ and $\varepsilon_2 \rightarrow 0$ as $(x, y) \rightarrow (x_0, y_0)$.

If we insert the formula for $L(x, y)$ into Equation (2) we see that

$$f(x, y) - f(x_0, y_0) = f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) + \varepsilon_1(x - x_0) + \varepsilon_2(y - y_0).$$

Setting $\Delta x = x - x_0$, $\Delta y = y - y_0$, and $\Delta z = f(x, y) - f(x_0, y_0)$, we get

$$\Delta z = f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y + \varepsilon_1\Delta x + \varepsilon_2\Delta y.$$

Based on these ideas, we now state the formal definition of differentiability, which captures the idea that f is well approximated by L .

DEFINITION A function $z = f(x, y)$ is **differentiable at** (x_0, y_0) if both $f_x(x_0, y_0)$ and $f_y(x_0, y_0)$ exist and if $\Delta z = f(x, y) - f(x_0, y_0)$ satisfies

$$\Delta z = f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y + \varepsilon_1\Delta x + \varepsilon_2\Delta y,$$

where $\Delta x = x - x_0$, $\Delta y = y - y_0$, and both $\varepsilon_1 \rightarrow 0$ and $\varepsilon_2 \rightarrow 0$ as $(x, y) \rightarrow (x_0, y_0)$. We call the function f **differentiable** if it is differentiable at every point in its domain, and we then say that its graph is a **smooth surface**.

Differentiability is defined in a similar way for functions of more than two variables.

The following theorem (proved in Appendix A.10) and its accompanying corollary tell us that functions with *continuous* first partial derivatives at (x_0, y_0) are differentiable there, and they are closely approximated locally by a linear function. We study this approximation in Section 13.6.

THEOREM 3—The Increment Theorem for Functions of Two Variables

Suppose that the first partial derivatives of $f(x, y)$ are defined throughout an open region R containing the point (x_0, y_0) and that f_x and f_y are continuous at (x_0, y_0) . Then the change

$$\Delta z = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0)$$

in the value of f that results from moving from (x_0, y_0) to another point $(x_0 + \Delta x, y_0 + \Delta y)$ in R satisfies an equation of the form

$$\Delta z = f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y + \varepsilon_1\Delta x + \varepsilon_2\Delta y,$$

in which each of $\varepsilon_1, \varepsilon_2 \rightarrow 0$ as both $\Delta x, \Delta y \rightarrow 0$.

In many cases the partial derivatives are defined and continuous at every point in the domain of f . We then have the following Corollary.

Corollary of Theorem 3

If the partial derivatives f_x and f_y of a function $f(x, y)$ are continuous throughout an open region R , then f is differentiable at every point of R .

If $z = f(x, y)$ is differentiable, then the definition of differentiability ensures that $\Delta z = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0)$ approaches 0 as Δx and Δy approach 0. This tells us that a function of two variables is continuous at every point where it is differentiable.

THEOREM 4—Differentiable Implies Continuous

If a function $f(x, y)$ is differentiable at (x_0, y_0) , then f is continuous at (x_0, y_0) .

As we can see from Corollary 3 and Theorem 4, a function $f(x, y)$ must be continuous at a point (x_0, y_0) if f_x and f_y are continuous throughout an open region containing (x_0, y_0) . Remember, however, that it is still possible for a function of two variables to be discontinuous at a point where its first partial derivatives exist, as we saw in Example 8. Existence alone of the partial derivatives at that point is not enough, but continuity of the partial derivatives guarantees differentiability.

EXERCISES 13.3

Calculating First-Order Partial Derivatives

In Exercises 1–22, find $\partial f/\partial x$ and $\partial f/\partial y$.

1. $f(x, y) = 2x^2 - 3y - 4$
2. $f(x, y) = x^2 - xy + y^2$
3. $f(x, y) = (x^2 - 1)(y + 2)$
4. $f(x, y) = 5xy - 7x^2 - y^2 + 3x - 6y + 2$
5. $f(x, y) = (xy - 1)^2$
6. $f(x, y) = (2x - 3y)^3$
7. $f(x, y) = \sqrt{x^2 + y^2}$
8. $f(x, y) = (x^3 + (y/2))^{2/3}$
9. $f(x, y) = 1/(x + y)$
10. $f(x, y) = x/(x^2 + y^2)$
11. $f(x, y) = (x + y)/(xy - 1)$
12. $f(x, y) = \tan^{-1}(y/x)$
13. $f(x, y) = e^{(x+y+1)}$
14. $f(x, y) = e^{-x} \sin(x + y)$

15. $f(x, y) = \ln(x + y)$
16. $f(x, y) = e^{xy} \ln y$
17. $f(x, y) = \sin^2(x - 3y)$
18. $f(x, y) = \cos^2(3x - y^2)$
19. $f(x, y) = x^y$
20. $f(x, y) = \log_y x$
21. $f(x, y) = \int_x^y g(t) dt$ (g continuous for all t)
22. $f(x, y) = \sum_{n=0}^{\infty} (xy)^n$ ($|xy| < 1$)

In Exercises 23–34, find $f_x, f_y,$ and f_z .

23. $f(x, y, z) = 1 + xy^2 - 2z^2$
24. $f(x, y, z) = xy + yz + xz$
25. $f(x, y, z) = x - \sqrt{y^2 + z^2}$

26. $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2}$
 27. $f(x, y, z) = \arcsin(xyz)$
 28. $f(x, y, z) = \operatorname{arcsec}(x + yz)$
 29. $f(x, y, z) = \ln(x + 2y + 3z)$
 30. $f(x, y, z) = yz \ln(xy)$
 31. $f(x, y, z) = e^{-(x^2+y^2+z^2)}$
 32. $f(x, y, z) = e^{-xyz}$
 33. $f(x, y, z) = \tanh(x + 2y + 3z)$
 34. $f(x, y, z) = \sinh(xy - z^2)$

In Exercises 35–40, find the partial derivative of the function with respect to each variable.

35. $f(t, \alpha) = \cos(2\pi t - \alpha)$
 36. $g(u, v) = v^2 e^{(2u/v)}$
 37. $h(\rho, \phi, \theta) = \rho \sin \phi \cos \theta$
 38. $g(r, \theta, z) = r(1 - \cos \theta) - z$
 39. **Work done by the heart** (Section 3.11, Exercise 59)

$$W(P, V, \delta, v, g) = PV + \frac{V\delta v^2}{2g}$$

40. **Wilson lot size formula** (Section 4.6, Exercise 61)

$$A(c, h, k, m, q) = \frac{km}{q} + cm + \frac{hq}{2}$$

Calculating Second-Order Partial Derivatives

Find all the second-order partial derivatives of the functions in Exercises 41–54.

41. $f(x, y) = x + y + xy$ 42. $f(x, y) = \sin xy$
 43. $g(x, y) = x^2y + \cos y + y \sin x$
 44. $h(x, y) = xe^y + y + 1$ 45. $r(x, y) = \ln(x + y)$
 46. $s(x, y) = \arctan(y/x)$ 47. $w = x^2 \tan(xy)$
 48. $w = ye^{x^2-y}$ 49. $w = x \sin(x^2y)$
 50. $w = \frac{x-y}{x^2+y}$ 51. $f(x, y) = x^2y^3 - x^4 + y^5$
 52. $g(x, y) = \cos x^2 - \sin 3y$ 53. $z = x \sin(2x - y^2)$
 54. $z = xe^{x/y^2}$

Mixed Partial Derivatives

In Exercises 55–60, verify that $w_{xy} = w_{yx}$.

55. $w = \ln(2x + 3y)$ 56. $w = e^x + x \ln y + y \ln x$
 57. $w = xy^2 + x^2y^3 + x^3y^4$
 58. $w = x \sin y + y \sin x + xy$
 59. $w = \frac{x^2}{y^3}$ 60. $w = \frac{3x-y}{x+y}$

61. Which order of differentiation enables one to calculate f_{xy} faster: x first or y first? Try to answer without writing anything down.

- a. $f(x, y) = x \sin y + e^y$
 b. $f(x, y) = 1/x$
 c. $f(x, y) = y + (x/y)$
 d. $f(x, y) = y + x^2y + 4y^3 - \ln(y^2 + 1)$
 e. $f(x, y) = x^2 + 5xy + \sin x + 7e^x$
 f. $f(x, y) = x \ln xy$

62. The fifth-order partial derivative $\partial^5 f / \partial x^2 \partial y^3$ is zero for each of the following functions. To show this as quickly as possible, which variable would you differentiate with respect to first: x or y ? Try to answer without writing anything down.

- a. $f(x, y) = y^2x^4e^x + 2$
 b. $f(x, y) = y^2 + y(\sin x - x^4)$
 c. $f(x, y) = x^2 + 5xy + \sin x + 7e^x$
 d. $f(x, y) = xe^{y^2/2}$

Using the Partial Derivative Definition

In Exercises 63–66, use the limit definition of partial derivative to compute the partial derivatives of the functions at the specified points.

63. $f(x, y) = 1 - x + y - 3x^2y$, $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at $(1, 2)$
 64. $f(x, y) = 4 + 2x - 3y - xy^2$, $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at $(-2, 1)$
 65. $f(x, y) = \sqrt{2x + 3y - 1}$, $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at $(-2, 3)$
 66. $f(x, y) = \begin{cases} \frac{\sin(x^3 + y^4)}{x^2 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0), \end{cases}$
 $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ at $(0, 0)$

67. **Three variables** Let $w = f(x, y, z)$ be a function of three independent variables and write the formal definition of the partial derivative $\partial f / \partial z$ at (x_0, y_0, z_0) . Use this definition to find $\partial f / \partial z$ at $(1, 2, 3)$ for $f(x, y, z) = x^2yz^2$.

68. **Three variables** Let $w = f(x, y, z)$ be a function of three independent variables and write the formal definition of the partial derivative $\partial f / \partial y$ at (x_0, y_0, z_0) . Use this definition to find $\partial f / \partial y$ at $(-1, 0, 3)$ for $f(x, y, z) = -2xy^2 + yz^2$.

Differentiating Implicitly

69. Find the value of $\partial z / \partial x$ at the point $(1, 1)$ if the equation

$$xy + z^3x - 2yz = 0$$

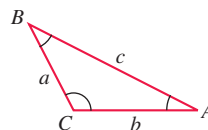

defines z as a function of the two independent variables x and y and the partial derivative exists.

70. Find the value of $\partial x / \partial z$ at the point $(1, -1, -3)$ if the equation

$$xz + y \ln x - x^2 + 4 = 0$$

defines x as a function of the two independent variables y and z and the partial derivative exists.

Exercises 71 and 72 are about the triangle shown here.

71. Express A implicitly as a function of a , b , and c and calculate $\partial A / \partial a$ and $\partial A / \partial b$.
 72. Express a implicitly as a function of A , b , and B and calculate $\partial a / \partial A$ and $\partial a / \partial B$.

- 73. Two dependent variables** Express v_x in terms of u and y if the equations $x = v \ln u$ and $y = u \ln v$ define u and v as functions of the independent variables x and y , and if v_x exists. (*Hint:* Differentiate both equations with respect to x and solve for v_x by eliminating u_x .)
- 74. Two dependent variables** Find $\partial x/\partial u$ and $\partial y/\partial u$ if the equations $u = x^2 - y^2$ and $v = x^2 - y$ define x and y as functions of the independent variables u and v , and the partial derivatives exist. (See the hint in Exercise 73.) Then let $s = x^2 + y^2$ and find $\partial s/\partial u$.

Theory and Examples

- 75.** Let $f(x, y) = 2x + 3y - 4$. Find the slope of the line tangent to this surface at the point $(2, -1)$ and lying in **a.** the plane $x = 2$
b. the plane $y = -1$.
- 76.** Let $f(x, y) = x^2 + y^3$. Find the slope of the line tangent to this surface at the point $(-1, 1)$ and lying in **a.** the plane $x = -1$
b. the plane $y = 1$.

In Exercises 77–80, find a function $z = f(x, y)$ whose partial derivatives are as given, or explain why this is impossible.

- 77.** $\frac{\partial f}{\partial x} = 3x^2y^2 - 2x$, $\frac{\partial f}{\partial y} = 2x^3y + 6y$
- 78.** $\frac{\partial f}{\partial x} = 2xe^{xy^2} + x^2y^2e^{xy^2} + 3$, $\frac{\partial f}{\partial y} = 2x^3ye^{xy^2} - e^y$
- 79.** $\frac{\partial f}{\partial x} = \frac{2y}{(x+y)^2}$, $\frac{\partial f}{\partial y} = \frac{2x}{(x+y)^2}$
- 80.** $\frac{\partial f}{\partial x} = xy \cos(xy) + \sin(xy)$, $\frac{\partial f}{\partial y} = x \cos(xy)$
- 81.** Let $f(x, y) = \begin{cases} y^3, & y \geq 0 \\ -y^2, & y < 0. \end{cases}$

Find f_x, f_y, f_{xy} , and f_{yx} , and state the domain for each partial derivative.

- 82.** Let $f(x, y) = \begin{cases} xy \frac{x^2 - y^2}{x^2 + y^2}, & \text{if } (x, y) \neq 0, \\ 0, & \text{if } (x, y) = 0. \end{cases}$
- a.** Show that $\frac{\partial f}{\partial y}(x, 0) = x$ for all x , and $\frac{\partial f}{\partial x}(0, y) = -y$ for all y .
- b.** Show that $\frac{\partial^2 f}{\partial y \partial x}(0, 0) \neq \frac{\partial^2 f}{\partial x \partial y}(0, 0)$.

The three-dimensional Laplace equation

$$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = 0$$

is satisfied by steady-state temperature distributions $T = f(x, y, z)$ in space, by gravitational potentials, and by electrostatic potentials. The **two-dimensional Laplace equation**

$$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = 0,$$

obtained by dropping the $\partial^2 f/\partial z^2$ term from the previous equation, describes potentials and steady-state temperature distributions in a plane. The plane may be treated as a thin slice of the solid perpendicular to the z -axis.

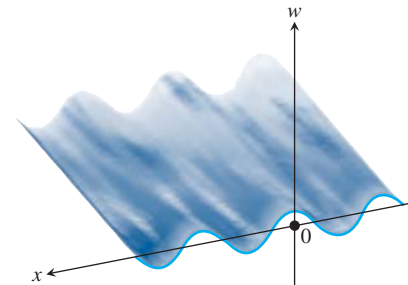

Show that each function in Exercises 83–90 satisfies a Laplace equation.

- 83.** $f(x, y, z) = x^2 + y^2 - 2z^2$
- 84.** $f(x, y, z) = 2z^3 - 3(x^2 + y^2)z$
- 85.** $f(x, y) = e^{-2y} \cos 2x$
- 86.** $f(x, y) = \ln \sqrt{x^2 + y^2}$
- 87.** $f(x, y) = 3x + 2y - 4$
- 88.** $f(x, y) = \arctan \frac{x}{y}$
- 89.** $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2}$
- 90.** $f(x, y, z) = e^{3x+4y} \cos 5z$

The wave equation If we stand on an ocean shore and take a snapshot of the waves, the picture shows a regular pattern of peaks and valleys in an instant of time. We see periodic vertical motion in space, with respect to distance. If we stand in the water, we can feel the rise and fall of the water as the waves go by. We see periodic vertical motion in time. In physics, this beautiful symmetry is expressed by the **one-dimensional wave equation**

$$\frac{\partial^2 w}{\partial t^2} = c^2 \frac{\partial^2 w}{\partial x^2},$$

where w is the wave height, x is the distance variable, t is the time variable, and c is the velocity with which the waves are propagated.

In our example, x is the distance across the ocean's surface, but in other applications, x might be the distance along a vibrating string, distance through air (sound waves), or distance through space (light waves). The number c varies with the medium and type of wave.

Show that the functions in Exercises 91–97 are all solutions of the wave equation.

- 91.** $w = \sin(x + ct)$ **92.** $w = \cos(2x + 2ct)$
- 93.** $w = \sin(x + ct) + \cos(2x + 2ct)$
- 94.** $w = \ln(2x + 2ct)$ **95.** $w = \tan(2x - 2ct)$
- 96.** $w = 5 \cos(3x + 3ct) + e^{x+ct}$
- 97.** $w = f(u)$, where f is a differentiable function of u , and $u = a(x + ct)$, where a is a constant
- 98.** Does a function $f(x, y)$ with continuous first partial derivatives throughout an open region R have to be continuous on R ? Give reasons for your answer.
- 99.** If a function $f(x, y)$ has continuous second partial derivatives throughout an open region R , must the first-order partial derivatives of f be continuous on R ? Give reasons for your answer.

- 100. The heat equation** An important partial differential equation that describes the distribution of heat in a region at time t can be represented by the *one-dimensional heat equation*

$$\frac{\partial f}{\partial t} = \frac{\partial^2 f}{\partial x^2}.$$

Show that $u(x, t) = \sin(\alpha x) \cdot e^{-\beta t}$ satisfies the heat equation for constants α and β . What is the relationship between α and β for this function to be a solution?

101. Let $f(x, y) = \begin{cases} \frac{xy^2}{x^2 + y^4}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0). \end{cases}$

Show that $f_x(0, 0)$ and $f_y(0, 0)$ exist, but f is not differentiable at $(0, 0)$. (*Hint:* Use Theorem 4 and show that f is not continuous at $(0, 0)$.)

102. Let $f(x, y) = \begin{cases} 0, & x^2 < y < 2x^2 \\ 1, & \text{otherwise.} \end{cases}$

Show that $f_x(0, 0)$ and $f_y(0, 0)$ exist, but f is not differentiable at $(0, 0)$.

103. The Korteweg–de Vries equation

This nonlinear differential equation, which describes wave motion on shallow water surfaces, is given by

$$u_t + u_{xxx} + 12uu_x = 0.$$

Show that $u(x, t) = \operatorname{sech}^2(x - t)$ satisfies the Korteweg–de Vries equation.

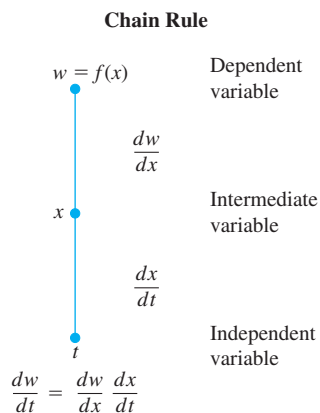

104. Show that $T = \frac{1}{\sqrt{x^2 + y^2}}$ satisfies the equation $T_{xx} + T_{yy} = T^3$.

13.4 The Chain Rule

The Chain Rule for functions of a single variable studied in Section 3.6 says that if $w = f(x)$ is a differentiable function of x , and $x = g(t)$ is a differentiable function of t , then w is a differentiable function of t , and dw/dt can be calculated by the formula

$$\frac{dw}{dt} = \frac{dw}{dx} \frac{dx}{dt}.$$

To find dw/dt , we read down the route from w to t , multiplying derivatives along the way.

For this composite function $w(t) = f(g(t))$, we can think of t as the independent variable and $x = g(t)$ as the “intermediate variable” because t determines the value of x that in turn gives the value of w from the function f . We display the Chain Rule in a “dependency diagram” in the margin. Such diagrams capture which variables depend on which.

For functions of several variables the Chain Rule has more than one form, which depends on how many independent and intermediate variables are involved. However, once the variables are taken into account, the Chain Rule works in the same way we just discussed.

Functions of Two Variables

The Chain Rule formula for a differentiable function $w = f(x, y)$ when $x = x(t)$ and $y = y(t)$ are both differentiable functions of t is given in the following theorem.

THEOREM 5—Chain Rule for Functions of One Independent Variable and Two Intermediate Variables

If $w = f(x, y)$ is differentiable and if $x = x(t)$, $y = y(t)$ are differentiable functions of t , then the composition $w = f(x(t), y(t))$ is a differentiable function of t and

$$\frac{dw}{dt} = f_x(x(t), y(t))x'(t) + f_y(x(t), y(t))y'(t),$$

or

$$\frac{dw}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt}.$$

Each of $\frac{\partial f}{\partial x}$, $\frac{\partial w}{\partial x}$, f_x indicates the partial derivative of f with respect to x .

Proof The proof consists of showing that if x and y are differentiable at $t = t_0$, then w is differentiable at t_0 and

$$\frac{dw}{dt}(t_0) = \frac{\partial w}{\partial x}(P_0) \frac{dx}{dt}(t_0) + \frac{\partial w}{\partial y}(P_0) \frac{dy}{dt}(t_0),$$

where $P_0 = (x(t_0), y(t_0))$.

Let Δx , Δy , and Δw be the increments that result from changing t from t_0 to $t_0 + \Delta t$. Since f is differentiable (see the definition in Section 13.3),

$$\Delta w = \frac{\partial w}{\partial x}(P_0) \Delta x + \frac{\partial w}{\partial y}(P_0) \Delta y + \varepsilon_1 \Delta x + \varepsilon_2 \Delta y,$$

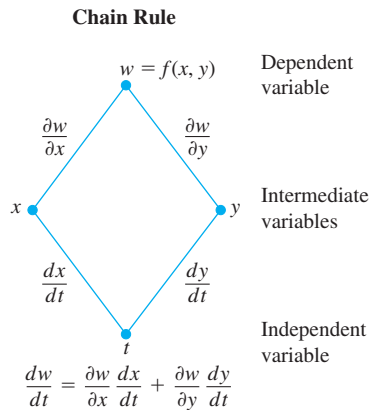

where $\varepsilon_1, \varepsilon_2 \rightarrow 0$ as $\Delta x, \Delta y \rightarrow 0$. To find dw/dt , we divide this equation through by Δt and let Δt approach zero (therefore, Δx and Δy approach zero as well since the fact that $x(t)$ and $y(t)$ are differentiable implies that they are continuous). The division gives

$$\frac{\Delta w}{\Delta t} = \frac{\partial w}{\partial x}(P_0) \frac{\Delta x}{\Delta t} + \frac{\partial w}{\partial y}(P_0) \frac{\Delta y}{\Delta t} + \varepsilon_1 \frac{\Delta x}{\Delta t} + \varepsilon_2 \frac{\Delta y}{\Delta t}.$$

Letting Δt approach zero gives

$$\begin{aligned} \frac{dw}{dt}(t_0) &= \lim_{\Delta t \rightarrow 0} \frac{\Delta w}{\Delta t} \\ &= \frac{\partial w}{\partial x}(P_0) \frac{dx}{dt}(t_0) + \frac{\partial w}{\partial y}(P_0) \frac{dy}{dt}(t_0) + 0 \cdot \frac{dx}{dt}(t_0) + 0 \cdot \frac{dy}{dt}(t_0). \quad \blacksquare \end{aligned}$$

To remember the Chain Rule, picture the diagram below. To find dw/dt , start at w and read down each route to t , multiplying derivatives along the way. Then add the products.

Often we write $\partial w/\partial x$ for the partial derivative $\partial f/\partial x$, so we can rewrite the Chain Rule in Theorem 5 in the form

$$\frac{dw}{dt} = \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt}.$$

However, the meaning of the dependent variable w is different on each side of the preceding equation. On the left-hand side, it refers to the composite function $w = f(x(t), y(t))$ as a function of the single variable t . On the right-hand side, it refers to the function $w = f(x, y)$ as a function of the two variables x and y . Moreover, the single derivatives dw/dt , dx/dt , and dy/dt are being evaluated at a point t_0 , whereas the partial derivatives $\partial w/\partial x$ and $\partial w/\partial y$ are being evaluated at the point (x_0, y_0) , with $x_0 = x(t_0)$ and $y_0 = y(t_0)$. With that understanding, we will use both of these forms interchangeably throughout the text whenever no confusion will arise.

The **dependency diagram** on the preceding page provides a convenient way to remember the Chain Rule. The “true” independent variable in the composite function is t , whereas x and y are *intermediate variables* (controlled by t) and w is the dependent variable.

A more precise notation for the Chain Rule shows where the various derivatives in Theorem 5 are evaluated:

$$\frac{dw}{dt}(t_0) = \frac{\partial f}{\partial x}(x_0, y_0) \frac{dx}{dt}(t_0) + \frac{\partial f}{\partial y}(x_0, y_0) \frac{dy}{dt}(t_0),$$

or, using another notation,

$$\left. \frac{dw}{dt} \right|_{t_0} = \left. \frac{\partial f}{\partial x} \right|_{(x_0, y_0)} \left. \frac{dx}{dt} \right|_{t_0} + \left. \frac{\partial f}{\partial y} \right|_{(x_0, y_0)} \left. \frac{dy}{dt} \right|_{t_0}.$$

EXAMPLE 1 Use the Chain Rule to find the derivative of

$$w = xy$$

with respect to t along the path $x = \cos t$, $y = \sin t$. What is the derivative's value at $t = \pi/2$?

Solution We apply the Chain Rule to find dw/dt as follows:

$$\begin{aligned} \frac{dw}{dt} &= \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} \\ &= \frac{\partial(xy)}{\partial x} \frac{d}{dt}(\cos t) + \frac{\partial(xy)}{\partial y} \frac{d}{dt}(\sin t) \\ &= (y)(-\sin t) + (x)(\cos t) \\ &= (\sin t)(-\sin t) + (\cos t)(\cos t) \\ &= -\sin^2 t + \cos^2 t \\ &= \cos 2t. \end{aligned}$$

In this example, we can check the result with a more direct calculation. As a function of t ,

$$w = xy = \cos t \sin t = \frac{1}{2} \sin 2t,$$

so

$$\frac{dw}{dt} = \frac{d}{dt} \left(\frac{1}{2} \sin 2t \right) = \frac{1}{2} (2 \cos 2t) = \cos 2t.$$

In either case, at the given value of t ,

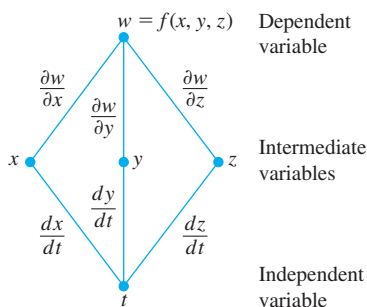

$$\left. \frac{dw}{dt} \right|_{t=\pi/2} = \cos \left(2 \frac{\pi}{2} \right) = \cos \pi = -1. \quad \blacksquare$$

Functions of Three Variables

You can probably predict the Chain Rule for functions of three intermediate variables, as it involves adding the expected third term to the two-variable formula.

Here we have three routes from w to t instead of two, but finding dw/dt is still the same. Read down each route, multiplying derivatives along the way; then add.

Chain Rule

$$\frac{dw}{dt} = \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt}$$

THEOREM 6—Chain Rule for Functions of One Independent Variable and Three Intermediate Variables

If $w = f(x, y, z)$ is differentiable and x , y , and z are differentiable functions of t , then w is a differentiable function of t , and

$$\frac{dw}{dt} = \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt}.$$

The proof is identical to the proof of Theorem 5, except that there are now three intermediate variables instead of two. The dependency diagram we use for remembering the new equation is similar as well, with three routes from w to t .

EXAMPLE 2 Find dw/dt if

$$w = xy + z, \quad x = \cos t, \quad y = \sin t, \quad z = t.$$

In this example the values of $w(t)$ are changing along the path of a helix (Section 12.1) as t changes. What is the derivative's value at $t = 0$?

Solution Using the Chain Rule for three intermediate variables, we have

$$\begin{aligned}\frac{dw}{dt} &= \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt} \\ &= (y)(-\sin t) + (x)(\cos t) + (1)(1) \\ &= (\sin t)(-\sin t) + (\cos t)(\cos t) + 1 && \text{Substitute for intermediate} \\ &= -\sin^2 t + \cos^2 t + 1 = 1 + \cos 2t, && \text{variables.}\end{aligned}$$

so

$$\left. \frac{dw}{dt} \right|_{t=0} = 1 + \cos(0) = 2. \quad \blacksquare$$

For a physical interpretation of change along a curve, think of an object whose position is changing with time t . If $w = T(x, y, z)$ is the temperature at each point (x, y, z) along a curve C with parametric equations $x = x(t)$, $y = y(t)$, and $z = z(t)$, then the composite function $w = T(x(t), y(t), z(t))$ represents the temperature relative to t along the curve. The derivative dw/dt is then the instantaneous rate of change of temperature due to the motion along the curve, as calculated in Theorem 6.

Functions Defined on Surfaces

If we are interested in the temperature $w = f(x, y, z)$ at points (x, y, z) on Earth's surface, we might prefer to think of x , y , and z as functions of the variables r and s that give the points' longitudes and latitudes. If $x = g(r, s)$, $y = h(r, s)$, and $z = k(r, s)$, we could then express the temperature as a function of r and s with the composite function

$$w = f(g(r, s), h(r, s), k(r, s)).$$

Under the conditions stated below, w has partial derivatives with respect to both r and s that can be calculated in the following way.

THEOREM 7—Chain Rule for Two Independent Variables and Three Intermediate Variables

Suppose that $w = f(x, y, z)$, $x = g(r, s)$, $y = h(r, s)$, and $z = k(r, s)$. If all four functions are differentiable, then w has partial derivatives with respect to r and s , given by the formulas

$$\begin{aligned}\frac{\partial w}{\partial r} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial r} \\ \frac{\partial w}{\partial s} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial s} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial s}.\end{aligned}$$

The first of these equations can be derived from the Chain Rule in Theorem 6 by holding s fixed and treating r as t . The second can be derived in the same way, holding r fixed and treating s as t . The dependency diagrams for both equations are shown in Figure 13.22.

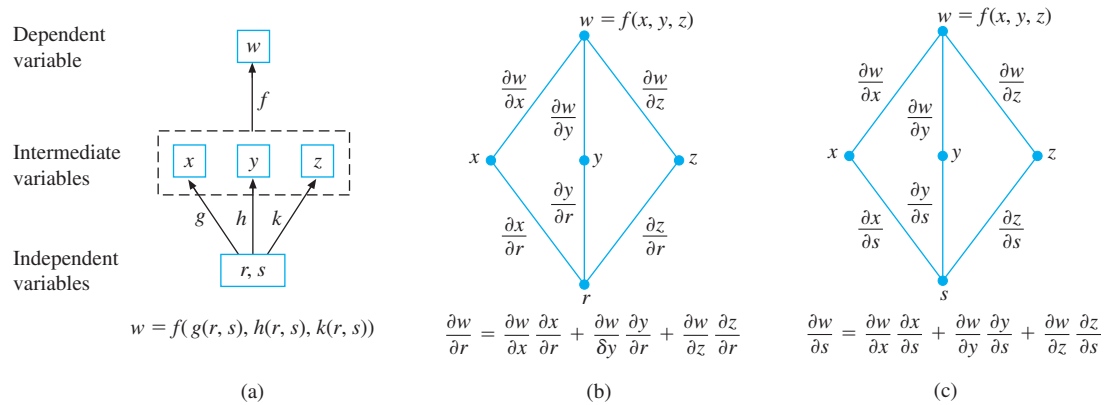

FIGURE 13.22 Composite function and dependency diagrams for Theorem 7.

EXAMPLE 3 Express $\partial w/\partial r$ and $\partial w/\partial s$ in terms of r and s if

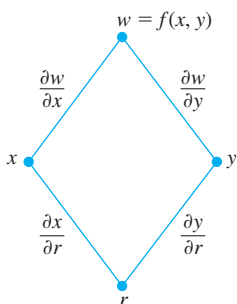

$$w = x + 2y + z^2, \quad x = \frac{r}{s}, \quad y = r^2 + \ln s, \quad z = 2r.$$

Solution Using the formulas in Theorem 7, we find

$$\begin{aligned} \frac{\partial w}{\partial r} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial r} \\ &= (1) \left(\frac{1}{s} \right) + (2)(2r) + (2z)(2) \\ &= \frac{1}{s} + 4r + (4r)(2) = \frac{1}{s} + 12r \quad \text{Substitute for intermediate variable } z. \end{aligned}$$

$$\begin{aligned} \frac{\partial w}{\partial s} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial s} + \frac{\partial w}{\partial z} \frac{\partial z}{\partial s} \\ &= (1) \left(-\frac{r}{s^2} \right) + (2) \left(\frac{1}{s} \right) + (2z)(0) = \frac{2}{s} - \frac{r}{s^2}. \end{aligned}$$

Chain Rule

$$\frac{\partial w}{\partial r} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r}$$

FIGURE 13.23 Dependency diagram for the equation

$$\frac{\partial w}{\partial r} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r}.$$

If f is a function of two intermediate variables instead of three, each equation in Theorem 7 becomes correspondingly one term shorter.

If $w = f(x, y)$, $x = g(r, s)$, and $y = h(r, s)$, then

$$\frac{\partial w}{\partial r} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r} \quad \text{and} \quad \frac{\partial w}{\partial s} = \frac{\partial w}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial s}.$$

Figure 13.23 shows the dependency diagram for the first of these equations. The diagram for the second equation is similar; just replace r with s .

EXAMPLE 4 Express $\partial w/\partial r$ and $\partial w/\partial s$ in terms of r and s if

$$w = x^2 + y^2, \quad x = r - s, \quad y = r + s.$$

Solution The preceding discussion gives the following.

$$\begin{aligned}\frac{\partial w}{\partial r} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial r} & \frac{\partial w}{\partial s} &= \frac{\partial w}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial w}{\partial y} \frac{\partial y}{\partial s} \\ &= (2x)(1) + (2y)(1) & &= (2x)(-1) + (2y)(1) \\ &= 2(r-s) + 2(r+s) & &= -2(r-s) + 2(r+s) \\ &= 4r & &= 4s\end{aligned}$$

Substitute for the intermediate variables.

If f is a function of a single intermediate variable x , our equations are even simpler.

If $w = f(x)$ and $x = g(r, s)$, then

$$\frac{\partial w}{\partial r} = \frac{dw}{dx} \frac{\partial x}{\partial r} \quad \text{and} \quad \frac{\partial w}{\partial s} = \frac{dw}{dx} \frac{\partial x}{\partial s}.$$

In this case, we use the ordinary (single-variable) derivative, dw/dx . The dependency diagram is shown in Figure 13.24.

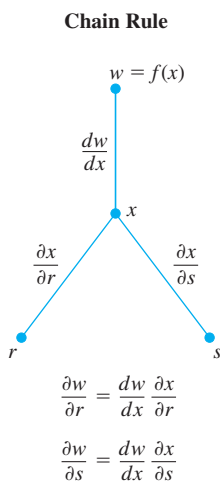

FIGURE 13.24 Dependency diagram for differentiating f as a composite function of r and s with one intermediate variable.

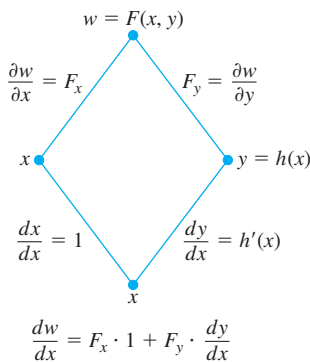

FIGURE 13.25 Dependency diagram for differentiating $w = F(x, y)$ with respect to x . Setting $dw/dx = 0$ leads to a simple computational formula for implicit differentiation (Theorem 8).

Implicit Differentiation Revisited

The two-variable Chain Rule in Theorem 5 leads to a formula that takes some of the algebra out of implicit differentiation. Suppose that

1. The function $F(x, y)$ is differentiable and
2. The equation $F(x, h(x)) = 0$ defines y implicitly as a differentiable function of x , say $y = h(x)$.

Since $w = F(x, h(x)) = 0$, the derivative dw/dx must be zero. Computing the derivative from the Chain Rule (dependency diagram in Figure 13.25), we find

$$\begin{aligned}0 &= \frac{dw}{dx} = F_x \frac{dx}{dx} + F_y \frac{dy}{dx} && \text{Theorem 5 with } t = x \text{ and } f = F \\ &= F_x \cdot 1 + F_y \cdot \frac{dy}{dx}.\end{aligned}$$

If $F_y = \partial w/\partial y \neq 0$, we can solve this equation for dy/dx to get

$$\frac{dy}{dx} = -\frac{F_x}{F_y}.$$

We state this result formally.

THEOREM 8—A Formula for Implicit Differentiation

Suppose that $F(x, y)$ is differentiable and that the equation $F(x, y) = 0$ defines y as a differentiable function of x . Then, at any point where $F_y \neq 0$,

$$\frac{dy}{dx} = -\frac{F_x}{F_y}. \quad (1)$$

EXAMPLE 5 Use Theorem 8 to find dy/dx if $y^2 - x^2 - \sin xy = 0$.

Solution Take $F(x, y) = y^2 - x^2 - \sin xy$. Then

$$\frac{dy}{dx} = -\frac{F_x}{F_y} = -\frac{-2x - y \cos xy}{2y - x \cos xy} = \frac{2x + y \cos xy}{2y - x \cos xy}.$$

This calculation is significantly shorter than a single-variable calculation using implicit differentiation. ■

The result in Theorem 8 is easily extended to three variables. Suppose that the equation $F(x, y, z) = 0$ defines the variable z implicitly as a function $z = f(x, y)$. Then, for all (x, y) in the domain of f , we have $F(x, y, f(x, y)) = 0$. Assuming that F and f are differentiable functions, we can use the Chain Rule to differentiate the equation $F(x, y, z) = 0$ with respect to the independent variable x :

$$\begin{aligned} 0 &= \frac{\partial F}{\partial x} \frac{\partial x}{\partial x} + \frac{\partial F}{\partial y} \frac{\partial y}{\partial x} + \frac{\partial F}{\partial z} \frac{\partial z}{\partial x} \\ &= F_x \cdot 1 + F_y \cdot 0 + F_z \cdot \frac{\partial z}{\partial x}, \end{aligned}$$

y is constant when we differentiate with respect to x .

so

$$F_x + F_z \frac{\partial z}{\partial x} = 0.$$

A similar calculation for differentiating with respect to the independent variable y gives

$$F_y + F_z \frac{\partial z}{\partial y} = 0.$$

Whenever $F_z \neq 0$, we can solve these last two equations for the partial derivatives of $z = f(x, y)$ to obtain

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z}. \quad (2)$$

An important result from advanced calculus, called the **Implicit Function Theorem**, states the conditions for which our results in Equations (2) are valid. If the partial derivatives F_x , F_y , and F_z are continuous throughout an open region R in space containing the point (x_0, y_0, z_0) , and if for some constant c , $F(x_0, y_0, z_0) = c$ and $F_z(x_0, y_0, z_0) \neq 0$, then the equation $F(x, y, z) = c$ defines z implicitly as a differentiable function of x and y near (x_0, y_0, z_0) , and the partial derivatives of z are given by Equations (2).

EXAMPLE 6 Find $\frac{\partial z}{\partial x}$ and $\frac{\partial z}{\partial y}$ at $(0, 0, 0)$ if $x^3 + z^2 + ye^{xz} + z \cos y = 0$.

Solution Let $F(x, y, z) = x^3 + z^2 + ye^{xz} + z \cos y$. Then

$$F_x = 3x^2 + zye^{xz}, \quad F_y = e^{xz} - z \sin y, \quad \text{and} \quad F_z = 2z + xye^{xz} + \cos y.$$

Since $F(0, 0, 0) = 0$, $F_z(0, 0, 0) = 1 \neq 0$, and all first partial derivatives are continuous, the Implicit Function Theorem says that $F(x, y, z) = 0$ defines z as a differentiable function of x and y near the point $(0, 0, 0)$. From Equations (2),

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{3x^2 + zye^{xz}}{2z + xye^{xz} + \cos y} \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{e^{xz} - z \sin y}{2z + xye^{xz} + \cos y}.$$

At $(0, 0, 0)$ we find

$$\frac{\partial z}{\partial x} = -\frac{0}{1} = 0 \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{1}{1} = -1. \quad \blacksquare$$

Functions of Many Variables

We have seen several different forms of the Chain Rule in this section, but each one is just a special case of one general formula. When solving particular problems, it may help to draw the appropriate dependency diagram by placing the dependent variable on top, the intermediate variables in the middle, and the selected independent variable at the bottom. To find the derivative of the dependent variable with respect to the selected independent variable, start at the dependent variable and read down each route of the dependency diagram to the independent variable, calculating and multiplying the derivatives along each route. Then add the products found for the different routes.

In general, suppose that $w = f(x_1, x_2, \dots, x_n)$ is a differentiable function of the intermediate variables x_1, x_2, \dots, x_n (a finite set) and that x_1, x_2, \dots, x_n are differentiable functions of the independent variables t_1, t_2, \dots, t_m (another finite set). Then w is a differentiable function of the variables t_1, t_2, \dots, t_m , and the partial derivatives of w with respect to these variables are given by equations of the form

$$\frac{\partial w}{\partial t_i} = \frac{\partial w}{\partial x_1} \frac{\partial x_1}{\partial t_i} + \frac{\partial w}{\partial x_2} \frac{\partial x_2}{\partial t_i} + \dots + \frac{\partial w}{\partial x_n} \frac{\partial x_n}{\partial t_i} \quad \text{for } i = 1, 2, \dots, m.$$

One way to remember this equation is to think of the right-hand side as the dot product of two n -dimensional vectors:

$$\frac{\partial w}{\partial t_i} = \underbrace{\left\langle \frac{\partial w}{\partial x_1}, \frac{\partial w}{\partial x_2}, \dots, \frac{\partial w}{\partial x_n} \right\rangle}_{\substack{\text{Derivatives of } w \text{ with} \\ \text{respect to the} \\ \text{intermediate variables}}} \cdot \underbrace{\left\langle \frac{\partial x_1}{\partial t_i}, \frac{\partial x_2}{\partial t_i}, \dots, \frac{\partial x_n}{\partial t_i} \right\rangle}_{\substack{\text{Derivatives of the} \\ \text{intermediate variables with} \\ \text{respect to the selected} \\ \text{independent variable}}}.$$

The first vector describes how w changes in various directions, while the second vector indicates the velocity vector of $\mathbf{x}(t_i) = \langle x_1(t_i), x_2(t_i), \dots, x_n(t_i) \rangle$. These concepts will be studied further in the next section.

EXERCISES 13.4

Chain Rule: One Independent Variable

In Exercises 1–6, (a) express dw/dt as a function of t , both by using the Chain Rule and by expressing w in terms of t and differentiating directly with respect to t . Then (b) evaluate dw/dt at the given value of t .

- $w = x^2 + y^2$, $x = \cos t$, $y = \sin t$; $t = \pi$
- $w = x^2 + y^2$, $x = \cos t + \sin t$, $y = \cos t - \sin t$; $t = 0$
- $w = \frac{x}{z} + \frac{y}{z}$, $x = \cos^2 t$, $y = \sin^2 t$, $z = 1/t$; $t = 3$
- $w = \ln(x^2 + y^2 + z^2)$, $x = \cos t$, $y = \sin t$, $z = 4\sqrt{t}$; $t = 3$

- $w = 2ye^x - \ln z$, $x = \ln(t^2 + 1)$, $y = \tan^{-1} t$, $z = e^t$; $t = 1$

- $w = z - \sin xy$, $x = t$, $y = \ln t$, $z = e^{t-1}$; $t = 1$

Chain Rule: Two and Three Independent Variables

In Exercises 7 and 8, (a) express $\partial z/\partial u$ and $\partial z/\partial v$ as functions of u and v both by using the Chain Rule and by expressing z directly in terms of u and v before differentiating. Then (b) evaluate $\partial z/\partial u$ and $\partial z/\partial v$ at the given point (u, v) .

- $z = 4e^x \ln y$, $x = \ln(u \cos v)$, $y = u \sin v$; $(u, v) = (2, \pi/4)$

$$8. z = \tan^{-1}(x/y), \quad x = u \cos v, \quad y = u \sin v;$$

$$(u, v) = (1.3, \pi/6)$$

In Exercises 9 and 10, (a) express $\partial w/\partial u$ and $\partial w/\partial v$ as functions of u and v both by using the Chain Rule and by expressing w directly in terms of u and v before differentiating. Then (b) evaluate $\partial w/\partial u$ and $\partial w/\partial v$ at the given point (u, v) .

$$9. w = xy + yz + xz, \quad x = u + v, \quad y = u - v, \quad z = uv;$$

$$(u, v) = (1/2, 1)$$

$$10. w = \ln(x^2 + y^2 + z^2), \quad x = ue^v \sin u, \quad y = ue^v \cos u,$$

$$z = ue^v; \quad (u, v) = (-2, 0)$$

In Exercises 11 and 12, (a) express $\partial u/\partial x$, $\partial u/\partial y$, and $\partial u/\partial z$ as functions of x , y , and z both by using the Chain Rule and by expressing u directly in terms of x , y , and z before differentiating. Then (b) evaluate $\partial u/\partial x$, $\partial u/\partial y$, and $\partial u/\partial z$ at the given point (x, y, z) .

$$11. u = \frac{p - q}{q - r}, \quad p = x + y + z, \quad q = x - y + z,$$

$$r = x + y - z; \quad (x, y, z) = (\sqrt{3}, 2, 1)$$

$$12. u = e^{qr} \sin^{-1} p, \quad p = \sin x, \quad q = z^2 \ln y, \quad r = 1/z;$$

$$(x, y, z) = (\pi/4, 1/2, -1/2)$$

Using a Dependency Diagram

In Exercises 13–24, draw a dependency diagram and write a Chain Rule formula for each derivative.

$$13. \frac{dz}{dt} \text{ for } z = f(x, y), \quad x = g(t), \quad y = h(t)$$

$$14. \frac{dz}{dt} \text{ for } z = f(u, v, w), \quad u = g(t), \quad v = h(t), \quad w = k(t)$$

$$15. \frac{\partial w}{\partial u} \text{ and } \frac{\partial w}{\partial v} \text{ for } w = h(x, y, z), \quad x = f(u, v), \quad y = g(u, v),$$

$$z = k(u, v)$$

$$16. \frac{\partial w}{\partial x} \text{ and } \frac{\partial w}{\partial y} \text{ for } w = f(r, s, t), \quad r = g(x, y), \quad s = h(x, y),$$

$$t = k(x, y)$$

$$17. \frac{\partial w}{\partial u} \text{ and } \frac{\partial w}{\partial v} \text{ for } w = g(x, y), \quad x = h(u, v), \quad y = k(u, v)$$

$$18. \frac{\partial w}{\partial x} \text{ and } \frac{\partial w}{\partial y} \text{ for } w = g(u, v), \quad u = h(x, y), \quad v = k(x, y)$$

$$19. \frac{\partial z}{\partial t} \text{ and } \frac{\partial z}{\partial s} \text{ for } z = f(x, y), \quad x = g(t, s), \quad y = h(t, s)$$

$$20. \frac{\partial y}{\partial r} \text{ for } y = f(u), \quad u = g(r, s)$$

$$21. \frac{\partial w}{\partial s} \text{ and } \frac{\partial w}{\partial t} \text{ for } w = g(u), \quad u = h(s, t)$$

$$22. \frac{\partial w}{\partial p} \text{ for } w = f(x, y, z, v), \quad x = g(p, q), \quad y = h(p, q),$$

$$z = j(p, q), \quad v = k(p, q)$$

$$23. \frac{\partial w}{\partial r} \text{ and } \frac{\partial w}{\partial s} \text{ for } w = f(x, y), \quad x = g(r), \quad y = h(s)$$

$$24. \frac{\partial w}{\partial s} \text{ for } w = g(x, y), \quad x = h(r, s, t), \quad y = k(r, s, t)$$

Implicit Differentiation

Assuming that the equations in Exercises 25–30 define y as a differentiable function of x , use Theorem 8 to find the value of dy/dx at the given point.

$$25. x^3 - 2y^2 + xy = 0, \quad (1, 1)$$

$$26. xy + y^2 - 3x - 3 = 0, \quad (-1, 1)$$

$$27. x^2 + xy + y^2 - 7 = 0, \quad (1, 2)$$

$$28. xe^y + \sin xy + y - \ln 2 = 0, \quad (0, \ln 2)$$

$$29. (x^3 - y^4)^6 + \ln(x^2 + y) = 1, \quad (-1, 0)$$

$$30. xe^{x^2y} - ye^x = x + y - 2, \quad (1, 1)$$

Find the values of $\partial z/\partial x$ and $\partial z/\partial y$ at the points in Exercises 31–34.

$$31. z^3 - xy + yz + y^3 - 2 = 0, \quad (1, 1, 1)$$

$$32. \frac{1}{x} + \frac{1}{y} + \frac{1}{z} - 1 = 0, \quad (2, 3, 6)$$

$$33. \sin(x + y) + \sin(y + z) + \sin(x + z) = 0, \quad (\pi, \pi, \pi)$$

$$34. xe^y + ye^z + 2 \ln x - 2 - 3 \ln 2 = 0, \quad (1, \ln 2, \ln 3)$$

Finding Partial Derivatives at Specified Points

$$35. \text{Find } \partial w/\partial r \text{ when } r = 1, s = -1 \text{ if } w = (x + y + z)^2,$$

$$x = r - s, y = \cos(r + s), z = \sin(r + s).$$

$$36. \text{Find } \partial w/\partial v \text{ when } u = -1, v = 2 \text{ if } w = xy + \ln z,$$

$$x = v^2/u, y = u + v, z = \cos u.$$

$$37. \text{Find } \partial w/\partial v \text{ when } u = 0, v = 0 \text{ if } w = x^2 + (y/x),$$

$$x = u - 2v + 1, y = 2u + v - 2.$$

$$38. \text{Find } \partial z/\partial u \text{ when } u = 0, v = 1 \text{ if } z = \sin xy + x \sin y,$$

$$x = u^2 + v^2, y = uv.$$

$$39. \text{Find } \partial z/\partial u \text{ and } \partial z/\partial v \text{ when } u = \ln 2, v = 1 \text{ if } z = 5 \tan^{-1} x$$

$$\text{and } x = e^u + \ln v.$$

$$40. \text{Find } \partial z/\partial u \text{ and } \partial z/\partial v \text{ when } u = 1, v = -2 \text{ if } z = \ln q \text{ and}$$

$$q = \sqrt{v+3} \tan^{-1} u.$$

Theory and Examples

$$41. \text{Assume that } w = f(s^3 + t^2) \text{ and } f'(x) = e^x. \text{ Find } \frac{\partial w}{\partial t} \text{ and } \frac{\partial w}{\partial s}.$$

$$42. \text{Assume that } w = f\left(ts^2, \frac{s}{t}\right), \quad \frac{\partial f}{\partial x}(x, y) = xy, \quad \text{and}$$

$$\frac{\partial f}{\partial y}(x, y) = \frac{x^2}{2}. \text{ Find } \frac{\partial w}{\partial t} \text{ and } \frac{\partial w}{\partial s}.$$

$$43. \text{Assume that } z = f(x, y), \quad x = g(t), \quad y = h(t), \quad f_x(2, -1) = 3,$$

$$\text{and } f_y(2, -1) = -2. \text{ If } g(0) = 2, \quad h(0) = -1, \quad g'(0) = 5, \quad \text{and}$$

$$h'(0) = -4, \text{ find } \left. \frac{dz}{dt} \right|_{t=0}.$$

$$44. \text{Assume that } z = f(x, y)^2, \quad x = g(t), \quad y = h(t), \quad f_x(1, 0) = -1,$$

$$f_y(1, 0) = 1, \quad \text{and } f(1, 0) = 2. \text{ If } g(3) = 1, \quad h(3) = 0,$$

$$g'(3) = -3, \quad \text{and } h'(3) = 4, \text{ find } \left. \frac{dz}{dt} \right|_{t=3}.$$

$$45. \text{Assume that } z = f(w), \quad w = g(x, y), \quad x = 2r^3 - s^2, \quad \text{and}$$

$$y = re^s. \text{ If } g_x(2, 1) = -3, \quad g_y(2, 1) = 2, \quad f'(7) = -1, \quad \text{and}$$

$$g(2, 1) = 7, \text{ find } \left. \frac{\partial z}{\partial r} \right|_{r=1, s=0} \text{ and } \left. \frac{\partial z}{\partial s} \right|_{r=1, s=0}.$$

$$46. \text{Assume that } z = \ln(f(w)), \quad w = g(x, y), \quad x = \sqrt{r - s}, \quad \text{and}$$

$$y = r^2s. \text{ If } g_x(2, -9) = -1, \quad g_y(2, -9) = 3, \quad f'(-2) = 2,$$

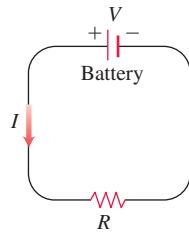

$$f(-2) = 5, \quad \text{and } g(2, -9) = -2, \text{ find } \left. \frac{\partial z}{\partial r} \right|_{r=3, s=-1} \text{ and}$$

$$\left. \frac{\partial z}{\partial s} \right|_{r=3, s=-1}.$$

47. **Changing voltage in a circuit** The voltage V in a circuit that satisfies the law $V = IR$ is slowly dropping as the battery wears out. At the same time, the resistance R is increasing as the resistor heats up. Use the equation

$$\frac{dV}{dt} = \frac{\partial V}{\partial I} \frac{dI}{dt} + \frac{\partial V}{\partial R} \frac{dR}{dt}$$

to find how the current is changing at the instant when $R = 600$ ohms, $I = 0.04$ amp, $dR/dt = 0.5$ ohm/s, and $dV/dt = -0.01$ volt/s.

48. Changing dimensions in a box The lengths a , b , and c of the edges of a rectangular box are changing with time. At the instant in question, $a = 1$ m, $b = 2$ m, $c = 3$ m, $da/dt = db/dt = 1$ m/s, and $dc/dt = -3$ m/s. At what rates are the box's volume V and surface area S changing at that instant? Are the box's interior diagonals increasing in length or decreasing?

49. If $f(u, v, w)$ is differentiable and $u = x - y$, $v = y - z$, and $w = z - x$, show that

$$\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} + \frac{\partial f}{\partial z} = 0.$$

50. Polar coordinates Suppose that we substitute polar coordinates $x = r \cos \theta$ and $y = r \sin \theta$ in a differentiable function $w = f(x, y)$.

a. Show that

$$\frac{\partial w}{\partial r} = f_x \cos \theta + f_y \sin \theta$$

and

$$\frac{1}{r} \frac{\partial w}{\partial \theta} = -f_x \sin \theta + f_y \cos \theta.$$

b. Solve the equations in part (a) to express f_x and f_y in terms of $\partial w / \partial r$ and $\partial w / \partial \theta$.

c. Show that

$$(f_x)^2 + (f_y)^2 = \left(\frac{\partial w}{\partial r}\right)^2 + \frac{1}{r^2} \left(\frac{\partial w}{\partial \theta}\right)^2.$$

51. Laplace equations Show that if $w = f(u, v)$ satisfies the Laplace equation $f_{uu} + f_{vv} = 0$ and if $u = (x^2 - y^2)/2$ and $v = xy$, then w satisfies the Laplace equation $w_{xx} + w_{yy} = 0$.

52. Laplace equations Let $w = f(u) + g(v)$, where $u = x + iy$, $v = x - iy$, and $i = \sqrt{-1}$. Show that w satisfies the Laplace equation $w_{xx} + w_{yy} = 0$ if all the necessary functions are differentiable.

53. Extreme values on a helix Suppose that the partial derivatives of a function $f(x, y, z)$ at points on the helix $x = \cos t$, $y = \sin t$, $z = t$ are

$$f_x = \cos t, \quad f_y = \sin t, \quad f_z = t^2 + t - 2.$$

At what points on the curve, if any, can f take on extreme values?

54. A space curve Let $w = x^2 e^{2y} \cos 3z$. Find the value of dw/dt at the point $(1, \ln 2, 0)$ on the curve $x = \cos t$, $y = \ln(t + 2)$, $z = t$.

55. Temperature on a circle Let $T = f(x, y)$ be the temperature at the point (x, y) on the circle $x = \cos t$, $y = \sin t$, $0 \leq t \leq 2\pi$, and suppose that

$$\frac{\partial T}{\partial x} = 8x - 4y, \quad \frac{\partial T}{\partial y} = 8y - 4x.$$

a. Find where the maximum and minimum temperatures on the circle occur by examining the derivatives dT/dt and d^2T/dt^2 .

b. Suppose that $T = 4x^2 - 4xy + 4y^2$. Find the maximum and minimum values of T on the circle.

56. Temperature on an ellipse Let $T = g(x, y)$ be the temperature at the point (x, y) on the ellipse

$$x = 2\sqrt{2} \cos t, \quad y = \sqrt{2} \sin t, \quad 0 \leq t \leq 2\pi,$$

and suppose that

$$\frac{\partial T}{\partial x} = y, \quad \frac{\partial T}{\partial y} = x.$$

a. Locate the maximum and minimum temperatures on the ellipse by examining dT/dt and d^2T/dt^2 .

b. Suppose that $T = xy - 2$. Find the maximum and minimum values of T on the ellipse.

57. The temperature $T = T(x, y)$ in $^\circ\text{C}$ at point (x, y) satisfies $T_x(1, 2) = 3$ and $T_y(1, 2) = -1$. If $x = e^{2t-2}$ cm and $y = 2 + \ln t$ cm, find the rate at which the temperature T changes when $t = 1$ s.

58. A bug crawls on the surface $z = x^2 - y^2$ directly above a path in the xy -plane given by $x = f(t)$ and $y = g(t)$. If $f(2) = 4$, $f'(2) = -1$, $g(2) = -2$, and $g'(2) = -3$, then at what rate is the bug's elevation z changing when $t = 2$?

Differentiating Integrals Under mild continuity restrictions, it is true that if

$$F(x) = \int_a^b g(t, x) dt,$$

then $F'(x) = \int_a^b g_x(t, x) dt$. Using this fact and the Chain Rule, we can find the derivative of

$$F(x) = \int_a^{f(x)} g(t, x) dt$$

by letting

$$G(u, x) = \int_a^u g(t, x) dt,$$

where $u = f(x)$. Find the derivatives of the functions in Exercises 59 and 60.

59. $F(x) = \int_0^{x^2} \sqrt{t^4 + x^3} dt$

60. $F(x) = \int_{x^2}^1 \sqrt{t^3 + x^2} dt$

61. Water is flowing into a tank in the form of a right-circular cylinder at the rate of $(4/5)\pi \text{ m}^3/\text{min}$. The tank is stretching in such a way that even though it remains cylindrical, its radius is increasing at the rate of 0.002 m/min. How fast is the surface of the water rising when the radius is 2 m and the volume of water in the tank is $20\pi \text{ m}^3$?

62. Suppose f is a differentiable function of x , y , and z and $u = f(x, y, z)$. Then if $x = r \sin \phi \cos \theta$, $y = r \sin \phi \sin \theta$, and $z = r \cos \phi$, express $\partial u / \partial r$, $\partial u / \partial \phi$, and $\partial u / \partial \theta$ in terms of $\partial u / \partial x$, $\partial u / \partial y$, and $\partial u / \partial z$.

63. At a given instant, the length of one leg of a right triangle is 10 m, and it is increasing at the rate of 1 m/min, and the length of the other leg of the right triangle is 12 m, and it is decreasing at the rate of 2 m/min. Find the rate of change of the measure of the acute angle opposite the leg of length 12 m at the given instant.

13.5 Directional Derivatives and Gradient Vectors

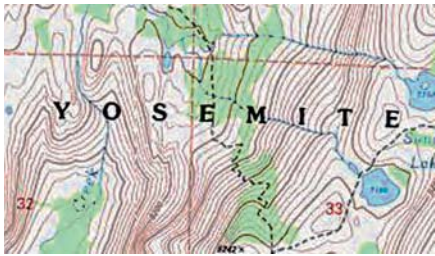

FIGURE 13.26 Contours within Yosemite National Park in California show streams, which follow paths of steepest descent, running perpendicular to the contours. (Source: Yosemite National Park Map from U.S. Geological Survey, <http://www.usgs.gov>)

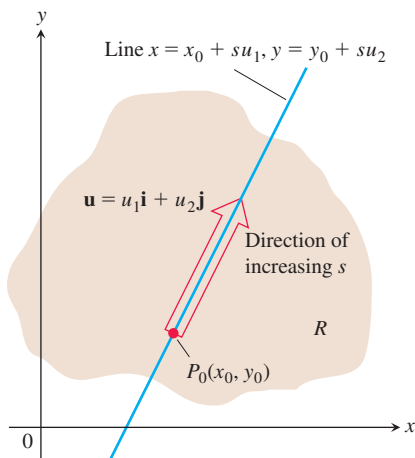

FIGURE 13.27 The rate of change of f in the direction of \mathbf{u} at a point P_0 is the rate at which f changes along this line at P_0 .

If you look at the map (Figure 13.26) showing contours within Yosemite National Park in California, you will notice that the streams flow perpendicular to the contours. The streams are following paths of steepest descent so the waters reach lower elevations as quickly as possible. Therefore, the fastest instantaneous rate of change in a stream's elevation above sea level has a particular direction. In this section, you will see why this direction, called the “downhill” direction, is perpendicular to the contours.

Directional Derivatives in the Plane

We know from Section 13.4 that if $f(x, y)$ is differentiable, then the rate at which f changes with respect to t along a differentiable curve $x = g(t)$, $y = h(t)$ is

$$\frac{df}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt}.$$

At any point $P_0(x_0, y_0) = P_0(g(t_0), h(t_0))$, this equation gives the rate of change of f with respect to increasing t and therefore depends, among other things, on the direction of motion along the curve. If the curve is a straight line and t is the arc length parameter along the line measured from P_0 in the direction of a given unit vector \mathbf{u} , then df/dt is the rate of change of f with respect to distance in its domain in the direction of \mathbf{u} . By varying \mathbf{u} , we find the rates at which f changes with respect to distance as we move through P_0 in different directions. We now define this idea more precisely.

Suppose that the function $f(x, y)$ is defined throughout a region R in the xy -plane, that $P_0(x_0, y_0)$ is a point in R , and that $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j}$ is a unit vector. Then the equations

$$x = x_0 + su_1, \quad y = y_0 + su_2$$

parametrize the line through P_0 parallel to \mathbf{u} . If the parameter s measures arc length from P_0 in the direction of \mathbf{u} , we find the rate of change of f at P_0 in the direction of \mathbf{u} by calculating df/ds at P_0 (Figure 13.27).

DEFINITION The **derivative of f at $P_0(x_0, y_0)$ in the direction of the unit vector $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j}$** is the number

$$\left(\frac{df}{ds}\right)_{\mathbf{u}, P_0} = \lim_{s \rightarrow 0} \frac{f(x_0 + su_1, y_0 + su_2) - f(x_0, y_0)}{s}, \quad (1)$$

provided the limit exists.

The **directional derivative** defined by Equation (1) is also denoted by

$$D_{\mathbf{u}}f(P_0) \quad \text{or} \quad D_{\mathbf{u}}f|_{P_0}.$$

“The derivative of f in the direction of \mathbf{u} , evaluated at P_0 ”

The partial derivatives $f_x(x_0, y_0)$ and $f_y(x_0, y_0)$ are the directional derivatives of f at P_0 in the \mathbf{i} and \mathbf{j} directions. This observation can be seen by comparing Equation (1) to the definitions of the two partial derivatives given in Section 13.3.

EXAMPLE 1 Using the definition, find the derivative of

$$f(x, y) = x^2 + xy$$

at $P_0(1, 2)$ in the direction of the unit vector $\mathbf{u} = (1/\sqrt{2})\mathbf{i} + (1/\sqrt{2})\mathbf{j}$.

Solution Applying the definition in Equation (1), we obtain

$$\begin{aligned}
 \left(\frac{df}{ds}\right)_{\mathbf{u}, P_0} &= \lim_{s \rightarrow 0} \frac{f(x_0 + su_1, y_0 + su_2) - f(x_0, y_0)}{s} && \text{Eq. (1)} \\
 &= \lim_{s \rightarrow 0} \frac{f\left(1 + s \cdot \frac{1}{\sqrt{2}}, 2 + s \cdot \frac{1}{\sqrt{2}}\right) - f(1, 2)}{s} && \text{Substitute.} \\
 &= \lim_{s \rightarrow 0} \frac{\left(1 + \frac{s}{\sqrt{2}}\right)^2 + \left(1 + \frac{s}{\sqrt{2}}\right)\left(2 + \frac{s}{\sqrt{2}}\right) - (1^2 + 1 \cdot 2)}{s} \\
 &= \lim_{s \rightarrow 0} \frac{\left(1 + \frac{2s}{\sqrt{2}} + \frac{s^2}{2}\right) + \left(2 + \frac{3s}{\sqrt{2}} + \frac{s^2}{2}\right) - 3}{s} \\
 &= \lim_{s \rightarrow 0} \frac{\frac{5s}{\sqrt{2}} + s^2}{s} = \lim_{s \rightarrow 0} \left(\frac{5}{\sqrt{2}} + s\right) = \frac{5}{\sqrt{2}}.
 \end{aligned}$$

The rate of change of $f(x, y) = x^2 + xy$ at $P_0(1, 2)$ in the direction \mathbf{u} is $5/\sqrt{2}$. ■

Interpretation of the Directional Derivative

The equation $z = f(x, y)$ represents a surface S in space. If $z_0 = f(x_0, y_0)$, then the point $P(x_0, y_0, z_0)$ lies on S . The vertical plane that passes through P and $P_0(x_0, y_0)$ parallel to \mathbf{u} intersects S in a curve C (Figure 13.28). The rate of change of f in the direction of \mathbf{u} is the slope of the tangent to C at P in the right-handed system formed by the vectors \mathbf{u} and \mathbf{k} .

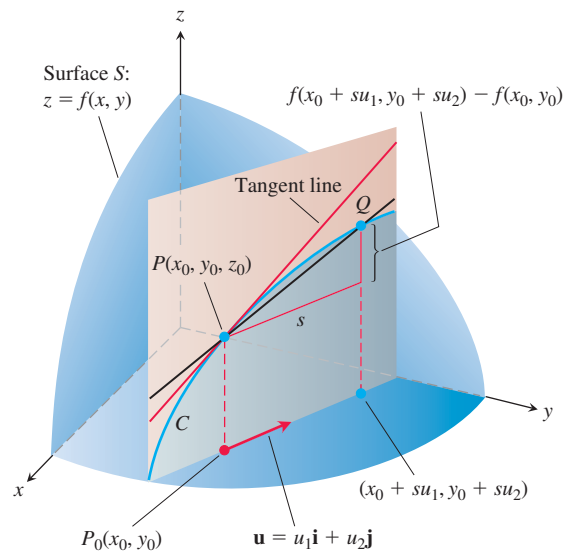

FIGURE 13.28 The slope of the trace curve C at P_0 is $\lim_{Q \rightarrow P} \text{slope}(PQ)$; this is the directional derivative

$$\left(\frac{df}{ds}\right)_{\mathbf{u}, P_0} = D_{\mathbf{u}}f \Big|_{P_0}.$$

When $\mathbf{u} = \mathbf{i}$, the directional derivative at P_0 is $\partial f / \partial x$ evaluated at (x_0, y_0) . When $\mathbf{u} = \mathbf{j}$, the directional derivative at P_0 is $\partial f / \partial y$ evaluated at (x_0, y_0) . The directional derivative generalizes the two partial derivatives. We can now ask for the rate of change of f in any direction \mathbf{u} , not just in the directions \mathbf{i} and \mathbf{j} .

For a physical interpretation of the directional derivative, suppose that $T = f(x, y)$ is the temperature at each point (x, y) over a region in the plane. Then $f(x_0, y_0)$ is the

temperature at the point $P_0(x_0, y_0)$, and $D_{\mathbf{u}}f|_{P_0}$ is the instantaneous rate of change of the temperature at P_0 stepping off in the direction \mathbf{u} .

Calculation and Gradients

We now develop an efficient formula to calculate the directional derivative for a differentiable function f . We begin with the line

$$x = x_0 + su_1, \quad y = y_0 + su_2, \quad (2)$$

through $P_0(x_0, y_0)$, parametrized with the arc length parameter s increasing in the direction of the unit vector $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j}$. Then, by the Chain Rule we find

$$\begin{aligned} \left(\frac{df}{ds}\right)_{\mathbf{u}, P_0} &= \left.\frac{\partial f}{\partial x}\right|_{P_0} \frac{dx}{ds} + \left.\frac{\partial f}{\partial y}\right|_{P_0} \frac{dy}{ds} && \text{Chain Rule for differentiable } f \\ &= \left.\frac{\partial f}{\partial x}\right|_{P_0} u_1 + \left.\frac{\partial f}{\partial y}\right|_{P_0} u_2 && \text{From Eqs. (2), } dx/ds = u_1 \\ &&& \text{and } dy/ds = u_2 \\ &= \underbrace{\left[\left.\frac{\partial f}{\partial x}\right|_{P_0} \mathbf{i} + \left.\frac{\partial f}{\partial y}\right|_{P_0} \mathbf{j}\right]}_{\text{Gradient of } f \text{ at } P_0} \cdot \underbrace{\left[u_1\mathbf{i} + u_2\mathbf{j}\right]}_{\text{Direction } \mathbf{u}}. \end{aligned} \quad (3)$$

Equation (3) says that the derivative of a differentiable function f in the direction of \mathbf{u} at P_0 is the dot product of \mathbf{u} with a special vector, which we now define.

DEFINITION The **gradient vector** (or **gradient**) of $f(x, y)$ is the vector

$$\nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j}.$$

The value of the gradient vector obtained by evaluating the partial derivatives at a point $P_0(x_0, y_0)$ is written

$$\nabla f|_{P_0} \quad \text{or} \quad \nabla f(x_0, y_0).$$

The notation ∇f is read “grad f ” as well as “gradient of f ” and “del f .” The symbol ∇ by itself is read “del.” Another notation for the gradient is $\text{grad } f$. Using the gradient notation, we restate Equation (3) as a theorem.

THEOREM 9—The Directional Derivative Is a Dot Product

If $f(x, y)$ is differentiable in an open region containing $P_0(x_0, y_0)$, then

$$\left(\frac{df}{ds}\right)_{\mathbf{u}, P_0} = \nabla f|_{P_0} \cdot \mathbf{u}, \quad (4)$$

the dot product of the gradient ∇f at P_0 with the vector \mathbf{u} . In brief, $D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u}$.

EXAMPLE 2 Find the derivative of $f(x, y) = xe^y + \cos(xy)$ at the point $(2, 0)$ in the direction of $\mathbf{v} = 3\mathbf{i} - 4\mathbf{j}$.

Solution Recall that the direction of a vector \mathbf{v} is the unit vector obtained by dividing \mathbf{v} by its length:

$$\mathbf{u} = \frac{\mathbf{v}}{|\mathbf{v}|} = \frac{\mathbf{v}}{5} = \frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}.$$

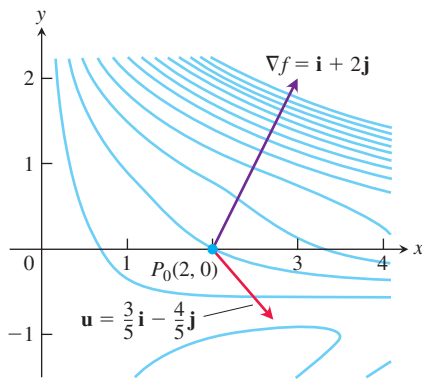

FIGURE 13.29 Picture ∇f as a vector in the domain of f . The figure shows a number of level curves of f . The rate at which f changes at $(2, 0)$ in the direction \mathbf{u} is $\nabla f \cdot \mathbf{u} = -1$, which is the component of ∇f in the direction of unit vector \mathbf{u} (Example 2).

The partial derivatives of f are everywhere continuous and at $(2, 0)$ are given by

$$f_x(2, 0) = (e^y - y \sin(xy)) \Big|_{(2,0)} = e^0 - 0 = 1$$

$$f_y(2, 0) = (xe^y - x \sin(xy)) \Big|_{(2,0)} = 2e^0 - 2 \cdot 0 = 2.$$

The gradient of f at $(2, 0)$ is

$$\nabla f|_{(2,0)} = f_x(2, 0)\mathbf{i} + f_y(2, 0)\mathbf{j} = \mathbf{i} + 2\mathbf{j}$$

(Figure 13.29). The derivative of f at $(2, 0)$ in the direction of \mathbf{v} is therefore

$$\begin{aligned} D_{\mathbf{u}}f|_{(2,0)} &= \nabla f|_{(2,0)} \cdot \mathbf{u} && \text{Eq. (4) with the } D_{\mathbf{u}}f|_{P_0} \text{ notation} \\ &= (\mathbf{i} + 2\mathbf{j}) \cdot \left(\frac{3}{5}\mathbf{i} - \frac{4}{5}\mathbf{j}\right) = \frac{3}{5} - \frac{8}{5} = -1. \end{aligned}$$

Evaluating the dot product in the brief version of Equation (4) gives

$$D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u} = |\nabla f||\mathbf{u}| \cos \theta = |\nabla f| \cos \theta,$$

where θ is the angle between the vectors \mathbf{u} and ∇f , and reveals the following properties.

Properties of the Directional Derivative $D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u} = |\nabla f| \cos \theta$

1. The function f increases most rapidly when $\cos \theta = 1$, which means that $\theta = 0$ and \mathbf{u} is the direction of ∇f . That is, at each point P in its domain, f increases most rapidly in the direction of the gradient vector ∇f at P . The derivative in this direction is

$$D_{\mathbf{u}}f = |\nabla f| \cos(0) = |\nabla f|.$$

2. Similarly, f decreases most rapidly in the direction of $-\nabla f$. The derivative in this direction is $D_{\mathbf{u}}f = |\nabla f| \cos(\pi) = -|\nabla f|$.
3. Any direction \mathbf{u} orthogonal to a gradient $\nabla f \neq 0$ is a direction of zero change in f because θ then equals $\pi/2$ and

$$D_{\mathbf{u}}f = |\nabla f| \cos(\pi/2) = |\nabla f| \cdot 0 = 0.$$

As we discuss later, these properties hold in three dimensions as well as two.

EXAMPLE 3 Find the directions in which $f(x, y) = (x^2/2) + (y^2/2)$

- (a) increases most rapidly at the point $(1, 1)$, and
- (b) decreases most rapidly at $(1, 1)$.
- (c) What are the directions of zero change in f at $(1, 1)$?

Solution

(a) The function increases most rapidly in the direction of ∇f at $(1, 1)$. The gradient there is

$$\nabla f|_{(1,1)} = (x\mathbf{i} + y\mathbf{j}) \Big|_{(1,1)} = \mathbf{i} + \mathbf{j}.$$

Its direction is

$$\mathbf{u} = \frac{\mathbf{i} + \mathbf{j}}{|\mathbf{i} + \mathbf{j}|} = \frac{\mathbf{i} + \mathbf{j}}{\sqrt{(1)^2 + (1)^2}} = \frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j}.$$

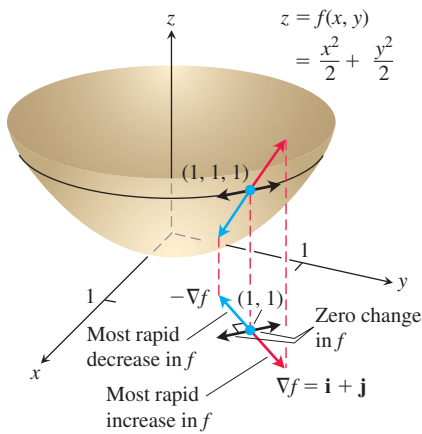

FIGURE 13.30 The direction in which $f(x, y)$ increases most rapidly at $(1, 1)$ is the direction of $\nabla f|_{(1,1)} = \mathbf{i} + \mathbf{j}$. It corresponds to the direction of steepest ascent on the surface at $(1, 1, 1)$ (Example 3).

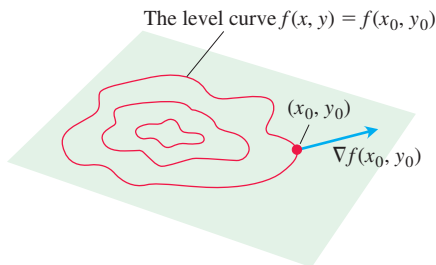

FIGURE 13.31 When it is nonzero, the gradient of a differentiable function of two variables at a point is always normal to the function's level curve through that point.

(b) The function decreases most rapidly in the direction of $-\nabla f$ at $(1, 1)$, which is

$$-\mathbf{u} = -\frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}.$$

(c) The directions of zero change at $(1, 1)$ are the directions orthogonal to ∇f :

$$\mathbf{n} = -\frac{1}{\sqrt{2}}\mathbf{i} + \frac{1}{\sqrt{2}}\mathbf{j} \quad \text{and} \quad -\mathbf{n} = \frac{1}{\sqrt{2}}\mathbf{i} - \frac{1}{\sqrt{2}}\mathbf{j}.$$

See Figure 13.30. ■

Gradients and Tangents to Level Curves

If a differentiable function $f(x, y)$ has a constant value c along a smooth curve $\mathbf{r} = g(t)\mathbf{i} + h(t)\mathbf{j}$ (making the curve part of a level curve of f), then $f(g(t), h(t)) = c$. Differentiating both sides of this equation with respect to t leads to the equations

$$\begin{aligned} \frac{d}{dt}f(g(t), h(t)) &= \frac{d}{dt}(c) \\ \frac{\partial f}{\partial x} \frac{dg}{dt} + \frac{\partial f}{\partial y} \frac{dh}{dt} &= 0 \end{aligned} \quad \text{Chain Rule} \quad (5)$$

$$\underbrace{\left(\frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} \right)}_{\nabla f} \cdot \underbrace{\left(\frac{dg}{dt} \mathbf{i} + \frac{dh}{dt} \mathbf{j} \right)}_{\frac{d\mathbf{r}}{dt}} = 0.$$

Assuming the gradient of f is a nonzero vector, Equation (5) says that ∇f is normal to the tangent vector $d\mathbf{r}/dt$, so it is normal to the curve. This is seen in Figure 13.31.

At every point (x_0, y_0) in the domain of a differentiable function $f(x, y)$ where the gradient of f is a nonzero vector, this vector is normal to the level curve through (x_0, y_0) (Figure 13.31).

Equation (5) validates our observation that streams flow perpendicular to the contours in topographical maps (see Figure 13.26). Since the downflowing stream will reach its destination in the fastest way, it must flow in the direction of the negative gradient vectors from Property 2 for the directional derivative. Equation (5) tells us these directions are perpendicular to the level curves.

This observation also enables us to find equations for tangent lines to level curves. They are the lines normal to the gradients. The line through a point $P_0(x_0, y_0)$ normal to a nonzero vector $\mathbf{N} = A\mathbf{i} + B\mathbf{j}$ has the equation

$$A(x - x_0) + B(y - y_0) = 0$$

(Exercise 39). If \mathbf{N} is the gradient $\nabla f|_{(x_0, y_0)} = f_x(x_0, y_0)\mathbf{i} + f_y(x_0, y_0)\mathbf{j}$, and this gradient is not the zero vector, then this equation gives the following formula.

Equation for the Tangent Line to a Level Curve

$$f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) = 0 \quad (6)$$

EXAMPLE 4 Find an equation for the tangent to the ellipse

$$\frac{x^2}{4} + y^2 = 2$$

(Figure 13.32) at the point $(-2, 1)$.

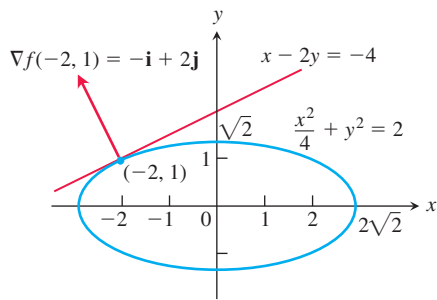

FIGURE 13.32 We can find the tangent to the ellipse $(x^2/4) + y^2 = 2$ by treating the ellipse as a level curve of the function $f(x, y) = (x^2/4) + y^2$ (Example 4).

Solution The ellipse is a level curve of the function

$$f(x, y) = \frac{x^2}{4} + y^2.$$

The gradient of f at $(-2, 1)$ is

$$\nabla f|_{(-2,1)} = \left(\frac{x}{2}\mathbf{i} + 2y\mathbf{j} \right) \Big|_{(-2,1)} = -\mathbf{i} + 2\mathbf{j}.$$

Because this gradient vector is nonzero, the tangent to the ellipse at $(-2, 1)$ is the line

$$(-1)(x + 2) + (2)(y - 1) = 0 \quad \text{Eq. (6)}$$

$$x - 2y = -4. \quad \text{Simplify.}$$

If we know the gradients of two functions f and g , we automatically know the gradients of their sum, difference, constant multiples, product, and quotient. You are asked to establish the following rules in Exercise 40. Notice that these rules have the same form as the corresponding rules for derivatives of single-variable functions.

Algebra Rules for Gradients

1. *Sum Rule:* $\nabla(f + g) = \nabla f + \nabla g$
 2. *Difference Rule:* $\nabla(f - g) = \nabla f - \nabla g$
 3. *Constant Multiple Rule:* $\nabla(kf) = k\nabla f$ (any number k)
 4. *Product Rule:* $\nabla(fg) = f\nabla g + g\nabla f$
 5. *Quotient Rule:* $\nabla\left(\frac{f}{g}\right) = \frac{g\nabla f - f\nabla g}{g^2}$
- Scalar multipliers on left of gradients

EXAMPLE 5 We illustrate two of the rules with

$$\begin{aligned} f(x, y) &= x - y & g(x, y) &= 3y \\ \nabla f &= \mathbf{i} - \mathbf{j} & \nabla g &= 3\mathbf{j}. \end{aligned}$$

We have

$$1. \nabla(f - g) = \nabla(x - 4y) = \mathbf{i} - 4\mathbf{j} = \nabla f - \nabla g \quad \text{Rule 2}$$

$$2. \nabla(fg) = \nabla(3xy - 3y^2) = 3y\mathbf{i} + (3x - 6y)\mathbf{j}$$

and

$$\begin{aligned} f\nabla g + g\nabla f &= (x - y)3\mathbf{j} + 3y(\mathbf{i} - \mathbf{j}) && \text{Substitute.} \\ &= 3y\mathbf{i} + (3x - 6y)\mathbf{j}. && \text{Simplify.} \end{aligned}$$

We have therefore verified that for this example, $\nabla(fg) = f\nabla g + g\nabla f$. ■

Functions of Three Variables

For a differentiable function $f(x, y, z)$ and a unit vector $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ in space, we have

$$\nabla f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}$$

and

$$D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u} = \frac{\partial f}{\partial x}u_1 + \frac{\partial f}{\partial y}u_2 + \frac{\partial f}{\partial z}u_3.$$

The directional derivative can once again be written in the form

$$D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u} = |\nabla f| |\mathbf{u}| \cos \theta = |\nabla f| \cos \theta,$$

so the properties listed earlier for functions of two variables extend to three variables. At any given point, f increases most rapidly in the direction of ∇f and decreases most rapidly in the direction of $-\nabla f$. In any direction orthogonal to ∇f , the derivative is zero.

EXAMPLE 6

- (a) Find the derivative of $f(x, y, z) = x^3 - xy^2 - z$ at $P_0(1, 1, 0)$ in the direction of $\mathbf{v} = 2\mathbf{i} - 3\mathbf{j} + 6\mathbf{k}$.
- (b) In what directions does f change most rapidly at P_0 , and what are the rates of change in these directions?

Solution

- (a) The direction of \mathbf{v} is obtained by dividing \mathbf{v} by its length:

$$|\mathbf{v}| = \sqrt{(2)^2 + (-3)^2 + (6)^2} = \sqrt{49} = 7$$

$$\mathbf{u} = \frac{\mathbf{v}}{|\mathbf{v}|} = \frac{2}{7}\mathbf{i} - \frac{3}{7}\mathbf{j} + \frac{6}{7}\mathbf{k}.$$

The partial derivatives of f at P_0 are

$$f_x = (3x^2 - y^2) \Big|_{(1,1,0)} = 2, \quad f_y = -2xy \Big|_{(1,1,0)} = -2, \quad f_z = -1 \Big|_{(1,1,0)} = -1.$$

The gradient of f at P_0 is

$$\nabla f \Big|_{(1,1,0)} = 2\mathbf{i} - 2\mathbf{j} - \mathbf{k}.$$

The derivative of f at P_0 in the direction of \mathbf{v} is therefore

$$D_{\mathbf{u}}f \Big|_{(1,1,0)} = \nabla f \Big|_{(1,1,0)} \cdot \mathbf{u} = (2\mathbf{i} - 2\mathbf{j} - \mathbf{k}) \cdot \left(\frac{2}{7}\mathbf{i} - \frac{3}{7}\mathbf{j} + \frac{6}{7}\mathbf{k} \right)$$

$$= \frac{4}{7} + \frac{6}{7} - \frac{6}{7} = \frac{4}{7}.$$

- (b) The function increases most rapidly in the direction of $\nabla f = 2\mathbf{i} - 2\mathbf{j} - \mathbf{k}$ and decreases most rapidly in the direction of $-\nabla f$. The rates of change in the directions are, respectively,

$$|\nabla f| = \sqrt{(2)^2 + (-2)^2 + (-1)^2} = \sqrt{9} = 3 \quad \text{and} \quad -|\nabla f| = -3. \quad \blacksquare$$

Functions of More Than Three Variables

The gradient of a differentiable function of n variables $f(x_1, x_2, \dots, x_n)$ is

$$\nabla f = \left\langle \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \dots, \frac{\partial f}{\partial x_n} \right\rangle.$$

If $\mathbf{u} = \langle u_1, u_2, \dots, u_n \rangle$ is an n -dimensional vector such that $u_1^2 + u_2^2 + \dots + u_n^2 = 1$ (so \mathbf{u} is a unit vector since $|\mathbf{u}| = \sqrt{u_1^2 + u_2^2 + \dots + u_n^2} = 1$), then the directional derivative of f in the direction of \mathbf{u} is

$$D_{\mathbf{u}}f = \nabla f \cdot \mathbf{u} = \frac{\partial f}{\partial x_1} u_1 + \frac{\partial f}{\partial x_2} u_2 + \dots + \frac{\partial f}{\partial x_n} u_n.$$

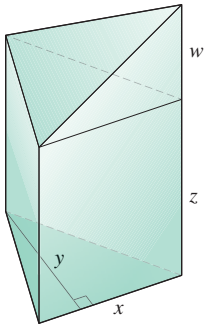

FIGURE 13.33 A tetrahedron on top of a triangular prism (Example 7).

EXAMPLE 7 The volume of the solid shown in Figure 13.33 consisting of a tetrahedron on top of a triangular prism is given by $f(x, y, z, w) = \frac{xy}{2} \left(z + \frac{w}{3} \right)$.

- (a) Calculate the derivative of $f(x, y, z, w)$ at the point $P_0(6, 5, 8, 4)$ in the direction of $\mathbf{v} = \langle 1, -1, -1, 1 \rangle$.
 (b) What is the geometric significance of the value obtained in part (a)?

Solution

- (a) The direction of \mathbf{v} is the unit vector

$$\begin{aligned} \mathbf{u} &= \frac{1}{|\mathbf{v}|} \mathbf{v} \\ &= \frac{1}{\sqrt{1^2 + (-1)^2 + (-1)^2 + 1^2}} \langle 1, -1, -1, 1 \rangle \\ &= \frac{1}{2} \langle 1, -1, -1, 1 \rangle \\ &= \left\langle \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}, \frac{1}{2} \right\rangle. \end{aligned}$$

The four partial derivatives of f at the point P_0 are

$$\begin{aligned} f_x &= \frac{y}{2} \left(z + \frac{w}{3} \right) \Big|_{(6,5,8,4)} = \frac{70}{3}, \\ f_y &= \frac{x}{2} \left(z + \frac{w}{3} \right) \Big|_{(6,5,8,4)} = 28, \\ f_z &= \frac{xy}{2} \Big|_{(6,5,8,4)} = 15, \\ f_w &= \frac{xy}{6} \Big|_{(6,5,8,4)} = 5. \end{aligned}$$

The gradient of f at P_0 is

$$\nabla f|_{(6,5,8,4)} = \left\langle \frac{70}{3}, 28, 15, 5 \right\rangle.$$

The derivative of f at $(6, 5, 8, 4)$ in the direction of \mathbf{v} is

$$\begin{aligned} D_{\mathbf{u}}f|_{P_0} &= \nabla f|_{P_0} \cdot \mathbf{u} \\ &= \left\langle \frac{70}{3}, 28, 15, 5 \right\rangle \cdot \left\langle \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}, \frac{1}{2} \right\rangle \\ &= \left(\frac{70}{3} \right) \left(\frac{1}{2} \right) + (28) \left(-\frac{1}{2} \right) + (15) \left(-\frac{1}{2} \right) + (5) \left(\frac{1}{2} \right) \\ &= -\frac{22}{3}. \end{aligned}$$

- (b) Geometrically, this means that if the dimensions are $x = 6, y = 5, z = 8$, and $w = 4$, and the dimensions are changed by moving at unit speed so that x and w increase at the same rate while both y and z decrease at that rate, then the volume of the solid decreases at the rate of $7 \frac{1}{3}$. ■

The Chain Rule for Paths

If $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$ is a smooth path C , and $w = f(\mathbf{r}(t))$ is a scalar function evaluated along C , then according to the Chain Rule, Theorem 6 in Section 13.4,

$$\frac{dw}{dt} = \frac{\partial w}{\partial x} \frac{dx}{dt} + \frac{\partial w}{\partial y} \frac{dy}{dt} + \frac{\partial w}{\partial z} \frac{dz}{dt}.$$

The partial derivatives on the right-hand side of the above equation are evaluated along the curve $\mathbf{r}(t)$, and the derivatives of the intermediate variables are evaluated at t . If we express this equation using vector notation, we have

The Derivative Along a Path

$$\frac{d}{dt}f(\mathbf{r}(t)) = \nabla f(\mathbf{r}(t)) \cdot \mathbf{r}'(t). \quad (7)$$

What Equation (7) says is that the derivative of the composite function $f(\mathbf{r}(t))$ is the “derivative” (gradient) of the outside function f , evaluated at $\mathbf{r}(t)$, “times” (dot product) the derivative of the inside function \mathbf{r} . This is analogous to the “Outside-Inside” Rule for derivatives of composite functions studied in Section 3.6. That is, the multivariable Chain Rule for paths has exactly *the same form* as the rule for single-variable differential calculus when appropriate interpretations are given to the meanings of the terms and operations involved.

EXERCISES 13.5

Calculating Gradients

In Exercises 1–6, find the gradient of the function at the given point. Then sketch the gradient, together with the level curve that passes through the point.

- $f(x, y) = y - x$, $(2, 1)$
- $f(x, y) = \ln(x^2 + y^2)$, $(1, 1)$
- $g(x, y) = xy^2$, $(2, -1)$
- $g(x, y) = \frac{x^2}{2} - \frac{y^2}{2}$, $(\sqrt{2}, 1)$
- $f(x, y) = \sqrt{2x + 3y}$, $(-1, 2)$
- $f(x, y) = \tan^{-1} \frac{\sqrt{x}}{y}$, $(4, -2)$

In Exercises 7–10, find ∇f at the given point.

- $f(x, y, z) = x^2 + y^2 - 2z^2 + z \ln x$, $(1, 1, 1)$
- $f(x, y, z) = 2z^3 - 3(x^2 + y^2)z + \arctan xz$, $(1, 1, 1)$
- $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2} + \ln(xyz)$, $(-1, 2, -2)$
- $f(x, y, z) = e^{x+y} \cos z + (y + 1) \arcsin x$, $(0, 0, \pi/6)$

Finding Directional Derivatives

In Exercises 11–18, find the derivative of the function at P_0 in the direction of \mathbf{v} .

- $f(x, y) = 2xy - 3y^2$, $P_0(5, 5)$, $\mathbf{v} = 4\mathbf{i} + 3\mathbf{j}$
- $f(x, y) = 2x^2 + y^2$, $P_0(-1, 1)$, $\mathbf{v} = 3\mathbf{i} - 4\mathbf{j}$
- $g(x, y) = \frac{x - y}{xy + 2}$, $P_0(1, -1)$, $\mathbf{v} = 12\mathbf{i} + 5\mathbf{j}$
- $h(x, y) = \arctan(y/x) + \sqrt{3} \arcsin(xy/2)$, $P_0(1, 1)$, $\mathbf{v} = 3\mathbf{i} - 2\mathbf{j}$
- $f(x, y, z) = xy + yz + zx$, $P_0(1, -1, 2)$, $\mathbf{v} = 3\mathbf{i} + 6\mathbf{j} - 2\mathbf{k}$
- $f(x, y, z) = x^2 + 2y^2 - 3z^2$, $P_0(1, 1, 1)$, $\mathbf{v} = \mathbf{i} + \mathbf{j} + \mathbf{k}$
- $g(x, y, z) = 3e^x \cos yz$, $P_0(0, 0, 0)$, $\mathbf{v} = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$
- $h(x, y, z) = \cos xy + e^{yz} + \ln xz$, $P_0(1, 0, 1/2)$, $\mathbf{v} = \mathbf{i} + 2\mathbf{j} + 2\mathbf{k}$

In Exercises 19–24, find the directions in which the functions increase most rapidly, and the directions in which they decrease most rapidly, at P_0 . Then find the derivatives of the functions in these directions.

- $f(x, y) = x^2 + xy + y^2$, $P_0(-1, 1)$

- $f(x, y) = x^2y + e^{xy} \sin y$, $P_0(1, 0)$
- $f(x, y, z) = (x/y) - yz$, $P_0(4, 1, 1)$
- $g(x, y, z) = xe^y + z^2$, $P_0(1, \ln 2, 1/2)$
- $f(x, y, z) = \ln xy + \ln yz + \ln xz$, $P_0(1, 1, 1)$
- $h(x, y, z) = \ln(x^2 + y^2 - 1) + y + 6z$, $P_0(1, 1, 0)$

Tangent Lines to Level Curves

In Exercises 25–28, sketch the curve $f(x, y) = c$, together with ∇f and the tangent line at the given point. Then write an equation for the tangent line.

- $x^2 + y^2 = 4$, $(\sqrt{2}, \sqrt{2})$
- $x^2 - y = 1$, $(\sqrt{2}, 1)$
- $xy = -4$, $(2, -2)$
- $x^2 - xy + y^2 = 7$, $(-1, 2)$

Theory and Examples

- Let $f(x, y) = x^2 - xy + y^2 - y$. Find the directions \mathbf{u} and the values of $D_{\mathbf{u}}f(1, -1)$ for which
 - $D_{\mathbf{u}}f(1, -1)$ is largest
 - $D_{\mathbf{u}}f(1, -1)$ is smallest
 - $D_{\mathbf{u}}f(1, -1) = 0$
 - $D_{\mathbf{u}}f(1, -1) = 4$
 - $D_{\mathbf{u}}f(1, -1) = -3$
- Let $f(x, y) = \frac{(x - y)}{(x + y)}$. Find the directions \mathbf{u} and the values of $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right)$ for which
 - $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right)$ is largest
 - $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right)$ is smallest
 - $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right) = 0$
 - $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right) = -2$
 - $D_{\mathbf{u}}f\left(-\frac{1}{2}, \frac{3}{2}\right) = 1$
- Zero directional derivative** In what direction is the derivative of $f(x, y) = xy + y^2$ at $P(3, 2)$ equal to zero?
- Zero directional derivative** In what directions is the derivative of $f(x, y) = (x^2 - y^2)/(x^2 + y^2)$ at $P(1, 1)$ equal to zero?
- Is there a direction \mathbf{u} in which the rate of change of $f(x, y) = x^2 - 3xy + 4y^2$ at $P(1, 2)$ equals 14? Give reasons for your answer.

- 34. Changing temperature along a circle** Is there a direction \mathbf{u} in which the rate of change of the temperature function $T(x, y, z) = 2xy - yz$ (temperature in degrees Celsius, distance in meters) at $P(1, -1, 1)$ is $-3^\circ\text{C}/\text{m}$? Give reasons for your answer.
- 35.** The derivative of $f(x, y)$ at $P_0(1, 2)$ in the direction of $\mathbf{i} + \mathbf{j}$ is $2\sqrt{2}$ and in the direction of $-2\mathbf{j}$ is -3 . What is the derivative of f in the direction of $-\mathbf{i} - 2\mathbf{j}$? Give reasons for your answer.
- 36.** The derivative of $f(x, y, z)$ at a point P is greatest in the direction of $\mathbf{v} = \mathbf{i} + \mathbf{j} - \mathbf{k}$. In this direction, the value of the derivative is $2\sqrt{3}$.
- What is ∇f at P ? Give reasons for your answer.
 - What is the derivative of f at P in the direction of $\mathbf{i} + \mathbf{j}$?
- 37. Directional derivatives and scalar components** How is the derivative of a differentiable function $f(x, y, z)$ at a point P_0 in the direction of a unit vector \mathbf{u} related to the scalar component of $\nabla f|_{P_0}$ in the direction of \mathbf{u} ? Give reasons for your answer.
- 38. Directional derivatives and partial derivatives** Assuming that the necessary derivatives of $f(x, y, z)$ are defined, how are $D_{\mathbf{i}}f$, $D_{\mathbf{j}}f$, and $D_{\mathbf{k}}f$ related to f_x , f_y , and f_z ? Give reasons for your answer.
- 39. Lines in the xy -plane** Show that $A(x - x_0) + B(y - y_0) = 0$ is an equation for the line in the xy -plane through the point (x_0, y_0) normal to the vector $\mathbf{N} = A\mathbf{i} + B\mathbf{j}$.
- 40. The algebra rules for gradients** Given a constant k and the gradients

$$\nabla f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k},$$

$$\nabla g = \frac{\partial g}{\partial x}\mathbf{i} + \frac{\partial g}{\partial y}\mathbf{j} + \frac{\partial g}{\partial z}\mathbf{k},$$

establish the algebra rules for gradients.

In Exercises 41–44, find a parametric equation for the line that is perpendicular to the graph of the given equation at the given point.

- 41.** $x^2 + y^2 = 25$, $(-3, 4)$
- 42.** $x^2 + xy + y^2 = 3$, $(2, -1)$
- 43.** $x^2 + y^2 + z^2 = 14$, $(3, -2, 1)$
- 44.** $z = x^3 - xy^2$, $(-1, 1, 0)$

Gradients and Directional Derivatives for Functions of More Than Three Variables

In Exercises 45–48, find ∇f at the given point.

- 45.** $f(x, y, z, w) = \frac{x\sqrt{y}}{w} - x^2z^3$, $(2, 4, -1, 3)$
- 46.** $f(x, y, z, w) = x^3 \sin y + w^2 \cos z$, $(-2, \pi, 0, 3)$
- 47.** $f(x, y, z, s, t) = e^y \ln s + x^2t \tan z$, $(3, 0, \frac{\pi}{4}, e, 5)$
- 48.** $f(x, y, z, s, t) = \frac{(x^2 + y^2) \arctan t}{z^2s}$, $(-2, 1, -1, 2, 1)$

In Exercises 49–52, find the derivative of the function at P_0 in the direction of \mathbf{v} .

- 49.** $f(x, y, z, w) = \frac{w \ln x}{y^2z^3}$, $P_0(e^2, -2, 1, -3)$, $\mathbf{v} = \langle -1, 2, -2, 4 \rangle$
- 50.** $f(x, y, z, w) = (x - y)^2 + e^{z-w}$, $P_0(4, 2, 3, 1)$, $\mathbf{v} = \langle 1, 0, -2, 2 \rangle$
- 51.** $f(x, y, z, s, t) = s \arcsin(x + y) - t^2 \arctan(x - z)$, $P_0(0, \frac{1}{2}, -1, 1, -1)$, $\mathbf{v} = \langle -1, 1, 0, 3, 5 \rangle$
- 52.** $f(x, y, z, s, t) = \sin tx + \cos sy - \frac{st}{z}$, $P_0(\frac{\pi}{4}, \frac{\pi}{6}, 2, 5, 1)$, $\mathbf{v} = \langle -3, 2, -2, 2, 2 \rangle$

13.6 Tangent Planes and Differentials

In single-variable differential calculus, we saw how the derivative defined the tangent line to the graph of a differentiable function at a point on the graph. The tangent line then provided for a linearization of the function at the point. In this section, we will see analogously how the gradient defines the *tangent plane* to the level surface of a function $w = f(x, y, z)$ at a point on the surface. The tangent plane then provides for a linearization of f at the point and defines the total differential of the function.

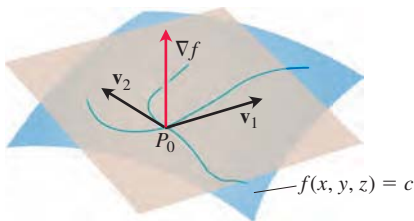

FIGURE 13.34 The gradient ∇f is orthogonal to the velocity vector of every smooth curve in the surface through P_0 . The velocity vectors at P_0 therefore lie in a common plane, which we call the tangent plane at P_0 .

Tangent Planes and Normal Lines

If $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$ is a smooth curve on the level surface $f(x, y, z) = c$ of a differentiable function f , we found in Equation (7) of the last section that

$$\frac{d}{dt}f(\mathbf{r}(t)) = \nabla f(\mathbf{r}(t)) \cdot \mathbf{r}'(t).$$

Since f is constant along the curve \mathbf{r} , the derivative on the left-hand side of the equation is 0, so the gradient ∇f is orthogonal to the curve's velocity vector \mathbf{r}' .

Now let us restrict our attention to the curves that pass through a point P_0 (Figure 13.34). All the velocity vectors at P_0 are orthogonal to ∇f at P_0 , so the curves' tangent lines all lie in the plane through P_0 normal to ∇f . (assuming it is a nonzero vector). We now define this plane.

DEFINITIONS The **tangent plane** to the level surface $f(x, y, z) = c$ of a differentiable function f at a point P_0 where the gradient is not zero is the plane through P_0 normal to $\nabla f|_{P_0}$.

The **normal line** of the surface at P_0 is the line through P_0 parallel to $\nabla f|_{P_0}$.

The results of Section 11.5 imply that the tangent plane and normal line satisfy the following equations, as long as the gradient at the point P_0 is not the zero vector.

Tangent Plane to $f(x, y, z) = c$ at $P_0(x_0, y_0, z_0)$

$$f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0) = 0 \quad (1)$$

Normal Line to $f(x, y, z) = c$ at $P_0(x_0, y_0, z_0)$

$$x = x_0 + f_x(P_0)t, \quad y = y_0 + f_y(P_0)t, \quad z = z_0 + f_z(P_0)t \quad (2)$$

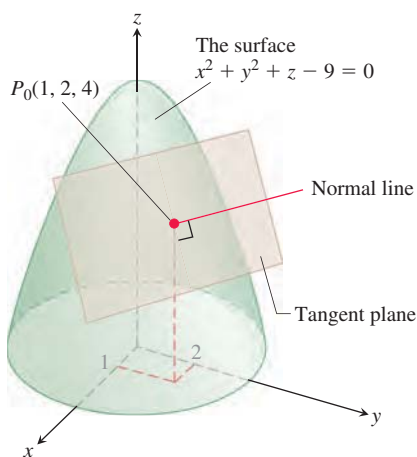

FIGURE 13.35 The tangent plane and normal line to this level surface at P_0 (Example 1).

EXAMPLE 1 Find the tangent plane and normal line of the level surface

$$f(x, y, z) = x^2 + y^2 + z - 9 = 0 \quad \text{A circular paraboloid}$$

at the point $P_0(1, 2, 4)$.

Solution The surface is shown in Figure 13.35.

The tangent plane is the plane through P_0 perpendicular to the gradient of f at P_0 . The gradient is

$$\nabla f|_{P_0} = (2x\mathbf{i} + 2y\mathbf{j} + \mathbf{k}) \Big|_{(1,2,4)} = 2\mathbf{i} + 4\mathbf{j} + \mathbf{k}.$$

The tangent plane is therefore the plane

$$2(x - 1) + 4(y - 2) + (z - 4) = 0, \quad \text{or} \quad 2x + 4y + z = 14.$$

The line normal to the surface at P_0 is

$$x = 1 + 2t, \quad y = 2 + 4t, \quad z = 4 + t. \quad \blacksquare$$

To find an equation for the plane tangent to a smooth surface $z = f(x, y)$ at a point $P_0(x_0, y_0, z_0)$ where $z_0 = f(x_0, y_0)$, we first observe that the equation $z = f(x, y)$ is equivalent to $f(x, y) - z = 0$. The surface $z = f(x, y)$ is therefore the zero level surface of the function $F(x, y, z) = f(x, y) - z$. The partial derivatives of F are

$$F_x = \frac{\partial}{\partial x}(f(x, y) - z) = f_x - 0 = f_x$$

$$F_y = \frac{\partial}{\partial y}(f(x, y) - z) = f_y - 0 = f_y$$

$$F_z = \frac{\partial}{\partial z}(f(x, y) - z) = 0 - 1 = -1.$$

The formula

$$F_x(P_0)(x - x_0) + F_y(P_0)(y - y_0) + F_z(P_0)(z - z_0) = 0$$

for the plane tangent to the level surface at P_0 therefore reduces to

$$f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) - (z - z_0) = 0.$$

Plane Tangent to a Surface $z = f(x, y)$ at $(x_0, y_0, f(x_0, y_0))$

The plane tangent to the surface $z = f(x, y)$ of a differentiable function f at the point $P_0(x_0, y_0, z_0) = (x_0, y_0, f(x_0, y_0))$ is

$$f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) - (z - z_0) = 0. \quad (3)$$

EXAMPLE 2 Find the plane tangent to the surface $z = x \cos y - ye^x$ at $(0, 0, 0)$.

Solution We calculate the partial derivatives of $f(x, y) = x \cos y - ye^x$ and use Equation (3):

$$f_x(0, 0) = (\cos y - ye^x) \Big|_{(0,0)} = 1 - 0 \cdot 1 = 1$$

$$f_y(0, 0) = (-x \sin y - e^x) \Big|_{(0,0)} = 0 - 1 = -1.$$

The tangent plane is therefore

$$1 \cdot (x - 0) - 1 \cdot (y - 0) - (z - 0) = 0, \quad \text{Eq. (3)}$$

or

$$x - y - z = 0. \quad \blacksquare$$

EXAMPLE 3 The surfaces

$$f(x, y, z) = x^2 + y^2 - 2 = 0 \quad \text{A cylinder}$$

and

$$g(x, y, z) = x + z - 4 = 0 \quad \text{A plane}$$

meet in an ellipse E (Figure 13.36). Find parametric equations for the line tangent to E at the point $P_0(1, 1, 3)$.

Solution The tangent line is orthogonal to both ∇f and ∇g at P_0 , and therefore parallel to $\mathbf{v} = \nabla f \times \nabla g$. The components of \mathbf{v} and the coordinates of P_0 give us equations for the line. We have

$$\nabla f|_{(1,1,3)} = (2x\mathbf{i} + 2y\mathbf{j}) \Big|_{(1,1,3)} = 2\mathbf{i} + 2\mathbf{j}$$

$$\nabla g|_{(1,1,3)} = (\mathbf{i} + \mathbf{k}) \Big|_{(1,1,3)} = \mathbf{i} + \mathbf{k}$$

$$\mathbf{v} = (2\mathbf{i} + 2\mathbf{j}) \times (\mathbf{i} + \mathbf{k}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 2 & 0 \\ 1 & 0 & 1 \end{vmatrix} = 2\mathbf{i} - 2\mathbf{j} - 2\mathbf{k}.$$

The tangent line to the ellipse of intersection is

$$x = 1 + 2t, \quad y = 1 - 2t, \quad z = 3 - 2t. \quad \blacksquare$$

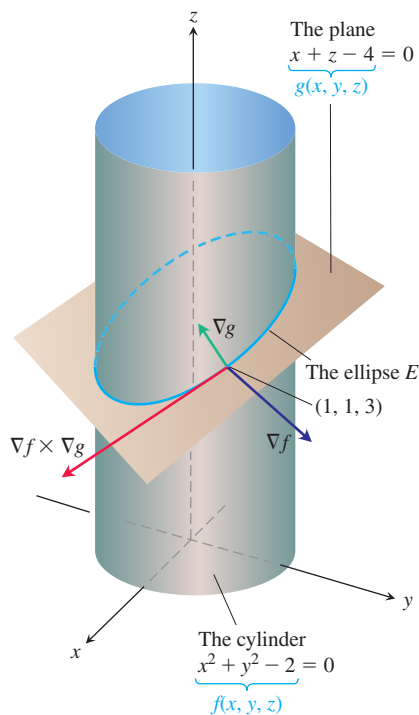

FIGURE 13.36 This cylinder and plane intersect in an ellipse E (Example 3).

Estimating Change in a Specific Direction

The directional derivative plays a role similar to that of an ordinary derivative when we want to estimate how much the value of a function f changes if we move a small distance ds from a point P_0 to another point nearby. If f were a function of a single variable, we would have

$$df = f'(P_0) ds. \quad \text{Ordinary derivative} \times \text{increment}$$

For a function of two or more variables, we use the formula

$$df = (\nabla f|_{P_0} \cdot \mathbf{u}) ds, \quad \text{Directional derivative} \times \text{increment}$$

where \mathbf{u} is the direction of the motion away from P_0 .

Estimating the Change in f in a Direction \mathbf{u}

To estimate the change in the value of a differentiable function f when we move a small distance ds from a point P_0 in a particular direction \mathbf{u} , use this formula:

$$df = \underbrace{(\nabla f|_{P_0} \cdot \mathbf{u})}_{\text{Directional derivative}} \underbrace{ds}_{\text{Distance increment}}$$

EXAMPLE 4 Estimate how much the value of

$$f(x, y, z) = y \sin x + 2yz$$

will change if the point $P(x, y, z)$ moves 0.1 unit from $P_0(0, 1, 0)$ straight toward $P_1(2, 2, -2)$.

Solution We first find the derivative of f at P_0 in the direction of the vector $\overrightarrow{P_0P_1} = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$. The direction of this vector is

$$\mathbf{u} = \frac{\overrightarrow{P_0P_1}}{|\overrightarrow{P_0P_1}|} = \frac{2\mathbf{i} + \mathbf{j} - 2\mathbf{k}}{3} = \frac{2}{3}\mathbf{i} + \frac{1}{3}\mathbf{j} - \frac{2}{3}\mathbf{k}.$$

The gradient of f at P_0 is

$$\nabla f|_{(0,1,0)} = ((y \cos x)\mathbf{i} + (\sin x + 2z)\mathbf{j} + 2y\mathbf{k}) \Big|_{(0,1,0)} = \mathbf{i} + 2\mathbf{k}.$$

Therefore,

$$\nabla f|_{P_0} \cdot \mathbf{u} = (\mathbf{i} + 2\mathbf{k}) \cdot \left(\frac{2}{3}\mathbf{i} + \frac{1}{3}\mathbf{j} - \frac{2}{3}\mathbf{k} \right) = \frac{2}{3} - \frac{4}{3} = -\frac{2}{3}.$$

The change df in f that results from moving $ds = 0.1$ unit away from P_0 in the direction of \mathbf{u} is approximately

$$df = (\nabla f|_{P_0} \cdot \mathbf{u})(ds) = \left(-\frac{2}{3}\right)(0.1) \approx -0.067 \text{ unit.}$$

See Figure 13.37. ■

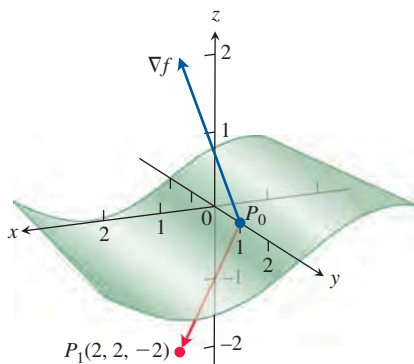

FIGURE 13.37 As $P(x, y, z)$ moves off the level surface at P_0 by 0.1 unit directly toward P_1 , the function f changes value by approximately -0.067 unit (Example 4).

How to Linearize a Function of Two Variables

Functions of two variables can be quite complicated, and we sometimes need to approximate them with simpler ones that give the accuracy required for specific applications without being so difficult to work with. We do this in a way that is similar to the way we find linear replacements for functions of a single variable (Section 3.11).

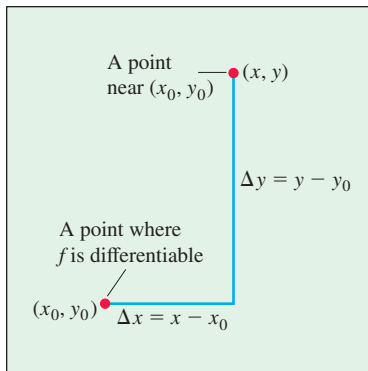

FIGURE 13.38 If f is differentiable at (x_0, y_0) , then the value of f at point (x, y) nearby is approximately $f(x_0, y_0) + f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y$.

Suppose the function we wish to approximate is $z = f(x, y)$ near a point (x_0, y_0) at which we know the values of $f, f_x,$ and f_y , and at which f is differentiable. If we move from (x_0, y_0) to a nearby point (x, y) by increments $\Delta x = x - x_0$ and $\Delta y = y - y_0$ (see Figure 13.38), then the definition of differentiability from Section 13.3 shows that the change

$$f(x, y) - f(x_0, y_0) = f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y + \varepsilon_1\Delta x + \varepsilon_2\Delta y,$$

where $\varepsilon_1, \varepsilon_2 \rightarrow 0$ as $\Delta x, \Delta y \rightarrow 0$. If the increments Δx and Δy are small, the products $\varepsilon_1\Delta x$ and $\varepsilon_2\Delta y$ will eventually be smaller still, and we have the approximation

$$f(x, y) \approx \underbrace{f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)}_{L(x, y)}.$$

In other words, as long as Δx and Δy are small, f will have approximately the same value as the linear function L .

DEFINITIONS The **linearization** of a function $f(x, y)$ at a point (x_0, y_0) where f is differentiable is the function

$$L(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

The approximation

$$f(x, y) \approx L(x, y)$$

is the **standard linear approximation** of f at (x_0, y_0) .

From Equation (3), we find that the plane $z = L(x, y)$ is tangent to the surface $z = f(x, y)$ at the point (x_0, y_0) . Thus, the linearization of a function of two variables is a *tangent-plane* approximation in the same way that the linearization of a function of a single variable is a *tangent-line* approximation. (See Exercise 57.)

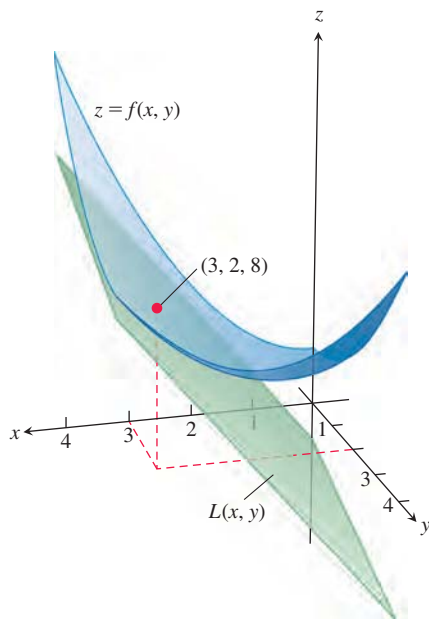

FIGURE 13.39 The tangent plane $L(x, y)$ represents the linearization of $f(x, y)$ in Example 5.

EXAMPLE 5 Find the linearization of

$$f(x, y) = x^2 - xy + \frac{1}{2}y^2 + 3$$

at the point $(3, 2)$.

Solution We first evaluate $f, f_x,$ and f_y at the point $(x_0, y_0) = (3, 2)$:

$$f(3, 2) = \left(x^2 - xy + \frac{1}{2}y^2 + 3\right)\Big|_{(3,2)} = 8$$

$$f_x(3, 2) = \frac{\partial}{\partial x}\left(x^2 - xy + \frac{1}{2}y^2 + 3\right)\Big|_{(3,2)} = (2x - y)\Big|_{(3,2)} = 4$$

$$f_y(3, 2) = \frac{\partial}{\partial y}\left(x^2 - xy + \frac{1}{2}y^2 + 3\right)\Big|_{(3,2)} = (-x + y)\Big|_{(3,2)} = -1,$$

which yields

$$\begin{aligned} L(x, y) &= f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) \\ &= 8 + (4)(x - 3) + (-1)(y - 2) = 4x - y - 2. \end{aligned}$$

The linearization of f at $(3, 2)$ is $L(x, y) = 4x - y - 2$ (see Figure 13.39). ■

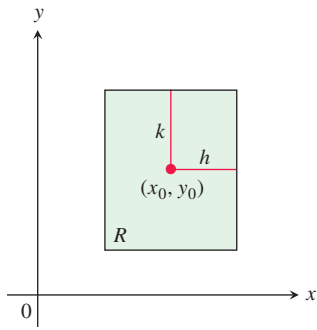

FIGURE 13.40 The rectangular region R : $|x - x_0| \leq h, |y - y_0| \leq k$ in the xy -plane.

When we approximate a differentiable function $f(x, y)$ by its linearization $L(x, y)$ at (x_0, y_0) , an important question is how accurate the approximation might be.

If we can find a common upper bound M for $|f_{xx}|$, $|f_{yy}|$, and $|f_{xy}|$ on a rectangle R centered at (x_0, y_0) (Figure 13.40), then we can bound the error E throughout R by using a simple formula. The **error** is defined by $E(x, y) = f(x, y) - L(x, y)$.

The Error in the Standard Linear Approximation

If f has continuous first and second partial derivatives throughout an open set containing a rectangle R centered at (x_0, y_0) , and if M is any upper bound for the values of $|f_{xx}|$, $|f_{yy}|$, and $|f_{xy}|$ on R , then the error $E(x, y)$ incurred in replacing $f(x, y)$ on R by its linearization

$$L(x, y) = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)$$

satisfies the inequality

$$|E(x, y)| \leq \frac{1}{2}M(|x - x_0| + |y - y_0|)^2.$$

To make $|E(x, y)|$ small for a given M , we just make $|x - x_0|$ and $|y - y_0|$ small.

Differentials

Recall from Section 3.11 that for a function of a single variable, $y = f(x)$, we defined the change in f as x changes from a to $a + \Delta x$ by

$$\Delta f = f(a + \Delta x) - f(a)$$

and the differential of f as

$$df = f'(a)\Delta x.$$

We now consider the differential of a function of two variables.

Suppose a differentiable function $f(x, y)$ and its partial derivatives exist at a point (x_0, y_0) . If we move to a nearby point $(x_0 + \Delta x, y_0 + \Delta y)$, the change in f is

$$\Delta f = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0).$$

A straightforward calculation based on the definition of $L(x, y)$, using the notation $x - x_0 = \Delta x$ and $y - y_0 = \Delta y$, shows that the corresponding change in L is

$$\Delta L = L(x_0 + \Delta x, y_0 + \Delta y) - L(x_0, y_0) = f_x(x_0, y_0)\Delta x + f_y(x_0, y_0)\Delta y.$$

The **differentials** dx and dy are independent variables, so they can be assigned any values. Often we take $dx = \Delta x = x - x_0$, and $dy = \Delta y = y - y_0$. We then have the following definition of the differential or *total differential* of f .

DEFINITION If we move from (x_0, y_0) to a point $(x_0 + dx, y_0 + dy)$ nearby, the resulting change

$$df = f_x(x_0, y_0)dx + f_y(x_0, y_0)dy$$

in the linearization of f is called the **total differential of f** .

EXAMPLE 6 Suppose that a cylindrical can is designed to have a radius of 1 cm and a height of 5 cm, but that the radius and height are off by the amounts $dr = +0.03$ and $dh = -0.1$. Estimate the resulting absolute change in the volume of the can.

Solution To estimate the absolute change in $V = \pi r^2 h$, we use

$$\Delta V \approx dV = V_r(r_0, h_0) dr + V_h(r_0, h_0) dh.$$

With $V_r = 2\pi r h$ and $V_h = \pi r^2$, we get

$$\begin{aligned} dV &= 2\pi r_0 h_0 dr + \pi r_0^2 dh = 2\pi(1)(5)(0.03) + \pi(1)^2(-0.1) \\ &= 0.3\pi - 0.1\pi = 0.2\pi \approx 0.63 \text{ cm}^3. \end{aligned}$$

EXAMPLE 7 Your company manufactures stainless steel right circular cylindrical molasses storage tanks that are 2.5 m high with a radius of 0.5 m. How sensitive are the tanks' volumes to small variations in height and radius?

Solution With $V = \pi r^2 h$, the total differential gives the approximation for the change in volume as

$$\begin{aligned} dV &= V_r(0.5, 2.5) dr + V_h(0.5, 2.5) dh \\ &= (2\pi r h) \Big|_{(0.5, 2.5)} dr + (\pi r^2) \Big|_{(0.5, 2.5)} dh \\ &= 2.5\pi dr + 0.25\pi dh. \end{aligned}$$

Thus, a 1-unit change in r will change V by about 2.5π units. A 1-unit change in h will change V by about 0.25π units. The tank's volume is 10 times more sensitive to a small change in r than it is to a small change of equal size in h . As a quality control engineer concerned with being sure the tanks have the correct volume, you would want to pay special attention to their radii.

In contrast, if the values of r and h are reversed to make $r = 2.5$ and $h = 0.5$, then the total differential in V becomes

$$dV = (2\pi r h) \Big|_{(2.5, 0.5)} dr + (\pi r^2) \Big|_{(2.5, 0.5)} dh = 2.5\pi dr + 6.25\pi dh.$$

Now the volume is more sensitive to changes in h than to changes in r (Figure 13.41).

The general rule is that functions are most sensitive to small changes in the variables that generate the largest partial derivatives. ■

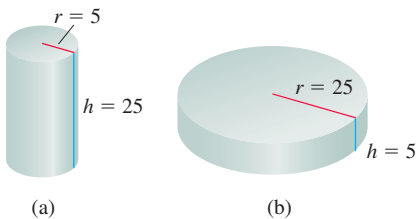

FIGURE 13.41 The volume of cylinder (a) is more sensitive to a small change in r than it is to an equally small change in h . The volume of cylinder (b) is more sensitive to small changes in h than it is to small changes in r (Example 7).

Functions of More Than Two Variables

Analogous results hold for differentiable functions of more than two variables.

1. The **linearization** of $f(x, y, z)$ at a point $P_0(x_0, y_0, z_0)$ is

$$L(x, y, z) = f(P_0) + f_x(P_0)(x - x_0) + f_y(P_0)(y - y_0) + f_z(P_0)(z - z_0).$$

2. Suppose that R is a closed rectangular solid centered at P_0 and lying in an open region on which the second partial derivatives of f are continuous. Suppose also that $|f_{xx}|, |f_{yy}|, |f_{zz}|, |f_{xy}|, |f_{xz}|$, and $|f_{yz}|$ are all less than or equal to M throughout R . Then the **error** $E(x, y, z) = f(x, y, z) - L(x, y, z)$ in the approximation of f by L is bounded throughout R by the inequality

$$|E| \leq \frac{1}{2} M (|x - x_0| + |y - y_0| + |z - z_0|)^2.$$

3. If the second partial derivatives of f are continuous and if x , y , and z change from x_0 , y_0 , and z_0 by small amounts dx , dy , and dz , the **total differential**

$$df = f_x(P_0) dx + f_y(P_0) dy + f_z(P_0) dz$$

gives a good approximation of the resulting change in f .

EXAMPLE 8 Find the linearization $L(x, y, z)$ of

$$f(x, y, z) = x^2 - xy + 3 \sin z$$

at the point $(x_0, y_0, z_0) = (2, 1, 0)$. Find an upper bound for the error incurred in replacing f by L on the rectangular region

$$R: |x - 2| \leq 0.01, \quad |y - 1| \leq 0.02, \quad |z| \leq 0.01.$$

Solution Routine calculations give

$$f(2, 1, 0) = 2, \quad f_x(2, 1, 0) = 3, \quad f_y(2, 1, 0) = -2, \quad f_z(2, 1, 0) = 3.$$

Thus,

$$L(x, y, z) = 2 + 3(x - 2) + (-2)(y - 1) + 3(z - 0) = 3x - 2y + 3z - 2.$$

Since

$$f_{xx} = 2, \quad f_{yy} = 0, \quad f_{zz} = -3 \sin z, \quad f_{xy} = -1, \quad f_{xz} = 0, \quad f_{yz} = 0,$$

and $|-3 \sin z| \leq 3 \sin 0.01 \approx 0.03$, we may take $M = 2$ as a bound on the second partials. Hence, the error incurred by replacing f by L on R satisfies

$$|E| \leq \frac{1}{2}(2)(0.01 + 0.02 + 0.01)^2 = 0.0016. \quad \blacksquare$$

EXERCISES 13.6

Tangent Planes and Normal Lines to Surfaces

In Exercises 1–10, find equations for the

(a) tangent plane and

(b) normal line at the point P_0 on the given surface.

1. $x^2 + y^2 + z^2 = 3$, $P_0(1, 1, 1)$
2. $x^2 + y^2 - z^2 = 18$, $P_0(3, 5, -4)$
3. $2z - x^2 = 0$, $P_0(2, 0, 2)$
4. $x^2 + 2xy - y^2 + z^2 = 7$, $P_0(1, -1, 3)$
5. $\cos \pi x - x^2 y + e^{xz} + yz = 4$, $P_0(0, 1, 2)$
6. $x^2 - xy - y^2 - z = 0$, $P_0(1, 1, -1)$
7. $x + y + z = 1$, $P_0(0, 1, 0)$
8. $x^2 + y^2 - 2xy - x + 3y - z = -4$, $P_0(2, -3, 18)$
9. $x \ln y + y \ln z = x$, $P_0(1, 1, e)$
10. $ye^x + ze^{y^2} = z$, $P_0(0, 0, 1)$

In Exercises 11–14, find an equation for the plane that is tangent to the given surface at the given point.

11. $z = \ln(x^2 + y^2)$, $(1, 0, 0)$
12. $z = e^{-(x^2 + y^2)}$, $(0, 0, 1)$

13. $z = \sqrt{y - x}$, $(1, 2, 1)$

14. $z = 4x^2 + y^2$, $(1, 1, 5)$

Tangent Lines to Intersecting Surfaces

In Exercises 15–20, find parametric equations for the line tangent to the curve of intersection of the surfaces at the given point.

15. Surfaces: $x + y^2 + 2z = 4$, $x = 1$
Point: $(1, 1, 1)$
16. Surfaces: $xyz = 1$, $x^2 + 2y^2 + 3z^2 = 6$
Point: $(1, 1, 1)$
17. Surfaces: $x^2 + 2y + 2z = 4$, $y = 1$
Point: $(1, 1, 1/2)$
18. Surfaces: $x + y^2 + z = 2$, $y = 1$
Point: $(1/2, 1, 1/2)$
19. Surfaces: $x^3 + 3x^2y^2 + y^3 + 4xy - z^2 = 0$,
 $x^2 + y^2 + z^2 = 11$
Point: $(1, 1, 3)$
20. Surfaces: $x^2 + y^2 = 4$, $x^2 + y^2 - z = 0$
Point: $(\sqrt{2}, \sqrt{2}, 4)$

Estimating Change

21. By about how much will

$$f(x, y, z) = \ln \sqrt{x^2 + y^2 + z^2}$$

change if the point $P(x, y, z)$ moves from $P_0(3, 4, 12)$ a distance of $ds = 0.1$ unit in the direction of $3\mathbf{i} + 6\mathbf{j} - 2\mathbf{k}$?

22. By about how much will

$$f(x, y, z) = e^x \cos yz$$

change as the point $P(x, y, z)$ moves from the origin a distance of $ds = 0.1$ unit in the direction of $2\mathbf{i} + 2\mathbf{j} - 2\mathbf{k}$?

23. By about how much will

$$g(x, y, z) = x + x \cos z - y \sin z + y$$

change if the point $P(x, y, z)$ moves from $P_0(2, -1, 0)$ a distance of $ds = 0.2$ unit toward the point $P_1(0, 1, 2)$?

24. By about how much will

$$h(x, y, z) = \cos(\pi xy) + xz^2$$

change if the point $P(x, y, z)$ moves from $P_0(-1, -1, -1)$ a distance of $ds = 0.1$ unit toward the origin?

25. **Temperature change along a circle** Suppose that the Celsius temperature at the point (x, y) in the xy -plane is $T(x, y) = x \sin 2y$ and that distance in the xy -plane is measured in meters. A particle is moving *clockwise* around the circle of radius 1 m centered at the origin at the constant rate of 2 m/s.

a. How fast is the temperature experienced by the particle changing in degrees Celsius per meter at the point $P(1/2, \sqrt{3}/2)$?

b. How fast is the temperature experienced by the particle changing in degrees Celsius per second at P ?

26. **Changing temperature along a space curve** The Celsius temperature in a region in space is given by $T(x, y, z) = 2x^2 - xyz$. A particle is moving in this region and its position at time t is given by $x = 2t^2, y = 3t, z = -t^2$, where time is measured in seconds and distance in meters.

a. How fast is the temperature experienced by the particle changing in degrees Celsius per meter when the particle is at the point $P(8, 6, -4)$?

b. How fast is the temperature experienced by the particle changing in degrees Celsius per second at P ?

Finding Linearizations

In Exercises 27–32, find the linearization $L(x, y)$ of the function at each point.

27. $f(x, y) = x^2 + y^2 + 1$ at **a.** $(0, 0)$, **b.** $(1, 1)$

28. $f(x, y) = (x + y + 2)^2$ at **a.** $(0, 0)$, **b.** $(1, 2)$

29. $f(x, y) = 3x - 4y + 5$ at **a.** $(0, 0)$, **b.** $(1, 1)$

30. $f(x, y) = x^3 y^4$ at **a.** $(1, 1)$, **b.** $(0, 0)$

31. $f(x, y) = e^x \cos y$ at **a.** $(0, 0)$, **b.** $(0, \pi/2)$

32. $f(x, y) = e^{2y-x}$ at **a.** $(0, 0)$, **b.** $(1, 2)$

33. **Wind chill factor** Wind chill, a measure of the apparent temperature felt on exposed skin, is a function of air temperature and

wind speed. The precise formula, updated by the National Weather Service in 2001 and based on modern heat transfer theory, a human face model, and skin tissue resistance, is (after unit conversion)

$$W = W(v, T) = 13.13 + 0.6215T - 11.36v^{0.16} + 0.396T \cdot v^{0.16},$$

where T is air temperature in $^{\circ}\text{C}$ and v is wind speed in km/h. A partial wind chill chart is given.

		$T(^{\circ}\text{C})$						
		5	0	-5	-10	-15	-20	-25
v (km/h)	10	2.7	-3.3	-9.3	-15.2	-21.2	-27.2	-33.1
	20	1.1	-5.2	-11.5	-17.8	-24.1	-30.4	-36.7
	30	0.1	-6.4	-13.0	-19.5	-26.0	-32.5	-39.0
	40	-0.7	-7.4	-14.0	-20.7	-27.4	-34.1	-40.8
	50	-1.3	-8.1	-14.9	-21.7	-28.5	-35.4	-42.2
	60	-1.8	-8.7	-15.7	-22.6	-29.5	-36.4	-43.3

- a. Use the table to find $W(30, -5)$, $W(50, -25)$, and $W(30, -10)$.
- b. Use the formula to find $W(15, -40)$, $W(80, -40)$, and $W(90, 0)$.
- c. Find the linearization $L(v, T)$ of the function $W(v, T)$ at the point $(40, -10)$.
- d. Use $L(v, T)$ in part (c) to estimate the following wind chill values.
- i) $W(39, -9)$ ii) $W(42, -12)$
- iii) $W(10, -25)$ (Explain why this value is much different from the value found in the table.)
34. Find the linearization $L(v, T)$ of the function $W(v, T)$ in Exercise 31 at the point $(50, -20)$. Use it to estimate the following wind chill values.
- a. $W(49, -22)$
- b. $W(53, -19)$
- c. $W(60, -30)$

Bounding the Error in Linear Approximations

In Exercises 35–40, find the linearization $L(x, y)$ of the function $f(x, y)$ at P_0 . Then find an upper bound for the magnitude $|E|$ of the error in the approximation $f(x, y) \approx L(x, y)$ over the rectangle R .

35. $f(x, y) = x^2 - 3xy + 5$ at $P_0(2, 1)$,

$R: |x - 2| \leq 0.1, |y - 1| \leq 0.1$

36. $f(x, y) = (1/2)x^2 + xy + (1/4)y^2 + 3x - 3y + 4$ at $P_0(2, 2)$,

$R: |x - 2| \leq 0.1, |y - 2| \leq 0.1$

37. $f(x, y) = 1 + y + x \cos y$ at $P_0(0, 0)$,

$R: |x| \leq 0.2, |y| \leq 0.2$

(Use $|\cos y| \leq 1$ and $|\sin y| \leq 1$ in estimating E .)

38. $f(x, y) = xy^2 + y \cos(x - 1)$ at $P_0(1, 2)$,

$R: |x - 1| \leq 0.1, |y - 2| \leq 0.1$

39. $f(x, y) = e^x \cos y$ at $P_0(0, 0)$,
 $R: |x| \leq 0.1, |y| \leq 0.1$
 (Use $e^x \leq 1.11$ and $|\cos y| \leq 1$ in estimating E .)
40. $f(x, y) = \ln x + \ln y$ at $P_0(1, 1)$,
 $R: |x - 1| \leq 0.2, |y - 1| \leq 0.2$

Linearizations for Three Variables

Find the linearizations $L(x, y, z)$ of the functions in Exercises 41–46 at the given points.

41. $f(x, y, z) = xy + yz + xz$ at
 a. $(1, 1, 1)$ b. $(1, 0, 0)$ c. $(0, 0, 0)$
42. $f(x, y, z) = x^2 + y^2 + z^2$ at
 a. $(1, 1, 1)$ b. $(0, 1, 0)$ c. $(1, 0, 0)$
43. $f(x, y, z) = \sqrt{x^2 + y^2 + z^2}$ at
 a. $(1, 0, 0)$ b. $(1, 1, 0)$ c. $(1, 2, 2)$
44. $f(x, y, z) = (\sin xy)/z$ at
 a. $(\pi/2, 1, 1)$ b. $(2, 0, 1)$
45. $f(x, y, z) = e^x + \cos(y + z)$ at
 a. $(0, 0, 0)$ b. $(0, \frac{\pi}{2}, 0)$ c. $(0, \frac{\pi}{4}, \frac{\pi}{4})$
46. $f(x, y, z) = \tan^{-1}(xyz)$ at
 a. $(1, 0, 0)$ b. $(1, 1, 0)$ c. $(1, 1, 1)$

In Exercises 47–50, find the linearization $L(x, y, z)$ of the function $f(x, y, z)$ at P_0 . Then find an upper bound for the magnitude of the error E in the approximation $f(x, y, z) \approx L(x, y, z)$ over the region R .

47. $f(x, y, z) = xz - 3yz + 2$ at $P_0(1, 1, 2)$,
 $R: |x - 1| \leq 0.01, |y - 1| \leq 0.01, |z - 2| \leq 0.02$
48. $f(x, y, z) = x^2 + xy + yz + (1/4)z^2$ at $P_0(1, 1, 2)$,
 $R: |x - 1| \leq 0.01, |y - 1| \leq 0.01, |z - 2| \leq 0.08$
49. $f(x, y, z) = xy + 2yz - 3xz$ at $P_0(1, 1, 0)$,
 $R: |x - 1| \leq 0.01, |y - 1| \leq 0.01, |z| \leq 0.01$
50. $f(x, y, z) = \sqrt{2} \cos x \sin(y + z)$ at $P_0(0, 0, \pi/4)$,
 $R: |x| \leq 0.01, |y| \leq 0.01, |z - \pi/4| \leq 0.01$

Estimating Error; Sensitivity to Change

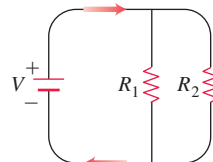

51. **Estimating maximum error** Suppose that T is to be found from the formula $T = x(e^y + e^{-y})$, where x and y are found to be 2 and $\ln 2$ with maximum possible errors of $|dx| = 0.1$ and $|dy| = 0.02$. Estimate the maximum possible error in the computed value of T .
52. **Variation in electrical resistance** The resistance R produced by wiring resistors of R_1 and R_2 ohms in parallel (see accompanying figure) can be calculated from the formula

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2}.$$

- a. Show that

$$dR = \left(\frac{R}{R_1}\right)^2 dR_1 + \left(\frac{R}{R_2}\right)^2 dR_2.$$

- b. You have designed a two-resistor circuit, like the one shown, to have resistances of $R_1 = 100$ ohms and $R_2 = 400$ ohms, but there is always some variation in manufacturing, and the resistors received by your firm will probably not have these exact values. Will the value of R be more sensitive to variation in R_1 or to variation in R_2 ? Give reasons for your answer.

- c. In another circuit like the one shown, you plan to change R_1 from 20 to 20.1 ohms and R_2 from 25 to 24.9 ohms. By about what percentage will this change R ?
53. You plan to calculate the area of a long, thin rectangle from measurements of its length and width. Which dimension should you measure more carefully? Give reasons for your answer.
54. a. Around the point $(1, 0)$, is $f(x, y) = x^2(y + 1)$ more sensitive to changes in x or to changes in y ? Give reasons for your answer.
 b. What ratio of dx to dy will make df equal zero at $(1, 0)$?

55. **Value of a 2×2 determinant** If $|a|$ is much greater than $|b|, |c|$, and $|d|$, to which of a, b, c , and d is the value of the determinant

$$f(a, b, c, d) = \begin{vmatrix} a & b \\ c & d \end{vmatrix}$$

most sensitive? Give reasons for your answer.

56. **The Wilson lot size formula** The Wilson lot size formula in economics says that the most economical quantity Q of goods (radios, shoes, brooms, whatever) for a store to order is given by the formula $Q = \sqrt{2KM/h}$, where K is the cost of placing the order, M is the number of items sold per week, and h is the weekly holding cost for each item (cost of space, utilities, security, and so on). To which of the variables K, M , and h is Q most sensitive near the point $(K_0, M_0, h_0) = (2, 20, 0.05)$? Give reasons for your answer.

Theory and Examples

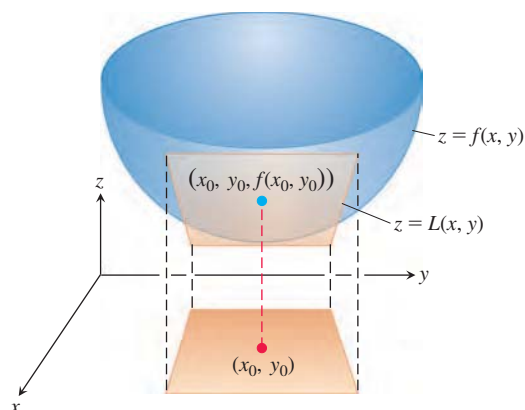

57. **The linearization of $f(x, y)$ is a tangent-plane approximation** Show that the tangent plane at the point $P_0(x_0, y_0, f(x_0, y_0))$ on the surface $z = f(x, y)$ defined by a differentiable function f is the plane

$$f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0) - (z - f(x_0, y_0)) = 0,$$

or

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

Thus, the tangent plane at P_0 is the graph of the linearization of f at P_0 (see accompanying figure).

- 58. Change along the involute of a circle** Find the derivative of $f(x, y) = x^2 + y^2$ in the direction of the unit tangent vector of the curve

$$\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}, \quad t > 0.$$

- 59. Tangent curves** A smooth curve is *tangent* to the surface at a point of intersection if its velocity vector is orthogonal to ∇f there.

Show that the curve

$$\mathbf{r}(t) = \sqrt{t}\mathbf{i} + \sqrt{t}\mathbf{j} + (2t - 1)\mathbf{k}$$

is tangent to the surface $x^2 + y^2 - z = 1$ when $t = 1$.

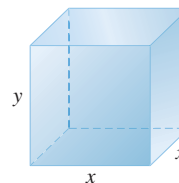

- 60. Normal curves** A smooth curve is *normal* to a surface $f(x, y, z) = c$ at a point of intersection if the curve's velocity vector is a nonzero scalar multiple of ∇f at the point.

Show that the curve

$$\mathbf{r}(t) = \sqrt{t}\mathbf{i} + \sqrt{t}\mathbf{j} - \frac{1}{4}(t + 3)\mathbf{k}$$

is normal to the surface $x^2 + y^2 - z = 3$ when $t = 1$.

- 61.** Consider a closed rectangular box with a square base, as shown in the figure. Assume x is measured with an error of at most 0.5% and y is measured with an error of at most 0.75%, so we have $|dx|/x < 0.005$ and $|dy|/y < 0.0075$.

- Use a differential to estimate the relative error $|dV|/V$ in computing the box's volume V .
- Use a differential to estimate the relative error $|dS|/S$ in computing the box's surface area S .

Hint for b: $\frac{4x^2 + 4xy}{2x^2 + 4xy} \leq \frac{4x^2 + 8xy}{2x^2 + 4xy} = 2$ and $\frac{4xy}{2x^2 + 4xy} \leq \frac{2x^2 + 4xy}{2x^2 + 4xy} = 1$.

13.7 Extreme Values and Saddle Points

HISTORICAL BIOGRAPHY

Siméon-Denis Poisson
(1781–1840)

French mathematician Poisson studied with Lagrange and Laplace at the École polytechnique and did so well that he was made an assistant professor upon his graduation. In 1806, he replaced Fourier as the professor of mathematics. Poisson's early work in mechanics appeared in his first volume of *Traité de mécanique* (1811), where he applied mathematics to applications in physics and mechanics, including elasticity and vibrations.

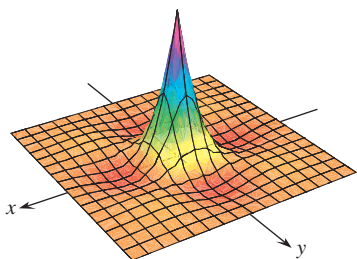

FIGURE 13.42 The function

$$z = (\cos x)(\cos y)e^{-\sqrt{x^2+y^2}}$$

has a maximum value of 1 and a minimum value of about -0.067 on the square region $|x| \leq 3\pi/2$, $|y| \leq 3\pi/2$.

Continuous functions of two variables assume extreme values on closed, bounded domains (see Figures 13.42 and 13.43). We see in this section that we can narrow the search for these extreme values by examining the functions' first partial derivatives. A function of two variables can assume extreme values only at boundary points of the domain or at interior domain points where both first partial derivatives are zero or where one or both of the first partial derivatives fail to exist. However, the vanishing of derivatives at an interior point (a, b) does not always signal the presence of an extreme value. The surface that is the graph of the function might be shaped like a saddle right above (a, b) and cross its tangent plane there.

Local Extreme Values for Functions of Two Variables

To find the local extreme values of a function of a single variable, we look for points where the graph has a horizontal tangent line. At such points, we then look for local maxima, local minima, and points of inflection. For a function $f(x, y)$ of two variables, we look for points where the surface $z = f(x, y)$ has a horizontal tangent plane. At such points, we then look for local maxima, local minima, and saddle points. We begin by defining maxima and minima.

DEFINITIONS Let $f(x, y)$ be defined on a region R containing the point (a, b) . Then

- $f(a, b)$ is a **local maximum** value of f if $f(a, b) \geq f(x, y)$ for all domain points (x, y) in an open disk centered at (a, b) . $f(a, b)$ is an **absolute maximum** value of f on R if $f(a, b) \geq f(x, y)$ for all domain points (x, y) in R .
- $f(a, b)$ is a **local minimum** value of f if $f(a, b) \leq f(x, y)$ for all domain points (x, y) in an open disk centered at (a, b) . $f(a, b)$ is an **absolute minimum** value of f on R if $f(a, b) \leq f(x, y)$ for all domain points (x, y) in R .

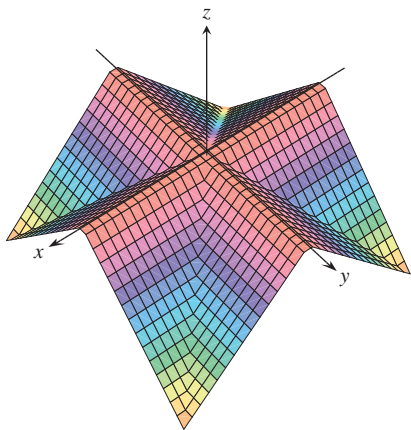

FIGURE 13.43 The “roof surface”

$$z = \frac{1}{2}(|x| - |y| - |x| - |y|)$$

has a maximum value of 0 and a minimum value of $-a$ on the square region $|x| \leq a$, $|y| \leq a$.

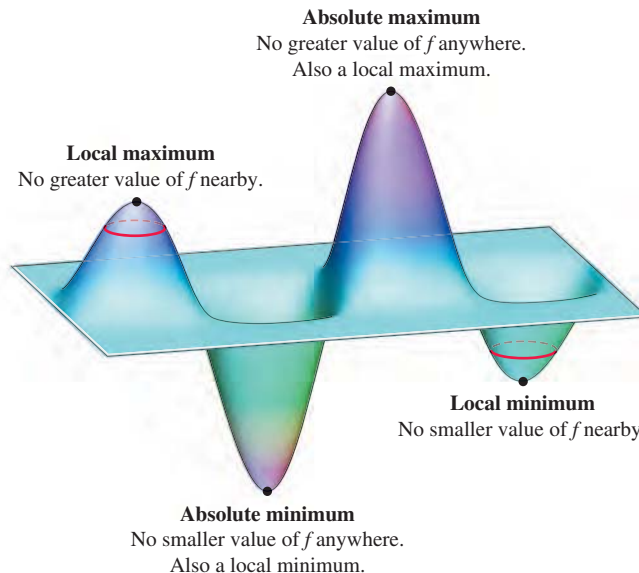

FIGURE 13.44 A local maximum occurs at a mountain peak, and a local minimum occurs at a valley low point.

THEOREM 10—First Derivative Theorem for Local Extreme Values

If $f(x, y)$ has a local maximum or minimum value at an interior point (a, b) of its domain and if the first partial derivatives exist there, then $f_x(a, b) = 0$ and $f_y(a, b) = 0$.

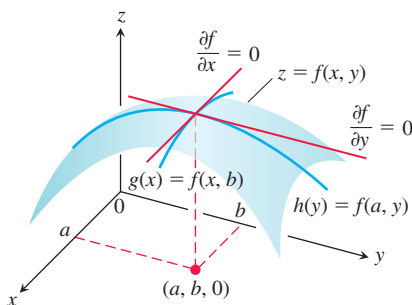

FIGURE 13.45 If a local maximum of f occurs at $x = a$, $y = b$, then the first partial derivatives $f_x(a, b)$ and $f_y(a, b)$ are both zero.

Proof If f has a local extremum at (a, b) , then the function $g(x) = f(x, b)$ has a local extremum at $x = a$ (Figure 13.45). Therefore, $g'(a) = 0$ (Chapter 4, Theorem 2). Now $g'(a) = f_x(a, b)$, so $f_x(a, b) = 0$. A similar argument with the function $h(y) = f(a, y)$ shows that $f_y(a, b) = 0$. ■

If we substitute the values $f_x(a, b) = 0$ and $f_y(a, b) = 0$ into the equation

$$f_x(a, b)(x - a) + f_y(a, b)(y - b) - (z - f(a, b)) = 0$$

for the tangent plane to the surface $z = f(x, y)$ at (a, b) , the equation reduces to

$$0 \cdot (x - a) + 0 \cdot (y - b) - z + f(a, b) = 0,$$

or

$$z = f(a, b).$$

Thus, Theorem 10 says that the surface does indeed have a horizontal tangent plane at a local extremum, provided there is a tangent plane there.

DEFINITION An interior point of the domain of a function $f(x, y)$ where both f_x and f_y are zero or where one or both of f_x and f_y do not exist is a **critical point** of f .

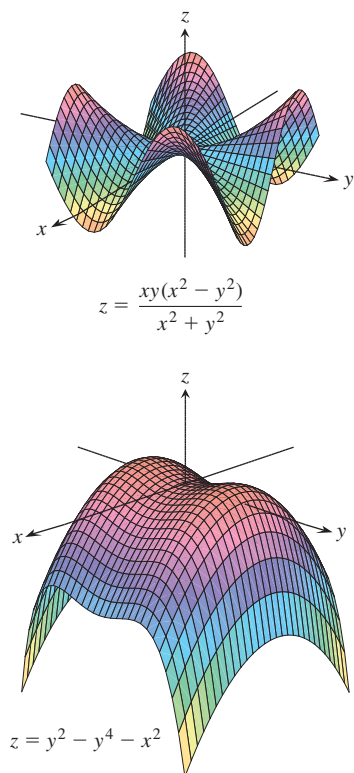

FIGURE 13.46 Saddle points at the origin.

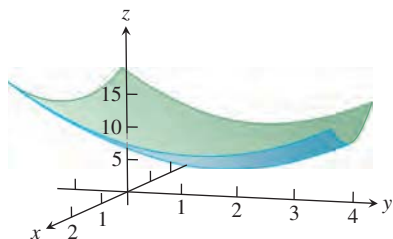

FIGURE 13.47 The graph of the function $f(x, y) = x^2 + y^2 - 4y + 9$ is a paraboloid which has a local minimum value of 5 at the point $(0, 2)$ (Example 1).

Theorem 10 says that the only points where a function $f(x, y)$ can assume extreme values are critical points and boundary points. As with differentiable functions of a single variable, not every critical point gives rise to a local extremum. A differentiable function of a single variable might have a point of inflection. A differentiable function of two variables might have a *saddle point*, with the graph of f crossing the tangent plane defined there.

DEFINITION A differentiable function $f(x, y)$ has a **saddle point** at a critical point (a, b) if in every open disk centered at (a, b) there are domain points (x, y) where $f(x, y) > f(a, b)$ and domain points (x, y) where $f(x, y) < f(a, b)$. The corresponding point $(a, b, f(a, b))$ on the surface $z = f(x, y)$ is called a saddle point of the surface (Figure 13.46).

EXAMPLE 1 Find the local extreme values of $f(x, y) = x^2 + y^2 - 4y + 9$.

Solution The domain of f is the entire plane (so there are no boundary points) and the partial derivatives $f_x = 2x$ and $f_y = 2y - 4$ exist everywhere. Therefore, local extreme values can occur only where

$$f_x = 2x = 0 \quad \text{and} \quad f_y = 2y - 4 = 0.$$

The only possibility is the point $(0, 2)$, where the value of f is 5. Since $f(x, y) = x^2 + (y - 2)^2 + 5$ is never less than 5, we see that the critical point $(0, 2)$ gives a local minimum (Figure 13.47). ■

EXAMPLE 2 Find the local extreme values (if any) of $f(x, y) = y^2 - x^2$.

Solution The domain of f is the entire plane (so there are no boundary points) and the partial derivatives $f_x = -2x$ and $f_y = 2y$ exist everywhere. Therefore, local extrema can occur only at the origin $(0, 0)$, where $f_x = 0$ and $f_y = 0$. The value of f at the origin is 0. However, away from the origin along the positive x -axis, f has the value $f(x, 0) = -x^2 < 0$; along the positive y -axis, f has the value $f(0, y) = y^2 > 0$. Therefore, every open disk in the xy -plane centered at $(0, 0)$ contains points where the function is positive and points where it is negative. The function has a saddle point at the origin and no local extreme values (Figure 13.48a). Figure 13.48b displays the level curves (they are hyperbolas) of f and shows the function decreasing and increasing in an alternating fashion among the groupings of hyperbolas. ■

That $f_x = f_y = 0$ at an interior point (a, b) of R does not guarantee that f has a local extreme value there. If f and its first and second partial derivatives are continuous on R , however, we may be able to learn more from the following theorem.

THEOREM 11—Second Derivative Test for Local Extreme Values

Suppose that $f(x, y)$ and its first and second partial derivatives are continuous throughout a disk centered at (a, b) and that $f_x(a, b) = f_y(a, b) = 0$. Then

- i) f has a **local maximum** at (a, b) if $f_{xx} < 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at (a, b) .
- ii) f has a **local minimum** at (a, b) if $f_{xx} > 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at (a, b) .
- iii) f has a **saddle point** at (a, b) if $f_{xx}f_{yy} - f_{xy}^2 < 0$ at (a, b) .
- iv) **the test is inconclusive** at (a, b) if $f_{xx}f_{yy} - f_{xy}^2 = 0$ at (a, b) . In this case, we must find some other way to determine the behavior of f at (a, b) .

The expression $f_{xx}f_{yy} - f_{xy}^2$ is called the **discriminant** or **Hessian** of f . It is sometimes easier to remember it in determinant form,

$$f_{xx}f_{yy} - f_{xy}^2 = \begin{vmatrix} f_{xx} & f_{xy} \\ f_{xy} & f_{yy} \end{vmatrix}.$$

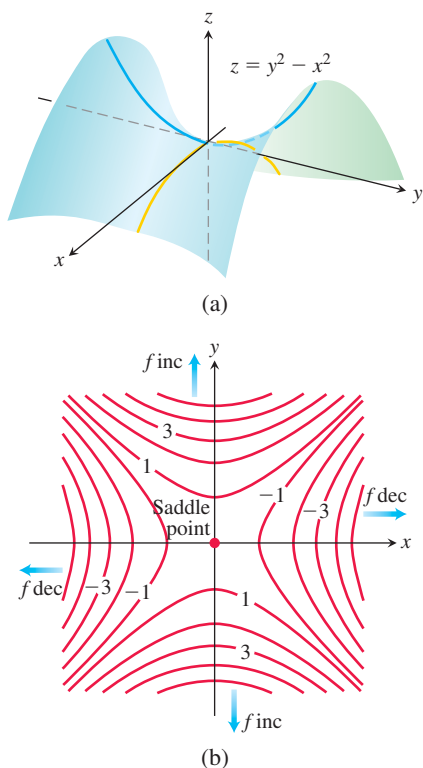

FIGURE 13.48 (a) The origin is a saddle point of the function $f(x, y) = y^2 - x^2$. There are no local extreme values (Example 2). (b) Level curves for the function f in Example 2.

The discriminant is the determinant of the **Hessian matrix** of f ,

$$Hf(x, y) = \begin{bmatrix} f_{xx} & f_{xy} \\ f_{yx} & f_{yy} \end{bmatrix}.$$

Note that by Theorem 2, we have $f_{xy}(a, b) = f_{yx}(a, b)$ at any point (a, b) satisfying the assumptions of Theorem 11.

Theorem 11 says that if the discriminant is positive at the point (a, b) , then the surface curves the same way in all directions: downward if $f_{xx} < 0$, giving rise to a local maximum, and upward if $f_{xx} > 0$, giving a local minimum. On the other hand, if the discriminant is negative at (a, b) , then the surface curves up in some directions and down in others, so we have a saddle point.

EXAMPLE 3 Find the local extreme values of the function

$$f(x, y) = xy - x^2 - y^2 - 2x - 2y + 4.$$

Solution The function is defined and differentiable for all x and y , and its domain has no boundary points. The function therefore has extreme values only at the points where f_x and f_y are simultaneously zero. This leads to

$$f_x = y - 2x - 2 = 0, \quad f_y = x - 2y - 2 = 0,$$

or

$$x = y = -2.$$

Therefore, the point $(-2, -2)$ is the only point where f may take on an extreme value. To see whether it does so, we calculate

$$f_{xx} = -2, \quad f_{yy} = -2, \quad f_{xy} = 1.$$

The discriminant of f at $(a, b) = (-2, -2)$ is

$$f_{xx}f_{yy} - f_{xy}^2 = (-2)(-2) - (1)^2 = 4 - 1 = 3.$$

The combination

$$f_{xx} < 0 \quad \text{and} \quad f_{xx}f_{yy} - f_{xy}^2 > 0$$

tells us that f has a local maximum at $(-2, -2)$. The value of f at this point is $f(-2, -2) = 8$. ■

EXAMPLE 4 Find the local extreme values of $f(x, y) = 3y^2 - 2y^3 - 3x^2 + 6xy$.

Solution Since f is differentiable everywhere, it can assume extreme values only where

$$f_x = 6y - 6x = 0 \quad \text{and} \quad f_y = 6y - 6y^2 + 6x = 0.$$

From the first of these equations we find $x = y$, and substitution for y into the second equation then gives

$$6x - 6x^2 + 6x = 0 \quad \text{or} \quad 6x(2 - x) = 0.$$

The two critical points are therefore $(0, 0)$ and $(2, 2)$.

To classify the critical points, we calculate the second derivatives:

$$f_{xx} = -6, \quad f_{yy} = 6 - 12y, \quad f_{xy} = 6.$$

The discriminant is given by

$$f_{xx}f_{yy} - f_{xy}^2 = (-36 + 72y) - 36 = 72(y - 1).$$

At the critical point $(0, 0)$ we see that the value of the discriminant is the negative number -72 , so the function has a saddle point at the origin. At the critical point $(2, 2)$ we see that the discriminant has the positive value 72 . Combining this result with the negative value of the second partial $f_{xx} = -6$, Theorem 11 says that the critical point $(2, 2)$ gives a local maximum value of $f(2, 2) = 12 - 16 - 12 + 24 = 8$. A graph of the surface is shown in Figure 13.49. ■

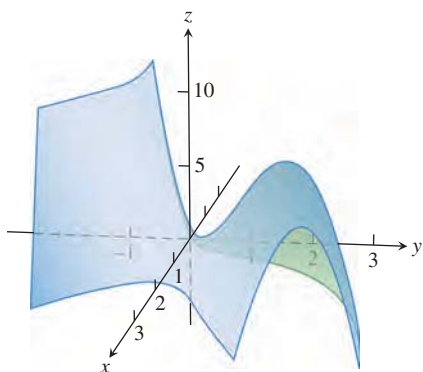

FIGURE 13.49 The surface $z = 3y^2 - 2y^3 - 3x^2 + 6xy$ has a saddle point at the origin and a local maximum at the point $(2, 2)$ (Example 4).

EXAMPLE 5 Find the critical points of the function $f(x, y) = 10xye^{-(x^2+y^2)}$ and use the Second Derivative Test to classify each point as one where a saddle, local minimum, or local maximum occurs.

Solution First we find the partial derivatives f_x and f_y and set them simultaneously to zero in seeking the critical points:

$$\begin{aligned} f_x &= 10ye^{-(x^2+y^2)} - 20x^2ye^{-(x^2+y^2)} = 10y(1 - 2x^2)e^{-(x^2+y^2)} = 0 \Rightarrow y = 0 \text{ or } 1 - 2x^2 = 0, \\ f_y &= 10xe^{-(x^2+y^2)} - 20xy^2e^{-(x^2+y^2)} = 10x(1 - 2y^2)e^{-(x^2+y^2)} = 0 \Rightarrow x = 0 \text{ or } 1 - 2y^2 = 0. \end{aligned}$$

Since both partial derivatives are continuous everywhere, the only critical points are

$$(0, 0), \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right), \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right), \left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right), \text{ and } \left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right).$$

Next we calculate the second partial derivatives in order to evaluate the discriminant at each critical point:

$$\begin{aligned} f_{xx} &= -20xy(1 - 2x^2)e^{-(x^2+y^2)} - 40xye^{-(x^2+y^2)} = -20xy(3 - 2x^2)e^{-(x^2+y^2)}, \\ f_{xy} &= f_{yx} = 10(1 - 2x^2)e^{-(x^2+y^2)} - 20y^2(1 - 2x^2)e^{-(x^2+y^2)} = 10(1 - 2x^2)(1 - 2y^2)e^{-(x^2+y^2)}, \\ f_{yy} &= -20xy(1 - 2y^2)e^{-(x^2+y^2)} - 40xye^{-(x^2+y^2)} = -20xy(3 - 2y^2)e^{-(x^2+y^2)}. \end{aligned}$$

The following table summarizes the values needed by the Second Derivative Test.

Critical Point	f_{xx}	f_{xy}	f_{yy}	Discriminant D
$(0, 0)$	0	10	0	-100
$\left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$	$-\frac{20}{e}$	0	$-\frac{20}{e}$	$\frac{400}{e^2}$
$\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$	$\frac{20}{e}$	0	$\frac{20}{e}$	$\frac{400}{e^2}$
$\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$	$\frac{20}{e}$	0	$\frac{20}{e}$	$\frac{400}{e^2}$
$\left(-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$	$-\frac{20}{e}$	0	$-\frac{20}{e}$	$\frac{400}{e^2}$

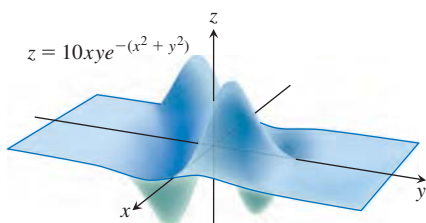

FIGURE 13.50 A graph of the function in Example 5.

From the table we find that $D < 0$ at the critical point $(0, 0)$, giving a saddle; $D > 0$ and $f_{xx} < 0$ at the critical points $(1/\sqrt{2}, 1/\sqrt{2})$ and $(-1/\sqrt{2}, -1/\sqrt{2})$, giving local maximum values there; and $D > 0$ and $f_{xx} > 0$ at the critical points $(-1/\sqrt{2}, 1/\sqrt{2})$ and $(1/\sqrt{2}, -1/\sqrt{2})$, each giving local minimum values. A graph of the surface is shown in Figure 13.50. ■

Absolute Maxima and Minima on Closed Bounded Regions

We organize the search for the absolute extrema of a continuous function $f(x, y)$ on a closed and bounded region R into three steps.

1. List the interior points of R where f may have local maxima and minima and evaluate f at these points. These are the critical points of f .
2. List the boundary points of R where f has local maxima and minima and evaluate f at these points. We show how to do this in the next example.
3. Look through the lists for the maximum and minimum values of f . These will be the absolute maximum and minimum values of f on R .

EXAMPLE 6 Find the absolute maximum and minimum values of

$$f(x, y) = 2 + 2x + 4y - x^2 - y^2$$

on the triangular region in the first quadrant bounded by the lines $x = 0$, $y = 0$, and $y = 9 - x$.

Solution Since f is differentiable, the only places where f can assume these values are points inside the triangle where $f_x = f_y = 0$ and points on the boundary (Figure 13.51a).

(a) Interior points. For these we have

$$f_x = 2 - 2x = 0, \quad f_y = 4 - 2y = 0,$$

yielding the single point $(x, y) = (1, 2)$. The value of f there is

$$f(1, 2) = 7.$$

(b) Boundary points. We take the triangle one side at a time:

i) On the segment OA we always have $y = 0$. Therefore, we can regard $f(x, y)$ as being solely a function of x on this segment. That is, on this segment we want to consider the function

$$g(x) = f(x, 0) = 2 + 2x - x^2$$

for $0 \leq x \leq 9$. Its extreme values (as we know from Chapter 4) may occur at the endpoints

$$x = 0 \quad \text{where} \quad g(0) = f(0, 0) = 2$$

$$x = 9 \quad \text{where} \quad g(9) = f(9, 0) = 2 + 18 - 81 = -61$$

or at the interior points where $g'(x) = 2 - 2x = 0$. The only interior point where $g'(x) = 0$ is $x = 1$, where

$$g(1) = f(1, 0) = 3.$$

ii) On the segment OB we always have $x = 0$. Therefore, on this segment we can regard $f(x, y)$ as being solely a function of y , and so we consider the function

$$h(y) = f(0, y) = 2 + 4y - y^2$$

on the closed interval $[0, 9]$. Its extreme values can occur at the endpoints or at interior points where $h'(y) = 0$. Since $h'(y) = 4 - 2y$, the only interior point where $h'(y) = 0$ occurs at $(0, 2)$, with $h(2) = 6$. So the candidates for this segment are

$$h(0) = f(0, 0) = 2, \quad h(9) = f(0, 9) = -43, \quad \text{and} \quad h(2) = f(0, 2) = 6.$$

iii) We have already accounted for the values of f at the endpoints of AB , so we need only look at the interior points of the line segment AB . On this segment we have $y = 9 - x$, so we consider the function

$$k(x) = f(x, 9 - x) = 2 + 2x + 4(9 - x) - x^2 - (9 - x)^2 = -43 + 16x - 2x^2.$$

Setting $k'(x) = 16 - 4x = 0$ gives

$$x = 4.$$

At this value of x ,

$$y = 9 - 4 = 5 \quad \text{and} \quad k(4) = f(4, 5) = -11.$$

Summary We list all the function value candidates: 7, 2, -61, 3, -43, 6, -11. The maximum is 7, which f assumes at $(1, 2)$. The minimum is -61, which f assumes at $(9, 0)$. See Figure 13.51b. ■

Solving extreme value problems with algebraic constraints on the variables usually requires the method of Lagrange multipliers, which is introduced in the next section. But sometimes we can solve such problems directly, as in the next example.

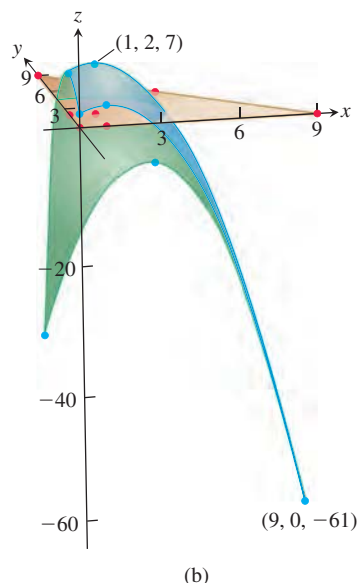

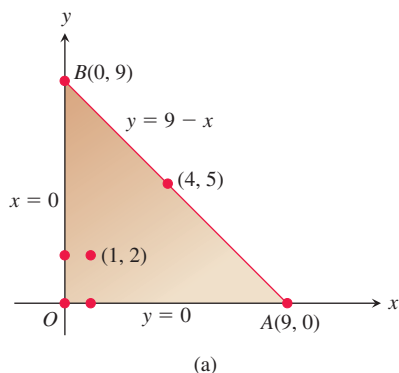

FIGURE 13.51 (a) This triangular region is the domain of the function in Example 6. (b) The graph of the function in Example 6. The blue points are the candidates for maxima or minima.

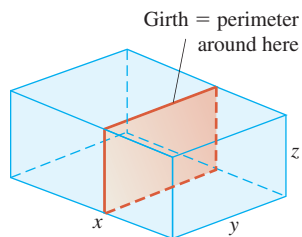

FIGURE 13.52 The box in Example 7.

EXAMPLE 7 A delivery company accepts only rectangular boxes the sum of whose length and girth (perimeter of a cross-section) does not exceed 270 cm. Find the dimensions of an acceptable box of largest volume.

Solution Let x , y , and z represent the length, width, and height of the rectangular box, respectively. Then the girth is $2y + 2z$. We want to maximize the volume $V = xyz$ of the box (Figure 13.52) satisfying $x + 2y + 2z = 270$ (the largest box accepted by the delivery company). Thus, we can write the volume of the box as a function of two variables:

$$\begin{aligned} V(y, z) &= (270 - 2y - 2z)yz & V &= xyz \text{ and} \\ &= 270yz - 2y^2z - 2yz^2. & x &= 270 - 2y - 2z \end{aligned}$$

Setting the first partial derivatives equal to zero,

$$V_y(y, z) = 270z - 4yz - 2z^2 = (270 - 4y - 2z)z = 0$$

$$V_z(y, z) = 270y - 2y^2 - 4yz = (270 - 2y - 4z)y = 0,$$

gives the critical points $(0, 0)$, $(0, 135)$, $(135, 0)$, and $(45, 45)$. The volume is zero at $(0, 0)$, $(0, 135)$, and $(135, 0)$, which are not maximum values. At the point $(45, 45)$, we apply the Second Derivative Test (Theorem 11):

$$V_{yy} = -4z, \quad V_{zz} = -4y, \quad V_{yz} = 270 - 4y - 4z.$$

Then

$$V_{yy}V_{zz} - V_{yz}^2 = 16yz - 4(135 - 2y - 2z)^2.$$

Thus,

$$V_{yy}(45, 45) = -4(45) < 0$$

and

$$\left. (V_{yy}V_{zz} - V_{yz}^2) \right|_{(45, 45)} = 16(45)(45) - 4(-45)^2 > 0,$$

so $(45, 45)$ gives a maximum volume. The dimensions of the package are $x = 270 - 2(45) - 2(45) = 90$ cm, $y = 45$ cm, and $z = 45$ cm. The maximum volume is $V = (90)(45)(45) = 182,250 \text{ cm}^3$, or 182.25 liters. ■

Despite the power of Theorem 11, we urge you to remember its limitations. It does not apply to boundary points of a function's domain, where it is possible for a function to have extreme values along with nonzero derivatives. Also, it does not apply to points where either f_x or f_y fails to exist.

Summary of Max-Min Tests

The extreme values of $f(x, y)$ can occur only at

- i) **boundary points** of the domain of f
- ii) **critical points** (interior points where $f_x = f_y = 0$ or points where f_x or f_y fails to exist)

If the first- and second-order partial derivatives of f are continuous throughout a disk centered at a point (a, b) and if $f_x(a, b) = f_y(a, b) = 0$, then the nature of $f(a, b)$ can be tested with the **Second Derivative Test**:

- i) $f_{xx} < 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at $(a, b) \Rightarrow$ **local maximum**
- ii) $f_{xx} > 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at $(a, b) \Rightarrow$ **local minimum**
- iii) $f_{xx}f_{yy} - f_{xy}^2 < 0$ at $(a, b) \Rightarrow$ **saddle point**
- iv) $f_{xx}f_{yy} - f_{xy}^2 = 0$ at $(a, b) \Rightarrow$ **test is inconclusive**

Finding maximum and minimum values for functions of more than two variables is an important problem with many important applications, from machine learning to making economic predictions. The problem becomes much harder as the number of variables increases. The process of finding extrema for functions with high-dimensional domains is discussed in Appendices B.2 and B.3.

EXERCISES 13.7

Finding Local Extrema

Find all the local maxima, local minima, and saddle points of the functions in Exercises 1–30.

- $f(x, y) = x^2 + xy + y^2 + 3x - 3y + 4$
- $f(x, y) = 2xy - 5x^2 - 2y^2 + 4x + 4y - 4$
- $f(x, y) = x^2 + xy + 3x + 2y + 5$
- $f(x, y) = 5xy - 7x^2 + 3x - 6y + 2$
- $f(x, y) = 2xy - x^2 - 2y^2 + 3x + 4$
- $f(x, y) = x^2 - 4xy + y^2 + 6y + 2$
- $f(x, y) = 2x^2 + 3xy + 4y^2 - 5x + 2y$
- $f(x, y) = x^2 - 2xy + 2y^2 - 2x + 2y + 1$
- $f(x, y) = x^2 - y^2 - 2x + 4y + 6$
- $f(x, y) = x^2 + 2xy$
- $f(x, y) = \sqrt{56x^2 - 8y^2 - 16x - 31} + 1 - 8x$
- $f(x, y) = 1 - \sqrt[3]{x^2 + y^2}$
- $f(x, y) = x^3 - y^3 - 2xy + 6$
- $f(x, y) = x^3 + 3xy + y^3$
- $f(x, y) = 6x^2 - 2x^3 + 3y^2 + 6xy$
- $f(x, y) = x^3 + y^3 + 3x^2 - 3y^2 - 8$
- $f(x, y) = x^3 + 3xy^2 - 15x + y^3 - 15y$
- $f(x, y) = 2x^3 + 2y^3 - 9x^2 + 3y^2 - 12y$
- $f(x, y) = 4xy - x^4 - y^4$
- $f(x, y) = x^4 + y^4 + 4xy$
- $f(x, y) = \frac{1}{x^2 + y^2 - 1}$
- $f(x, y) = \frac{1}{x} + xy + \frac{1}{y}$
- $f(x, y) = y \sin x$
- $f(x, y) = e^{2x} \cos y$
- $f(x, y) = e^{x^2 + y^2 - 4x}$
- $f(x, y) = e^y - ye^x$
- $f(x, y) = e^{-y}(x^2 + y^2)$
- $f(x, y) = e^x(x^2 - y^2)$
- $f(x, y) = 2 \ln x + \ln y - 4x - y$
- $f(x, y) = \ln(x + y) + x^2 - y$

Finding Absolute Extrema

In Exercises 31–38, find the absolute maxima and minima of the functions on the given domains.

- $f(x, y) = 2x^2 - 4x + y^2 - 4y + 1$ on the closed triangular plate bounded by the lines $x = 0$, $y = 2$, $y = 2x$ in the first quadrant
- $D(x, y) = x^2 - xy + y^2 + 1$ on the closed triangular plate in the first quadrant bounded by the lines $x = 0$, $y = 4$, $y = x$
- $f(x, y) = x^2 + y^2$ on the closed triangular plate bounded by the lines $x = 0$, $y = 0$, $y + 2x = 2$ in the first quadrant
- $T(x, y) = x^2 + xy + y^2 - 6x$ on the rectangular plate $0 \leq x \leq 5$, $-3 \leq y \leq 3$

- $T(x, y) = x^2 + xy + y^2 - 6x + 2$ on the rectangular plate $0 \leq x \leq 5$, $-3 \leq y \leq 0$

- $f(x, y) = 48xy - 32x^3 - 24y^2$ on the rectangular plate $0 \leq x \leq 1$, $0 \leq y \leq 1$

- $f(x, y) = (4x - x^2)\cos y$ on the rectangular plate $1 \leq x \leq 3$, $-\pi/4 \leq y \leq \pi/4$

- $f(x, y) = 4x - 8xy + 2y + 1$ on the triangular plate bounded by the lines $x = 0$, $y = 0$, $x + y = 1$ in the first quadrant

- Find two numbers a and b with $a \leq b$ such that

$$\int_a^b (6 - x - x^2) dx$$

has its largest value.

- Find two numbers a and b with $a \leq b$ such that

$$\int_a^b (24 - 2x - x^2)^{1/3} dx$$

has its largest value.

- Temperatures** A flat circular plate has the shape of the region $x^2 + y^2 \leq 1$. The plate, including the boundary where $x^2 + y^2 = 1$, is heated so that the temperature at the point (x, y) is

$$T(x, y) = x^2 + 2y^2 - x.$$

Find the temperatures at the hottest and coldest points on the plate.

- Find the critical point of

$$f(x, y) = xy + 2x - \ln x^2 y$$

in the open first quadrant ($x > 0$, $y > 0$) and show that f takes on a minimum there.

Theory and Examples

- Find the maxima, minima, and saddle points of $f(x, y)$, if any, given that

$$\text{a. } f_x = 2x - 4y \quad \text{and} \quad f_y = 2y - 4x$$

$$\text{b. } f_x = 2x - 2 \quad \text{and} \quad f_y = 2y - 4$$

$$\text{c. } f_x = 9x^2 - 9 \quad \text{and} \quad f_y = 2y + 4$$

Describe your reasoning in each case.

- The discriminant $f_{xx}f_{yy} - f_{xy}^2$ is zero at the origin for each of the following functions, so the Second Derivative Test fails there. Determine whether the function has a maximum, a minimum, or neither at the origin by imagining what the surface $z = f(x, y)$ looks like. Describe your reasoning in each case.

$$\text{a. } f(x, y) = x^2 y^2$$

$$\text{b. } f(x, y) = 1 - x^2 y^2$$

$$\text{c. } f(x, y) = xy^2$$

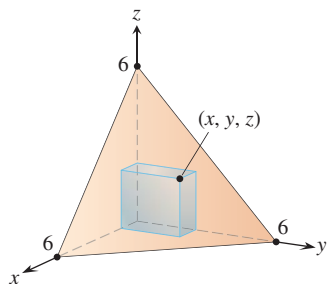

$$\text{d. } f(x, y) = x^3 y^2$$

$$\text{e. } f(x, y) = x^3 y^3$$

$$\text{f. } f(x, y) = x^4 y^4$$

- Show that $(0, 0)$ is a critical point of $f(x, y) = x^2 + kxy + y^2$ no matter what value the constant k has. (*Hint:* Consider two cases: $k = 0$ and $k \neq 0$.)

46. For what values of the constant k does the Second Derivative Test guarantee that $f(x, y) = x^2 + kxy + y^2$ will have a saddle point at $(0, 0)$? A local minimum at $(0, 0)$? For what values of k is the Second Derivative Test inconclusive? Give reasons for your answers.
47. If $f_x(a, b) = f_y(a, b) = 0$, must f have a local maximum or minimum value at (a, b) ? Give reasons for your answer.
48. Can you conclude anything about $f(a, b)$ if f and its first and second partial derivatives are continuous throughout a disk centered at the critical point (a, b) and $f_{xx}(a, b)$ and $f_{yy}(a, b)$ differ in sign? Give reasons for your answer.
49. Among all the points on the graph of $z = 10 - x^2 - y^2$ that lie above the plane $x + 2y + 3z = 0$, find the point farthest from the plane.
50. Find the point on the graph of $z = x^2 + y^2 + 10$ nearest the plane $x + 2y - z = 0$.
51. Find the point on the plane $3x + 2y + z = 6$ that is nearest the origin.
52. Find the minimum distance from the point $(2, -1, 1)$ to the plane $x + y - z = 2$.
53. Find three numbers whose sum is 9 and whose sum of squares is a minimum.
54. Find three positive numbers whose sum is 3 and whose product is a maximum.
55. Find the maximum value of $s = xy + yz + xz$ where $x + y + z = 6$.
56. Find the minimum distance from the cone $z = \sqrt{x^2 + y^2}$ to the point $(-6, 4, 0)$.
57. Find the dimensions of the rectangular box of maximum volume that can be inscribed inside the sphere $x^2 + y^2 + z^2 = 4$.
58. Among all closed rectangular boxes of volume 27 cm^3 , what is the smallest surface area?
59. You are to construct an open rectangular box from 12 m^2 of material. What dimensions will result in a box of maximum volume?
60. Consider the function $f(x, y) = x^2 + y^2 + 2xy - x - y + 1$ over the square $0 \leq x \leq 1$ and $0 \leq y \leq 1$.
- Show that f has an absolute minimum along the line segment $2x + 2y = 1$ in this square. What is the absolute minimum value?
 - Find the absolute maximum value of f over the square.
61. Find the point on the graph of $y^2 - xz^2 = 4$ nearest the origin.
62. A rectangular box is inscribed in the region in the first octant bounded above by the plane with x -intercept 6, y -intercept 6, and z -intercept 6.

- Find an equation for the plane.
- Find the dimensions of the box of maximum volume.

Extreme Values on Parametrized Curves To find the extreme values of a function $f(x, y)$ on a curve $x = x(t)$, $y = y(t)$, we treat f as a function of the single variable t and use the Chain Rule to find where df/dt is zero. As in any other single-variable case, the extreme values of f are then found among the values at

- The critical points (points where df/dt is zero or fails to exist), and
- The endpoints of the parameter domain.

In Exercises 63–66, find the absolute maximum and minimum values of the following functions on the given curves.

63. Functions:

a. $f(x, y) = x + y$ b. $g(x, y) = xy$

c. $h(x, y) = 2x^2 + y^2$

Curves:

i) The semicircle $x^2 + y^2 = 4$, $y \geq 0$

ii) The quarter circle $x^2 + y^2 = 4$, $x \geq 0$, $y \geq 0$

Use the parametric equations $x = 2 \cos t$, $y = 2 \sin t$.

64. Functions:

a. $f(x, y) = 2x + 3y$ b. $g(x, y) = xy$

c. $h(x, y) = x^2 + 3y^2$

Curves:

i) The semiellipse $(x^2/9) + (y^2/4) = 1$, $y \geq 0$

ii) The quarter ellipse $(x^2/9) + (y^2/4) = 1$, $x \geq 0$, $y \geq 0$

Use the parametric equations $x = 3 \cos t$, $y = 2 \sin t$.

65. Function: $f(x, y) = xy$

Curves:

i) The line $x = 2t$, $y = t + 1$

ii) The line segment $x = 2t$, $y = t + 1$, $-1 \leq t \leq 0$

iii) The line segment $x = 2t$, $y = t + 1$, $0 \leq t \leq 1$

66. Functions:

a. $f(x, y) = x^2 + y^2$ b. $g(x, y) = 1/(x^2 + y^2)$

Curves:

i) The line $x = t$, $y = 2 - 2t$

ii) The line segment $x = t$, $y = 2 - 2t$, $0 \leq t \leq 1$

67. **Least squares and regression lines** When we try to fit a line $y = mx + b$ to a set of numerical data points $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$, we usually choose the line that minimizes the sum of the squares of the vertical distances from the points to the line. In theory, this means finding the values of m and b that minimize the value of the function

$$w = (mx_1 + b - y_1)^2 + \dots + (mx_n + b - y_n)^2. \quad (1)$$

(See the accompanying figure.) Show that the values of m and b that do this are

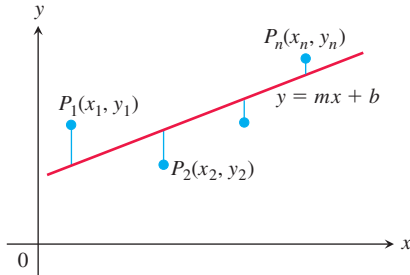

$$m = \frac{(\sum x_k)(\sum y_k) - n \sum x_k y_k}{(\sum x_k)^2 - n \sum x_k^2}, \quad (2)$$

$$b = \frac{1}{n}(\sum y_k - m \sum x_k), \quad (3)$$

with all sums running from $k = 1$ to $k = n$. Many scientific calculators have these formulas built in, enabling you to find m and b with only a few keystrokes after you have entered the data.

The line $y = mx + b$ determined by these values of m and b is called the **least squares line**, **regression line**, or **trend line** for the data under study. Finding a least squares line lets you

1. summarize data with a simple expression,
2. predict values of y for other, experimentally untried values of x ,
3. handle data analytically.

In Exercises 68–70, use Equations (2) and (3) to find the least squares line for each set of data points. Then use the linear equation you obtain to predict the value of y that would correspond to $x = 4$.

68. $(-2, 0), (0, 2), (2, 3)$

69. $(-1, 2), (0, 1), (3, -4)$

70. $(0, 0), (1, 2), (2, 3)$

COMPUTER EXPLORATIONS

In Exercises 71–76, you will explore functions to identify their local extrema. Use a CAS to perform the following steps:

- a. Plot the function over the given rectangle.
- b. Plot some level curves in the rectangle.
- c. Calculate the function's first partial derivatives and use the CAS equation solver to find the critical points. How are the critical points related to the level curves plotted in part (b)? Which critical points, if any, appear to give a saddle point? Give reasons for your answer.
- d. Calculate the function's second partial derivatives and find the discriminant $f_{xx}f_{yy} - f_{xy}^2$.
- e. Using the max-min tests, classify the critical points found in part (c). Are your findings consistent with your discussion in part (c)?

71. $f(x, y) = x^2 + y^3 - 3xy, \quad -5 \leq x \leq 5, \quad -5 \leq y \leq 5$

72. $f(x, y) = x^3 - 3xy^2 + y^2, \quad -2 \leq x \leq 2, \quad -2 \leq y \leq 2$

73. $f(x, y) = x^4 + y^2 - 8x^2 - 6y + 16, \quad -3 \leq x \leq 3, \quad -6 \leq y \leq 6$

74. $f(x, y) = 2x^4 + y^4 - 2x^2 - 2y^2 + 3, \quad -3/2 \leq x \leq 3/2, \quad -3/2 \leq y \leq 3/2$

75. $f(x, y) = 5x^6 + 18x^5 - 30x^4 + 30xy^2 - 120x^3, \quad -4 \leq x \leq 3, \quad -2 \leq y \leq 2$

76. $f(x, y) = \begin{cases} x^5 \ln(x^2 + y^2), & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0) \end{cases}, \quad -2 \leq x \leq 2, \quad -2 \leq y \leq 2$

13.8 Lagrange Multipliers

HISTORICAL BIOGRAPHY

Joseph Louis Lagrange
(1736–1813)

Lagrange was born in Turin, Italy. He enjoyed studying mathematics, despite his father's wish that he study law. Lagrange's mathematical contributions began as early as 1754 with the discovery of the calculus of variations and continued with applications to mechanics in 1756.

Sometimes we need to find the extreme values of a function whose domain is constrained to lie within some particular subset of the plane—for example, a disk, a closed triangular region, or along a curve. We saw an instance of this situation in Example 6 of the previous section. Here we explore a powerful method for finding extreme values of constrained functions: the method of *Lagrange multipliers*.

Constrained Maxima and Minima

To gain some insight, we first consider a problem where a constrained minimum can be found by eliminating a variable.

EXAMPLE 1 Find the point $p(x, y, z)$ on the plane $2x + y - z - 5 = 0$ that is closest to the origin.

Solution The problem asks us to find the minimum value of the function

$$|\overline{OP}| = \sqrt{(x-0)^2 + (y-0)^2 + (z-0)^2} = \sqrt{x^2 + y^2 + z^2}$$

subject to the constraint that

$$2x + y - z - 5 = 0.$$

Since $|\overline{OP}|$ has a minimum value wherever the function

$$f(x, y, z) = x^2 + y^2 + z^2$$

has a minimum value, we may solve the problem by finding the minimum value of $f(x, y, z)$ subject to the constraint $2x + y - z - 5 = 0$ (thus avoiding square roots). If we regard x and y as the independent variables in this equation and write z as

$$z = 2x + y - 5,$$

our problem reduces to finding the points (x, y) at which the function

$$h(x, y) = f(x, y, 2x + y - 5) = x^2 + y^2 + (2x + y - 5)^2$$

has its minimum value or values. Since the domain of h is the entire xy -plane, the First Derivative Theorem of Section 13.7 tells us that any minima that h might have must occur at points where

$$h_x = 2x + 2(2x + y - 5)(2) = 0, \quad h_y = 2y + 2(2x + y - 5) = 0.$$

This leads to

$$10x + 4y = 20, \quad 4x + 4y = 10,$$

which has the solution

$$x = \frac{5}{3}, \quad y = \frac{5}{6}.$$

We may apply a geometric argument together with the Second Derivative Test to show that these values minimize h . The z -coordinate of the corresponding point on the plane $z = 2x + y - 5$ is

$$z = 2\left(\frac{5}{3}\right) + \frac{5}{6} - 5 = -\frac{5}{6}.$$

Therefore, the point we seek is

$$\text{Closest point: } P\left(\frac{5}{3}, \frac{5}{6}, -\frac{5}{6}\right).$$

The distance from P to the origin is $5/\sqrt{6} \approx 2.04$. ■

Attempts to solve a constrained maximum or minimum problem by substitution, as we might call the method of Example 1, do not always go smoothly.

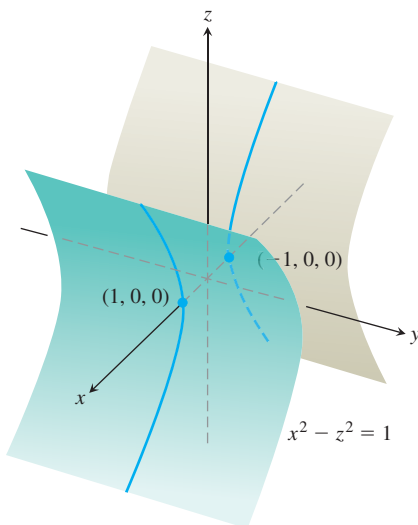

FIGURE 13.53 The hyperbolic cylinder $x^2 - z^2 - 1 = 0$ in Example 2.

EXAMPLE 2 Find the points on the hyperbolic cylinder $x^2 - z^2 - 1 = 0$ that are closest to the origin.

Solution 1 The cylinder is shown in Figure 13.53. We seek the points on the cylinder closest to the origin. These are the points whose coordinates minimize the value of the function

$$f(x, y, z) = x^2 + y^2 + z^2 \quad \text{Square of the distance}$$

subject to the constraint that $x^2 - z^2 - 1 = 0$. If we regard x and y as independent variables in the constraint equation, then

$$z^2 = x^2 - 1,$$

and the values of $f(x, y, z) = x^2 + y^2 + z^2$ on the cylinder are given by the function

$$h(x, y) = x^2 + y^2 + (x^2 - 1) = 2x^2 + y^2 - 1.$$

To find the points on the cylinder whose coordinates minimize f , we look for the points in the xy -plane whose coordinates minimize h . The only extreme value of h occurs where

$$h_x = 4x = 0 \quad \text{and} \quad h_y = 2y = 0,$$

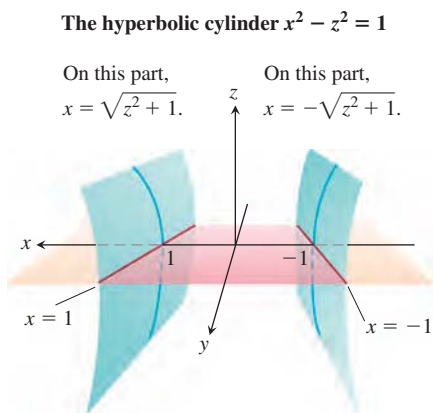

FIGURE 13.54 The region in the xy -plane from which the first two coordinates of the points (x, y, z) on the hyperbolic cylinder $x^2 - z^2 = 1$ are selected excludes the band $-1 < x < 1$ in the xy -plane (Example 2).

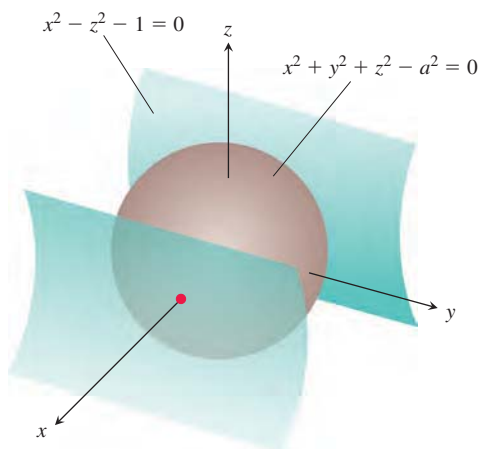

FIGURE 13.55 A sphere expanding like a soap bubble centered at the origin until it just touches the hyperbolic cylinder $x^2 - z^2 - 1 = 0$ (Example 2).

λ is the Greek letter lambda.

that is, at the point $(0, 0)$. But there are no points on the cylinder where both x and y are zero. What went wrong?

What happened is that the First Derivative Theorem found (as it should have) the point *in the domain of h* where h has a minimum value. We, on the other hand, want the points *on the cylinder* where h has a minimum value. Although the domain of h is the entire xy -plane, the domain from which we can select the first two coordinates of the points (x, y, z) on the cylinder is restricted to the projection, or “shadow” of the cylinder on the xy -plane; it does not include the band between the lines $x = -1$ and $x = 1$ (Figure 13.54).

We can avoid this problem if we treat y and z as independent variables (instead of x and y) and express x in terms of y and z as

$$x^2 = z^2 + 1.$$

With this substitution, $f(x, y, z) = x^2 + y^2 + z^2$ becomes

$$k(y, z) = (z^2 + 1) + y^2 + z^2 = 1 + y^2 + 2z^2$$

and we look for the points where k takes on its smallest value. The domain of k in the yz -plane now matches the domain from which we select the y - and z -coordinates of the points (x, y, z) on the cylinder. Hence, the points that minimize k in the plane will have corresponding points on the cylinder. The smallest values of k occur where

$$k_y = 2y = 0 \quad \text{and} \quad k_z = 4z = 0,$$

or where $y = z = 0$. This leads to

$$x^2 = z^2 + 1 = 1, \quad x = \pm 1.$$

The corresponding points on the cylinder are $(\pm 1, 0, 0)$. We can see from the inequality

$$k(y, z) = 1 + y^2 + 2z^2 \geq 1$$

that the points $(\pm 1, 0, 0)$ give a minimum value for k . We can also see that the minimum distance from the origin to a point on the cylinder is 1 unit.

Solution 2 Another way to find the points on the cylinder closest to the origin is to imagine a small sphere centered at the origin expanding like a soap bubble until it just touches the cylinder (Figure 13.55). At each point of contact, the cylinder and sphere have the same tangent plane and normal line. Therefore, if the sphere and cylinder are represented as the level surfaces obtained by setting

$$f(x, y, z) = x^2 + y^2 + z^2 - a^2 \quad \text{and} \quad g(x, y, z) = x^2 - z^2 - 1$$

equal to 0, then the gradients ∇f and ∇g will be parallel where the surfaces touch. At any point of contact, we should therefore be able to find a scalar λ (“lambda”) such that

$$\nabla f = \lambda \nabla g,$$

or

$$2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k} = \lambda(2x\mathbf{i} - 2z\mathbf{k}).$$

Thus, the coordinates x , y , and z of any point of tangency will have to satisfy the three scalar equations

$$2x = 2\lambda x, \quad 2y = 0, \quad 2z = -2\lambda z.$$

For what values of λ will a point (x, y, z) whose coordinates satisfy these scalar equations also lie on the surface $x^2 - z^2 - 1 = 0$? To answer this question, we use our knowledge that no point on the surface has a zero x -coordinate to conclude that $x \neq 0$. Hence, $2x = 2\lambda x$ only if

$$2 = 2\lambda, \quad \text{or} \quad \lambda = 1.$$

For $\lambda = 1$, the equation $2z = -2\lambda z$ becomes $2z = -2z$. If this equation is to be satisfied as well, z must be zero. Since $y = 0$ also (from the equation $2y = 0$), we conclude that the points we seek all have coordinates of the form

$$(x, 0, 0).$$

What points on the surface $x^2 - z^2 = 1$ have coordinates of this form? The answer is the points $(x, 0, 0)$ for which

$$x^2 - (0)^2 = 1, \quad x^2 = 1, \quad \text{or} \quad x = \pm 1.$$

The points on the cylinder closest to the origin are the points $(\pm 1, 0, 0)$. ■

The Method of Lagrange Multipliers

In Solution 2 of Example 2, we used the **method of Lagrange multipliers**. The method says that the local extreme values of a function $f(x, y, z)$ whose variables are subject to a constraint $g(x, y, z) = 0$ are to be found on the surface $g = 0$ among the points where

$$\nabla f = \lambda \nabla g$$

for some scalar λ (called a **Lagrange multiplier**).

To explore the method further and see why it works, we first make the following observation, which we state as a theorem.

THEOREM 12—The Orthogonal Gradient Theorem

Suppose that $f(x, y, z)$ is differentiable in a region whose interior contains a smooth curve

$$C: \mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}.$$

If P_0 is a point on C where f has a local maximum or minimum relative to its values on C , then ∇f is orthogonal to the curve's tangent vector \mathbf{r}' at P_0 .

Proof The values of f on C are given by the composition $f(x(t), y(t), z(t))$, whose derivative with respect to t is

$$\frac{df}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt} + \frac{\partial f}{\partial z} \frac{dz}{dt} = \nabla f \cdot \mathbf{r}'.$$

At any point P_0 where f has a local maximum or minimum relative to its values on the curve, $df/dt = 0$, so

$$\nabla f \cdot \mathbf{r}' = 0. \quad \blacksquare$$

By dropping the z -terms in Theorem 12, we obtain a similar result for functions of two variables.

COROLLARY At the points on a smooth curve $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j}$ where a differentiable function $f(x, y)$ takes on its local maxima or minima relative to its values on the curve, we have $\nabla f \cdot \mathbf{r}' = 0$.

Theorem 12 is the key to the method of Lagrange multipliers. Suppose that $f(x, y, z)$ and $g(x, y, z)$ are differentiable and that P_0 is a point on the surface $g(x, y, z) = 0$ where f has a local maximum or minimum value relative to its other values on the surface. We assume also that $\nabla g \neq \mathbf{0}$ at points on the surface $g(x, y, z) = 0$. Then f takes on a local maximum or minimum at P_0 relative to its values on every differentiable curve through P_0 on the surface $g(x, y, z) = 0$. Therefore, ∇f is orthogonal to the tangent vector of every

such differentiable curve through P_0 . Moreover, so is ∇g (because ∇g is perpendicular to the level surface $g = 0$, as we saw in Section 13.5). Therefore, at P_0 , ∇f is some scalar multiple λ of ∇g .

The Method of Lagrange Multipliers

Suppose that $f(x, y, z)$ and $g(x, y, z)$ are differentiable and $\nabla g \neq \mathbf{0}$ when $g(x, y, z) = 0$. To find the local maximum and minimum values of f subject to the constraint $g(x, y, z) = 0$ (if these exist), find the values of x, y, z , and λ that simultaneously satisfy the equations

$$\nabla f = \lambda \nabla g \quad \text{and} \quad g(x, y, z) = 0. \quad (1)$$

If they exist, absolute extrema can be found by comparing these values of f at each critical point satisfying Equation (1). For functions of two independent variables, the condition is similar, but without the variable z .

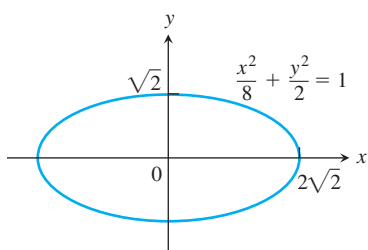

FIGURE 13.56 Example 3 shows how to find the largest and smallest values of the product xy on this ellipse.

Some care must be used in applying this method. An extreme value may not actually exist (Exercise 45).

EXAMPLE 3 Find the largest and smallest values that the function

$$f(x, y) = xy$$

takes on the ellipse (Figure 13.56)

$$\frac{x^2}{8} + \frac{y^2}{2} = 1.$$

Solution We want to find the extreme values of $f(x, y) = xy$ subject to the constraint

$$g(x, y) = \frac{x^2}{8} + \frac{y^2}{2} - 1 = 0.$$

To do so, we first find the values of x, y , and λ for which

$$\nabla f = \lambda \nabla g \quad \text{and} \quad g(x, y) = 0.$$

The gradient equation in Equations (1) gives

$$y\mathbf{i} + x\mathbf{j} = \frac{\lambda}{4}x\mathbf{i} + \lambda y\mathbf{j},$$

from which we find

$$y = \frac{\lambda}{4}x, \quad x = \lambda y,$$

and

$$y = \frac{\lambda}{4}(\lambda y) = \frac{\lambda^2}{4}y,$$

Caution: Don't cancel y without considering the case where $y = 0$.

so that

$$y = 0 \text{ or } \lambda = \pm 2.$$

We now consider these two cases.

Case 1: If $y = 0$, then $x = y = 0$. But $(0, 0)$ is not on the ellipse. Hence, $y \neq 0$.

Case 2: If $y \neq 0$, then $\lambda = \pm 2$ and $x = \pm 2y$. Substituting this in the equation $g(x, y) = 0$ gives

$$\frac{(\pm 2y)^2}{8} + \frac{y^2}{2} = 1, \quad 4y^2 + 4y^2 = 8 \quad \text{and} \quad y = \pm 1.$$

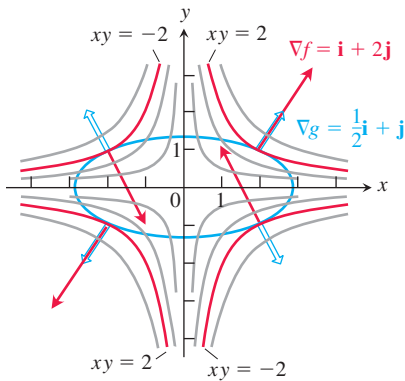

FIGURE 13.57 When subjected to the constraint $g(x, y) = x^2/8 + y^2/2 - 1 = 0$, the function $f(x, y) = xy$ takes on extreme values at the four points $(\pm 2, \pm 1)$. These are the points on the ellipse where ∇f (red) is a scalar multiple of ∇g (blue) (Example 3).

The function $f(x, y) = xy$ therefore has critical points on the ellipse at the four points $(\pm 2, 1)$, $(\pm 2, -1)$. The extreme values are found by examining the values of f at these four points. The absolute maximum is $f(2, 1) = f(-2, -1) = 2$, and the absolute minimum is $f(-2, 1) = f(2, -1) = -2$.

The Geometry of the Solution The level curves of the function $f(x, y) = xy$ are the hyperbolas $xy = c$ (Figure 13.57). The farther the hyperbolas lie from the origin, the larger the absolute value of f . We want to find the extreme values of $f(x, y)$, given that the point (x, y) also lies on the ellipse $x^2 + 4y^2 = 8$. Which hyperbolas intersecting the ellipse lie farthest from the origin? The hyperbolas that just graze the ellipse, the ones that are tangent to it, are farthest. At these points, any vector normal to the hyperbola is normal to the ellipse, so $\nabla f = y\mathbf{i} + x\mathbf{j}$ is a multiple ($\lambda = \pm 2$) of $\nabla g = (x/4)\mathbf{i} + y\mathbf{j}$. At the point $(2, 1)$, for example,

$$\nabla f = \mathbf{i} + 2\mathbf{j}, \quad \nabla g = \frac{1}{2}\mathbf{i} + \mathbf{j}, \quad \text{and} \quad \nabla f = 2\nabla g.$$

At the point $(-2, 1)$,

$$\nabla f = \mathbf{i} - 2\mathbf{j}, \quad \nabla g = -\frac{1}{2}\mathbf{i} + \mathbf{j}, \quad \text{and} \quad \nabla f = -2\nabla g. \quad \blacksquare$$

EXAMPLE 4 Find the maximum and minimum values of the function $f(x, y) = 3x + 4y$ on the circle $x^2 + y^2 = 1$.

Solution We model this as a Lagrange multiplier problem with

$$f(x, y) = 3x + 4y, \quad g(x, y) = x^2 + y^2 - 1$$

and look for the values of x , y , and λ that satisfy the equations

$$\begin{aligned} \nabla f &= \lambda \nabla g: & 3\mathbf{i} + 4\mathbf{j} &= 2x\lambda\mathbf{i} + 2y\lambda\mathbf{j} \\ g(x, y) &= 0: & x^2 + y^2 - 1 &= 0. \end{aligned}$$

The gradient equation implies that $\lambda \neq 0$ and gives

$$x = \frac{3}{2\lambda}, \quad y = \frac{2}{\lambda}.$$

These equations tell us, among other things, that x and y have the same sign. With these values for x and y , the equation $g(x, y) = 0$ gives

$$\left(\frac{3}{2\lambda}\right)^2 + \left(\frac{2}{\lambda}\right)^2 - 1 = 0,$$

so

$$\frac{9}{4\lambda^2} + \frac{4}{\lambda^2} = 1, \quad 9 + 16 = 4\lambda^2, \quad 4\lambda^2 = 25, \quad \text{and} \quad \lambda = \pm \frac{5}{2}.$$

Thus,

$$x = \frac{3}{2\lambda} = \pm \frac{3}{5}, \quad y = \frac{2}{\lambda} = \pm \frac{4}{5},$$

and $f(x, y) = 3x + 4y$ has critical points at $(x, y) = \pm(3/5, 4/5)$.

By calculating the value of $3x + 4y$ at the points $\pm(3/5, 4/5)$, we see that its maximum and minimum values on the circle $x^2 + y^2 = 1$ are

$$3\left(\frac{3}{5}\right) + 4\left(\frac{4}{5}\right) = \frac{25}{5} = 5 \quad \text{and} \quad 3\left(-\frac{3}{5}\right) + 4\left(-\frac{4}{5}\right) = -\frac{25}{5} = -5.$$

The Geometry of the Solution The level curves of $f(x, y) = 3x + 4y$ are the lines $3x + 4y = c$ (Figure 13.58). The farther the lines lie from the origin, the larger the absolute value of f . We want to find the extreme values of $f(x, y)$ given that the point (x, y)

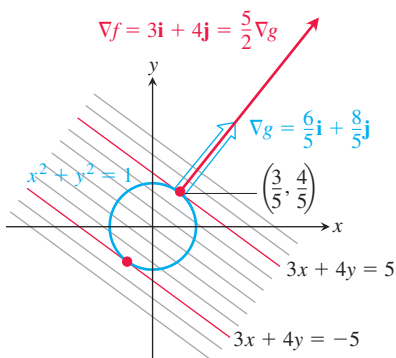

FIGURE 13.58 The function $f(x, y) = 3x + 4y$ takes on its largest value on the unit circle $g(x, y) = x^2 + y^2 - 1 = 0$ at the point $(3/5, 4/5)$ and its smallest value at the point $(-3/5, -4/5)$ (Example 4). At each of these points, ∇f is a scalar multiple of ∇g . The figure shows the gradients at the first point but not at the second.

also lies on the circle $x^2 + y^2 = 1$. Which lines intersecting the circle lie farthest from the origin? The lines tangent to the circle are farthest. At the points of tangency, any vector normal to the line is normal to the circle, so the gradient $\nabla f = 3\mathbf{i} + 4\mathbf{j}$ is a multiple ($\lambda = \pm 5/2$) of the gradient $\nabla g = 2x\mathbf{i} + 2y\mathbf{j}$. At the point $(3/5, 4/5)$, for example,

$$\nabla f = 3\mathbf{i} + 4\mathbf{j}, \quad \nabla g = \frac{6}{5}\mathbf{i} + \frac{8}{5}\mathbf{j}, \quad \text{and} \quad \nabla f = \frac{5}{2}\nabla g. \quad \blacksquare$$

Lagrange Multipliers with Two Constraints

Many problems require us to find the extreme values of a differentiable function $f(x, y, z)$ whose variables are subject to two constraints. If the constraints are

$$g_1(x, y, z) = 0 \quad \text{and} \quad g_2(x, y, z) = 0$$

and g_1 and g_2 are differentiable, with ∇g_1 not parallel to ∇g_2 , we find the constrained local maxima and minima of f by introducing two Lagrange multipliers λ and μ (mu, pronounced “mew”). That is, we locate the points $P(x, y, z)$ where f takes on its constrained extreme values by finding the values of x, y, z, λ , and μ that simultaneously satisfy the three equations

$$\nabla f = \lambda \nabla g_1 + \mu \nabla g_2, \quad g_1(x, y, z) = 0, \quad g_2(x, y, z) = 0 \quad (2)$$

Equations (2) have a nice geometric interpretation. The surfaces $g_1 = 0$ and $g_2 = 0$ (usually) intersect in a smooth curve, say C (Figure 13.59). Along this curve we seek the points where f has local maximum and minimum values relative to its other values on the curve. These are the points where ∇f is normal to C , as we saw in Theorem 12. But ∇g_1 and ∇g_2 are also normal to C at these points because C lies in the surfaces $g_1 = 0$ and $g_2 = 0$. Therefore, ∇f lies in the plane determined by ∇g_1 and ∇g_2 , which means that $\nabla f = \lambda \nabla g_1 + \mu \nabla g_2$ for some λ and μ . Since the points we seek also lie in both surfaces, their coordinates must satisfy the equations $g_1(x, y, z) = 0$ and $g_2(x, y, z) = 0$, which are the remaining requirements in Equations (2).

EXAMPLE 5 The plane $x + y + z = 1$ cuts the cylinder $x^2 + y^2 = 1$ in an ellipse (Figure 13.60). Find the points on the ellipse that lie closest to and farthest from the origin.

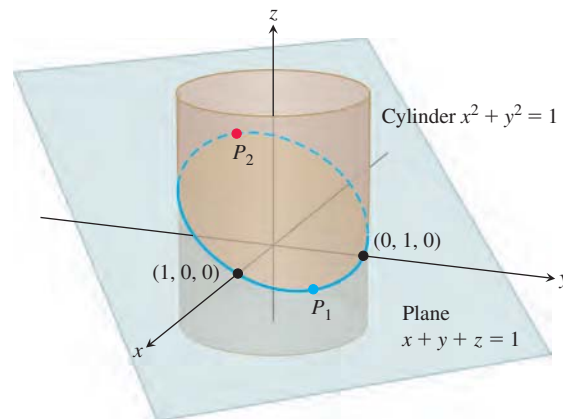

FIGURE 13.60 On the ellipse where the plane and cylinder meet, we find the points closest to and farthest from the origin (Example 5).

Solution We find the extreme values of

$$f(x, y, z) = x^2 + y^2 + z^2$$

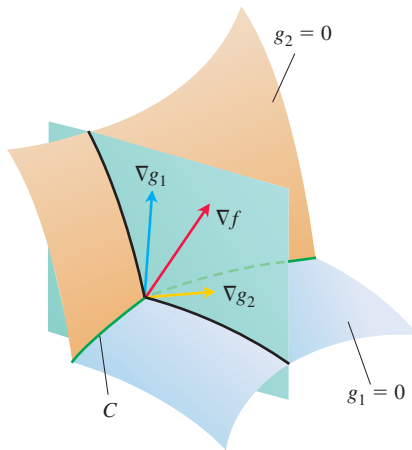

FIGURE 13.59 The vectors ∇g_1 and ∇g_2 lie in a plane perpendicular to the curve C , because ∇g_1 is normal to the surface $g_1 = 0$ and ∇g_2 is normal to the surface $g_2 = 0$.

μ is the Greek letter mu, pronounced “mew”.

(the square of the distance from (x, y, z) to the origin) subject to the constraints

$$g_1(x, y, z) = x^2 + y^2 - 1 = 0 \quad (3)$$

$$g_2(x, y, z) = x + y + z - 1 = 0. \quad (4)$$

The gradient equation in Equations (2) then gives

$$\begin{aligned} \nabla f &= \lambda \nabla g_1 + \mu \nabla g_2 \\ 2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k} &= \lambda(2x\mathbf{i} + 2y\mathbf{j}) + \mu(\mathbf{i} + \mathbf{j} + \mathbf{k}) \\ 2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k} &= (2\lambda x + \mu)\mathbf{i} + (2\lambda y + \mu)\mathbf{j} + \mu\mathbf{k}, \end{aligned}$$

or

$$2x = 2\lambda x + \mu, \quad 2y = 2\lambda y + \mu, \quad 2z = \mu. \quad (5)$$

The scalar equations in Equations (5) yield

$$\begin{aligned} 2x &= 2\lambda x + 2z \Rightarrow (1 - \lambda)x = z, \\ 2y &= 2\lambda y + 2z \Rightarrow (1 - \lambda)y = z. \end{aligned} \quad (6)$$

Equations (6) are satisfied simultaneously if either $\lambda = 1$ and $z = 0$ or $\lambda \neq 1$ and $x = y = z/(1 - \lambda)$.

In the first case, where $z = 0$, solving Equations (3) and (4) simultaneously to find the corresponding points on the ellipse gives the two points $(1, 0, 0)$ and $(0, 1, 0)$. This makes sense when you look at Figure 13.60.

In the second case, where $x = y$, Equations (3) and (4) give

$$\begin{aligned} x^2 + x^2 - 1 &= 0 & x + x + z - 1 &= 0 \\ 2x^2 &= 1 & z &= 1 - 2x \\ x &= \pm \frac{\sqrt{2}}{2} & z &= 1 \mp \sqrt{2}. \end{aligned}$$

The corresponding points on the ellipse are

$$P_1 = \left(\frac{\sqrt{2}}{2}, \frac{\sqrt{2}}{2}, 1 - \sqrt{2} \right) \quad \text{and} \quad P_2 = \left(-\frac{\sqrt{2}}{2}, -\frac{\sqrt{2}}{2}, 1 + \sqrt{2} \right).$$

To find the points at maximum and minimum distance from the origin, we evaluate f at the four critical points $(1, 0, 0)$, $(0, 1, 0)$, P_1 , and P_2 . We see that

$$f(1, 0, 0) = f(0, 1, 0) = 1, \quad f(P_1) = 4 - 2\sqrt{2}, \quad \text{and} \quad f(P_2) = 4 + 2\sqrt{2}.$$

The largest and smallest of these give the absolute extrema. Since

$$1 < 4 - 2\sqrt{2} < 4 + 2\sqrt{2},$$

we see that the absolute minimum value of f is 1 and is attained when f is evaluated at either $(1, 0, 0)$ or $(0, 1, 0)$. The absolute maximum value of f is $4 + 2\sqrt{2}$ and occurs when f is evaluated at P_2 . The value $f(P_1) = 4 - 2\sqrt{2}$ is neither the largest nor the smallest among the values of f at the critical points, so f does not have an absolute extremum at P_1 .

The points on the ellipse closest to the origin are $(1, 0, 0)$ and $(0, 1, 0)$. The point on the ellipse farthest from the origin is P_2 . (See Figure 13.60.) ■

EXERCISES 13.8

Two Independent Variables with One Constraint

- Extrema on an ellipse** Find the points on the ellipse $x^2 + 2y^2 = 1$ where $f(x, y) = xy$ has its extreme values.
- Extrema on a circle** Find the extreme values of $f(x, y) = xy$ subject to the constraint $g(x, y) = x^2 + y^2 - 10 = 0$.

- Maximum on a line** Find the maximum value of $f(x, y) = 49 - x^2 - y^2$ on the line $x + 3y = 10$.
- Extrema on a line** Find the local extreme values of $f(x, y) = x^2y$ on the line $x + y = 3$.

- 5. Constrained minimum** Find the points on the curve $xy^2 = 54$ nearest the origin.
- 6. Constrained minimum** Find the points on the curve $x^2y = 2$ nearest the origin.
- 7.** Use the method of Lagrange multipliers to find
- Minimum on a hyperbola** The minimum value of $x + y$, subject to the constraints $xy = 16$, $x > 0$, $y > 0$.
 - Maximum on a line** The maximum value of xy , subject to the constraint $x + y = 16$.
- Comment on the geometry of each solution.
- 8. Extrema on a curve** Find the points on the curve $x^2 + xy + y^2 = 1$ in the xy -plane that are nearest to and farthest from the origin.
- 9. Minimum surface area with fixed volume** Find the dimensions of the closed right circular cylindrical can of smallest surface area whose volume is $16\pi \text{ cm}^3$.
- 10. Cylinder in a sphere** Find the radius and height of the open right circular cylinder of largest surface area that can be inscribed in a sphere of radius a . What is the largest surface area?
- 11. Rectangle of greatest area in an ellipse** Use the method of Lagrange multipliers to find the dimensions of the rectangle of greatest area that can be inscribed in the ellipse $x^2/16 + y^2/9 = 1$ with sides parallel to the coordinate axes.
- 12. Rectangle of longest perimeter in an ellipse** Find the dimensions of the rectangle of largest perimeter that can be inscribed in the ellipse $x^2/a^2 + y^2/b^2 = 1$ with sides parallel to the coordinate axes. What is the largest perimeter?
- 13. Extrema on a circle** Find the maximum and minimum values of $x^2 + y^2$ subject to the constraint $x^2 - 2x + y^2 - 4y = 0$.
- 14. Extrema on a circle** Find the maximum and minimum values of $3x - y + 6$ subject to the constraint $x^2 + y^2 = 4$.
- 15. Ant on a metal plate** The temperature at a point (x, y) on a metal plate is $T(x, y) = 4x^2 - 4xy + y^2$. An ant on the plate walks around the circle of radius 5 centered at the origin. What are the highest and lowest temperatures encountered by the ant?
- 16. Cheapest storage tank** Your firm has been asked to design a storage tank for liquid petroleum gas. The customer's specifications call for a cylindrical tank with hemispherical ends, and the tank is to hold 8000 m^3 of gas. The customer also wants to use the smallest amount of material possible in building the tank. What radius and height do you recommend for the cylindrical portion of the tank?

Three Independent Variables with One Constraint

- 17. Minimum distance to a point** Find the point on the plane $x + 2y + 3z = 13$ closest to the point $(1, 1, 1)$.
- 18. Maximum distance to a point** Find the point on the sphere $x^2 + y^2 + z^2 = 4$ farthest from the point $(1, -1, 1)$.
- 19. Minimum distance to the origin** Find the minimum distance from the surface $x^2 - y^2 - z^2 = 1$ to the origin.
- 20. Minimum distance to the origin** Find the point on the surface $z = xy + 1$ nearest the origin.
- 21. Minimum distance to the origin** Find the points on the surface $z^2 = xy + 4$ closest to the origin.
- 22. Minimum distance to the origin** Find the point(s) on the surface $xyz = 1$ closest to the origin.
- 23. Extrema on a sphere** Find the maximum and minimum values of
- $$f(x, y, z) = x - 2y + 5z$$
- on the sphere $x^2 + y^2 + z^2 = 30$.
- 24. Extrema on a sphere** Find the points on the sphere $x^2 + y^2 + z^2 = 25$ where $f(x, y, z) = x + 2y + 3z$ has its maximum and minimum values.
- 25. Minimizing a sum of squares** Find three real numbers whose sum is 9 and the sum of whose squares is as small as possible.
- 26. Maximizing a product** Find the largest product the positive numbers x , y , and z can have if $x + y + z^2 = 16$.
- 27. Rectangular box of largest volume in a sphere** Find the dimensions of the closed rectangular box with maximum volume that can be inscribed in the unit sphere.
- 28. Box with vertex on a plane** Find the volume of the largest closed rectangular box in the first octant having three faces in the coordinate planes and a vertex on the plane $x/a + y/b + z/c = 1$, where $a > 0$, $b > 0$, and $c > 0$.
- 29. Hottest point on a space probe** A space probe in the shape of the ellipsoid
- $$4x^2 + y^2 + 4z^2 = 16$$
- enters Earth's atmosphere and its surface begins to heat. After 1 hour, the temperature at the point (x, y, z) on the probe's surface is
- $$T(x, y, z) = 8x^2 + 4yz - 16z + 600.$$
- Find the hottest point on the probe's surface.
- 30. Extreme temperatures on a sphere** Suppose that the Celsius temperature at the point (x, y, z) on the sphere $x^2 + y^2 + z^2 = 1$ is $T = 400xyz^2$. Locate the highest and lowest temperatures on the sphere.
- 31. Cobb–Douglas production function** During the 1920s, Charles Cobb and Paul Douglas modeled total production output P (of a firm, industry, or entire economy) as a function of labor hours involved x and capital invested y (which includes the monetary worth of all buildings and equipment). The Cobb–Douglas production function is given by
- $$P(x, y) = kx^\alpha y^{1-\alpha},$$
- where k and α are constants representative of a particular firm or economy.
- Show that a doubling of both labor and capital results in a doubling of production P .
 - Suppose a particular firm has the production function for $k = 120$ and $\alpha = 3/4$. Assume that each unit of labor costs \$250 and each unit of capital costs \$400, and that the total expenses for all costs cannot exceed \$100,000. Find the maximum production level for the firm.
- 32. (Continuation of Exercise 31.)** If the cost of a unit of labor is c_1 and the cost of a unit of capital is c_2 , and if the firm can spend only B dollars as its total budget, then production P is constrained by $c_1x + c_2y = B$. Show that the maximum production level subject to the constraint occurs at the point
- $$x = \frac{\alpha B}{c_1} \quad \text{and} \quad y = \frac{(1 - \alpha)B}{c_2}.$$

33. Maximizing a utility function: an example from economics

In economics, the usefulness or *utility* of amounts x and y of two capital goods G_1 and G_2 is sometimes measured by a function $U(x, y)$. For example, G_1 and G_2 might be two chemicals a pharmaceutical company needs to have on hand, and $U(x, y)$ might be the gain from manufacturing a product whose synthesis requires different amounts of the chemicals depending on the process used. If G_1 costs a dollars per kilogram, G_2 costs b dollars per kilogram, and the total amount allocated for the purchase of G_1 and G_2 together is c dollars, then the company's managers want to maximize $U(x, y)$ given that $ax + by = c$. Thus, they need to solve a typical Lagrange multiplier problem.

Suppose that

$$U(x, y) = xy + 2x$$

and that the equation $ax + by = c$ simplifies to

$$2x + y = 30.$$

Find the maximum value of U and the corresponding values of x and y subject to this latter constraint.

34. Blood types Human blood types are classified by three gene forms A, B, and O. Blood types AA, BB, and OO are *homozygous*, and blood types AB, AO, and BO are *heterozygous*. If p , q , and r represent the proportions of the three gene forms to the population, respectively, then the *Hardy–Weinberg Law* asserts that the proportion Q of heterozygous persons in any specific population is modeled by

$$Q(p, q, r) = 2(pq + pr + qr),$$

subject to $p + q + r = 1$. Find the maximum value of Q .

35. Length of a beam In Section 4.6, Exercise 47, we posed a problem of finding the length L of the shortest beam that can reach over a wall of height h to a tall building located k units from the wall. Use Lagrange multipliers to show that

$$L = (h^{2/3} + k^{2/3})^{3/2}.$$

36. Locating a radio telescope You are in charge of erecting a radio telescope on a newly discovered planet. To minimize interference, you want to place it where the magnetic field of the planet is weakest. The planet is spherical, with a radius of 6 units. Based on a coordinate system whose origin is at the center of the planet, the strength of the magnetic field is given by $M(x, y, z) = 6x - y^2 + xz + 60$. Where should you locate the radio telescope?

Extreme Values Subject to Two Constraints

37. Maximize the function $f(x, y, z) = x^2 + 2y - z^2$ subject to the constraints $2x - y = 0$ and $y + z = 0$.

38. Minimize the function $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraints $x + 2y + 3z = 6$ and $x + 3y + 9z = 9$.

39. Minimum distance to the origin Find the point closest to the origin on the line of intersection of the planes $y + 2z = 12$ and $x + y = 6$.

40. Find the extreme values of $f(x, y, z) = 2x^2 + yz$ on the intersection of the cylinder $x^2 + z^2 = 9$ and the plane $y - z = 4$.

41. Extrema on a curve of intersection Find the extreme values of $f(x, y, z) = x^2yz + 1$ on the intersection of the plane $z = 1$ with the sphere $x^2 + y^2 + z^2 = 10$.

42. a. Maximum on line of intersection Find the maximum value of $w = xyz$ on the line of intersection of the two planes $x + y + z = 40$ and $x + y - z = 0$.

b. Give a geometric argument to support your claim that you have found a maximum, and not a minimum, value of w .

43. Extrema on a circle of intersection Find the extreme values of the function $f(x, y, z) = xy + z^2$ on the circle in which the plane $y - x = 0$ intersects the sphere $x^2 + y^2 + z^2 = 4$.

44. Minimum distance to the origin Find the point closest to the origin on the curve of intersection of the plane $2y + 4z = 5$ and the cone $z^2 = 4x^2 + 4y^2$.

Theory and Examples

45. The condition $\nabla f = \lambda \nabla g$ is not sufficient Even though $\nabla f = \lambda \nabla g$ is a necessary condition for the occurrence of an extreme value of $f(x, y)$ subject to the conditions $g(x, y) = 0$ and $\nabla g \neq \mathbf{0}$, it does not in itself guarantee that one exists. As a case in point, try using the method of Lagrange multipliers to find a maximum value of $f(x, y) = x + y$ subject to the constraint that $xy = 16$. The method will identify the two points $(4, 4)$ and $(-4, -4)$ as candidates for the location of extreme values. Yet the sum $x + y$ has no maximum value on the hyperbola $xy = 16$. The farther you go from the origin on this hyperbola in the first quadrant, the larger the sum $f(x, y) = x + y$ becomes.

46. A least squares plane The plane $z = Ax + By + C$ is to be “fitted” to the following points (x_k, y_k, z_k) :

$$(0, 0, 0), \quad (0, 1, 1), \quad (1, 1, 1), \quad (1, 0, -1).$$

Find the values of A , B , and C that minimize

$$\sum_{k=1}^4 (Ax_k + By_k + C - z_k)^2,$$

the sum of the squares of the deviations.

47. a. Maximum on a sphere Show that the maximum value of $a^2b^2c^2$ on a sphere of radius r centered at the origin of a Cartesian abc -coordinate system is $(r^2/3)^3$.

b. Geometric and arithmetic means Using part (a), show that for nonnegative numbers a , b , and c ,

$$(abc)^{1/3} \leq \frac{a + b + c}{3};$$

that is, the *geometric mean* of three nonnegative numbers is less than or equal to their *arithmetic mean*.

48. Sum of products Let a_1, a_2, \dots, a_n be n positive numbers. Find the maximum of $\sum_{i=1}^n a_i x_i$ subject to the constraint $\sum_{i=1}^n x_i^2 = 1$.

COMPUTER EXPLORATIONS

In Exercises 49–54, use a CAS to perform the following steps implementing the method of Lagrange multipliers for finding constrained extrema:

a. Form the function $h = f - \lambda_1 g_1 - \lambda_2 g_2$, where f is the function to optimize subject to the constraints $g_1 = 0$ and $g_2 = 0$.

b. Determine all the first partial derivatives of h , including the partials with respect to λ_1 and λ_2 , and set them equal to 0.

c. Solve the system of equations found in part (b) for all the unknowns, including λ_1 and λ_2 .

d. Evaluate f at each of the solution points found in part (c), and select the extreme value subject to the constraints asked for in the exercise.

49. Minimize $f(x, y, z) = xy + yz$ subject to the constraints $x^2 + y^2 - 2 = 0$ and $x^2 + z^2 - 2 = 0$.
50. Minimize $f(x, y, z) = xyz$ subject to the constraints $x^2 + y^2 - 1 = 0$ and $x - z = 0$.
51. Maximize $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraints $2y + 4z - 5 = 0$ and $4x^2 + 4y^2 - z^2 = 0$.
52. Minimize $f(x, y, z) = x^2 + y^2 + z^2$ subject to the constraints $x^2 - xy + y^2 - z^2 - 1 = 0$ and $x^2 + y^2 - 1 = 0$.
53. Minimize $f(x, y, z, w) = x^2 + y^2 + z^2 + w^2$ subject to the constraints $2x - y + z - w - 1 = 0$ and $x + y - z + w - 1 = 0$.
54. Determine the distance from the line $y = x + 1$ to the parabola $y^2 = x$. (Hint: Let (x, y) be a point on the line and (w, z) a point on the parabola. You want to minimize $(x - w)^2 + (y - z)^2$.)

13.9 Taylor's Formula for Two Variables

In this section we use Taylor's formula to derive the Second Derivative Test for local extreme values (Section 13.7) and the error formula for linearizations of functions of two independent variables (Section 13.6). The use of Taylor's formula in these derivations leads to an extension of the formula that provides polynomial approximations of all orders for functions of two independent variables.

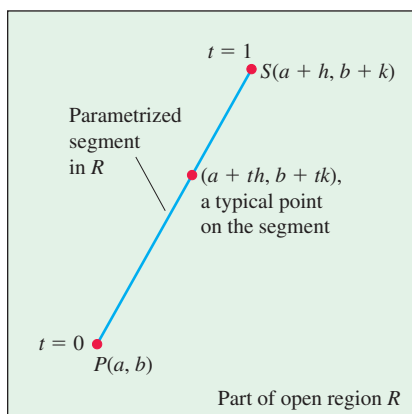

FIGURE 13.61 We begin the derivation of the Second Derivative Test at $P(a, b)$ by parametrizing a typical line segment from P to a point S nearby.

Derivation of the Second Derivative Test

Let $f(x, y)$ have continuous first and second partial derivatives in an open region R containing a point $P(a, b)$ where $f_x = f_y = 0$ (Figure 13.61). Let h and k be increments small enough to put the point $S(a + h, b + k)$ and the line segment joining it to P inside R . We parametrize the segment PS as

$$x = a + th, \quad y = b + tk, \quad 0 \leq t \leq 1.$$

If $F(t) = f(a + th, b + tk)$, the Chain Rule gives

$$F'(t) = f_x \frac{dx}{dt} + f_y \frac{dy}{dt} = hf_x + kf_y.$$

Since f_x and f_y are differentiable (because they have continuous partial derivatives), F' is a differentiable function of t and

$$\begin{aligned} F'' &= \frac{\partial F'}{\partial x} \frac{dx}{dt} + \frac{\partial F'}{\partial y} \frac{dy}{dt} = \frac{\partial}{\partial x}(hf_x + kf_y) \cdot h + \frac{\partial}{\partial y}(hf_x + kf_y) \cdot k \\ &= h^2 f_{xx} + 2hkf_{xy} + k^2 f_{yy}. \quad f_{xy} = f_{yx} \end{aligned}$$

Since F and F' are continuous on $[0, 1]$ and F' is differentiable on $(0, 1)$, we can apply Taylor's formula with $n = 2$ and $a = 0$ to obtain

$$\begin{aligned} F(1) &= F(0) + F'(0)(1 - 0) + F''(c) \frac{(1 - 0)^2}{2} \\ &= F(0) + F'(0) + \frac{1}{2} F''(c) \end{aligned} \quad (1)$$

for some c between 0 and 1. Writing Equation (1) in terms of f gives

$$\begin{aligned} f(a + h, b + k) &= f(a, b) + hf_x(a, b) + kf_y(a, b) \\ &\quad + \frac{1}{2} (h^2 f_{xx} + 2hkf_{xy} + k^2 f_{yy}) \Big|_{(a+ch, b+ck)}. \end{aligned} \quad (2)$$

Since $f_x(a, b) = f_y(a, b) = 0$, this reduces to

$$f(a + h, b + k) - f(a, b) = \frac{1}{2} (h^2 f_{xx} + 2hkf_{xy} + k^2 f_{yy}) \Big|_{(a+ch, b+ck)}. \quad (3)$$

To determine whether f has an extremum at (a, b) , we examine the sign of the difference $f(a + h, b + k) - f(a, b)$. By Equation (3), this is the same as the sign of

$$Q(c) = (h^2 f_{xx} + 2hkf_{xy} + k^2 f_{yy}) \Big|_{(a+ch, b+ck)}.$$

Now, if $Q(0) \neq 0$, the sign of $Q(c)$ will be the same as the sign of $Q(0)$ for sufficiently small values of h and k . We can predict the sign of

$$Q(0) = h^2 f_{xx}(a, b) + 2hkf_{xy}(a, b) + k^2 f_{yy}(a, b) \quad (4)$$

from the signs of f_{xx} and $f_{xx}f_{yy} - f_{xy}^2$ at (a, b) . Multiply both sides of Equation (4) by f_{xx} and rearrange the right-hand side to get

$$f_{xx}Q(0) = (hf_{xx} + kf_{xy})^2 + (f_{xx}f_{yy} - f_{xy}^2)k^2. \quad (5)$$

From Equation (5) we see that

1. If $f_{xx} < 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at (a, b) , then $Q(0) < 0$ for all sufficiently small nonzero values of h and k , and f has a *local maximum* value at (a, b) .
2. If $f_{xx} > 0$ and $f_{xx}f_{yy} - f_{xy}^2 > 0$ at (a, b) , then $Q(0) > 0$ for all sufficiently small nonzero values of h and k , and f has a *local minimum* value at (a, b) .
3. If $f_{xx}f_{yy} - f_{xy}^2 < 0$ at (a, b) , there are combinations of arbitrarily small nonzero values of h and k for which $Q(0) > 0$, and other values for which $Q(0) < 0$. Arbitrarily close to the point $P_0(a, b, f(a, b))$ on the surface $z = f(x, y)$ there are points above P_0 and points below P_0 , so f has a *saddle point* at (a, b) .
4. If $f_{xx}f_{yy} - f_{xy}^2 = 0$, another test is needed. The possibility that $Q(0)$ equals zero prevents us from drawing conclusions about the sign of $Q(c)$.

The Error Formula for Linear Approximations

We want to show that the difference $E(x, y)$ between the values of a function $f(x, y)$ and its linearization $L(x, y)$ at (x_0, y_0) satisfies the inequality

$$|E(x, y)| \leq \frac{1}{2}M(|x - x_0| + |y - y_0|)^2.$$

The function f is assumed to have continuous second partial derivatives throughout an open set containing a closed rectangular region R centered at (x_0, y_0) . The number M is an upper bound for $|f_{xx}|$, $|f_{yy}|$, and $|f_{xy}|$ on R .

The inequality we want comes from Equation (2). We substitute x_0 and y_0 for a and b , and $x - x_0$ and $y - y_0$ for h and k , respectively, and rearrange the result as

$$\begin{aligned} f(x, y) &= \underbrace{f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0)}_{\text{linearization } L(x, y)} \\ &+ \underbrace{\frac{1}{2}((x - x_0)^2 f_{xx} + 2(x - x_0)(y - y_0)f_{xy} + (y - y_0)^2 f_{yy})}_{\text{error } E(x, y)} \Big|_{(x_0+c(x-x_0), y_0+c(y-y_0))}. \end{aligned}$$

This equation reveals that

$$|E| \leq \frac{1}{2}(|x - x_0|^2 |f_{xx}| + 2|x - x_0||y - y_0| |f_{xy}| + |y - y_0|^2 |f_{yy}|).$$

Hence, if M is an upper bound for the values of $|f_{xx}|$, $|f_{xy}|$, and $|f_{yy}|$ on R , then

$$\begin{aligned} |E| &\leq \frac{1}{2}(|x - x_0|^2 M + 2|x - x_0||y - y_0| M + |y - y_0|^2 M) \\ &= \frac{1}{2}M(|x - x_0| + |y - y_0|)^2. \end{aligned}$$

Taylor's Formula for Functions of Two Variables

The formulas derived earlier for F' and F'' can be obtained by applying to $f(x, y)$ the differentiation operators

$$\left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right) \quad \text{and} \quad \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right)^2 = h^2 \frac{\partial^2}{\partial x^2} + 2hk \frac{\partial^2}{\partial x \partial y} + k^2 \frac{\partial^2}{\partial y^2}.$$

These are the first two instances of a more general formula,

$$F^{(n)}(t) = \frac{d^n}{dt^n} F(t) = \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right)^n f(x, y), \quad (6)$$

which says that applying d^n/dt^n to $F(t)$ gives the same result as applying the operator

$$\left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right)^n$$

to $f(x, y)$ after expanding it by the Binomial Theorem.

If the partial derivatives of f through order $n + 1$ are continuous throughout a rectangular region centered at (a, b) , we may extend the Taylor formula for $F(t)$ to

$$F(t) = F(0) + F'(0)t + \frac{F''(0)}{2!}t^2 + \cdots + \frac{F^{(n)}(0)}{n!}t^n + \text{remainder},$$

and take $t = 1$ to obtain

$$F(1) = F(0) + F'(0) + \frac{F''(0)}{2!} + \cdots + \frac{F^{(n)}(0)}{n!} + \text{remainder}.$$

When we replace the first n derivatives on the right of this last series by their equivalent expressions from Equation (6) evaluated at $t = 0$ and add the appropriate remainder term, we arrive at the following formula.

Taylor's Formula for $f(x, y)$ at the Point (a, b)

Suppose $f(x, y)$ and its partial derivatives through order $n + 1$ are continuous throughout an open rectangular region R centered at a point (a, b) . Then, throughout R ,

$$\begin{aligned} f(a + h, b + k) &= f(a, b) + \left(hf_x + kf_y\right)\Big|_{(a,b)} + \frac{1}{2!} \left(h^2 f_{xx} + 2hk f_{xy} + k^2 f_{yy}\right)\Big|_{(a,b)} \\ &+ \frac{1}{3!} \left(h^3 f_{xxx} + 3h^2 k f_{xxy} + 3hk^2 f_{xyy} + k^3 f_{yyy}\right)\Big|_{(a,b)} + \cdots + \frac{1}{n!} \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right)^n f\Big|_{(a,b)} \\ &+ \frac{1}{(n+1)!} \left(h \frac{\partial}{\partial x} + k \frac{\partial}{\partial y}\right)^{n+1} f\Big|_{(a+ch, b+ck)}. \end{aligned} \quad (7)$$

The first n derivative terms are evaluated at (a, b) . The last term is evaluated at some point $(a + ch, b + ck)$ on the line segment joining (a, b) and $(a + h, b + k)$.

If $(a, b) = (0, 0)$ and we treat h and k as independent variables (denoting them now by x and y), then Equation (7) assumes the following form.

Taylor's Formula for $f(x, y)$ at the Origin

$$\begin{aligned}
f(x, y) = & f(0, 0) + xf_x + yf_y + \frac{1}{2!} \left(x^2 f_{xx} + 2xyf_{xy} + y^2 f_{yy} \right) \\
& + \frac{1}{3!} \left(x^3 f_{xxx} + 3x^2 y f_{xxy} + 3xy^2 f_{xyy} + y^3 f_{yyy} \right) + \cdots + \frac{1}{n!} \left(x^n \frac{\partial^n f}{\partial x^n} + nx^{n-1} y \frac{\partial^n f}{\partial x^{n-1} \partial y} + \cdots + y^n \frac{\partial^n f}{\partial y^n} \right) \\
& + \frac{1}{(n+1)!} \left(x^{n+1} \frac{\partial^{n+1} f}{\partial x^{n+1}} + (n+1)x^n y \frac{\partial^{n+1} f}{\partial x^n \partial y} + \cdots + y^{n+1} \frac{\partial^{n+1} f}{\partial y^{n+1}} \right) \Bigg|_{(cx, cy)} \quad (8)
\end{aligned}$$

The first n derivative terms are evaluated at $(0, 0)$. The last term is evaluated at a point on the line segment joining the origin and (x, y) .

Taylor's formula provides polynomial approximations of two-variable functions. The first n derivative terms give the polynomial; the last term gives the approximation error. The first three terms of Taylor's formula give the function's linearization. To improve on the linearization, we add higher-power terms.

EXAMPLE 1 Find a quadratic approximation to $f(x, y) = \sin x \sin y$ near the origin. How accurate is the approximation if $|x| \leq 0.1$ and $|y| \leq 0.1$?

Solution We take $n = 2$ in Equation (8):

$$\begin{aligned}
f(x, y) = & f(0, 0) + (xf_x + yf_y) + \frac{1}{2}(x^2 f_{xx} + 2xyf_{xy} + y^2 f_{yy}) \\
& + \frac{1}{6}(x^3 f_{xxx} + 3x^2 y f_{xxy} + 3xy^2 f_{xyy} + y^3 f_{yyy}) \Bigg|_{(cx, cy)}.
\end{aligned}$$

Calculating the values of the partial derivatives,

$$\begin{aligned}
f(0, 0) = \sin x \sin y \Big|_{(0,0)} &= 0, & f_{xx}(0, 0) = -\sin x \sin y \Big|_{(0,0)} &= 0, \\
f_x(0, 0) = \cos x \sin y \Big|_{(0,0)} &= 0, & f_{xy}(0, 0) = \cos x \cos y \Big|_{(0,0)} &= 1, \\
f_y(0, 0) = \sin x \cos y \Big|_{(0,0)} &= 0, & f_{yy}(0, 0) = -\sin x \sin y \Big|_{(0,0)} &= 0,
\end{aligned}$$

we have the result

$$\sin x \sin y \approx 0 + 0 + 0 + \frac{1}{2}(x^2(0) + 2xy(1) + y^2(0)), \quad \text{or} \quad \sin x \sin y \approx xy.$$

The error in the approximation is

$$E(x, y) = \frac{1}{6}(x^3 f_{xxx} + 3x^2 y f_{xxy} + 3xy^2 f_{xyy} + y^3 f_{yyy}) \Bigg|_{(cx, cy)}.$$

The third derivatives never exceed 1 in absolute value because they are products of sines and cosines. Also, $|x| \leq 0.1$ and $|y| \leq 0.1$. Hence

$$|E(x, y)| \leq \frac{1}{6}((0.1)^3 + 3(0.1)^3 + 3(0.1)^3 + (0.1)^3) = \frac{8}{6}(0.1)^3 \leq 0.00134$$

(rounded up). The error will not exceed 0.00134 if $|x| \leq 0.1$ and $|y| \leq 0.1$. ■

EXERCISES 13.9

Finding Quadratic and Cubic Approximations

In Exercises 1–10, use Taylor's formula for $f(x, y)$ at the origin to find quadratic and cubic approximations of f near the origin.

1. $f(x, y) = xe^y$
2. $f(x, y) = e^x \cos y$
3. $f(x, y) = y \sin x$
4. $f(x, y) = \sin x \cos y$
5. $f(x, y) = e^x \ln(1 + y)$
6. $f(x, y) = \ln(2x + y + 1)$
7. $f(x, y) = \sin(x^2 + y^2)$
8. $f(x, y) = \cos(x^2 + y^2)$

$$9. f(x, y) = \frac{1}{1 - x - y} \quad 10. f(x, y) = \frac{1}{1 - x - y + xy}$$

11. Use Taylor's formula to find a quadratic approximation of $f(x, y) = \cos x \cos y$ at the origin. Estimate the error in the approximation if $|x| \leq 0.1$ and $|y| \leq 0.1$.
12. Use Taylor's formula to find a quadratic approximation of $e^x \sin y$ at the origin. Estimate the error in the approximation if $|x| \leq 0.1$ and $|y| \leq 0.1$.

13.10 Partial Derivatives with Constrained Variables

In finding partial derivatives of functions like $w = f(x, y)$, we have assumed x and y to be independent. In many applications, however, this is not the case. For example, the internal energy U of a gas may be expressed as a function $U = f(P, V, T)$ of pressure P , volume V , and temperature T . If the individual molecules of the gas do not interact, however, P , V , and T obey (and are constrained by) the ideal gas law

$$PV = nRT \quad (n \text{ and } R \text{ constant}),$$

and fail to be independent. In this section we learn how to find partial derivatives in situations like this, which occur in economics, engineering, and physics.

Decide Which Variables Are Dependent and Which Are Independent

If the variables in a function $w = f(x, y, z)$ are constrained by a relation like the one imposed on x , y , and z by the equation $z = x^2 + y^2$, the geometric meanings and the numerical values of the partial derivatives of f will depend on which variables are chosen to be dependent and which are chosen to be independent. To see how this choice can affect the outcome, we consider the calculation of $\partial w / \partial x$ when $w = x^2 + y^2 + z^2$ and $z = x^2 + y^2$.

EXAMPLE 1 Find $\partial w / \partial x$ if $w = x^2 + y^2 + z^2$ and $z = x^2 + y^2$.

Solution We are given two equations in the four unknowns x , y , z , and w . Like many such systems, this one can be solved for two of the unknowns (the dependent variables) in terms of the others (the independent variables). In being asked for $\partial w / \partial x$, we are told that w is to be a dependent variable and x an independent variable. The possible choices for the other variables come down to

	<i>Dependent</i>	<i>Independent</i>
Choice 1:	w, z	x, y
Choice 2:	w, y	x, z

In either case, we can express w explicitly in terms of the selected independent variables. We do this by using the second equation $z = x^2 + y^2$ to eliminate the remaining dependent variable in the first equation.

In the first case, the remaining dependent variable is z . We eliminate it from the first equation by replacing it by $x^2 + y^2$. The resulting expression for w is

$$\begin{aligned} w &= x^2 + y^2 + z^2 = x^2 + y^2 + (x^2 + y^2)^2 \\ &= x^2 + y^2 + x^4 + 2x^2y^2 + y^4 \end{aligned}$$

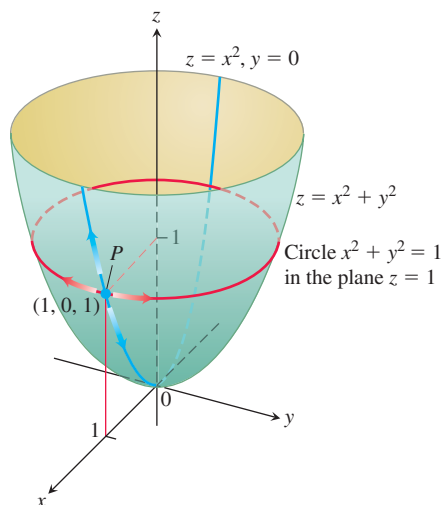

FIGURE 13.62 If P is constrained to lie on the paraboloid $z = x^2 + y^2$, the value of the partial derivative of $w = x^2 + y^2 + z^2$ with respect to x at P depends on the direction of motion (Example 1). (1) As x changes, with $y = 0$, P moves up or down the surface on the parabola $z = x^2$ in the xz -plane with $\partial w/\partial x = 2x + 4x^3$. (2) As x changes, with $z = 1$, P moves on the circle $x^2 + y^2 = 1$, $z = 1$, and $\partial w/\partial x = 0$.

and therefore

$$\frac{\partial w}{\partial x} = 2x + 4x^3 + 4xy^2. \quad (1)$$

This is the formula for $\partial w/\partial x$ when x and y are the independent variables.

In the second case, where the independent variables are x and z and the remaining dependent variable is y , we eliminate the dependent variable y in the expression for w by replacing y^2 in the second equation by $z - x^2$. This gives

$$w = x^2 + y^2 + z^2 = x^2 + (z - x^2) + z^2 = z + z^2$$

and therefore

$$\frac{\partial w}{\partial x} = 0. \quad (2)$$

This is the formula for $\partial w/\partial x$ when x and z are the independent variables.

The formulas for $\partial w/\partial x$ in Equations (1) and (2) are genuinely different. We cannot change either formula into the other by using the relation $z = x^2 + y^2$. There is not just one $\partial w/\partial x$, there are two, and we see that the original instruction to find $\partial w/\partial x$ was incomplete. *Which $\partial w/\partial x$?* we ask.

The geometric interpretations of Equations (1) and (2) help to explain why the equations differ. The function $w = x^2 + y^2 + z^2$ measures the square of the distance from the point (x, y, z) to the origin. The condition $z = x^2 + y^2$ says that the point (x, y, z) lies on the paraboloid of revolution shown in Figure 13.62. What does it mean to calculate $\partial w/\partial x$ at a point $P(x, y, z)$ that can move only on this surface? What is the value of $\partial w/\partial x$ when the coordinates of P are, say, $(1, 0, 1)$?

If we take x and y to be independent, then we find $\partial w/\partial x$ by holding y fixed (at $y = 0$ in this case) and letting x vary. Hence, P moves along the parabola $z = x^2$ in the xz -plane. As P moves on this parabola, w , which is the square of the distance from P to the origin, changes. We calculate $\partial w/\partial x$ in this case (our first solution above) to be

$$\frac{\partial w}{\partial x} = 2x + 4x^3 + 4xy^2.$$

At the point $P(1, 0, 1)$, the value of this derivative is

$$\frac{\partial w}{\partial x} = 2 + 4 + 0 = 6.$$

If we take x and z to be independent, then we find $\partial w/\partial x$ by holding z fixed while x varies. Since the z -coordinate of P is 1, varying x moves P along a circle in the plane $z = 1$. As P moves along this circle, its distance from the origin remains constant, and w , being the square of this distance, does not change. That is,

$$\frac{\partial w}{\partial x} = 0,$$

as we found in our second solution. ■

How to Find $\partial w/\partial x$ When the Variables in $w = f(x, y, z)$ Are Constrained by Another Equation

As we saw in Example 1, a typical routine for finding $\partial w/\partial x$ when the variables in the function $w = f(x, y, z)$ are related by another equation has three steps. These steps apply to finding $\partial w/\partial y$ and $\partial w/\partial z$ as well.

1. *Decide* which variables are to be dependent and which are to be independent. (In practice, the decision is based on the physical or theoretical context of our work. In the exercises at the end of this section, we say which variables are which.)
2. *Eliminate* the other dependent variable(s) in the expression for w .
3. *Differentiate* as usual.

If we cannot carry out Step 2 after deciding which variables are dependent, we differentiate the equations as they are and try to solve for $\partial w/\partial x$ afterward. The next example shows how this is done.

EXAMPLE 2 Find $\partial w/\partial x$ at the point $(x, y, z) = (2, -1, 1)$ if

$$w = x^2 + y^2 + z^2, \quad z^3 - xy + yz + y^3 = 1,$$

and x and y are the independent variables.

Solution It is not convenient to eliminate z in the expression for w . We therefore differentiate both equations implicitly with respect to x , treating x and y as independent variables and w and z as dependent variables. This gives

$$\frac{\partial w}{\partial x} = 2x + 2z \frac{\partial z}{\partial x} \quad (3)$$

and

$$3z^2 \frac{\partial z}{\partial x} - y + y \frac{\partial z}{\partial x} + 0 = 0. \quad (4)$$

These equations may now be combined to express $\partial w/\partial x$ in terms of x , y , and z . We solve Equation (4) for $\partial z/\partial x$ to get

$$\frac{\partial z}{\partial x} = \frac{y}{y + 3z^2}$$

and substitute into Equation (3) to get

$$\frac{\partial w}{\partial x} = 2x + \frac{2yz}{y + 3z^2}.$$

The value of this derivative at $(x, y, z) = (2, -1, 1)$ is

$$\left. \frac{\partial w}{\partial x} \right|_{(2, -1, 1)} = 2(2) + \frac{2(-1)(1)}{-1 + 3(1)^2} = 4 + \frac{-2}{2} = 3. \quad \blacksquare$$

HISTORICAL BIOGRAPHY

Sonya Kovalevsky
(1850–1891)

Kovalevsky, a Russian mathematician, primarily worked on the theory of partial differential equations, and a central result on the existence of solutions still bears her name. She published numerous papers on partial differential equations, eventually gaining recognition as the first woman to be elected a member of the Russian Imperial Academy of Sciences in 1889.

Notation

To show what variables are assumed to be independent in calculating a derivative, we can use the following notation:

$$\left(\frac{\partial w}{\partial x} \right)_y \quad \partial w/\partial x \text{ with } x \text{ and } y \text{ independent}$$

$$\left(\frac{\partial f}{\partial y} \right)_{x,t} \quad \partial f/\partial y \text{ with } y, x, \text{ and } t \text{ independent.}$$

EXAMPLE 3 Find $(\partial w/\partial x)_{y,z}$ if $w = x^2 + y - z + \sin t$ and $x + y = t$.

Solution With x, y, z independent, we have

$$\begin{aligned} t &= x + y, & w &= x^2 + y - z + \sin(x + y) \\ \left(\frac{\partial w}{\partial x}\right)_{y,z} &= 2x + 0 - 0 + \cos(x + y) \frac{\partial}{\partial x}(x + y) \\ &= 2x + \cos(x + y). \end{aligned}$$

Arrow Diagrams

In solving problems like the one in Example 3, it often helps to start with an arrow diagram that shows how the variables and functions are related. If

$$w = x^2 + y - z + \sin t \quad \text{and} \quad x + y = t$$

and we are asked to find $\partial w/\partial x$ when x, y , and z are independent, the appropriate diagram is one like this:

$$\begin{array}{ccc} \begin{pmatrix} x \\ y \\ z \end{pmatrix} & \rightarrow & \begin{pmatrix} x \\ y \\ z \\ t \end{pmatrix} & \rightarrow & w \end{array} \quad (5)$$

Independent variables Intermediate variables Dependent variable

To avoid confusion between the independent and intermediate variables with the same symbolic names in the diagram, it is helpful to rename the intermediate variables (so they are seen as *functions* of the independent variables). Thus, let $u = x, v = y$, and $s = z$ denote the renamed intermediate variables. With this notation, the arrow diagram becomes

$$\begin{array}{ccc} \begin{pmatrix} x \\ y \\ z \end{pmatrix} & \rightarrow & \begin{pmatrix} u \\ v \\ s \\ t \end{pmatrix} & \rightarrow & w \end{array} \quad (6)$$

Independent variables Intermediate variables and relations Dependent variable

$u = x$
 $v = y$
 $s = z$
 $t = x + y$

The diagram shows the independent variables on the left, the intermediate variables and their relation to the independent variables in the middle, and the dependent variable on the right. The function w now becomes

$$w = u^2 + v - s + \sin t,$$

where

$$u = x, \quad v = y, \quad s = z, \quad \text{and} \quad t = x + y.$$

To find $\partial w/\partial x$, we apply the four-variable form of the Chain Rule to w , guided by the arrow diagram in Equation (6):

$$\begin{aligned} \frac{\partial w}{\partial x} &= \frac{\partial w}{\partial u} \frac{\partial u}{\partial x} + \frac{\partial w}{\partial v} \frac{\partial v}{\partial x} + \frac{\partial w}{\partial s} \frac{\partial s}{\partial x} + \frac{\partial w}{\partial t} \frac{\partial t}{\partial x} \\ &= (2u)(1) + (1)(0) + (-1)(0) + (\cos t)(1) \\ &= 2u + \cos t \\ &= 2x + \cos(x + y). \end{aligned}$$

Substitute the original independent variables $u = x$ and $t = x + y$

EXERCISES 13.10

Finding Partial Derivatives with Constrained Variables

In Exercises 1–3, begin by drawing a diagram that shows the relations among the variables.

1. If $w = x^2 + y^2 + z^2$ and $z = x^2 + y^2$, find

a. $\left(\frac{\partial w}{\partial y}\right)_z$ b. $\left(\frac{\partial w}{\partial z}\right)_x$ c. $\left(\frac{\partial w}{\partial z}\right)_y$.

2. If $w = x^2 + y - z + \sin t$ and $x + y = t$, find

a. $\left(\frac{\partial w}{\partial y}\right)_{x,z}$ b. $\left(\frac{\partial w}{\partial y}\right)_{z,t}$ c. $\left(\frac{\partial w}{\partial z}\right)_{x,y}$

d. $\left(\frac{\partial w}{\partial z}\right)_{y,t}$ e. $\left(\frac{\partial w}{\partial t}\right)_{x,z}$ f. $\left(\frac{\partial w}{\partial t}\right)_{y,z}$.

3. Let $U = f(P, V, T)$ be the internal energy of a gas that obeys the ideal gas law $PV = nRT$ (n and R constant). Find

a. $\left(\frac{\partial U}{\partial P}\right)_V$ b. $\left(\frac{\partial U}{\partial T}\right)_V$.

4. Find

a. $\left(\frac{\partial w}{\partial x}\right)_y$ b. $\left(\frac{\partial w}{\partial z}\right)_y$

at the point $(x, y, z) = (0, 1, \pi)$ if

$$w = x^2 + y^2 + z^2 \quad \text{and} \quad y \sin z + z \sin x = 0.$$

5. Find

a. $\left(\frac{\partial w}{\partial y}\right)_x$ b. $\left(\frac{\partial w}{\partial y}\right)_z$

at the point $(w, x, y, z) = (4, 2, 1, -1)$ if

$$w = x^2y^2 + yz - z^3 \quad \text{and} \quad x^2 + y^2 + z^2 = 6.$$

6. Find $(\partial u / \partial y)_x$ at the point $(u, v) = (\sqrt{2}, 1)$ if $x = u^2 + v^2$ and $y = uv$.

7. Suppose that $x^2 + y^2 = r^2$ and $x = r \cos \theta$, as in polar coordinates. Find

$$\left(\frac{\partial x}{\partial r}\right)_\theta \quad \text{and} \quad \left(\frac{\partial r}{\partial x}\right)_y.$$

8. Suppose that

$$w = x^2 - y^2 + 4z + t \quad \text{and} \quad x + 2z + t = 25.$$

Show that the equations

$$\frac{\partial w}{\partial x} = 2x - 1 \quad \text{and} \quad \frac{\partial w}{\partial x} = 2x - 2$$

each give $\partial w / \partial x$, depending on which variables are chosen to be dependent and which variables are chosen to be independent. Identify the independent variables in each case.

Theory and Examples

9. Establish the fact, widely used in hydrodynamics, that if $f(x, y, z) = 0$, then

$$\left(\frac{\partial x}{\partial y}\right)_z \left(\frac{\partial y}{\partial z}\right)_x \left(\frac{\partial z}{\partial x}\right)_y = -1.$$

(Hint: Express all the derivatives in terms of the formal partial derivatives $\partial f / \partial x$, $\partial f / \partial y$, and $\partial f / \partial z$.)

10. If $z = x + f(u)$, where $u = xy$, show that

$$x \frac{\partial z}{\partial x} - y \frac{\partial z}{\partial y} = x.$$

11. Suppose that the equation $g(x, y, z) = 0$ determines z as a differentiable function of the independent variables x and y and that $g_z \neq 0$. Show that

$$\left(\frac{\partial z}{\partial y}\right)_x = -\frac{\partial g / \partial y}{\partial g / \partial z}.$$

12. Suppose that $f(x, y, z, w) = 0$ and $g(x, y, z, w) = 0$ determine z and w as differentiable functions of the independent variables x and y , and suppose that

$$\frac{\partial f}{\partial z} \frac{\partial g}{\partial w} - \frac{\partial f}{\partial w} \frac{\partial g}{\partial z} \neq 0.$$

Show that

$$\left(\frac{\partial z}{\partial x}\right)_y = -\frac{\frac{\partial f}{\partial x} \frac{\partial g}{\partial w} - \frac{\partial f}{\partial w} \frac{\partial g}{\partial x}}{\frac{\partial f}{\partial z} \frac{\partial g}{\partial w} - \frac{\partial f}{\partial w} \frac{\partial g}{\partial z}}$$

and

$$\left(\frac{\partial w}{\partial y}\right)_x = -\frac{\frac{\partial f}{\partial z} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial z}}{\frac{\partial f}{\partial z} \frac{\partial g}{\partial w} - \frac{\partial f}{\partial w} \frac{\partial g}{\partial z}}.$$

CHAPTER 13 Questions to Guide Your Review

1. What is a real-valued function of two independent variables? Three independent variables? Give examples.
2. What does it mean for sets in the plane or in space to be open? Closed? Give examples. Give examples of sets that are neither open nor closed.
3. How can you display the values of a function $f(x, y)$ of two independent variables graphically? How do you do the same for a function $f(x, y, z)$ of three independent variables?
4. What does it mean for a function $f(x, y)$ to have limit L as $(x, y) \rightarrow (x_0, y_0)$? What are the basic properties of limits of functions of two independent variables?
5. When is a function of two (three) independent variables continuous at a point in its domain? Give examples of functions that are continuous at some points but not others.
6. What can be said about algebraic combinations and compositions of continuous functions?

7. Explain the two-path test for nonexistence of limits.
8. How are the partial derivatives $\partial f/\partial x$ and $\partial f/\partial y$ of a function $f(x, y)$ defined? How are they interpreted and calculated?
9. How does the relation between first partial derivatives and continuity of functions of two independent variables differ from the relation between first derivatives and continuity for real-valued functions of a single independent variable? Give an example.
10. What is the Mixed Derivative Theorem for mixed second-order partial derivatives? How can it help in calculating partial derivatives of second and higher orders? Give examples.
11. What does it mean for a function $f(x, y)$ to be differentiable? What does the Increment Theorem say about differentiability?
12. How can you sometimes decide from examining f_x and f_y that a function $f(x, y)$ is differentiable? What is the relation between the differentiability of f and the continuity of f at a point?
13. What is the general Chain Rule? What form does it take for functions of two independent variables? Three independent variables? Functions defined on surfaces? How do you diagram these different forms? Give examples. What pattern enables one to remember all the different forms?
14. What is the derivative of a function $f(x, y)$ at a point P_0 in the direction of a unit vector \mathbf{u} ? What rate does it describe? What geometric interpretation does it have? Give examples.
15. What is the gradient vector of a differentiable function $f(x, y)$? How is it related to the function's directional derivatives? State the analogous results for functions of three independent variables.
16. How do you find the tangent line at a point on a level curve of a differentiable function $f(x, y)$? How do you find the tangent plane and normal line at a point on a level surface of a differentiable function $f(x, y, z)$? Give examples.
17. How can you use directional derivatives to estimate change?
18. How do you linearize a function $f(x, y)$ of two independent variables at a point (x_0, y_0) ? Why might you want to do this? How do you linearize a function of three independent variables?
19. What can you say about the accuracy of linear approximations of functions of two (three) independent variables?
20. If (x, y) moves from (x_0, y_0) to a point $(x_0 + dx, y_0 + dy)$ nearby, how can you estimate the resulting change in the value of a differentiable function $f(x, y)$? Give an example.
21. How do you define local maxima, local minima, and saddle points for a differentiable function $f(x, y)$? Give examples.
22. What derivative tests are available for determining the local extreme values of a function $f(x, y)$? How do they enable you to narrow your search for these values? Give examples.
23. How do you find the extrema of a continuous function $f(x, y)$ on a closed bounded region of the xy -plane? Give an example.
24. Describe the method of Lagrange multipliers and give examples.
25. How does Taylor's formula for a function $f(x, y)$ generate polynomial approximations and error estimates?
26. If $w = f(x, y, z)$, where the variables $x, y,$ and z are constrained by an equation $g(x, y, z) = 0$, what is the meaning of the notation $(\partial w/\partial x)_y$? How can an arrow diagram help you calculate this partial derivative with constrained variables? Give examples.

CHAPTER 13 Practice Exercises

Domain, Range, and Level Curves

In Exercises 1–4, find the domain and range of the given function and identify its level curves. Sketch a typical level curve.

1. $f(x, y) = 9x^2 + y^2$
2. $f(x, y) = e^{x+y}$
3. $g(x, y) = 1/xy$
4. $g(x, y) = \sqrt{x^2 - y}$

In Exercises 5–8, find the domain and range of the given function and identify its level surfaces. Sketch a typical level surface.

5. $f(x, y, z) = x^2 + y^2 - z$
6. $g(x, y, z) = x^2 + 4y^2 + 9z^2$
7. $h(x, y, z) = \frac{1}{x^2 + y^2 + z^2}$
8. $k(x, y, z) = \frac{1}{x^2 + y^2 + z^2 + 1}$

Evaluating Limits

Find the limits in Exercises 9–14.

9. $\lim_{(x,y) \rightarrow (\pi, \ln 2)} e^y \cos x$
10. $\lim_{(x,y) \rightarrow (0,0)} \frac{2+y}{x+\cos y}$
11. $\lim_{(x,y) \rightarrow (1,1)} \frac{x-y}{x^2-y^2}$
12. $\lim_{(x,y) \rightarrow (1,1)} \frac{x^3y^3-1}{xy-1}$
13. $\lim_{P \rightarrow (1, -1, e)} \ln|x+y+z|$
14. $\lim_{P \rightarrow (1, -1, -1)} \arctan(x+y+z)$

By considering different paths of approach, show that the limits in Exercises 15 and 16 do not exist.

15. $\lim_{\substack{(x,y) \rightarrow (0,0) \\ y=x^2}} \frac{y}{x^2 - y}$
16. $\lim_{\substack{(x,y) \rightarrow (0,0) \\ xy \neq 0}} \frac{x^2 + y^2}{xy}$

17. **Continuous extension** Let $f(x, y) = (x^2 - y^2)/(x^2 + y^2)$ for $(x, y) \neq (0, 0)$. Is it possible to define $f(0, 0)$ in a way that makes f continuous at the origin? Why?

18. **Continuous extension** Let

$$f(x, y) = \begin{cases} \frac{\sin(x-y)}{|x|+|y|}, & |x|+|y| \neq 0 \\ 0, & (x, y) = (0, 0). \end{cases}$$

Is f continuous at the origin? Why?

Partial Derivatives

In Exercises 19–24, find the partial derivative of the function with respect to each variable.

19. $g(r, \theta) = r \cos \theta + r \sin \theta$
20. $f(x, y) = \frac{1}{2} \ln(x^2 + y^2) + \arctan \frac{y}{x}$

21. $f(R_1, R_2, R_3) = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}$
22. $h(x, y, z) = \sin(2\pi x + y - 3z)$
23. $P(n, R, T, V) = \frac{nRT}{V}$ (the ideal gas law)
24. $f(r, l, T, w) = \frac{1}{2rl} \sqrt{\frac{T}{\pi w}}$

Second-Order Partial Derivatives

Find the second-order partial derivatives of the functions in Exercises 25–28.

25. $g(x, y) = y + \frac{x}{y}$ 26. $g(x, y) = e^x + y \sin x$
27. $f(x, y) = x + xy - 5x^3 + \ln(x^2 + 1)$
28. $f(x, y) = y^2 - 3xy + \cos y + 7e^y$

Chain Rule Calculations

29. Find dw/dt at $t = 0$ if $w = \sin(xy + \pi)$, $x = e^t$, and $y = \ln(t + 1)$.
30. Find dw/dt at $t = 1$ if $w = xe^y + y \sin z - \cos z$, $x = 2\sqrt{t}$, $y = t - 1 + \ln t$, and $z = \pi t$.
31. Find $\partial w/\partial r$ and $\partial w/\partial s$ when $r = \pi$ and $s = 0$ if $w = \sin(2x - y)$, $x = r + \sin s$, $y = rs$.
32. Find $\partial w/\partial u$ and $\partial w/\partial v$ when $u = v = 0$ if $w = \ln\sqrt{1 + x^2} - \tan^{-1}x$ and $x = 2e^u \cos v$.
33. Find the value of the derivative of $f(x, y, z) = xy + yz + xz$ with respect to t on the curve $x = \cos t$, $y = \sin t$, $z = \cos 2t$ at $t = 1$.
34. Show that if $w = f(s)$ is any differentiable function of s and if $s = y + 5x$, then

$$\frac{\partial w}{\partial x} - 5 \frac{\partial w}{\partial y} = 0.$$

Implicit Differentiation

Assuming that the equations in Exercises 35 and 36 define y as a differentiable function of x , find the value of dy/dx at point P .

35. $1 - x - y^2 - \sin xy = 0$, $P(0, 1)$
36. $2xy + e^{x+y} - 2 = 0$, $P(0, \ln 2)$

Directional Derivatives

In Exercises 37–40, find the directions in which f increases and decreases most rapidly at P_0 and find the derivative of f in each direction. Also, find the derivative of f at P_0 in the direction of the vector \mathbf{v} .

37. $f(x, y) = \cos x \cos y$, $P_0(\pi/4, \pi/4)$, $\mathbf{v} = 3\mathbf{i} + 4\mathbf{j}$
38. $f(x, y) = x^2 e^{-2y}$, $P_0(1, 0)$, $\mathbf{v} = \mathbf{i} + \mathbf{j}$
39. $f(x, y, z) = \ln(2x + 3y + 6z)$, $P_0(-1, -1, 1)$, $\mathbf{v} = 2\mathbf{i} + 3\mathbf{j} + 6\mathbf{k}$
40. $f(x, y, z) = x^2 + 3xy - z^2 + 2y + z + 4$, $P_0(0, 0, 0)$, $\mathbf{v} = \mathbf{i} + \mathbf{j} + \mathbf{k}$
41. **Derivative in velocity direction** Find the derivative of $f(x, y, z) = xyz$ in the direction of the velocity vector of the helix

$$\mathbf{r}(t) = (\cos 3t)\mathbf{i} + (\sin 3t)\mathbf{j} + 3t\mathbf{k}$$

at $t = \pi/3$.

42. **Maximum directional derivative** What is the largest value that the directional derivative of $f(x, y, z) = xyz$ can have at the point $(1, 1, 1)$?

43. **Directional derivatives with given values** At the point $(1, 2)$, the function $f(x, y)$ has a derivative of 2 in the direction toward $(2, 2)$ and a derivative of -2 in the direction toward $(1, 1)$.

- a. Find $f_x(1, 2)$ and $f_y(1, 2)$.
- b. Find the derivative of f at $(1, 2)$ in the direction toward the point $(4, 6)$.
44. Which of the following statements are true if $f(x, y)$ is differentiable at (x_0, y_0) ? Give reasons for your answers.
- a. If \mathbf{u} is a unit vector, the derivative of f at (x_0, y_0) in the direction of \mathbf{u} is $(f_x(x_0, y_0)\mathbf{i} + f_y(x_0, y_0)\mathbf{j}) \cdot \mathbf{u}$.
- b. The derivative of f at (x_0, y_0) in the direction of \mathbf{u} is a vector.
- c. The directional derivative of f at (x_0, y_0) has its greatest value in the direction of ∇f .
- d. At (x_0, y_0) , vector ∇f is normal to the curve $f(x, y) = f(x_0, y_0)$.

Gradients, Tangent Planes, and Normal Lines

In Exercises 45 and 46, sketch the surface $f(x, y, z) = c$ together with ∇f at the given points.

45. $x^2 + y + z^2 = 0$; $(0, -1, \pm 1)$, $(0, 0, 0)$
46. $y^2 + z^2 = 4$; $(2, \pm 2, 0)$, $(2, 0, \pm 2)$

In Exercises 47 and 48, find an equation for the plane tangent to the level surface $f(x, y, z) = c$ at the point P_0 . Also, find parametric equations for the line that is normal to the surface at P_0 .

47. $x^2 - y - 5z = 0$, $P_0(2, -1, 1)$
48. $x^2 + y^2 + z = 4$, $P_0(1, 1, 2)$

In Exercises 49 and 50, find an equation for the plane tangent to the surface $z = f(x, y)$ at the given point.

49. $z = \ln(x^2 + y^2)$, $(0, 1, 0)$
50. $z = 1/(x^2 + y^2)$, $(1, 1, 1/2)$

In Exercises 51 and 52, find equations for the lines that are tangent and normal to the level curve $f(x, y) = c$ at the point P_0 . Then sketch the lines and level curve together with ∇f at P_0 .

51. $y - \sin x = 1$, $P_0(\pi, 1)$
52. $\frac{y^2}{2} - \frac{x^2}{2} = \frac{3}{2}$, $P_0(1, 2)$

Tangent Lines to Curves

In Exercises 53 and 54, find parametric equations for the line that is tangent to the curve of intersection of the surfaces at the given point.

53. Surfaces: $x^2 + 2y + 2z = 4$, $y = 1$
Point: $(1, 1, 1/2)$
54. Surfaces: $x + y^2 + z = 2$, $y = 1$
Point: $(1/2, 1, 1/2)$

Linearizations

In Exercises 55 and 56, find the linearization $L(x, y)$ of the function $f(x, y)$ at the point P_0 . Then find an upper bound for the magnitude of the error E in the approximation $f(x, y) \approx L(x, y)$ over the rectangle R .

55. $f(x, y) = \sin x \cos y$, $P_0(\pi/4, \pi/4)$
 $R: \left|x - \frac{\pi}{4}\right| \leq 0.1, \left|y - \frac{\pi}{4}\right| \leq 0.1$
56. $f(x, y) = xy - 3y^2 + 2$, $P_0(1, 1)$
 $R: |x - 1| \leq 0.1, |y - 1| \leq 0.2$

Find the linearizations of the functions in Exercises 57 and 58 at the given points.

57. $f(x, y, z) = xy + 2yz - 3xz$ at $(1, 0, 0)$ and $(1, 1, 0)$
 58. $f(x, y, z) = \sqrt{2} \cos x \sin(y + z)$ at $(0, 0, \pi/4)$ and $(\pi/4, \pi/4, 0)$

Estimates and Sensitivity to Change

59. **Measuring the volume of a pipeline** You plan to calculate the volume inside a stretch of pipeline that is about 36 cm in diameter and 1 km long. With which measurement should you be more careful, the length or the diameter? Why?
60. **Sensitivity to change** Is $f(x, y) = x^2 - xy + y^2 - 3$ more sensitive to changes in x or to changes in y when it is near the point $(1, 2)$? How do you know?
61. **Change in an electrical circuit** Suppose that the current I (amperes) in an electrical circuit is related to the voltage V (volts) and the resistance R (ohms) by the equation $I = V/R$. If the voltage drops from 24 to 23 volts and the resistance drops from 100 to 80 ohms, will I increase or decrease? By about how much? Is the change in I more sensitive to change in the voltage or to change in the resistance? How do you know?
62. **Maximum error in estimating the area of an ellipse** If $a = 10$ cm and $b = 16$ cm to the nearest millimeter, what should you expect the maximum percentage error to be in the calculated area $A = \pi ab$ of the ellipse $x^2/a^2 + y^2/b^2 = 1$?
63. **Error in estimating a product** Let $y = uv$ and $z = u + v$, where u and v are positive independent variables.
- If u is measured with an error of 2% and v with an error of 3%, about what is the percentage error in the calculated value of y ?
 - Show that the percentage error in the calculated value of z is less than the percentage error in the value of y .
64. **Cardiac index** To make different people comparable in studies of cardiac output, researchers divide the measured cardiac output by the body surface area to find the *cardiac index* C :

$$C = \frac{\text{cardiac output}}{\text{body surface area}}.$$

The body surface area B of a person with weight w and height h is approximated by the formula

$$B = 71.84w^{0.425}h^{0.725},$$

which gives B in square centimeters when w is measured in kilograms and h in centimeters. You are about to calculate the cardiac index of a person 180 cm tall, weighing 70 kg, with cardiac output of 7 L/min. Which will have a greater effect on the calculation, a 1-kg error in measuring the weight or a 1-cm error in measuring the height?

Local Extrema

Test the functions in Exercises 65–70 for local maxima and minima and saddle points. Find each function's value at these points.

65. $f(x, y) = x^2 - xy + y^2 + 2x + 2y - 4$
 66. $f(x, y) = 5x^2 + 4xy - 2y^2 + 4x - 4y$
 67. $f(x, y) = 2x^3 + 3xy + 2y^3$
 68. $f(x, y) = x^3 + y^3 - 3xy + 15$
 69. $f(x, y) = x^3 + y^3 + 3x^2 - 3y^2$
 70. $f(x, y) = x^4 - 8x^2 + 3y^2 - 6y$

Absolute Extrema

In Exercises 71–78, find the absolute maximum and minimum values of f on the region R .

71. $f(x, y) = x^2 + xy + y^2 - 3x + 3y$
 R : The triangular region cut from the first quadrant by the line $x + y = 4$
72. $f(x, y) = x^2 - y^2 - 2x + 4y + 1$
 R : The rectangular region in the first quadrant bounded by the coordinate axes and the lines $x = 4$ and $y = 2$
73. $f(x, y) = y^2 - xy - 3y + 2x$
 R : The square region enclosed by the lines $x = \pm 2$ and $y = \pm 2$
74. $f(x, y) = 2x + 2y - x^2 - y^2$
 R : The square region bounded by the coordinate axes and the lines $x = 2, y = 2$ in the first quadrant
75. $f(x, y) = x^2 - y^2 - 2x + 4y$
 R : The triangular region bounded below by the x -axis, above by the line $y = x + 2$, and on the right by the line $x = 2$
76. $f(x, y) = 4xy - x^4 - y^4 + 16$
 R : The triangular region bounded below by the line $y = -2$, above by the line $y = x$, and on the right by the line $x = 2$
77. $f(x, y) = x^3 + y^3 + 3x^2 - 3y^2$
 R : The square region enclosed by the lines $x = \pm 1$ and $y = \pm 1$
78. $f(x, y) = x^3 + 3xy + y^3 + 1$
 R : The square region enclosed by the lines $x = \pm 1$ and $y = \pm 1$

Lagrange Multipliers

79. **Extrema on a circle** Find the extreme values of $f(x, y) = x^3 + y^2$ on the circle $x^2 + y^2 = 1$.
80. **Extrema on a circle** Find the extreme values of $f(x, y) = xy$ on the circle $x^2 + y^2 = 1$.
81. **Extrema in a disk** Find the extreme values of $f(x, y) = x^2 + 3y^2 + 2y$ on the unit disk $x^2 + y^2 \leq 1$.
82. **Extrema in a disk** Find the extreme values of $f(x, y) = x^2 + y^2 - 3x - xy$ on the disk $x^2 + y^2 \leq 9$.
83. **Extrema on a sphere** Find the extreme values of $f(x, y, z) = x - y + z$ on the unit sphere $x^2 + y^2 + z^2 = 1$.
84. **Minimum distance to origin** Find the points on the surface $x^2 - zy = 4$ closest to the origin.
85. **Minimizing cost of a box** A closed rectangular box is to have volume V cm³. The cost of the material used in the box is a cents/cm² for top and bottom, b cents/cm² for front and back, and c cents/cm² for the remaining sides. What dimensions minimize the total cost of materials?
86. **Least volume** Find the plane $x/a + y/b + z/c = 1$ that passes through the point $(2, 1, 2)$ and cuts off the least volume from the first octant.
87. **Extrema on curve of intersecting surfaces** Find the extreme values of $f(x, y, z) = x(y + z)$ on the curve of intersection of the right circular cylinder $x^2 + y^2 = 1$ and the hyperbolic cylinder $xz = 1$.
88. **Minimum distance to origin on curve of intersecting plane and cone** Find the point closest to the origin on the curve of intersection of the plane $x + y + z = 1$ and the cone $z^2 = 2x^2 + 2y^2$.

Theory and Examples

89. Let $w = f(r, \theta)$, $r = \sqrt{x^2 + y^2}$, and $\theta = \tan^{-1}(y/x)$. Find $\partial w/\partial x$ and $\partial w/\partial y$, and express your answers in terms of r and θ .
90. Let $z = f(u, v)$, $u = ax + by$, and $v = ax - by$. Express z_x and z_y in terms of f_u , f_v , and the constants a and b .
91. If a and b are constants, $w = u^3 + \tanh u + \cos u$, and $u = ax + by$, show that

$$a \frac{\partial w}{\partial y} = b \frac{\partial w}{\partial x}.$$

92. **Using the Chain Rule** If $w = \ln(x^2 + y^2 + 2z)$, $x = r + s$, $y = r - s$, and $z = 2rs$, find w_r and w_s by the Chain Rule. Then check your answer another way.
93. **Angle between vectors** The equations $e^u \cos v - x = 0$ and $e^u \sin v - y = 0$ define u and v as differentiable functions of x and y . Show that the angle between the vectors

$$\frac{\partial u}{\partial x} \mathbf{i} + \frac{\partial u}{\partial y} \mathbf{j} \quad \text{and} \quad \frac{\partial v}{\partial x} \mathbf{i} + \frac{\partial v}{\partial y} \mathbf{j}$$

is constant.

94. **Polar coordinates and second derivatives** Introducing polar coordinates $x = r \cos \theta$ and $y = r \sin \theta$ changes $f(x, y)$ to $g(r, \theta)$. Find the value of $\partial^2 g/\partial \theta^2$ at the point $(r, \theta) = (2, \pi/2)$, given that

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial y} = \frac{\partial^2 f}{\partial x^2} = \frac{\partial^2 f}{\partial y^2} = 1$$

at that point.

95. **Normal line parallel to a plane** Find the points on the surface

$$(y + z)^2 + (z - x)^2 = 16$$

where the normal line is parallel to the yz -plane.

96. **Tangent plane parallel to xy -plane** Find the points on the surface

$$xy + yz + zx - x - z^2 = 0$$

where the tangent plane is parallel to the xy -plane.

97. **When gradient is parallel to position vector** Suppose that $\nabla f(x, y, z)$ is always parallel to the position vector $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$. Show that $f(0, 0, a) = f(0, 0, -a)$ for any a .

98. **One-sided directional derivative in all directions, but no gradient** The one-sided directional derivative of f at $P(x_0, y_0, z_0)$ in the direction $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ is the number

$$\lim_{s \rightarrow 0^+} \frac{f(x_0 + su_1, y_0 + su_2, z_0 + su_3) - f(x_0, y_0, z_0)}{s}.$$

Show that the one-sided directional derivative of

$$f(x, y, z) = \sqrt{x^2 + y^2 + z^2}$$

at the origin equals 1 in any direction but that f has no gradient vector at the origin.

99. **Normal line through origin** Show that the line normal to the surface $xy + z = 2$ at the point $(1, 1, 1)$ passes through the origin.

100. **Tangent plane and normal line**

- a. Sketch the surface $x^2 - y^2 + z^2 = 4$.
- b. Find a vector normal to the surface at $(2, -3, 3)$. Add the vector to your sketch.
- c. Find equations for the tangent plane and the normal line at $(2, -3, 3)$.

Partial Derivatives with Constrained Variables

In Exercises 101 and 102, begin by drawing a diagram that shows the relations among the variables.

101. If $w = x^2 e^{yz}$ and $z = x^2 - y^2$ find

$$\mathbf{a.} \left(\frac{\partial w}{\partial y} \right)_z \quad \mathbf{b.} \left(\frac{\partial w}{\partial z} \right)_x \quad \mathbf{c.} \left(\frac{\partial w}{\partial z} \right)_y.$$

102. Let $U = f(P, V, T)$ be the internal energy of a gas that obeys the ideal gas law $PV = nRT$ (n and R constant). Find

$$\mathbf{a.} \left(\frac{\partial U}{\partial T} \right)_P \quad \mathbf{b.} \left(\frac{\partial U}{\partial V} \right)_T.$$

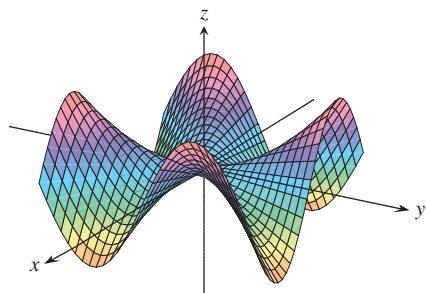

CHAPTER 13 Additional and Advanced Exercises

Partial Derivatives

1. **Function with saddle at the origin** If you did Exercise 64 in Section 13.2, you know that the function

$$f(x, y) = \begin{cases} xy \frac{x^2 - y^2}{x^2 + y^2}, & (x, y) \neq (0, 0) \\ 0, & (x, y) = (0, 0) \end{cases}$$

(see the accompanying figure) is continuous at $(0, 0)$. Find $f_{xy}(0, 0)$ and $f_{yx}(0, 0)$.

2. **Finding a function from second partials** Find a function $w = f(x, y)$ whose first partial derivatives are $\partial w/\partial x = 1 + e^x \cos y$ and $\partial w/\partial y = 2y - e^x \sin y$ and whose value at the point $(\ln 2, 0)$ is $\ln 2$.

3. **A proof of Leibniz's Rule** Leibniz's Rule says that if f is continuous on $[a, b]$ and if $u(x)$ and $v(x)$ are differentiable functions of x whose values lie in $[a, b]$, then

$$\frac{d}{dx} \int_{u(x)}^{v(x)} f(t) dt = f(v(x)) \frac{dv}{dx} - f(u(x)) \frac{du}{dx}.$$

Prove the rule by setting

$$g(u, v) = \int_u^v f(t) dt, \quad u = u(x), \quad v = v(x)$$

and calculating dg/dx with the Chain Rule.

4. **Finding a function with constrained second partials** Suppose that f is a twice-differentiable function of r , that $r = \sqrt{x^2 + y^2 + z^2}$, and that

$$f_{xx} + f_{yy} + f_{zz} = 0.$$

Show that for some constants a and b ,

$$f(r) = \frac{a}{r} + b.$$

5. Homogeneous functions A function $f(x, y)$ is *homogeneous of degree n* (n a nonnegative integer) if $f(tx, ty) = t^n f(x, y)$ for all t , x , and y . For such a function (sufficiently differentiable), prove that

a. $x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} = nf(x, y)$

b. $x^2 \left(\frac{\partial^2 f}{\partial x^2} \right) + 2xy \left(\frac{\partial^2 f}{\partial x \partial y} \right) + y^2 \left(\frac{\partial^2 f}{\partial y^2} \right) = n(n-1)f.$

6. Surface in polar coordinates Let

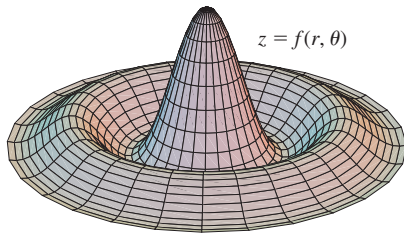

$$f(r, \theta) = \begin{cases} \frac{\sin 6r}{6r}, & r \neq 0 \\ 1, & r = 0, \end{cases}$$

where r and θ are polar coordinates. Find

a. $\lim_{r \rightarrow 0} f(r, \theta)$

b. $f_r(0, 0)$

c. $f_\theta(r, \theta)$, $r \neq 0$.

Gradients and Tangents

7. Properties of position vectors Let $\mathbf{r} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ and let $r = |\mathbf{r}|$.

a. Show that $\nabla r = \mathbf{r}/r$.

b. Show that $\nabla(r^n) = nr^{n-2}\mathbf{r}$.

c. Find a function whose gradient equals \mathbf{r} .

d. Show that $\mathbf{r} \cdot d\mathbf{r} = r dr$.

e. Show that $\nabla(\mathbf{A} \cdot \mathbf{r}) = \mathbf{A}$ for any constant vector \mathbf{A} .

8. Gradient orthogonal to tangent Suppose that a differentiable function $f(x, y)$ has the constant value c along the differentiable curve $x = g(t)$, $y = h(t)$; that is,

$$f(g(t), h(t)) = c$$

for all values of t . Differentiate both sides of this equation with respect to t to show that ∇f is orthogonal to the curve's tangent vector at every point on the curve.

9. Curve tangent to a surface Show that the curve

$$\mathbf{r}(t) = (\ln t)\mathbf{i} + (t \ln t)\mathbf{j} + t\mathbf{k}$$

is tangent to the surface

$$xz^2 - yz + \cos xy = 1$$

at $(0, 0, 1)$.

10. Curve tangent to a surface Show that the curve

$$\mathbf{r}(t) = \left(\frac{t^3}{4} - 2 \right) \mathbf{i} + \left(\frac{4}{t} - 3 \right) \mathbf{j} + \cos(t-2) \mathbf{k}$$

is tangent to the surface

$$x^3 + y^3 + z^3 - xyz = 0$$

at $(0, -1, 1)$.

Extreme Values

11. Extrema on a surface Show that the only possible maxima and minima of z on the surface $z = x^3 + y^3 - 9xy + 27$ occur at $(0, 0)$ and $(3, 3)$. Show that neither a maximum nor a minimum occurs at $(0, 0)$. Determine whether z has a maximum or a minimum at $(3, 3)$.

12. Maximum in closed first quadrant Find the maximum value of $f(x, y) = 6xye^{-(2x+3y)}$ in the closed first quadrant (includes the nonnegative axes).

13. Minimum volume cut from first octant Find the minimum volume for a region bounded by the planes $x = 0$, $y = 0$, $z = 0$ and a plane tangent to the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

at a point in the first octant.

14. Minimum distance from a line to a parabola in xy -plane By minimizing the function $f(x, y, u, v) = (x - u)^2 + (y - v)^2$ subject to the constraints $y = x + 1$ and $u = v^2$, find the minimum distance in the xy -plane from the line $y = x + 1$ to the parabola $y^2 = x$.

Theory and Examples

15. Boundedness of first partials implies continuity Prove the following theorem: If $f(x, y)$ is defined in an open region R of the xy -plane and if f_x and f_y are bounded on R , then $f(x, y)$ is continuous on R . (The assumption of boundedness is essential.)

16. Suppose that $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$ is a smooth curve in the domain of a differentiable function $f(x, y, z)$. Describe the relation among df/dt , ∇f , and $\mathbf{v} = d\mathbf{r}/dt$. What can be said about ∇f and \mathbf{v} at interior points of the curve where f has extreme values relative to its other values on the curve? Give reasons for your answer.

17. Finding functions from partial derivatives Suppose that f and g are functions of x and y such that

$$\frac{\partial f}{\partial y} = \frac{\partial g}{\partial x} \quad \text{and} \quad \frac{\partial f}{\partial x} = \frac{\partial g}{\partial y},$$

and suppose that

$$\frac{\partial f}{\partial x} = 0, \quad f(1, 2) = g(1, 2) = 5, \quad \text{and} \quad f(0, 0) = 4.$$

Find $f(x, y)$ and $g(x, y)$.

18. Rate of change of the rate of change We know that if $f(x, y)$ is a function of two variables and if $\mathbf{u} = a\mathbf{i} + b\mathbf{j}$ is a unit vector, then $D_{\mathbf{u}}f(x, y) = f_x(x, y)a + f_y(x, y)b$ is the rate of change of $f(x, y)$ at (x, y) in the direction of \mathbf{u} . Give a similar formula for the rate of change of the rate of change of $f(x, y)$ at (x, y) in the direction \mathbf{u} .

19. Path of a heat-seeking particle A heat-seeking particle has the property that at any point (x, y) in the plane, it moves in the direction of maximum temperature increase. If the temperature at (x, y) is $T(x, y) = -e^{-2y} \cos x$, find an equation $y = f(x)$ for the path of a heat-seeking particle at the point $(\pi/4, 0)$.

- 20. Velocity after a ricochet** A particle traveling in a straight line with constant velocity $\mathbf{i} + \mathbf{j} - 5\mathbf{k}$ passes through the point $(0, 0, 30)$ and hits the surface $z = 2x^2 + 3y^2$. The particle ricochets off the surface, the angle of reflection being equal to the angle of incidence. Assuming no loss of speed, what is the velocity of the particle after the ricochet? Simplify your answer.
- 21. Directional derivatives tangent to a surface** Let S be the surface that is the graph of $f(x, y) = 10 - x^2 - y^2$. Suppose that the temperature in space at each point (x, y, z) is $T(x, y, z) = x^2y + y^2z + 4x + 14y + z$.
- Among all the possible directions tangential to the surface S at the point $(0, 0, 10)$, which direction will make the rate of change of temperature at $(0, 0, 10)$ a maximum?
 - Which direction tangential to S at the point $(1, 1, 8)$ will make the rate of change of temperature a maximum?
- 22. Drilling another borehole** On a flat surface of land, geologists drilled a borehole straight down and hit a mineral deposit at 300 m. They drilled a second borehole 30 m to the north of the first and hit the mineral deposit at 285 m. A third borehole 30 m east of the first borehole struck the mineral deposit at 307.5 m. The geologists have reasons to believe that the mineral deposit is in the

shape of a dome, and for the sake of economy, they would like to find where the deposit is closest to the surface. Assuming the surface to be the xy -plane, in what direction from the first borehole would you suggest the geologists drill their fourth borehole?

The one-dimensional heat equation If $w(x, t)$ represents the temperature at position x at time t in a uniform wire with perfectly insulated sides, then the partial derivatives w_{xx} and w_t satisfy a differential equation of the form

$$w_{xx} = \frac{1}{c^2} w_t.$$

This equation is called the *one-dimensional heat equation*. The value of the positive constant c^2 is determined by the material from which the wire is made.

- Find all solutions of the one-dimensional heat equation of the form $w = e^{rt} \sin \pi x$, where r is a constant.
- Find all solutions of the one-dimensional heat equation that have the form $w = e^{rt} \sin kx$ and satisfy the conditions that $w(0, t) = 0$ and $w(L, t) = 0$. What happens to these solutions as $t \rightarrow \infty$?

Multiple Integrals

OVERVIEW In this chapter we define the *double integral* of a function of two variables $f(x, y)$ over a region in the plane as the limit of approximating Riemann sums. Just as a single integral can represent signed area, so can a double integral represent signed volume. Double integrals can be evaluated using the Fundamental Theorem of Calculus studied in Section 5.4, but now the evaluations are done twice by integrating with respect to each of the variables x and y in turn. Double integrals can be used to find areas of more general regions in the plane than those encountered in Chapter 5. Moreover, just as the Substitution Rule could simplify finding single integrals, we can sometimes use polar coordinates to simplify computing a double integral. We study more general substitutions for evaluating double integrals as well.

We also define the *triple integral* of a function of three variables $f(x, y, z)$ over a region in space. Triple integrals can be used to find volumes of still more general regions in space, and their evaluation is like that of double integrals with yet a third evaluation. *Cylindrical* or *spherical coordinates* can sometimes be used to simplify the calculation of a triple integral, and we investigate those techniques. Double and triple integrals have a number of applications, such as calculating the average value of a multivariable function, and finding moments and centers of mass.

14.1 Double and Iterated Integrals over Rectangles

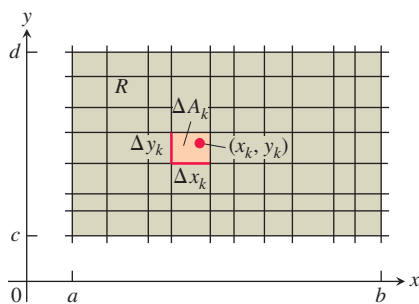

FIGURE 14.1 Rectangular grid partitioning the region R into small rectangles of area $\Delta A_k = \Delta x_k \Delta y_k$.

In Chapter 5 we defined the definite integral of a function $f(x)$ over an interval $[a, b]$ as a limit of Riemann sums. In this section we extend this idea to define the *double integral* of a function of two variables $f(x, y)$ over a bounded rectangle R in the plane. The Riemann sums for the integral of a single-variable function $f(x)$ are obtained by partitioning a finite interval into thin subintervals, multiplying the width of each subinterval by the value of f at a point c_k inside that subinterval, and then adding together all the products. A similar method of partitioning, multiplying, and summing is used to construct double integrals as limits of approximating Riemann sums.

Double Integrals

We begin our investigation of double integrals by considering the simplest type of planar region, a rectangle. We consider a function $f(x, y)$ defined on a rectangular region R ,

$$R: a \leq x \leq b, \quad c \leq y \leq d.$$

We subdivide R into small rectangles using a network of lines parallel to the x - and y -axes (Figure 14.1). The lines divide R into n rectangular pieces, where the number of such pieces n gets large as the width and height of each piece gets small. These rectangles form a **partition** of R . A small rectangular piece of width Δx and height Δy has area

$\Delta A = \Delta x \Delta y$. If we number the small pieces partitioning R in some order, then their areas are given by numbers $\Delta A_1, \Delta A_2, \dots, \Delta A_n$, where ΔA_k is the area of the k th small rectangle.

To form a Riemann sum over R , we choose a point (x_k, y_k) in the k th small rectangle, multiply the value of f at that point by the area ΔA_k , and add together the products:

$$S_n = \sum_{k=1}^n f(x_k, y_k) \Delta A_k.$$

Depending on how we pick (x_k, y_k) in the k th small rectangle, we may get different values for S_n .

We are interested in what happens to these Riemann sums as the widths and heights of all the small rectangles in the partition of R approach zero. The **norm** of a partition P , written $\|P\|$, is the largest width or height of any rectangle in the partition. If $\|P\| = 0.1$, then all the rectangles in the partition of R have width at most 0.1 and height at most 0.1. Sometimes the Riemann sums converge as the norm of P goes to zero, which is written $\|P\| \rightarrow 0$. The resulting limit is then written as

$$\lim_{\|P\| \rightarrow 0} \sum_{k=1}^n f(x_k, y_k) \Delta A_k.$$

As $\|P\| \rightarrow 0$ and the rectangles get narrow and short, their number n increases, so we can also write this limit as

$$\lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k, y_k) \Delta A_k,$$

with the understanding that $\|P\| \rightarrow 0$, and hence $\Delta A_k \rightarrow 0$, as $n \rightarrow \infty$.

Many choices are involved in a limit of this kind. The collection of small rectangles is determined by the grid of vertical and horizontal lines that determine a rectangular partition of R . In each of the resulting small rectangles there is a choice of an arbitrary point (x_k, y_k) at which f is evaluated. These choices together determine a single Riemann sum. To form a limit, we repeat the whole process again and again, choosing partitions whose rectangle widths and heights both go to zero and whose number goes to infinity.

When a limit of the sums S_n exists, giving the same limiting value no matter what choices are made, then the function f is said to be **integrable** and the limit is called the **double integral** of f over R , which is written as

$$\iint_R f(x, y) dA \quad \text{or} \quad \iint_R f(x, y) dx dy.$$

It can be shown that if $f(x, y)$ is a continuous function throughout R , then f is integrable, as in the single-variable case discussed in Chapter 5. Many discontinuous functions are also integrable, including functions that are discontinuous only on a finite number of points or smooth curves. We leave the proof of these facts to a more advanced text.

Double Integrals as Volumes

When $f(x, y)$ is a positive function over a rectangular region R in the xy -plane, we may interpret the double integral of f over R as the volume of the three-dimensional solid region over the xy -plane bounded below by R and above by the surface $z = f(x, y)$ (Figure 14.2). Each term $f(x_k, y_k) \Delta A_k$ in the sum $S_n = \sum f(x_k, y_k) \Delta A_k$ is the volume of a vertical rectangular box that approximates the volume of the portion of the solid that stands directly above the base ΔA_k . The sum S_n thus approximates what we want to call the total volume of the solid. We *define* this volume to be

$$\text{Volume} = \lim_{n \rightarrow \infty} S_n = \iint_R f(x, y) dA,$$

where $\Delta A_k \rightarrow 0$ as $n \rightarrow \infty$.

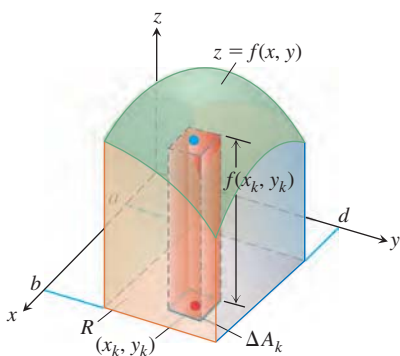

FIGURE 14.2 Approximating solids with rectangular boxes leads us to define the volumes of more general solids as double integrals. The volume of the solid shown here is the double integral of $f(x, y)$ over the base region R .

As you might expect, this more general method of calculating volume agrees with the methods in Chapter 6, but we do not prove this here. Figure 14.3 shows Riemann sum approximations to the volume becoming more accurate as the number n of boxes increases.

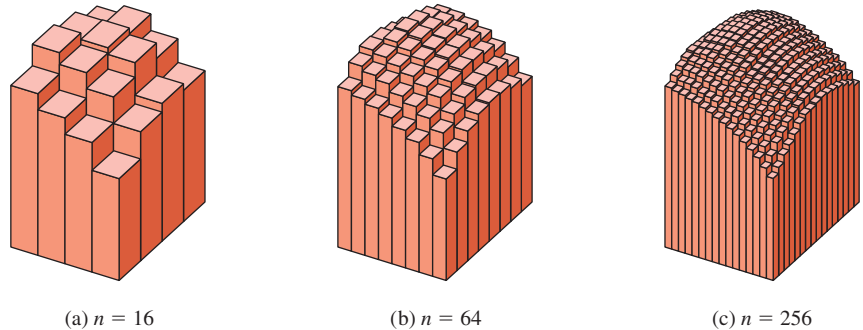

FIGURE 14.3 As n increases, the Riemann sum approximations approach the total volume of the solid shown in Figure 14.2.

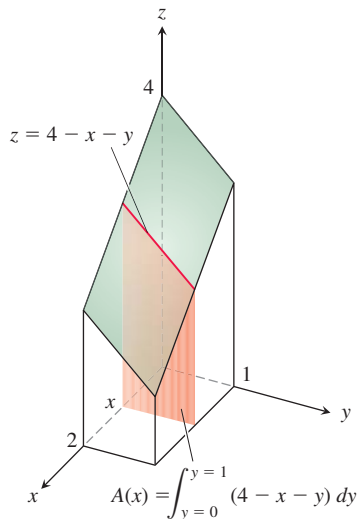

FIGURE 14.4 To obtain the cross-sectional area $A(x)$, we hold x fixed and integrate with respect to y .

Fubini's Theorem for Calculating Double Integrals

Suppose that we wish to calculate the volume under the plane $z = 4 - x - y$ over the rectangular region $R: 0 \leq x \leq 2, 0 \leq y \leq 1$ in the xy -plane. If we apply the method of slicing from Section 6.1, with slices perpendicular to the x -axis (Figure 14.4), then the volume is

$$\int_{x=0}^{x=2} A(x) dx, \quad (1)$$

where $A(x)$ is the cross-sectional area at x . For each value of x , we may calculate $A(x)$ as the integral

$$A(x) = \int_{y=0}^{y=1} (4 - x - y) dy, \quad (2)$$

which is the area under the curve $z = 4 - x - y$ in the plane of the cross-section at x . In calculating $A(x)$, x is held fixed and the integration takes place with respect to y . Combining Equations (1) and (2), we see that the volume of the entire solid is

$$\begin{aligned} \text{Volume} &= \int_{x=0}^{x=2} A(x) dx = \int_{x=0}^{x=2} \left(\int_{y=0}^{y=1} (4 - x - y) dy \right) dx \\ &= \int_{x=0}^{x=2} \left[4y - xy - \frac{y^2}{2} \right]_{y=0}^{y=1} dx = \int_{x=0}^{x=2} \left(\frac{7}{2} - x \right) dx \\ &= \left[\frac{7}{2}x - \frac{x^2}{2} \right]_0^2 = 5. \end{aligned}$$

We often omit parentheses separating the two integrals in the formula above and write

$$\text{Volume} = \int_0^2 \int_0^1 (4 - x - y) dy dx. \quad (3)$$

The expression on the right, called an **iterated** or **repeated integral**, says that the volume is obtained by integrating $4 - x - y$ with respect to y from $y = 0$ to $y = 1$ while holding x fixed, and then integrating the resulting expression in x from $x = 0$ to $x = 2$. The limits of integration 0 and 1 are associated with y , so they are placed on the integral closest to dy . The other limits of integration, 0 and 2, are associated with the variable x , so they are placed on the outside integral symbol that is paired with dx .

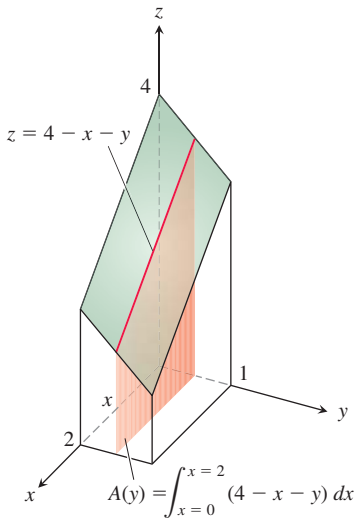

FIGURE 14.5 To obtain the cross-sectional area $A(y)$, we hold y fixed and integrate with respect to x .

HISTORICAL BIOGRAPHY

Guido Fubini
(1879–1943)

Fubini attended secondary school in Venice, Italy, where he showed that he was brilliant at mathematics. His advanced study was at the Scuola Normale Superiore di Pisa, where his doctoral thesis was in geometry. He then worked on harmonic functions in curved spaces. Fubini's interests were wide ranging, from differential geometry to analysis and to the applications of differential equations.

To know more, visit the companion Website.

What would have happened if we had calculated the volume by slicing with planes perpendicular to the y -axis (Figure 14.5)? As a function of y , the typical cross-sectional area is

$$A(y) = \int_{x=0}^{x=2} (4 - x - y) dx = \left[4x - \frac{x^2}{2} - xy \right]_{x=0}^{x=2} = 6 - 2y. \quad (4)$$

The volume of the entire solid is therefore

$$\text{Volume} = \int_{y=0}^{y=1} A(y) dy = \int_{y=0}^{y=1} (6 - 2y) dy = \left[6y - y^2 \right]_0^1 = 5,$$

in agreement with our earlier calculation.

Again, we may give a formula for the volume as an iterated integral by writing

$$\text{Volume} = \int_0^1 \int_0^2 (4 - x - y) dx dy.$$

The expression on the right says we can find the volume by integrating $4 - x - y$ with respect to x from $x = 0$ to $x = 2$ as in Equation (4) and integrating the result with respect to y from $y = 0$ to $y = 1$. In this iterated integral, the order of integration is first x and then y , the reverse of the order in Equation (3).

What do these two volume calculations with iterated integrals have to do with the double integral

$$\iint_R (4 - x - y) dA$$

over the rectangle $R: 0 \leq x \leq 2, 0 \leq y \leq 1$? The answer is that both iterated integrals give the value of the double integral. This is what we would reasonably expect, since the double integral measures the volume of the same region as the two iterated integrals. A theorem published in 1907 by Guido Fubini says that the double integral of any continuous function over a rectangle can be calculated as an iterated integral in either order of integration. (Fubini proved his theorem in greater generality, but this is what it says in our setting.)

THEOREM 1—Fubini's Theorem (First Form)

If $f(x, y)$ is continuous throughout the rectangular region $R: a \leq x \leq b, c \leq y \leq d$, then

$$\iint_R f(x, y) dA = \int_c^d \int_a^b f(x, y) dx dy = \int_a^b \int_c^d f(x, y) dy dx.$$

Fubini's Theorem says that double integrals over rectangles can be calculated as iterated integrals. Thus, we can evaluate a double integral by integrating with respect to one variable at a time using the Fundamental Theorem of Calculus.

Fubini's Theorem also says that we may calculate the double integral by integrating in *either* order, a genuine convenience. When we calculate a volume by slicing, we may use either planes perpendicular to the x -axis or planes perpendicular to the y -axis.

EXAMPLE 1 Calculate $\iint_R f(x, y) dA$ for

$$f(x, y) = 100 - 6x^2y \quad \text{and} \quad R: 0 \leq x \leq 2, -1 \leq y \leq 1.$$

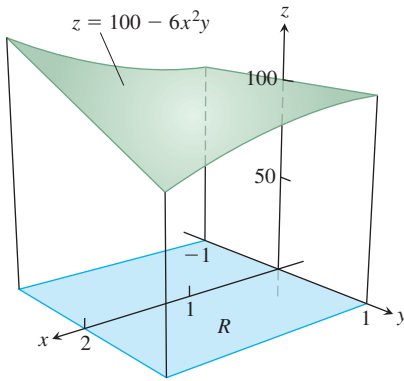

FIGURE 14.6 The double integral $\iint_R f(x, y) dA$ gives the volume under this surface over the rectangular region R (Example 1).

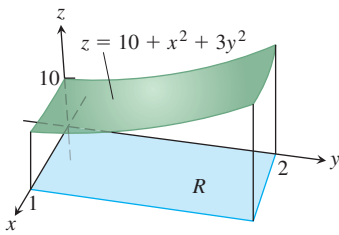

FIGURE 14.7 The double integral $\iint_R f(x, y) dA$ gives the volume under this surface over the rectangular region R (Example 2).

Solution Figure 14.6 displays the volume beneath the surface. By Fubini's Theorem,

$$\begin{aligned} \iint_R f(x, y) dA &= \int_{-1}^1 \int_0^2 (100 - 6x^2y) dx dy = \int_{-1}^1 \left[100x - 2x^3y \right]_{x=0}^{x=2} dy \\ &= \int_{-1}^1 (200 - 16y) dy = \left[200y - 8y^2 \right]_{-1}^1 = 400. \end{aligned}$$

Reversing the order of integration gives the same answer:

$$\begin{aligned} \int_0^2 \int_{-1}^1 (100 - 6x^2y) dy dx &= \int_0^2 \left[100y - 3x^2y^2 \right]_{y=-1}^{y=1} dx \\ &= \int_0^2 [(100 - 3x^2) - (-100 - 3x^2)] dx \\ &= \int_0^2 200 dx = 400. \end{aligned}$$

EXAMPLE 2 Find the volume of the region bounded above by the elliptical paraboloid $z = 10 + x^2 + 3y^2$ and below by the rectangle $R: 0 \leq x \leq 1, 0 \leq y \leq 2$.

Solution The surface and volume are shown in Figure 14.7. The volume is given by the double integral

$$\begin{aligned} V &= \iint_R (10 + x^2 + 3y^2) dA = \int_0^1 \int_0^2 (10 + x^2 + 3y^2) dy dx \\ &= \int_0^1 \left[10y + x^2y + y^3 \right]_{y=0}^{y=2} dx \\ &= \int_0^1 (28 + 2x^2) dx = \left[28x + \frac{2}{3}x^3 \right]_0^1 = \frac{86}{3}. \end{aligned}$$

EXERCISES 14.1

Evaluating Iterated Integrals

In Exercises 1–14, evaluate the iterated integral.

1. $\int_1^2 \int_0^4 2xy dy dx$

2. $\int_0^2 \int_{-1}^1 (x - y) dy dx$

3. $\int_{-1}^0 \int_{-1}^1 (x + y + 1) dx dy$

4. $\int_0^1 \int_0^1 \left(1 - \frac{x^2 + y^2}{2} \right) dx dy$

5. $\int_0^3 \int_0^2 (4 - y^2) dy dx$

6. $\int_0^3 \int_{-2}^0 (x^2y - 2xy) dy dx$

7. $\int_0^1 \int_0^1 \frac{y}{1 + xy} dx dy$

8. $\int_1^4 \int_0^4 \left(\frac{x}{2} + \sqrt{y} \right) dx dy$

9. $\int_0^{\ln 2} \int_1^{\ln 5} e^{2x+y} dy dx$

10. $\int_0^1 \int_1^2 xye^x dy dx$

11. $\int_{-1}^2 \int_0^{\pi/2} y \sin x dx dy$

12. $\int_{\pi}^{2\pi} \int_0^{\pi} (\sin x + \cos y) dx dy$

13. $\int_1^4 \int_1^e \frac{\ln x}{xy} dx dy$

14. $\int_{-1}^2 \int_1^2 x \ln y dy dx$

15. Find all values of the constant c so that $\int_0^1 \int_0^c (2x + y) dx dy = 3$.

16. Find all values of the constant c so that

$$\int_{-1}^c \int_0^2 (xy + 1) dy dx = 4 + 4c.$$

Evaluating Double Integrals over Rectangles

In Exercises 17–24, evaluate the double integral over the given region R .

17. $\iint_R (6y^2 - 2x) dA$, $R: 0 \leq x \leq 1, 0 \leq y \leq 2$

18. $\iint_R \left(\frac{\sqrt{x}}{y^2} \right) dA$, $R: 0 \leq x \leq 4, 1 \leq y \leq 2$

19. $\iint_R xy \cos y \, dA$, $R: -1 \leq x \leq 1, 0 \leq y \leq \pi$
20. $\iint_R y \sin(x + y) \, dA$, $R: -\pi \leq x \leq 0, 0 \leq y \leq \pi$
21. $\iint_R e^{x-y} \, dA$, $R: 0 \leq x \leq \ln 2, 0 \leq y \leq \ln 2$
22. $\iint_R xy e^{xy^2} \, dA$, $R: 0 \leq x \leq 2, 0 \leq y \leq 1$
23. $\iint_R \frac{xy^3}{x^2 + 1} \, dA$, $R: 0 \leq x \leq 1, 0 \leq y \leq 2$
24. $\iint_R \frac{y}{x^2 y^2 + 1} \, dA$, $R: 0 \leq x \leq 1, 0 \leq y \leq 1$

In Exercises 25 and 26, integrate f over the given region.

25. **Square** $f(x, y) = 1/(xy)$ over the square $1 \leq x \leq 2, 1 \leq y \leq 2$
26. **Rectangle** $f(x, y) = y \cos xy$ over the rectangle $0 \leq x \leq \pi, 0 \leq y \leq 1$

In Exercises 27 and 28, sketch the solid whose volume is given by the specified integral.

27. $\int_0^1 \int_0^2 (9 - x^2 - y^2) \, dy \, dx$ 28. $\int_0^3 \int_1^4 (7 - x - y) \, dx \, dy$
29. Find the volume of the region bounded above by the paraboloid $z = x^2 + y^2$ and below by the square $R: -1 \leq x \leq 1, -1 \leq y \leq 1$.
30. Find the volume of the region bounded above by the elliptical paraboloid $z = 16 - x^2 - y^2$ and below by the square $R: 0 \leq x \leq 2, 0 \leq y \leq 2$.

31. Find the volume of the region bounded above by the plane $z = 2 - x - y$ and below by the square $R: 0 \leq x \leq 1, 0 \leq y \leq 1$.
32. Find the volume of the region bounded above by the plane $z = y/2$ and below by the rectangle $R: 0 \leq x \leq 4, 0 \leq y \leq 2$.
33. Find the volume of the region bounded above by the surface $z = 2 \sin x \cos y$ and below by the rectangle $R: 0 \leq x \leq \pi/2, 0 \leq y \leq \pi/4$.
34. Find the volume of the region bounded above by the surface $z = 4 - y^2$ and below by the rectangle $R: 0 \leq x \leq 1, 0 \leq y \leq 2$.

35. Find a value of the constant k so that $\int_1^2 \int_0^3 kx^2 y \, dx \, dy = 1$.

36. Evaluate $\int_{-1}^1 \int_0^{\pi/2} x \sin \sqrt{y} \, dy \, dx$.

37. Use Fubini's Theorem to evaluate

$$\int_0^2 \int_0^1 \frac{x}{1 + xy} \, dx \, dy.$$

38. Use Fubini's Theorem to evaluate

$$\int_0^1 \int_0^3 x e^{-xy} \, dx \, dy.$$

T 39. Use a software application to compute the integrals

$$\text{a. } \int_0^1 \int_0^2 \frac{y-x}{(x+y)^3} \, dx \, dy \qquad \text{b. } \int_0^2 \int_0^1 \frac{y-x}{(x+y)^3} \, dy \, dx$$

Explain why your results do not contradict Fubini's Theorem.

40. If $f(x, y)$ is continuous over $R: a \leq x \leq b, c \leq y \leq d$ and

$$F(x, y) = \int_a^x \int_c^y f(u, v) \, dv \, du$$

on the interior of R , find the second partial derivatives F_{xy} and F_{yx} .

14.2 Double Integrals over General Regions

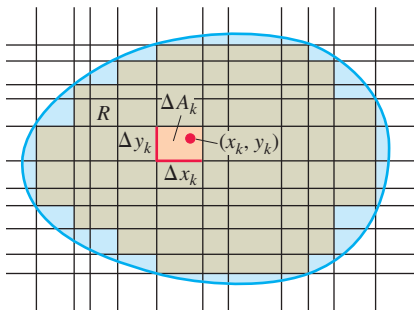

FIGURE 14.8 A rectangular grid partitioning a bounded, nonrectangular region into rectangular cells.

In this section we define and evaluate double integrals over bounded regions in the plane that are more general than rectangles. These double integrals are also evaluated as iterated integrals, with the main practical problem being that of determining the limits of integration. Since the region of integration may have boundaries other than line segments parallel to the coordinate axes, the limits of integration often involve variables, not just constants.

Double Integrals over Bounded, Nonrectangular Regions

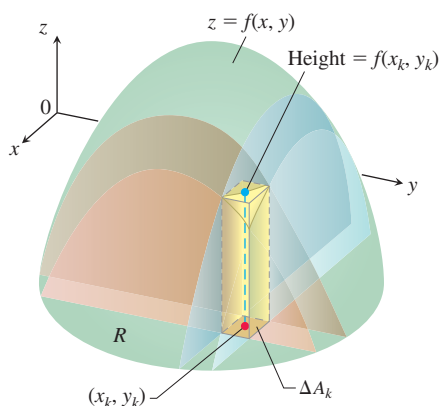

To define the double integral of a function $f(x, y)$ over a bounded, nonrectangular region R , such as the one in Figure 14.8, we again begin by covering R with a grid of small rectangular cells whose union contains all points of R . This time, however, we cannot exactly fill R with a finite number of rectangles lying inside R since its boundary is curved, and some of the small rectangles in the grid lie partly outside R . A partition of R is formed by taking the rectangles that lie completely inside it, not using any that are either partly or completely outside. For commonly arising regions, more and more of R is included as the norm of a partition (the largest width or height of any rectangle used) approaches zero.

Once we have a partition of R , we number the rectangles in some order from 1 to n and let ΔA_k be the area of the k th rectangle. We then choose a point (x_k, y_k) in the k th rectangle and form the Riemann sum

$$S_n = \sum_{k=1}^n f(x_k, y_k) \Delta A_k.$$

As the norm of the partition forming S_n goes to zero, $\|P\| \rightarrow 0$, the width and height of each enclosed rectangle go to zero, their area ΔA_k goes to zero, and their number goes to infinity. If $f(x, y)$ is a continuous function, then these Riemann sums converge to a limiting value that is not dependent on any of the choices we made. This limit is called the **double integral** of $f(x, y)$ over R :

$$\lim_{\|P\| \rightarrow 0} \sum_{k=1}^n f(x_k, y_k) \Delta A_k = \iint_R f(x, y) dA.$$

$$\text{Volume} = \lim \sum f(x_k, y_k) \Delta A_k = \iint_R f(x, y) dA$$

FIGURE 14.9 We define the volume of a solid with a curved base as a limit of the sums of volumes of approximating rectangular boxes.

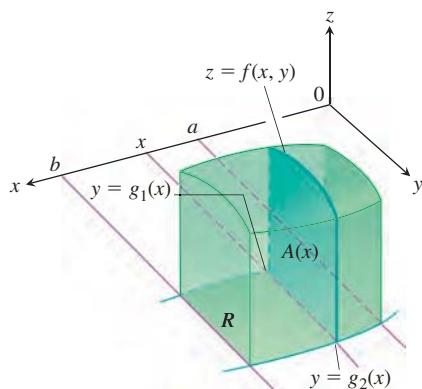

FIGURE 14.10 The area of the vertical slice shown here is $A(x)$. To calculate the volume of the solid, we integrate this area from $x = a$ to $x = b$:

$$\int_a^b A(x) dx = \int_a^b \int_{g_1(x)}^{g_2(x)} f(x, y) dy dx.$$

The nature of the boundary of R introduces issues not found in integrals over an interval. When R has a curved boundary, the n rectangles of a partition lie inside R but do not cover all of R . In order for a partition to approximate R well, the parts of R covered by small rectangles lying partly outside R must become negligible as the norm of the partition approaches zero. This property of being nearly filled in by a partition of small norm is satisfied by all the regions that we will encounter. There is no problem with boundaries made from polygons, circles, and ellipses or from continuous graphs over an interval, joined end to end. A curve with a “fractal” type of shape would be problematic, but such curves arise rarely in most applications. A careful discussion of which types of regions R can be used for computing double integrals is left to a more advanced text.

Volumes

If $f(x, y)$ is positive and continuous over R , we define the volume of the solid region between R and the surface $z = f(x, y)$ to be $\iint_R f(x, y) dA$, as before (Figure 14.9).

If R is a region like the one shown in the xy -plane in Figure 14.10, bounded “above” and “below” by the curves $y = g_2(x)$ and $y = g_1(x)$ and on the sides by the lines $x = a, x = b$, we may again calculate the volume by the method of slicing. We first calculate the cross-sectional area

$$A(x) = \int_{y=g_1(x)}^{y=g_2(x)} f(x, y) dy$$

and then integrate $A(x)$ from $x = a$ to $x = b$ to get the volume as an iterated integral:

$$V = \int_a^b A(x) dx = \int_a^b \int_{g_1(x)}^{g_2(x)} f(x, y) dy dx. \quad (1)$$

Similarly, if R is a region like the one shown in Figure 14.11, bounded by the curves $x = h_2(y)$ and $x = h_1(y)$ and the lines $y = c$ and $y = d$, then the volume calculated by slicing is given by the iterated integral

$$\text{Volume} = \int_c^d \int_{h_1(y)}^{h_2(y)} f(x, y) dx dy. \quad (2)$$

That the iterated integrals in Equations (1) and (2) both give the volume that we defined to be the double integral of f over R is a consequence of the following stronger form of Fubini’s Theorem.

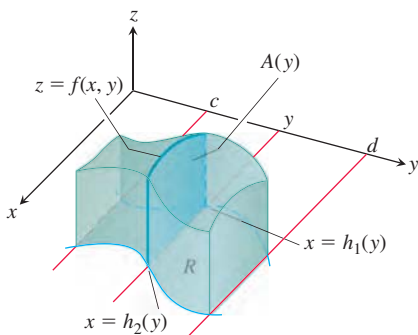

FIGURE 14.11 The volume of the solid shown here is

$$\int_c^d A(y) dy = \int_c^d \int_{h_1(y)}^{h_2(y)} f(x, y) dx dy.$$

For a given solid, Theorem 2 says we can calculate the volume as in Figure 14.10 or in the way shown here. Both calculations have the same result.

THEOREM 2—Fubini's Theorem (Stronger Form)

Let $f(x, y)$ be continuous on a region R .

1. If R is defined by $a \leq x \leq b$, $g_1(x) \leq y \leq g_2(x)$, with g_1 and g_2 continuous on $[a, b]$, then

$$\iint_R f(x, y) dA = \int_a^b \int_{g_1(x)}^{g_2(x)} f(x, y) dy dx.$$

2. If R is defined by $c \leq y \leq d$, $h_1(y) \leq x \leq h_2(y)$, with h_1 and h_2 continuous on $[c, d]$, then

$$\iint_R f(x, y) dA = \int_c^d \int_{h_1(y)}^{h_2(y)} f(x, y) dx dy.$$

Some iterated double integrals we will encounter later in this text will use variables of integration other than x and y . For instance, we may write

$$\int_{u=p}^{u=q} \int_{v=G_1(u)}^{v=G_2(u)} F(u, v) dv du = \int_p^q \int_{G_1(u)}^{G_2(u)} F(u, v) dv du.$$

Regardless of which specific variables of integration are used, the limits of an iterated double integral always satisfy these properties:

- The limits of the *outside* integral are *constants* (they do not depend on either variable of integration), and
- the limits of the *inside* integral are *functions* that may depend on the variable of the *outside* integral.

EXAMPLE 1 Find the volume of the right prism whose base is the triangle in the xy -plane bounded by the x -axis and the lines $y = x$ and $x = 1$ and whose top lies in the plane

$$z = f(x, y) = 3 - x - y.$$

Solution See Figure 14.12a. For any x between 0 and 1, y may vary from $y = 0$ to $y = x$ (Figure 14.12b). Hence,

$$\begin{aligned} V &= \int_0^1 \int_0^x (3 - x - y) dy dx = \int_0^1 \left[3y - xy - \frac{y^2}{2} \right]_{y=0}^{y=x} dx \\ &= \int_0^1 \left(3x - \frac{3x^2}{2} \right) dx = \left[\frac{3x^2}{2} - \frac{x^3}{2} \right]_{x=0}^{x=1} = 1. \end{aligned}$$

When the order of integration is reversed (Figure 14.12c), the integral for the volume is

$$\begin{aligned} V &= \int_0^1 \int_y^1 (3 - x - y) dx dy = \int_0^1 \left[3x - \frac{x^2}{2} - xy \right]_{x=y}^{x=1} dy \\ &= \int_0^1 \left(3 - \frac{1}{2} - y - 3y + \frac{y^2}{2} + y^2 \right) dy \\ &= \int_0^1 \left(\frac{5}{2} - 4y + \frac{3}{2}y^2 \right) dy = \left[\frac{5}{2}y - 2y^2 + \frac{y^3}{2} \right]_{y=0}^{y=1} = 1. \end{aligned}$$

The two integrals are equal, as they should be. ■

Although Fubini's Theorem assures us that a double integral may be calculated as an iterated integral in either order of integration, the value of one integral may be easier to find than the value of the other. The next example shows how this can happen.

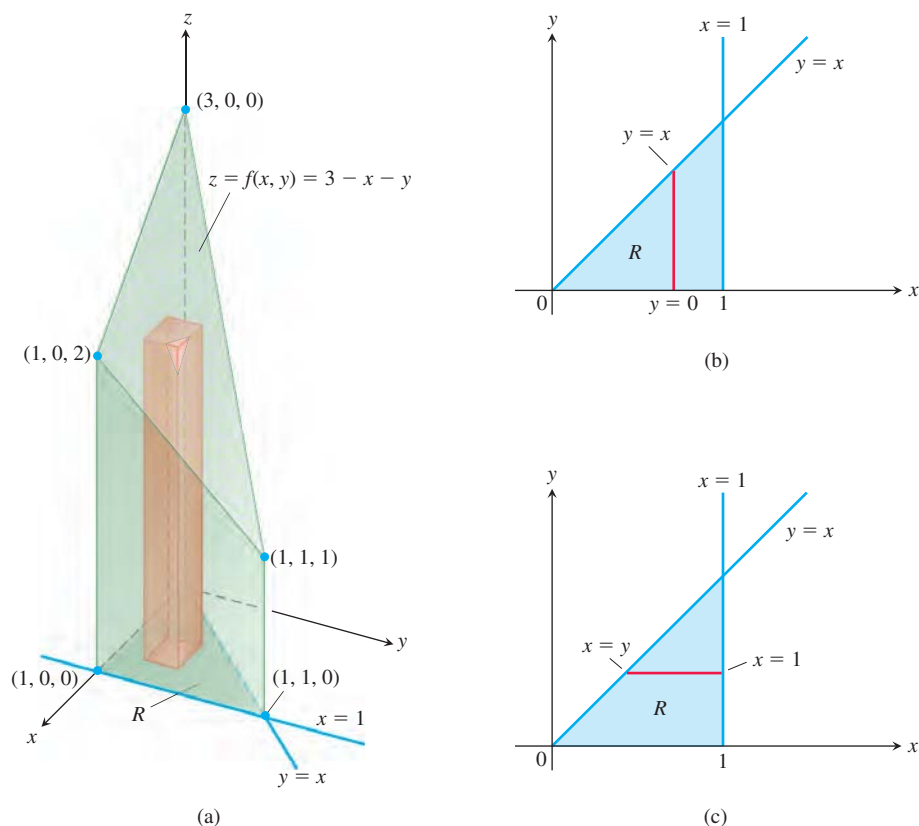

FIGURE 14.12 (a) Prism with a triangular base in the xy -plane. The volume of this prism is defined as a double integral over R . To evaluate it as an iterated integral, we may integrate first with respect to y and then with respect to x , or the other way around (Example 1). (b) Integration limits of

$$\int_{x=0}^{x=1} \int_{y=0}^{y=x} f(x, y) dy dx.$$

If we integrate first with respect to y , we integrate along a vertical line through R and then integrate from left to right to include all the vertical lines in R . (c) Integration limits of

$$\int_{y=0}^{y=1} \int_{x=y}^{x=1} f(x, y) dx dy.$$

If we integrate first with respect to x , we integrate along a horizontal line through R and then integrate from bottom to top to include all the horizontal lines in R .

EXAMPLE 2 Calculate

$$\iint_R \frac{\sin x}{x} dA,$$

where R is the triangle in the xy -plane bounded by the x -axis, the line $y = x$, and the line $x = 1$.

Solution The region of integration is shown in Figure 14.13. If we integrate first with respect to y and next with respect to x , then because x is held fixed in the first integration, we find

$$\int_0^1 \left(\int_0^x \frac{\sin x}{x} dy \right) dx = \int_0^1 \left[y \frac{\sin x}{x} \right]_{y=0}^{y=x} dx = \int_0^1 \sin x dx = -\cos(1) + 1 \approx 0.46.$$

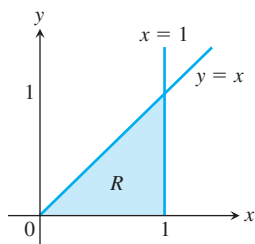

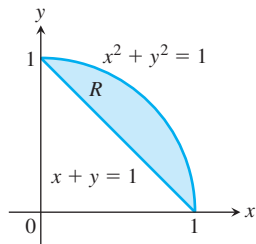

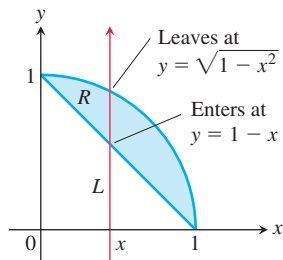

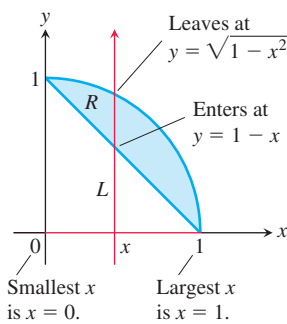

FIGURE 14.13 The region of integration in Example 2.

(a)

(b)

(c)

FIGURE 14.14 Finding the limits of integration when integrating first with respect to y and then with respect to x .

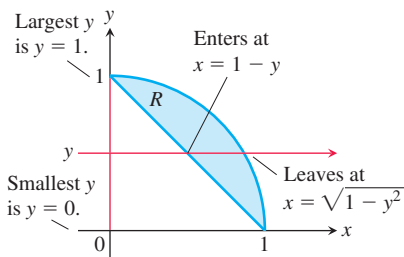

FIGURE 14.15 Finding the limits of integration when integrating first with respect to x and then with respect to y .

If we reverse the order of integration and attempt to calculate

$$\int_0^1 \int_y^1 \frac{\sin x}{x} dx dy,$$

we run into a problem because $\int ((\sin x)/x) dx$ cannot be expressed in terms of elementary functions (there is no simple antiderivative).

There is no general rule for predicting which order of integration will be the good one in circumstances like these. If the order you first choose doesn't work, try the other. Sometimes neither order will work, and then we may need to use numerical approximations. ■

Finding Limits of Integration

We now give a procedure for finding limits of integration that applies for many regions in the plane. Regions that are more complicated, and for which this procedure fails, can often be split up into pieces on which the procedure works.

Using Vertical Cross-Sections When faced with evaluating $\iint_R f(x, y) dA$, integrating first with respect to y and then with respect to x , do the following three steps:

1. *Sketch.* Sketch the region of integration and label the bounding curves (Figure 14.14a).
2. *Find the y -limits of integration.* Imagine a vertical line L cutting through R in the direction of increasing y . Mark the y -values where L enters and leaves. These are the y -limits of integration and are usually functions of x (instead of constants) (Figure 14.14b).
3. *Find the x -limits of integration.* Choose x -limits that include all the vertical lines through R . These must be constants. The integral whose region of integration is shown in Figure 14.14c is

$$\iint_R f(x, y) dA = \int_{x=0}^{x=1} \int_{y=1-x}^{y=\sqrt{1-x^2}} f(x, y) dy dx.$$

Using Horizontal Cross-Sections To evaluate the same double integral as an iterated integral with the order of integration reversed, use horizontal lines instead of vertical lines in Steps 2 and 3 (see Figure 14.15). The integral is

$$\iint_R f(x, y) dA = \int_0^1 \int_{1-y}^{\sqrt{1-y^2}} f(x, y) dx dy.$$

EXAMPLE 3 Sketch the region of integration for the integral

$$\int_0^2 \int_{x^2}^{2x} (4x + 2) dy dx$$

and write an equivalent integral with the order of integration reversed.

Solution The region of integration is given by the inequalities $x^2 \leq y \leq 2x$ and $0 \leq x \leq 2$. It is therefore the region bounded by the curves $y = x^2$ and $y = 2x$ between $x = 0$ and $x = 2$ (Figure 14.16a).

To find limits for integrating in the reverse order, we imagine a horizontal line passing from left to right through the region. It enters at $x = y/2$ and leaves at $x = \sqrt{y}$. To include all such lines, we let y run from $y = 0$ to $y = 4$ (Figure 14.16b). The integral is

$$\int_0^4 \int_{y/2}^{\sqrt{y}} (4x + 2) dx dy.$$

The common value of these integrals is 8. ■

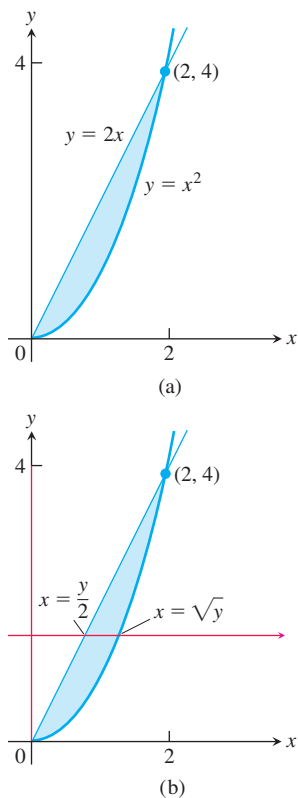

FIGURE 14.16 Region of integration for Example 3.

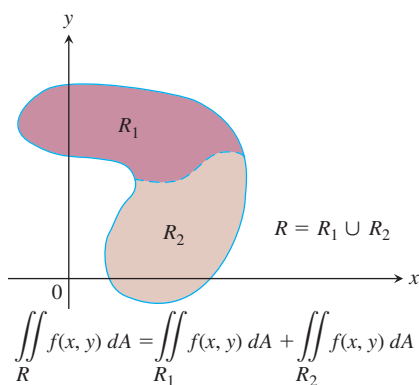

FIGURE 14.17 The Additivity Property for rectangular regions holds for regions bounded by smooth curves.

Properties of Double Integrals

Like single integrals, double integrals of continuous functions have algebraic properties that are useful in computations and applications.

If $f(x, y)$ and $g(x, y)$ are continuous on the bounded region R , then the following properties hold.

1. **Constant Multiple:**
$$\iint_R cf(x, y) \, dA = c \iint_R f(x, y) \, dA \quad (\text{any number } c)$$

2. **Sum and Difference:**

$$\iint_R (f(x, y) \pm g(x, y)) \, dA = \iint_R f(x, y) \, dA \pm \iint_R g(x, y) \, dA$$

3. **Domination:**

(a)
$$\iint_R f(x, y) \, dA \geq 0 \quad \text{if } f(x, y) \geq 0 \text{ on } R$$

(b)
$$\iint_R f(x, y) \, dA \geq \iint_R g(x, y) \, dA \quad \text{if } f(x, y) \geq g(x, y) \text{ on } R$$

4. **Additivity:** If R is the union of two nonoverlapping regions R_1 and R_2 , then

$$\iint_R f(x, y) \, dA = \iint_{R_1} f(x, y) \, dA + \iint_{R_2} f(x, y) \, dA$$

Property 4 assumes that the region of integration R is decomposed into nonoverlapping regions R_1 and R_2 with boundaries consisting of a finite number of line segments or smooth curves. Figure 14.17 illustrates an example of this property.

The idea behind these properties is that integrals behave like sums. If the function $f(x, y)$ is replaced by its constant multiple $cf(x, y)$, then a Riemann sum for f ,

$$S_n = \sum_{k=1}^n f(x_k, y_k) \Delta A_k,$$

is replaced by a Riemann sum for cf :

$$\sum_{k=1}^n cf(x_k, y_k) \Delta A_k = c \sum_{k=1}^n f(x_k, y_k) \Delta A_k = cS_n.$$

Taking limits as $n \rightarrow \infty$ shows that $c \lim_{n \rightarrow \infty} S_n = c \iint_R f \, dA$ and $\lim_{n \rightarrow \infty} cS_n = \iint_R cf \, dA$ are equal. It follows that the Constant Multiple Property carries over from sums to double integrals.

The other properties are also easy to verify for Riemann sums, and carry over to double integrals for the same reason. While this discussion gives the idea, an actual proof that these properties hold requires a more careful analysis of how Riemann sums converge.

EXAMPLE 4 Find the volume of the wedgelike solid that lies beneath the surface $z = 16 - x^2 - y^2$ and above the region R bounded by the curve $y = 2\sqrt{x}$, the line $y = 4x - 2$, and the x -axis.

Solution Figure 14.18a shows the surface and the “wedgelike” solid whose volume we want to calculate. Figure 14.18b shows the region of integration in the xy -plane. If we integrate in the order $dy \, dx$ (first with respect to y and then with respect to x), two integrations

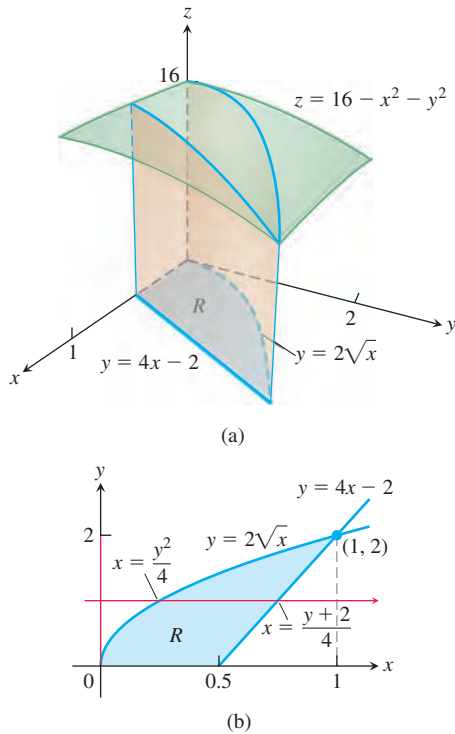

FIGURE 14.18 (a) The solid “wedge-like” region whose volume is found in Example 4. (b) The region of integration R showing the order $dx dy$.

will be required because y varies from $y = 0$ to $y = 2\sqrt{x}$ for $0 \leq x \leq 0.5$, and then varies from $y = 4x - 2$ to $y = 2\sqrt{x}$ for $0.5 \leq x \leq 1$. So we choose to integrate in the order $dx dy$, which requires only one double integral whose limits of integration are indicated in Figure 14.18b. The volume is then calculated as the iterated integral:

$$\begin{aligned} & \iint_R (16 - x^2 - y^2) dA \\ &= \int_0^2 \int_{y^2/4}^{(y+2)/4} (16 - x^2 - y^2) dx dy \\ &= \int_0^2 \left[16x - \frac{x^3}{3} - xy^2 \right]_{x=y^2/4}^{x=(y+2)/4} dy \\ &= \int_0^2 \left[4(y+2) - \frac{(y+2)^3}{3 \cdot 64} - \frac{(y+2)y^2}{4} - 4y^2 + \frac{y^6}{3 \cdot 64} + \frac{y^4}{4} \right] dy \\ &= \left[\frac{191y}{24} + \frac{63y^2}{32} - \frac{145y^3}{96} - \frac{49y^4}{768} + \frac{y^5}{20} + \frac{y^7}{1344} \right]_0^2 = \frac{20803}{1680} \approx 12.4. \end{aligned}$$

Our development of the double integral has focused on its representation of the volume of the solid region between R and the surface $z = f(x, y)$ of a positive continuous function. Just as we saw with signed area in the case of single integrals, when $f(x_k, y_k)$ is negative, the product $f(x_k, y_k) \Delta A_k$ is the negative of the volume of the rectangular box shown in Figure 14.9 that was used to form the approximating Riemann sum. So for an arbitrary continuous function f defined over R , the limit of any Riemann sum represents the *signed* volume (not the total volume) of the solid region between R and the surface. The double integral has other interpretations as well, and in the next section we will see how it is used to calculate the area of a general region in the plane.

EXERCISES 14.2

Sketching Regions of Integration

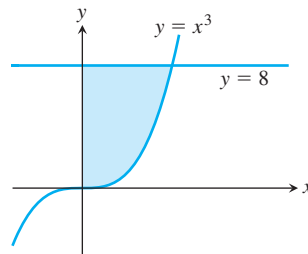

In Exercises 1–8, sketch the regions of integration associated with the given double integrals.

- $\int_0^3 \int_0^{2x} f(x, y) dy dx$
- $\int_{-1}^2 \int_{x-1}^{x^2} f(x, y) dy dx$
- $\int_{-2}^2 \int_{y^2}^4 f(x, y) dx dy$
- $\int_0^1 \int_y^{2y} f(x, y) dx dy$
- $\int_0^1 \int_{e^x}^e f(x, y) dy dx$
- $\int_1^{e^2} \int_0^{\ln x} f(x, y) dy dx$
- $\int_0^1 \int_0^{\arcsin y} f(x, y) dx dy$
- $\int_0^8 \int_{y/4}^{y^{1/3}} f(x, y) dx dy$

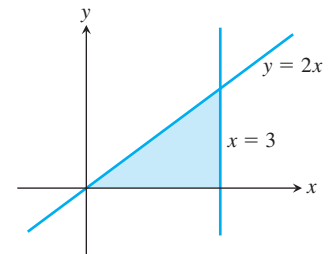

Finding Limits of Integration

In Exercises 9–18, write an iterated integral for $\iint_R dA$ over the described region R using (a) vertical cross-sections, (b) horizontal cross-sections.

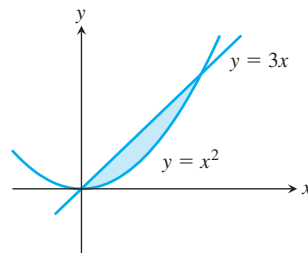

9.

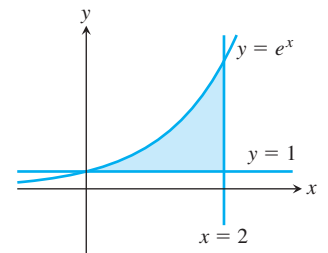

10.

11.

12.

13. Bounded by $y = \sqrt{x}$, $y = 0$, and $x = 9$
 14. Bounded by $y = \tan x$, $x = 0$, and $y = 1$
 15. Bounded by $y = e^{-x}$, $y = 1$, and $x = \ln 3$
 16. Bounded by $y = 0$, $x = 0$, $y = 1$, and $y = \ln x$
 17. Bounded by $y = 3 - 2x$, $y = x$, and $x = 0$
 18. Bounded by $y = x^2$ and $y = x + 2$

Evaluating Iterated Integrals

In Exercises 19–26, evaluate the integral.

19. $\int_1^2 \int_0^{2x} xy^3 dy dx$ 20. $\int_1^3 \int_y^{2y} y dx dy$
 21. $\int_0^1 \int_y^1 (\sqrt{x} + xy) dx dy$ 22. $\int_0^2 \int_0^{x^3} (y^2 - x) dy dx$
 23. $\int_0^{\sqrt{\pi}} \int_0^{x^2} x \sin y dy dx$ 24. $\int_0^1 \int_0^{\arctan y} \frac{1}{1+y^2} dx dy$
 25. $\int_1^4 \int_y^{y^2} \sqrt{\frac{y}{x}} dx dy$ 26. $\int_3^5 \int_1^{e^x} \frac{1}{xy} dy dx$

Finding Regions of Integration and Double Integrals

In Exercises 27–32, sketch the region of integration and evaluate the integral.

27. $\int_0^{\pi} \int_0^x x \sin y dy dx$ 28. $\int_0^{\pi} \int_0^{\sin x} y dy dx$
 29. $\int_1^{\ln 8} \int_1^{\ln y} e^{x+y} dx dy$ 30. $\int_1^2 \int_y^2 dx dy$
 31. $\int_0^1 \int_0^{y^2} 3y^3 e^{xy} dx dy$ 32. $\int_1^4 \int_0^{\sqrt{x}} \frac{3}{2} e^{y/\sqrt{x}} dy dx$

In Exercises 33–36, integrate f over the given region.

33. **Quadrilateral** $f(x, y) = x/y$ over the region in the first quadrant bounded by the lines $y = x$, $y = 2x$, $x = 1$, and $x = 2$
 34. **Triangle** $f(x, y) = x^2 + y^2$ over the triangular region with vertices $(0, 0)$, $(1, 0)$, and $(0, 1)$
 35. **Triangle** $f(u, v) = v - \sqrt{u}$ over the triangular region cut from the first quadrant of the uv -plane by the line $u + v = 1$
 36. **Curved region** $f(s, t) = e^s \ln t$ over the region in the first quadrant of the st -plane that lies above the curve $s = \ln t$ from $t = 1$ to $t = 2$

Each of Exercises 37–40 gives an integral over a region in a Cartesian coordinate plane. Sketch the region and evaluate the integral.

37. $\int_{-2}^0 \int_v^{-v} 2 dp dv$ (the pv -plane)
 38. $\int_0^1 \int_0^{\sqrt{1-s^2}} 8t dt ds$ (the st -plane)
 39. $\int_{-\pi/3}^{\pi/3} \int_0^{\sec t} 3 \cos t du dt$ (the tu -plane)
 40. $\int_0^{3/2} \int_1^{4-2u} \frac{4-2u}{v^2} dv du$ (the uv -plane)

Reversing the Order of Integration

In Exercises 41–54, sketch the region of integration, and write an equivalent double integral with the order of integration reversed.

41. $\int_0^1 \int_2^{4-2x} dy dx$ 42. $\int_0^2 \int_{y-2}^0 dx dy$
 43. $\int_0^1 \int_y^{\sqrt{y}} dx dy$ 44. $\int_0^1 \int_{1-x}^{1-x^2} dy dx$

45. $\int_0^1 \int_1^{e^x} dy dx$ 46. $\int_0^{\ln 2} \int_{e^y}^2 dx dy$
 47. $\int_0^{3/2} \int_0^{9-4x^2} 16x dy dx$ 48. $\int_0^2 \int_0^{4-y^2} y dx dy$
 49. $\int_0^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} 3y dx dy$ 50. $\int_0^2 \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} 6x dy dx$
 51. $\int_1^e \int_0^{\ln x} xy dy dx$ 52. $\int_0^{\pi/6} \int_{\sin x}^{1/2} xy^2 dy dx$
 53. $\int_0^3 \int_1^{e^y} (x + y) dx dy$ 54. $\int_0^{\sqrt{3}} \int_0^{\tan^{-1} y} \sqrt{xy} dx dy$

In Exercises 55–64, sketch the region of integration, reverse the order of integration, and evaluate the integral.

55. $\int_0^{\pi} \int_x^{\pi} \frac{\sin y}{y} dy dx$ 56. $\int_0^2 \int_x^2 2y^2 \sin xy dy dx$
 57. $\int_0^1 \int_y^1 x^2 e^{xy} dx dy$ 58. $\int_0^2 \int_0^{4-x^2} \frac{xe^{2y}}{4-y} dy dx$
 59. $\int_0^{2\sqrt{\ln 3}} \int_{y/2}^{\sqrt{\ln 3}} e^{x^2} dx dy$
 60. $\int_0^3 \int_{\sqrt{x/3}}^1 e^{y^3} dy dx$
 61. $\int_0^{1/16} \int_{y^{1/4}}^{1/2} \cos(16\pi x^5) dx dy$
 62. $\int_0^8 \int_{\sqrt[3]{x}}^2 \frac{dy dx}{y^4 + 1}$

63. **Square region** $\iint_R (y - 2x^2) dA$ where R is the region bounded by the square $|x| + |y| = 1$

64. **Triangular region** $\iint_R xy dA$ where R is the region bounded by the lines $y = x$, $y = 2x$, and $x + y = 2$

Volume Beneath a Surface $z = f(x, y)$

65. Find the volume of the region bounded above by the paraboloid $z = x^2 + y^2$ and below by the triangle enclosed by the lines $y = x$, $x = 0$, and $x + y = 2$ in the xy -plane.
 66. Find the volume of the solid that is bounded above by the cylinder $z = x^2$ and below by the region enclosed by the parabola $y = 2 - x^2$ and the line $y = x$ in the xy -plane.
 67. Find the volume of the solid whose base is the region in the xy -plane that is bounded by the parabola $y = 4 - x^2$ and the line $y = 3x$, while the top of the solid is bounded by the plane $z = x + 4$.
 68. Find the volume of the solid in the first octant bounded by the coordinate planes, the cylinder $x^2 + y^2 = 4$, and the plane $z + y = 3$.
 69. Find the volume of the solid in the first octant bounded by the coordinate planes, the plane $x = 3$, and the parabolic cylinder $z = 4 - y^2$.
 70. Find the volume of the solid cut from the first octant by the surface $z = 4 - x^2 - y$.
 71. Find the volume of the wedge cut from the first octant by the cylinder $z = 12 - 3y^2$ and the plane $x + y = 2$.
 72. Find the volume of the solid cut from the square column $|x| + |y| \leq 1$ by the planes $z = 0$ and $3x + z = 3$.

73. Find the volume of the solid that is bounded on the front and back by the planes $x = 2$ and $x = 1$, on the sides by the cylinders $y = \pm 1/x$, and above and below by the planes $z = x + 1$ and $z = 0$.
74. Find the volume of the solid bounded on the front and back by the planes $x = \pm \pi/3$, on the sides by the cylinders $y = \pm \sec x$, above by the cylinder $z = 1 + y^2$, and below by the xy -plane.

In Exercises 75 and 76, sketch the region of integration and the solid whose volume is given by the double integral.

$$75. \int_0^3 \int_0^{2-2x/3} \left(1 - \frac{1}{3}x - \frac{1}{2}y\right) dy dx$$

$$76. \int_0^4 \int_{-\sqrt{16-y^2}}^{\sqrt{16-y^2}} \sqrt{25 - x^2 - y^2} dx dy$$

Integrals over Unbounded Regions

Improper double integrals can often be computed similarly to improper integrals of one variable. The first iteration of the following improper integrals is conducted just as if they were proper integrals. One then evaluates an improper integral of a single variable by taking appropriate limits, as in Section 8.8. Evaluate the improper integrals in Exercises 77–80 as iterated integrals.

$$77. \int_1^{\infty} \int_{e^{-x}}^1 \frac{1}{x^3 y} dy dx \quad 78. \int_{-1}^1 \int_{-1/\sqrt{1-x^2}}^{1/\sqrt{1-x^2}} (2y + 1) dy dx$$

$$79. \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{1}{(x^2 + 1)(y^2 + 1)} dx dy$$

$$80. \int_0^{\infty} \int_0^{\infty} x e^{-(x+2y)} dx dy$$

Approximating Integrals with Finite Sums

In Exercises 81 and 82, approximate the double integral of $f(x, y)$ over the region R partitioned by the given vertical lines $x = a$ and horizontal lines $y = c$. In each subrectangle, use (x_k, y_k) as indicated for your approximation.

$$\iint_R f(x, y) dA \approx \sum_{k=1}^n f(x_k, y_k) \Delta A_k$$

81. $f(x, y) = x + y$ over the region R bounded above by the semicircle $y = \sqrt{1 - x^2}$ and below by the x -axis, using the partition $x = -1, -1/2, 0, 1/4, 1/2, 1$ and $y = 0, 1/2, 1$ with (x_k, y_k) the lower left corner in the k th subrectangle (provided the subrectangle lies within R)
82. $f(x, y) = x + 2y$ over the region R inside the circle $(x - 2)^2 + (y - 3)^2 = 1$ using the partition $x = 1, 3/2, 2, 5/2, 3$ and $y = 2, 5/2, 3, 7/2, 4$ with (x_k, y_k) the center (centroid) in the k th subrectangle (provided the subrectangle lies within R)

Theory and Examples

83. **Circular sector** Integrate $f(x, y) = \sqrt{4 - x^2}$ over the smaller sector cut from the disk $x^2 + y^2 \leq 4$ by the rays $\theta = \pi/6$ and $\theta = \pi/2$.
84. **Unbounded region** Integrate $f(x, y) = 1/[(x^2 - x)(y - 1)^{2/3}]$ over the infinite rectangle $2 \leq x < \infty, 0 \leq y \leq 2$.

85. **Noncircular cylinder** A solid right (noncircular) cylinder has its base R in the xy -plane and is bounded above by the paraboloid $z = x^2 + y^2$. The cylinder's volume is

$$V = \int_0^1 \int_0^y (x^2 + y^2) dx dy + \int_1^2 \int_0^{2-y} (x^2 + y^2) dx dy.$$

Sketch the base region R , and express the cylinder's volume as a single iterated integral with the order of integration reversed. Then evaluate the integral to find the volume.

86. **Converting to a double integral** Evaluate the integral

$$\int_0^2 (\arctan \pi x - \arctan x) dx.$$

(Hint: Write the integrand as an integral.)

87. **Maximizing a double integral** What region R in the xy -plane maximizes the value of

$$\iint_R (4 - x^2 - 2y^2) dA?$$

Give reasons for your answer.

88. **Minimizing a double integral** What region R in the xy -plane minimizes the value of

$$\iint_R (x^2 + y^2 - 9) dA?$$

Give reasons for your answer.

89. Is it possible to evaluate the integral of a continuous function $f(x, y)$ over a rectangular region in the xy -plane and get different answers depending on the order of integration? Give reasons for your answer.

90. How would you evaluate the double integral of a continuous function $f(x, y)$ over the region R in the xy -plane enclosed by the triangle with vertices $(0, 1)$, $(2, 0)$, and $(1, 2)$? Give reasons for your answer.

91. **Unbounded region** Prove that

$$\begin{aligned} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-x^2-y^2} dx dy &= \lim_{b \rightarrow \infty} \int_{-b}^b \int_{-b}^b e^{-x^2-y^2} dx dy \\ &= 4 \left(\int_0^{\infty} e^{-x^2} dx \right)^2. \end{aligned}$$

92. **Improper double integral** Evaluate the improper integral

$$\int_0^1 \int_0^3 \frac{x^2}{(y-1)^{2/3}} dy dx.$$

COMPUTER EXPLORATIONS

Use a CAS double-integral evaluator to estimate the values of the integrals in Exercises 93–96.

$$93. \int_1^3 \int_1^x \frac{1}{xy} dy dx \quad 94. \int_0^1 \int_0^1 e^{-(x^2+y^2)} dy dx$$

$$95. \int_0^1 \int_0^1 \arctan xy dy dx$$

$$96. \int_{-1}^1 \int_0^{\sqrt{1-x^2}} 3\sqrt{1-x^2-y^2} dy dx$$

Use a CAS double-integral evaluator to find the integrals in Exercises 97–102. Then reverse the order of integration and evaluate, again with a CAS.

$$97. \int_0^1 \int_{2y}^4 e^{x^2} dx dy$$

$$98. \int_0^3 \int_{x^2}^9 x \cos(y^2) dy dx$$

$$99. \int_0^2 \int_{y^3}^{4\sqrt{2}y} (x^2y - xy^2) dx dy$$

$$100. \int_0^2 \int_0^{4-y^2} e^{xy} dx dy$$

$$101. \int_1^2 \int_0^{x^2} \frac{1}{x+y} dy dx$$

$$102. \int_1^2 \int_{y^3}^8 \frac{1}{\sqrt{x^2 + y^2}} dx dy$$

14.3 Area by Double Integration

In this section we show how to use double integrals to calculate the areas of bounded regions in the plane, and to find the average value of a function of two variables.

Areas of Bounded Regions in the Plane

If we take $f(x, y) = 1$ in the definition of the double integral over a region R in the preceding section, the Riemann sums reduce to

$$S_n = \sum_{k=1}^n f(x_k, y_k) \Delta A_k = \sum_{k=1}^n \Delta A_k. \quad (1)$$

This is simply the sum of the areas of the small rectangles in the partition of R , and it approximates what we would like to call the area of R . As the norm of a partition of R approaches zero, the height and width of all rectangles in the partition approach zero, and the coverage of R becomes increasingly complete (Figure 14.8). We define the area of R to be the limit

$$\lim_{\|P\| \rightarrow 0} \sum_{k=1}^n \Delta A_k = \iint_R dA. \quad (2)$$

DEFINITION The **area** of a closed, bounded plane region R is

$$A = \iint_R dA.$$

As with the other definitions in this chapter, the definition here applies to a greater variety of regions than does the earlier single-variable definition of area, but it agrees with the earlier definition on regions to which they both apply. To evaluate the integral in the definition of area, we integrate the constant function $f(x, y) = 1$ over R .

EXAMPLE 1 Find the area of the region R bounded by $y = x$ and $y = x^2$ in the first quadrant.

Solution We sketch the region (Figure 14.19), noting where the two curves intersect at the origin and $(1, 1)$, and calculate the area as

$$A = \int_0^1 \int_{x^2}^x dy dx = \int_0^1 \left[y \right]_{y=x^2}^{y=x} dx = \int_0^1 (x - x^2) dx = \left[\frac{x^2}{2} - \frac{x^3}{3} \right]_0^1 = \frac{1}{6}.$$

Notice that the single-variable integral $\int_0^1 (x - x^2) dx$, obtained from evaluating the inside iterated integral, is the integral for the area between these two curves using the method of Section 5.6. ■

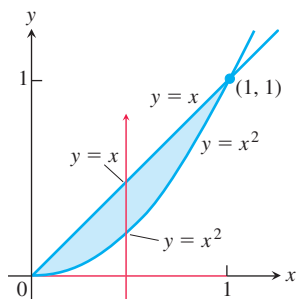

FIGURE 14.19 The region in Example 1.

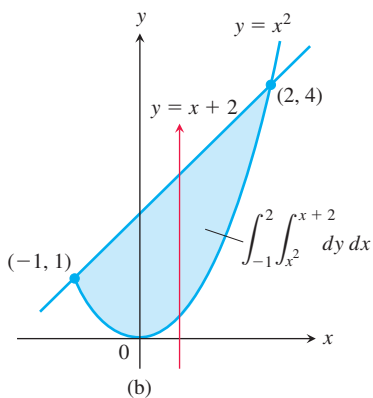

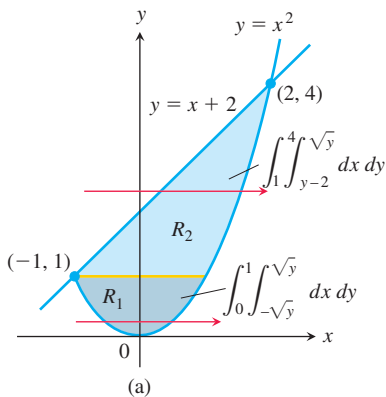

FIGURE 14.20 Calculating this area takes (a) two double integrals if the first integration is with respect to x , but (b) only one if the first integration is with respect to y (Example 2).

EXAMPLE 2 Find the area of the region R enclosed by the parabola $y = x^2$ and the line $y = x + 2$.

Solution If we divide R into the regions R_1 and R_2 shown in Figure 14.20a, we may calculate the area as

$$A = \iint_{R_1} dA + \iint_{R_2} dA = \int_0^1 \int_{-x^2}^0 dx dy + \int_1^4 \int_{y-2}^{\sqrt{y}} dx dy.$$

On the other hand, reversing the order of integration (Figure 14.20b) gives

$$A = \int_{-1}^2 \int_{x^2}^{x+2} dy dx.$$

This second result, which requires only one integral, is simpler to evaluate, giving

$$A = \int_{-1}^2 \left[y \right]_{y=x^2}^{y=x+2} dx = \int_{-1}^2 (x + 2 - x^2) dx = \left[\frac{x^2}{2} + 2x - \frac{x^3}{3} \right]_{-1}^2 = \frac{9}{2}. \quad \blacksquare$$

EXAMPLE 3 Find the area of the playing field described by R : $-2 \leq x \leq 2$, $-1 - \sqrt{4 - x^2} \leq y \leq 1 + \sqrt{4 - x^2}$, using

(a) Fubini's Theorem (b) simple geometry.

Solution The region R is shown in Figure 14.21a.

(a) From the symmetries observed in the figure, we see that the area of R is 4 times its area in the first quadrant. As shown in Figure 14.21b, a vertical line at x enters this part of the region at $y = 0$ and exits at $y = 1 + \sqrt{4 - x^2}$. Therefore, using Fubini's Theorem, we have

$$\begin{aligned} A &= \iint_R dA = 4 \int_0^2 \int_0^{1+\sqrt{4-x^2}} dy dx \\ &= 4 \int_0^2 (1 + \sqrt{4 - x^2}) dx \\ &= 4 \left[x + \frac{x}{2} \sqrt{4 - x^2} + \frac{4}{2} \sin^{-1} \frac{x}{2} \right]_0^2 \\ &= 4 \left(2 + 0 + 2 \cdot \frac{\pi}{2} - 0 \right) = 8 + 4\pi. \end{aligned}$$

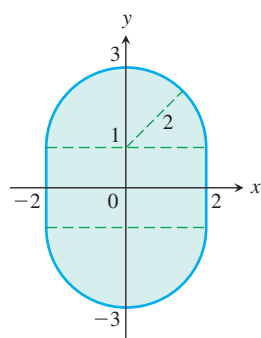

Integral Table Formula 45

(b) The region R consists of a rectangle mounted on two sides by half disks of radius 2. The area can be computed by summing the area of the 4×2 rectangle and the area of a circle of radius 2, so

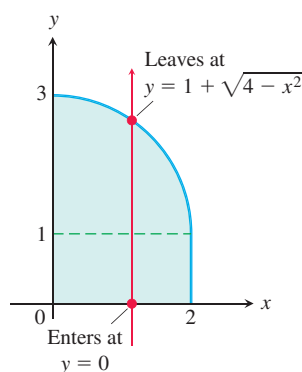

$$A = 8 + \pi 2^2 = 8 + 4\pi. \quad \blacksquare$$

Average Value

The average value of an integrable function of one variable on a closed interval is the integral of the function over the interval divided by the length of the interval. For an integrable function of two variables defined on a bounded region in the plane, the average value is the integral over the region divided by the area of the region. This can be visualized by thinking of the region as being the base of a tank with vertical walls around the boundary of the region, and imagining that the tank is filled with water that is sloshing around. The value

(a)

(b)

FIGURE 14.21 (a) The playing field described by the region R in Example 3. (b) First quadrant of the playing field.

$f(x, y)$ is then the height of the water that is directly above the point (x, y) . The average height of the water in the tank can be found by letting the water settle down to a constant height. This height is equal to the volume of water in the tank divided by the area of R . We therefore define the average value of an integrable function f over a region R as follows:

$$\text{Average value of } f \text{ over } R = \frac{1}{\text{area of } R} \iint_R f \, dA. \quad (3)$$

If f is the temperature of a thin plate covering R , then the double integral of f over R divided by the area of R is the plate's average temperature. If $f(x, y)$ is the distance from the point (x, y) to a fixed point P , then the average value of f over R is the average distance of points in R from P .

EXAMPLE 4 Find the average value of $f(x, y) = x \cos xy$ over the rectangle $R: 0 \leq x \leq \pi, 0 \leq y \leq 1$.

Solution The value of the integral of f over R is

$$\begin{aligned} \int_0^\pi \int_0^1 x \cos xy \, dy \, dx &= \int_0^\pi \left[\sin xy \right]_{y=0}^{y=1} dx && \int x \cos xy \, dy = \sin xy + C \\ &= \int_0^\pi (\sin x - 0) \, dx = -\cos x \Big|_0^\pi = 1 + 1 = 2. \end{aligned}$$

The area of R is π . The average value of f over R is $2/\pi$. ■

EXERCISES 14.3

Area by Double Integrals

In Exercises 1–12, sketch the region bounded by the given lines and curves. Then express the region's area as an iterated double integral and evaluate the integral.

- The coordinate axes and the line $x + y = 2$
- The lines $x = 0$, $y = 2x$, and $y = 4$
- The parabola $x = -y^2$ and the line $y = x + 2$
- The parabola $x = y - y^2$ and the line $y = -x$
- The curve $y = e^x$ and the lines $y = 0$, $x = 0$, and $x = \ln 2$
- The curves $y = \ln x$ and $y = 2 \ln x$ and the line $x = e$, in the first quadrant
- The parabolas $x = y^2$ and $x = 2y - y^2$
- The parabolas $x = y^2 - 1$ and $x = 2y^2 - 2$
- The lines $y = x$, $y = x/3$, and $y = 2$
- The lines $y = 1 - x$ and $y = 2$ and the curve $y = e^x$
- The lines $y = 2x$, $y = x/2$, and $y = 3 - x$
- The lines $y = x - 2$ and $y = -x$ and the curve $y = \sqrt{x}$

Identifying the Region of Integration

The integrals and sums of integrals in Exercises 13–18 give the areas of regions in the xy -plane. Sketch each region, label each bounding

curve with its equation, and give the coordinates of the points where the curves intersect. Then find the area of the region.

- $\int_0^6 \int_{y^2/3}^{2y} dx \, dy$
- $\int_0^3 \int_{-x}^{x(2-x)} dy \, dx$
- $\int_0^{\pi/4} \int_{\sin x}^{\cos x} dy \, dx$
- $\int_{-1}^2 \int_{y^2}^{y+2} dx \, dy$
- $\int_{-1}^0 \int_{-2x}^{1-x} dy \, dx + \int_0^2 \int_{-x/2}^{1-x} dy \, dx$
- $\int_0^2 \int_{x^2-4}^0 dy \, dx + \int_0^4 \int_0^{\sqrt{x}} dy \, dx$

Finding Average Values

- Find the average value of $f(x, y) = \sin(x + y)$ over
 - the rectangle $0 \leq x \leq \pi, 0 \leq y \leq \pi$.
 - the rectangle $0 \leq x \leq \pi, 0 \leq y \leq \pi/2$.
- Which do you think will be larger, the average value of $f(x, y) = xy$ over the square $0 \leq x \leq 1, 0 \leq y \leq 1$, or the average value of f over the quarter circle $x^2 + y^2 \leq 1$ in the first quadrant? Calculate them to find out.
- Find the average height of the paraboloid $z = x^2 + y^2$ over the square $0 \leq x \leq 2, 0 \leq y \leq 2$.

22. Find the average value of $f(x, y) = 1/(xy)$ over the square $\ln 2 \leq x \leq 2 \ln 2$, $\ln 2 \leq y \leq 2 \ln 2$.

Theory and Examples

23. **Geometric area** Find the area of the region

$$R: 0 \leq x \leq 2, 2 - x \leq y \leq \sqrt{4 - x^2},$$

using (a) Fubini's Theorem, (b) simple geometry.

24. **Geometric area** Find the area of the circular washer with outer radius 2 and inner radius 1, using (a) Fubini's Theorem, (b) simple geometry.
25. **Bacterium population** If $f(x, y) = (10,000e^y)/(1 + |x|/2)$ represents the "population density" of a certain bacterium on the xy -plane, where x and y are measured in centimeters, find the total population of bacteria within the rectangle $-5 \leq x \leq 5$ and $-2 \leq y \leq 0$.
26. **Regional population** If $f(x, y) = 100(y + 1)$ represents the population density of a planar region on Earth, where x and y are measured in kilometers, find the number of people in the region bounded by the curves $x = y^2$ and $x = 2y - y^2$.
27. **Average temperature in Texas** According to the *Texas Almanac*, Texas has 254 counties and a National Weather Service

station in each county. Assume that at time t_0 , each of the 254 weather stations recorded the local temperature. Find a formula that would give a reasonable approximation of the average temperature in Texas at time t_0 . Your answer should involve information that you would expect to be readily available in the *Texas Almanac*.

28. If $y = f(x)$ is a nonnegative continuous function over the closed interval $a \leq x \leq b$, show that the double integral definition of area for the closed plane region bounded by the graph of f , the vertical lines $x = a$ and $x = b$, and the x -axis agrees with the definition for area beneath the curve in Section 5.3.
29. Suppose $f(x, y)$ is continuous over a region R in the plane and that the area $A(R)$ of the region is defined. If there are constants m and M such that $m \leq f(x, y) \leq M$ for all $(x, y) \in R$, prove that

$$mA(R) \leq \iint_R f(x, y) dA \leq MA(R).$$

30. Suppose $f(x, y)$ is continuous and nonnegative over a region R in the plane with a defined area $A(R)$. If $\iint_R f(x, y) dA = 0$, prove that $f(x, y) = 0$ at every point $(x, y) \in R$.

14.4 Double Integrals in Polar Form

Double integrals are sometimes easier to evaluate if we change to polar coordinates. This section shows how to accomplish the change and how to evaluate double integrals over regions whose boundaries are given by polar equations.

Integrals in Polar Coordinates

When we defined the double integral of a function over a region R in the xy -plane, we began by cutting R into rectangles whose sides were parallel to the coordinate axes. These were the natural shapes to use because their sides have either constant x -values or constant y -values. In polar coordinates, the natural shape is a "polar rectangle" whose sides have constant r - and θ -values. To avoid ambiguities when describing the region of integration with polar coordinates, we use polar coordinate points (r, θ) where $r \geq 0$.

Suppose that a function $f(r, \theta)$ is defined over a region R that is bounded by the rays $\theta = \alpha$ and $\theta = \beta$ and by the continuous curves $r = g_1(\theta)$ and $r = g_2(\theta)$. Suppose also that $0 \leq g_1(\theta) \leq g_2(\theta) \leq a$ for every value of θ between α and β . Then R lies in a fan-shaped region Q defined by the inequalities $0 \leq r \leq a$ and $\alpha \leq \theta \leq \beta$, where $0 \leq \beta - \alpha \leq 2\pi$. See Figure 14.22.

We cover Q by a grid of circular arcs and rays. The arcs are cut from circles centered at the origin, with radii Δr , $2\Delta r$, ..., $m\Delta r$, where $\Delta r = a/m$. The rays are given by

$$\theta = \alpha, \quad \theta = \alpha + \Delta\theta, \quad \theta = \alpha + 2\Delta\theta, \quad \dots, \quad \theta = \alpha + m'\Delta\theta = \beta,$$

where $\Delta\theta = (\beta - \alpha)/m'$. The arcs and rays partition Q into small patches called "polar rectangles."

We number the polar rectangles that lie inside R (the order does not matter), calling their areas $\Delta A_1, \Delta A_2, \dots, \Delta A_n$. We let (r_k, θ_k) be any point in the polar rectangle whose area is ΔA_k . We then form the sum

$$S_n = \sum_{k=1}^n f(r_k, \theta_k) \Delta A_k.$$

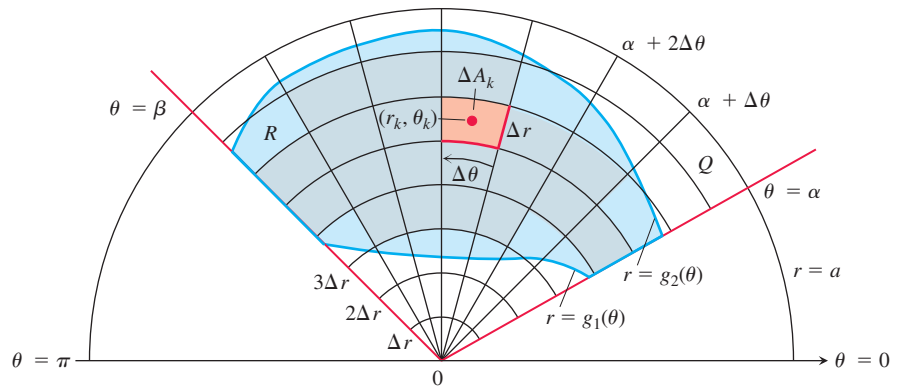

FIGURE 14.22 The region $R: g_1(\theta) \leq r \leq g_2(\theta)$, $\alpha \leq \theta \leq \beta$, is contained in the fan-shaped region $Q: 0 \leq r \leq a$, $\alpha \leq \theta \leq \beta$, where $0 \leq \beta - \alpha \leq 2\pi$. The partition of Q by circular arcs and rays induces a partition of R .

If f is continuous throughout R , this sum will approach a limit as we refine the grid to make Δr and $\Delta\theta$ go to zero. The limit is the double integral of f over R . In symbols,

$$\lim_{n \rightarrow \infty} S_n = \iint_R f(r, \theta) dA.$$

To evaluate this limit, we first have to write the sum S_n in a way that expresses ΔA_k in terms of Δr and $\Delta\theta$. For convenience we choose r_k to be the average of the radii of the inner and outer arcs bounding the k th polar rectangle ΔA_k . The radius of the inner arc bounding ΔA_k is then $r_k - (\Delta r/2)$ (Figure 14.23). The radius of the outer arc is $r_k + (\Delta r/2)$.

The area of a wedge-shaped sector of a circle having radius r and central angle $\Delta\theta$ is

$$A = \frac{1}{2} \Delta\theta \cdot r^2,$$

as can be seen by multiplying πr^2 , the area of the circle, by $\Delta\theta/2\pi$, the fraction of the circle's area contained in the wedge. So the areas of the circular sectors subtended by these arcs at the origin are

$$\text{Area of small sector: } \frac{1}{2} \left(r_k - \frac{\Delta r}{2} \right)^2 \Delta\theta$$

$$\text{Area of large sector: } \frac{1}{2} \left(r_k + \frac{\Delta r}{2} \right)^2 \Delta\theta.$$

Therefore,

$$\begin{aligned} \Delta A_k &= \text{area of large sector} - \text{area of small sector} \\ &= \frac{\Delta\theta}{2} \left[\left(r_k + \frac{\Delta r}{2} \right)^2 - \left(r_k - \frac{\Delta r}{2} \right)^2 \right] = \frac{\Delta\theta}{2} (2r_k \Delta r) = r_k \Delta r \Delta\theta. \end{aligned}$$

Combining this result with the sum defining S_n gives

$$S_n = \sum_{k=1}^n f(r_k, \theta_k) r_k \Delta r \Delta\theta.$$

As $n \rightarrow \infty$ and the values of Δr and $\Delta\theta$ approach zero, these sums converge to the double integral

$$\lim_{n \rightarrow \infty} S_n = \iint_R f(r, \theta) r dr d\theta.$$

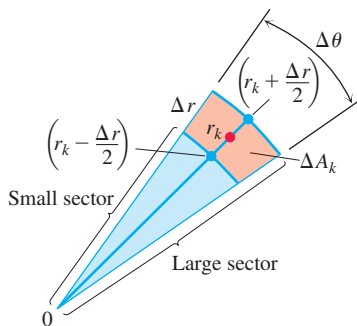

FIGURE 14.23 The observation that

$$\Delta A_k = \left(\text{area of large sector} \right) - \left(\text{area of small sector} \right)$$

leads to the formula $\Delta A_k = r_k \Delta r \Delta\theta$.

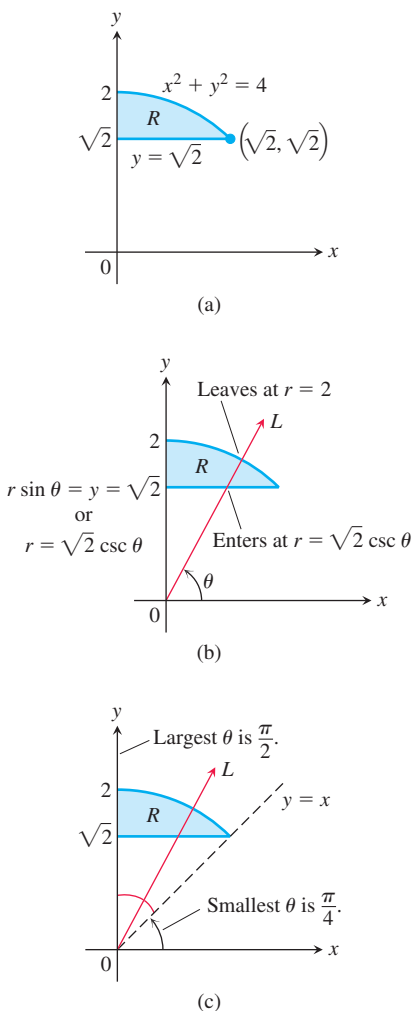

FIGURE 14.24 Finding the limits of integration in polar coordinates.

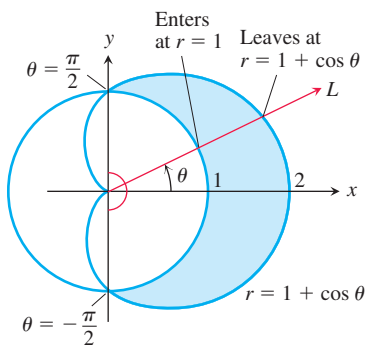

FIGURE 14.25 Finding the limits of integration in polar coordinates for the region in Example 1.

A version of Fubini's Theorem says that the limit approached by these sums can be evaluated by repeated single integrations with respect to r and θ as

$$\iint_R f(r, \theta) dA = \int_{\theta=\alpha}^{\theta=\beta} \int_{r=g_1(\theta)}^{r=g_2(\theta)} f(r, \theta) r dr d\theta.$$

Finding Limits of Integration

The procedure for finding limits of integration in rectangular coordinates also works for polar coordinates. We illustrate this using the region R shown in Figure 14.24. To evaluate $\iint_R f(r, \theta) dA$ in polar coordinates, integrating first with respect to r and then with respect to θ , take the following steps.

1. *Sketch.* Sketch the region and label the bounding curves (Figure 14.24a).
2. *Find the r -limits of integration.* Imagine a ray L from the origin cutting through R in the direction of increasing r . Mark the r -values where L enters and leaves R . These are the r -limits of integration. They usually depend on the angle θ that L makes with the positive x -axis (Figure 14.24b).
3. *Find the θ -limits of integration.* Find the smallest and largest θ -values that bound R . These are the θ -limits of integration (Figure 14.24c). The polar iterated integral is

$$\iint_R f(r, \theta) dA = \int_{\theta=\pi/4}^{\theta=\pi/2} \int_{r=\sqrt{2}\cos\theta}^{r=2} f(r, \theta) r dr d\theta.$$

EXAMPLE 1 Find the limits of integration for integrating $f(r, \theta)$ over the region R that lies inside the cardioid $r = 1 + \cos \theta$ and outside the circle $r = 1$.

Solution

1. We first sketch the region and label the bounding curves (Figure 14.25).
2. Next we find the r -limits of integration. A typical ray from the origin enters R where $r = 1$ and leaves where $r = 1 + \cos \theta$.
3. Finally, we find the θ -limits of integration. The rays from the origin that intersect R run from $\theta = -\pi/2$ to $\theta = \pi/2$. The integral is

$$\int_{-\pi/2}^{\pi/2} \int_1^{1+\cos\theta} f(r, \theta) r dr d\theta. \quad \blacksquare$$

If $f(r, \theta)$ is the constant function whose value is 1, then the integral of f over R is the area of R .

Area in Polar Coordinates

The area of a closed and bounded region R in the polar coordinate plane is

$$A = \iint_R r dr d\theta.$$

Area Differential in Polar Coordinates

$$dA = r dr d\theta$$

This formula for area is consistent with all earlier formulas.

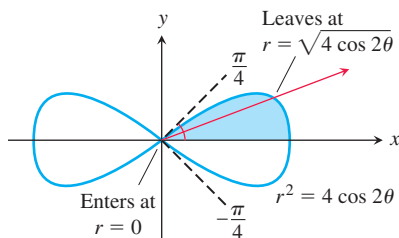

FIGURE 14.26 To integrate over the shaded region, we run r from 0 to $\sqrt{4 \cos 2\theta}$ and θ from 0 to $\pi/4$ (Example 2).

EXAMPLE 2 Find the area enclosed by the lemniscate $r^2 = 4 \cos 2\theta$.

Solution We graph the lemniscate to determine the limits of integration (Figure 14.26) and see from the symmetry of the region that the total area is 4 times the first-quadrant portion.

$$\begin{aligned} A &= 4 \int_0^{\pi/4} \int_0^{\sqrt{4 \cos 2\theta}} r \, dr \, d\theta = 4 \int_0^{\pi/4} \left[\frac{r^2}{2} \right]_{r=0}^{r=\sqrt{4 \cos 2\theta}} d\theta \\ &= 4 \int_0^{\pi/4} 2 \cos 2\theta \, d\theta = 4 \sin 2\theta \Big|_0^{\pi/4} = 4. \end{aligned}$$

Changing Cartesian Integrals into Polar Integrals

The procedure for changing a Cartesian integral $\iint_R f(x, y) \, dx \, dy$ into a polar integral has two steps. First substitute $x = r \cos \theta$ and $y = r \sin \theta$, and replace $dx \, dy$ by $r \, dr \, d\theta$ in the Cartesian integral. Then supply polar limits of integration for the boundary of R . The Cartesian integral then becomes

$$\iint_R f(x, y) \, dx \, dy = \iint_G f(r \cos \theta, r \sin \theta) r \, dr \, d\theta,$$

where G denotes the same region of integration, but now described in polar coordinates. This is like the substitution method in Chapter 5 except that there are now two variables to substitute for instead of one. Notice that the area differential $dx \, dy$ is replaced not by $dr \, d\theta$ but by $r \, dr \, d\theta$. A more general discussion of changes of variables (substitutions) in multiple integrals is given in Section 14.8.

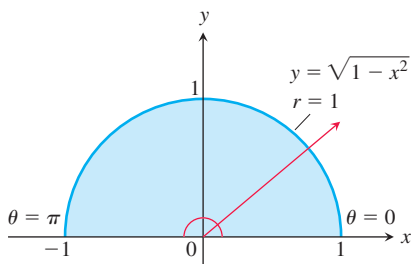

FIGURE 14.27 The semicircular region in Example 3 is the region

$$0 \leq r \leq 1, \quad 0 \leq \theta \leq \pi.$$

EXAMPLE 3 Evaluate

$$\iint_R e^{x^2+y^2} \, dy \, dx,$$

where R is the semicircular region bounded by the x -axis and the curve $y = \sqrt{1 - x^2}$ (Figure 14.27).

Solution In Cartesian coordinates, the integral in question is a nonelementary integral and there is no direct way to integrate $e^{x^2+y^2}$ with respect to either x or y . Yet this integral and others like it are important in mathematics—in statistics, for example—and we need to evaluate it. Polar coordinates make this possible. Substituting $x = r \cos \theta$ and $y = r \sin \theta$ and replacing $dy \, dx$ by $r \, dr \, d\theta$ give

$$\begin{aligned} \iint_R e^{x^2+y^2} \, dy \, dx &= \int_0^\pi \int_0^1 e^{r^2} r \, dr \, d\theta = \int_0^\pi \left[\frac{1}{2} e^{r^2} \right]_{r=0}^{r=1} d\theta \\ &= \int_0^\pi \frac{1}{2} (e - 1) \, d\theta = \frac{\pi}{2} (e - 1). \end{aligned}$$

The r in the $r \, dr \, d\theta$ is what allowed us to integrate e^{r^2} . Without it, we would have been unable to find an antiderivative for the first (innermost) iterated integral.

EXAMPLE 4 Evaluate the integral

$$\int_0^1 \int_0^{\sqrt{1-x^2}} (x^2 + y^2) \, dy \, dx.$$

Solution Integration with respect to y gives

$$\int_0^1 \left(x^2 \sqrt{1-x^2} + \frac{(1-x^2)^{3/2}}{3} \right) dx,$$

which is difficult to evaluate without tables. Things go better if we change the original integral to polar coordinates. The region of integration in Cartesian coordinates is given by the inequalities $0 \leq y \leq \sqrt{1-x^2}$ and $0 \leq x \leq 1$, which correspond to the interior of the unit quarter circle $x^2 + y^2 = 1$ in the first quadrant. (See Figure 14.27, first quadrant.) Substituting the polar coordinates $x = r \cos \theta$, $y = r \sin \theta$, $0 \leq \theta \leq \pi/2$, and $0 \leq r \leq 1$, and replacing $dy dx$ by $r dr d\theta$ in the double integral, we get

$$\begin{aligned} \int_0^1 \int_0^{\sqrt{1-x^2}} (x^2 + y^2) dy dx &= \int_0^{\pi/2} \int_0^1 (r^2) r dr d\theta \\ &= \int_0^{\pi/2} \left[\frac{r^4}{4} \right]_{r=0}^{r=1} d\theta = \int_0^{\pi/2} \frac{1}{4} d\theta = \frac{\pi}{8}. \end{aligned}$$

The polar coordinate transformation is effective here because $x^2 + y^2$ simplifies to r^2 and the limits of integration become constants. ■

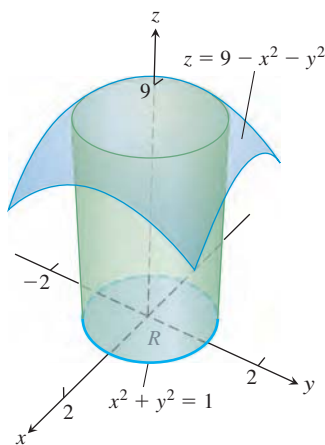

FIGURE 14.28 The solid region in Example 5.

EXAMPLE 5 Find the volume of the solid region bounded above by the paraboloid $z = 9 - x^2 - y^2$ and below by the unit circle in the xy -plane.

Solution The region of integration R is bounded by the unit circle $x^2 + y^2 = 1$, which is described in polar coordinates by $r = 1$, $0 \leq \theta \leq 2\pi$. The solid region is shown in Figure 14.28. The volume is given by the double integral

$$\begin{aligned} \iint_R (9 - x^2 - y^2) dA &= \int_0^{2\pi} \int_0^1 (9 - r^2) r dr d\theta \quad r^2 = x^2 + y^2, \quad dA = r dr d\theta. \\ &= \int_0^{2\pi} \int_0^1 (9r - r^3) dr d\theta \\ &= \int_0^{2\pi} \left[\frac{9}{2}r^2 - \frac{1}{4}r^4 \right]_{r=0}^{r=1} d\theta \\ &= \frac{17}{4} \int_0^{2\pi} d\theta = \frac{17\pi}{2}. \end{aligned}$$

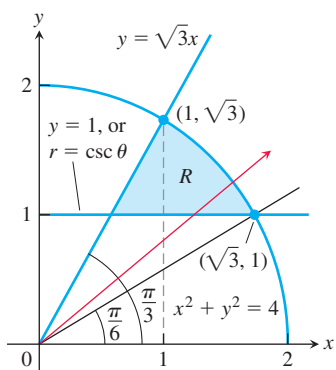

FIGURE 14.29 The region R in Example 6.

EXAMPLE 6 Using polar integration, find the area of the region R enclosed by the circle $x^2 + y^2 = 4$, above the line $y = 1$, and below the line $y = \sqrt{3}x$.

Solution A sketch of the region R is shown in Figure 14.29. First we note that the line $y = \sqrt{3}x$ has slope $\sqrt{3} = \tan \theta$, so $\theta = \pi/3$. Next we observe that the line $y = 1$ intersects the circle $x^2 + y^2 = 4$ when $x^2 + 1 = 4$, or $x = \sqrt{3}$. Moreover, the radial line from the origin through the point $(\sqrt{3}, 1)$ has slope $1/\sqrt{3} = \tan \theta$, giving its angle of inclination as $\theta = \pi/6$. This information is shown in Figure 14.29.

Now, for the region R , as θ varies from $\pi/6$ to $\pi/3$, the polar coordinate r varies from the horizontal line $y = 1$ to the circle $x^2 + y^2 = 4$. Substituting $r \sin \theta$ for y in the equation for the horizontal line, we have $r \sin \theta = 1$, or $r = \csc \theta$, which is the polar equation of the line. The polar equation for the circle is $r = 2$. So in polar coordinates, for $\pi/6 \leq \theta \leq \pi/3$, r varies from $r = \csc \theta$ to $r = 2$. It follows that the iterated integral for the area is

$$\begin{aligned}
 \iint_R dA &= \int_{\pi/6}^{\pi/3} \int_{\csc \theta}^2 r \, dr \, d\theta \\
 &= \int_{\pi/6}^{\pi/3} \left[\frac{1}{2} r^2 \right]_{r=\csc \theta}^{r=2} d\theta \\
 &= \int_{\pi/6}^{\pi/3} \frac{1}{2} [4 - \csc^2 \theta] d\theta \\
 &= \frac{1}{2} \left[4\theta + \cot \theta \right]_{\pi/6}^{\pi/3} \\
 &= \frac{1}{2} \left(\frac{4\pi}{3} + \frac{1}{\sqrt{3}} \right) - \frac{1}{2} \left(\frac{4\pi}{6} + \sqrt{3} \right) = \frac{\pi - \sqrt{3}}{3}.
 \end{aligned}$$

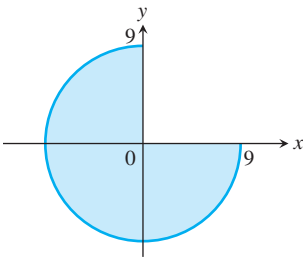

■

EXERCISES 14.4

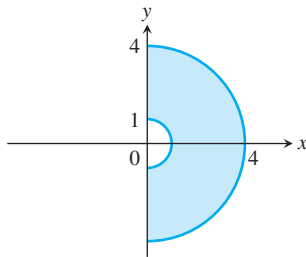

Regions in Polar Coordinates

In Exercises 1–8, describe the given region in polar coordinates.

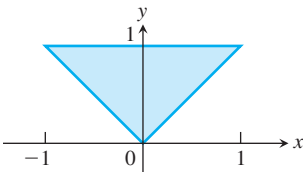

1.

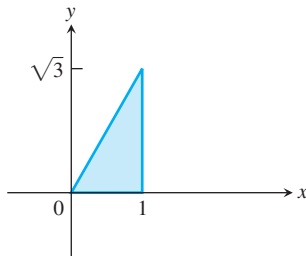

2.

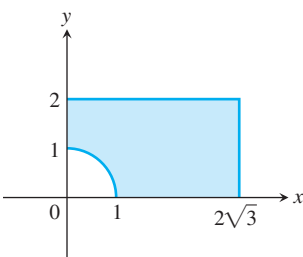

3.

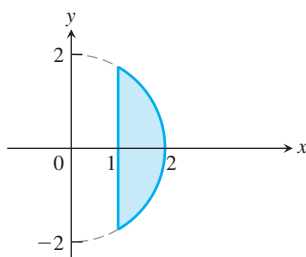

4.

5.

6.

7. The region enclosed by the circle $x^2 + y^2 = 2x$ 8. The region enclosed by the semicircle $x^2 + y^2 = 2y$, $y \geq 1$

Evaluating Polar Integrals

In Exercises 9–22, change the Cartesian integral into an equivalent polar integral. Then evaluate the polar integral.

9. $\int_{-1}^1 \int_0^{\sqrt{1-x^2}} dy \, dx$

10. $\int_0^1 \int_0^{\sqrt{1-y^2}} (x^2 + y^2) \, dx \, dy$

11. $\int_0^2 \int_0^{\sqrt{4-y^2}} (x^2 + y^2) \, dx \, dy$

12. $\int_{-a}^a \int_{-\sqrt{a^2-x^2}}^{\sqrt{a^2-x^2}} dy \, dx$

13. $\int_0^6 \int_0^y x \, dx \, dy$

14. $\int_0^2 \int_0^x y \, dy \, dx$

15. $\int_1^{\sqrt{3}} \int_1^x dy \, dx$

16. $\int_{\sqrt{2}}^2 \int_{\sqrt{4-y^2}}^y dx \, dy$

17. $\int_{-1}^0 \int_{-\sqrt{1-x^2}}^0 \frac{2}{1 + \sqrt{x^2 + y^2}} dy \, dx$

18. $\int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{2}{(1 + x^2 + y^2)^2} dy \, dx$

19. $\int_0^{\ln 2} \int_0^{\sqrt{(\ln 2)^2 - y^2}} e^{\sqrt{x^2 + y^2}} dx \, dy$

20. $\int_{-1}^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} \ln(x^2 + y^2 + 1) dx \, dy$

21. $\int_0^1 \int_x^{\sqrt{2-x^2}} (x + 2y) dy \, dx$

$$22. \int_1^2 \int_0^{\sqrt{2x-x^2}} \frac{1}{(x^2 + y^2)^2} dy dx$$

In Exercises 23–26, sketch the region of integration, and convert each polar integral or sum of integrals into a Cartesian integral or sum of integrals. Do not evaluate the integrals.

$$23. \int_0^{\pi/2} \int_0^1 r^3 \sin \theta \cos \theta dr d\theta$$

$$24. \int_{\pi/6}^{\pi/2} \int_1^{\csc \theta} r^2 \cos \theta dr d\theta$$

$$25. \int_0^{\pi/4} \int_0^{2 \sec \theta} r^5 \sin^2 \theta dr d\theta$$

$$26. \int_0^{\arctan \frac{4}{3}} \int_0^{3 \sec \theta} r^7 dr d\theta + \int_{\arctan \frac{4}{3}}^{\pi/2} \int_0^{4 \csc \theta} r^7 dr d\theta$$

Area in Polar Coordinates

27. Find the area of the region cut from the first quadrant by the curve $r = 2(2 - \sin 2\theta)^{1/2}$.

28. **Cardioid overlapping a circle** Find the area of the region that lies inside the cardioid $r = 1 + \cos \theta$ and outside the circle $r = 1$.

29. **One leaf of a rose** Find the area enclosed by one leaf of the rose $r = 12 \cos 3\theta$.

30. **Snail shell** Find the area of the region enclosed by the positive x -axis and spiral $r = 4\theta/3$, $0 \leq \theta \leq 2\pi$. The region looks like a snail shell.

31. **Cardioid in the first quadrant** Find the area of the region cut from the first quadrant by the cardioid $r = 1 + \sin \theta$.

32. **Overlapping cardioids** Find the area of the region common to the interiors of the cardioids $r = 1 + \cos \theta$ and $r = 1 - \cos \theta$.

Average Values

In polar coordinates, the **average value** of a function over a region R (Section 14.3) is given by

$$\frac{1}{\text{Area}(R)} \iint_R f(r, \theta) r dr d\theta.$$

33. **Average height of a hemisphere** Find the average height of the hemispherical surface $z = \sqrt{a^2 - x^2 - y^2}$ above the disk $x^2 + y^2 \leq a^2$ in the xy -plane.

34. **Average height of a cone** Find the average height of the (single) cone $z = \sqrt{x^2 + y^2}$ above the disk $x^2 + y^2 \leq a^2$ in the xy -plane.

35. **Average distance from interior of disk to center** Find the average distance from a point $P(x, y)$ in the disk $x^2 + y^2 \leq a^2$ to the origin.

36. **Average distance squared from a point in a disk to a point in its boundary** Find the average value of the *square* of the distance from the point $P(x, y)$ in the disk $x^2 + y^2 \leq 1$ to the boundary point $A(1, 0)$.

Theory and Examples

37. **Converting to a polar integral** Integrate $f(x, y) = [\ln(x^2 + y^2)]/\sqrt{x^2 + y^2}$ over the region $1 \leq x^2 + y^2 \leq e$.

38. **Converting to a polar integral** Integrate $f(x, y) = [\ln(x^2 + y^2)]/(x^2 + y^2)$ over the region $1 \leq x^2 + y^2 \leq e^2$.

39. **Volume of noncircular right cylinder** The region that lies inside the cardioid $r = 1 + \cos \theta$ and outside the circle $r = 1$ is the base of a solid right cylinder. The top of the cylinder lies in the plane $z = x$. Find the cylinder's volume.

40. **Volume of noncircular right cylinder** The region enclosed by the lemniscate $r^2 = 2 \cos 2\theta$ is the base of a solid right cylinder whose top is bounded by the sphere $z = \sqrt{2 - r^2}$. Find the cylinder's volume.

41. Converting to polar integrals

a. The usual way to evaluate the improper integral $I = \int_0^\infty e^{-x^2} dx$ is first to calculate its square:

$$I^2 = \left(\int_0^\infty e^{-x^2} dx \right) \left(\int_0^\infty e^{-y^2} dy \right) = \int_0^\infty \int_0^\infty e^{-(x^2+y^2)} dx dy.$$

Evaluate the last integral using polar coordinates and solve the resulting equation for I .

b. Evaluate

$$\lim_{x \rightarrow \infty} \text{erf}(x) = \lim_{x \rightarrow \infty} \int_0^x \frac{2e^{-t^2}}{\sqrt{\pi}} dt.$$

42. **Converting to a polar integral** Evaluate the integral

$$\int_0^\infty \int_0^\infty \frac{1}{(1 + x^2 + y^2)^2} dx dy.$$

43. **Existence** Integrate the function $f(x, y) = 1/(1 - x^2 - y^2)$ over the disk $x^2 + y^2 \leq 3/4$. Does the integral of $f(x, y)$ over the disk $x^2 + y^2 \leq 1$ exist? Give reasons for your answer.

44. **Area formula in polar coordinates** Use the double integral in polar coordinates to derive the formula

$$A = \int_\alpha^\beta \frac{1}{2} r^2 d\theta$$

for the area of the fan-shaped region between the origin and the polar curve $r = f(\theta)$, $\alpha \leq \theta \leq \beta$.

45. **Average distance to a given point inside a disk** Let P_0 be a point inside a circle of radius a and let h denote the distance from P_0 to the center of the circle. Let d denote the distance from an arbitrary point P to P_0 . Find the average value of d^2 over the region enclosed by the circle. (*Hint*: Simplify your work by placing the center of the circle at the origin and P_0 on the x -axis.)

46. **Area** Suppose that the area of a region in the polar coordinate plane is

$$A = \int_{\pi/4}^{3\pi/4} \int_{\csc \theta}^{2 \sin \theta} r dr d\theta.$$

Sketch the region and find its area.

47. Evaluate the integral $\iint_R \sqrt{x^2 + y^2} dA$, where R is the region inside the upper semicircle of radius 2 centered at the origin, but outside the circle $x^2 + (y - 1)^2 = 1$.

48. Evaluate the integral $\iint_R (x^2 + y^2)^{-2} dA$, where R is the region inside the circle $x^2 + y^2 = 2$ for $x \leq -1$.

COMPUTER EXPLORATIONS

In Exercises 49–52, use a CAS to change the Cartesian integrals into an equivalent polar integral and evaluate the polar integral. Perform the following steps in each exercise.

- Plot the Cartesian region of integration in the xy -plane.
- Change each boundary curve of the Cartesian region in part (a) to its polar representation by solving its Cartesian equation for r and θ .
- Using the results in part (b), plot the polar region of integration in the $r\theta$ -plane.

- Change the integrand from Cartesian to polar coordinates. Determine the limits of integration from your plot in part (c) and evaluate the polar integral using the CAS integration utility.

$$49. \int_0^1 \int_x^1 \frac{y}{x^2 + y^2} dy dx \qquad 50. \int_0^1 \int_0^{x/2} \frac{x}{x^2 + y^2} dy dx$$

$$51. \int_0^1 \int_{-y/3}^{y/3} \frac{y}{\sqrt{x^2 + y^2}} dx dy \qquad 52. \int_0^1 \int_y^{2-y} \sqrt{x + y} dx dy$$

14.5 Triple Integrals in Rectangular Coordinates

Just as double integrals allow us to deal with more general situations than could be handled by single integrals, triple integrals enable us to solve still more general problems. We use triple integrals to calculate the volumes of three-dimensional shapes and the average value of a function over a three-dimensional region. Triple integrals also arise in the study of vector fields and fluid flow in three dimensions, as we will see in Chapter 15.

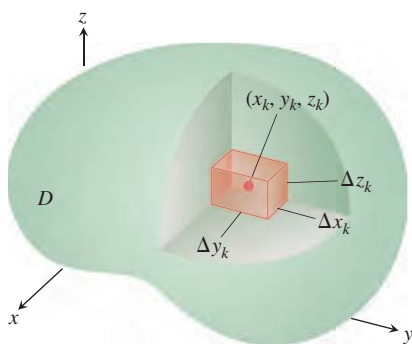

FIGURE 14.30 Partitioning a solid with rectangular cells of volume ΔV_k .

Triple Integrals

If $F(x, y, z)$ is a function defined on a closed bounded solid region D in space, such as the region occupied by a solid ball or a lump of clay, then the integral of F over D may be defined in the following way. We partition a rectangular boxlike region containing D into rectangular cells by planes parallel to the coordinate axes (Figure 14.30). We number the cells that lie completely inside D from 1 to n in some order, the k th cell having dimensions Δx_k by Δy_k by Δz_k and volume $\Delta V_k = \Delta x_k \Delta y_k \Delta z_k$. We choose a point (x_k, y_k, z_k) in each cell and form the sum

$$S_n = \sum_{k=1}^n F(x_k, y_k, z_k) \Delta V_k. \quad (1)$$

We are interested in what happens as D is partitioned by smaller and smaller cells, so that Δx_k , Δy_k , Δz_k , and the norm of the partition $\|P\|$, the largest value among Δx_k , Δy_k , Δz_k , all approach zero. When a single limiting value is attained, no matter how the partitions and points (x_k, y_k, z_k) are chosen, we say that F is **integrable** over D . As before, it can be shown that when F is continuous and the bounding surface of D is formed from finitely many smooth surfaces joined together along finitely many smooth curves, then F is integrable. In this case, as $\|P\| \rightarrow 0$ and the number of cells n goes to ∞ , the sums S_n approach a limit. We call this limit the **triple integral of F over D** and write

$$\lim_{n \rightarrow \infty} S_n = \iiint_D F(x, y, z) dV \quad \text{or} \quad \lim_{\|P\| \rightarrow 0} S_n = \iiint_D F(x, y, z) dx dy dz.$$

The regions D over which continuous functions are integrable are those having “reasonably smooth” boundaries.

Volume of a Solid Region in Space

If F is the constant function whose value is 1, then the sums in Equation (1) reduce to

$$S_n = \sum_{k=1}^n F(x_k, y_k, z_k) \Delta V_k = \sum_{k=1}^n 1 \cdot \Delta V_k = \sum_{k=1}^n \Delta V_k.$$

As Δx_k , Δy_k , and Δz_k approach zero, the cells ΔV_k become smaller and more numerous and fill up more and more of D . We therefore define the volume of D to be the triple integral

$$\lim_{n \rightarrow \infty} \sum_{k=1}^n \Delta V_k = \iiint_D dV.$$

DEFINITION The **volume** of a closed and bounded solid region D in space is

$$V = \iiint_D dV.$$

This definition is in agreement with our previous definitions of volume, although we omit the verification of this fact. As we will see in a moment, this integral enables us to calculate the volumes of solids enclosed by curved surfaces. These are more general solids than the ones encountered before (Chapter 6 and Section 14.2).

Iterated Integrals

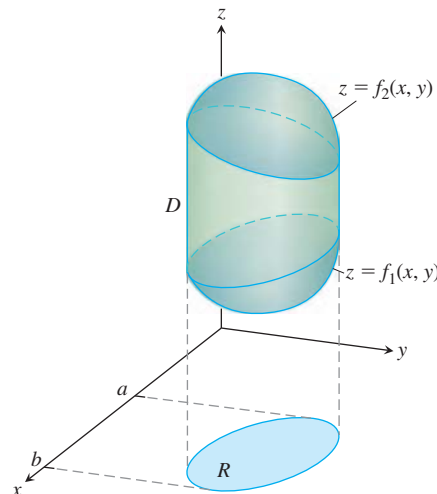

We evaluate a triple integral by applying a three-dimensional version of Fubini's Theorem (Section 14.2) to evaluate it by three repeated single integrations. As with double integrals, there is a geometric procedure for finding the limits of integration for these iterated integrals.

To evaluate

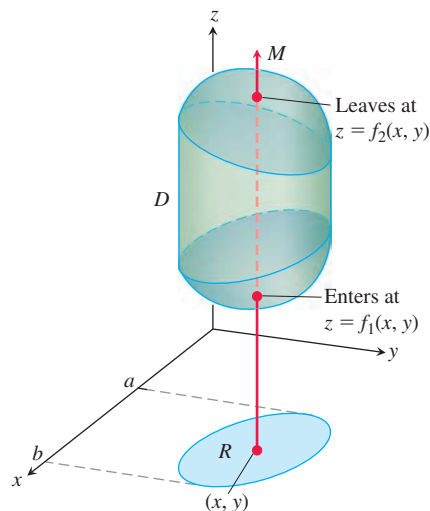

$$\iiint_D F(x, y, z) dV$$

over a solid region D , integrate first with respect to z , then with respect to y , and finally with respect to x . (You might choose a different order of integration, but the procedure is similar, as we illustrate in Example 2.)

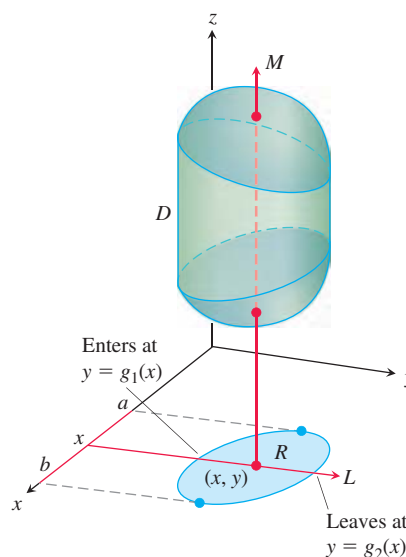

- Sketch.** Sketch the solid region D along with its “shadow” R (vertical projection) in the xy -plane. Label the upper and lower bounding surfaces of D and the upper and lower bounding curves of R .

2. Find the z -limits of integration. Draw a line M passing through a typical point (x, y) in R parallel to the z -axis. As z increases, M enters D at $z = f_1(x, y)$ and leaves at $z = f_2(x, y)$. These are the z -limits of integration.

3. Find the y -limits of integration. Draw a line L through (x, y) parallel to the y -axis. As y increases, L enters R at $y = g_1(x)$ and leaves at $y = g_2(x)$. These are the y -limits of integration.

4. Find the x -limits of integration. Choose x -limits that include all lines through R parallel to the y -axis ($x = a$ and $x = b$ in the preceding figure). These are the x -limits of integration. The integral is

$$\int_{x=a}^{x=b} \int_{y=g_1(x)}^{y=g_2(x)} \int_{z=f_1(x,y)}^{z=f_2(x,y)} F(x, y, z) dz dy dx.$$

Follow similar procedures if you change the order of integration. The “shadow” of the solid region D lies in the plane of the last two variables with respect to which the iterated integration takes place. The limits of an iterated triple integral satisfy these properties:

- The limits of the *outside* integral are *constants* (they do not depend on any of the three variables of integration),
- the limits of the *middle* integral are *functions* that may depend on the variable of the *outside* integral, and
- the limits of the *inside* integral are *functions* that may depend on two variables: the *middle* integration variable and the *outside* integration variable.

The preceding procedure applies whenever a solid region D is bounded above and below by a surface, and when the “shadow” region R is bounded by a lower and upper curve. It does not apply to regions with more complicated shapes (such as regions containing holes); although, sometimes such regions can be subdivided into simpler regions for which the procedure does apply.

We illustrate this method of finding the limits of integration in our first example.

EXAMPLE 1 Let S be the sphere of radius 5 centered at the origin, and let D be the solid region under the sphere that lies above the plane $z = 3$. Set up the limits of integration for evaluating the triple integral of a function $F(x, y, z)$ over the region D .

Solution The solid region under the sphere that lies above the plane $z = 3$ is enclosed by the surfaces $x^2 + y^2 + z^2 = 25$ and $z = 3$.

To find the limits of integration, we first sketch the solid region, as shown in Figure 14.31. The “shadow region” R in the xy -plane is a circle of some radius centered at the origin. By considering a side view of the region D , we can determine that the radius of this circle is 4; see Figure 14.32a.

If we fix a point (x, y) in R and draw a vertical line M above (x, y) , then we see that this line enters the region D at the height $z = 3$ and leaves the region at the height $z = \sqrt{25 - x^2 - y^2}$; see Figure 14.31. This gives us the z -limits of integration.

To find the y -limits of integration, we consider a line L that lies in the region R , passes through the point (x, y) , and is parallel to the y -axis. For clarity we have separately pictured the region R and the line L in Figure 14.32b. The line L enters R when $y = -\sqrt{16 - x^2}$ and exits when $y = \sqrt{16 - x^2}$. This gives us the y -limits of integration.

Finally, as L sweeps across R from left to right, the value of x varies from $x = -4$ to $x = 4$. This gives us the x -limits of integration. Therefore, the triple integral of F over the region D is given by

$$\iiint_D F(x, y, z) \, dz \, dy \, dx = \int_{-4}^4 \int_{-\sqrt{16-x^2}}^{\sqrt{16-x^2}} \int_3^{\sqrt{25-x^2-y^2}} F(x, y, z) \, dz \, dy \, dx. \quad \blacksquare$$

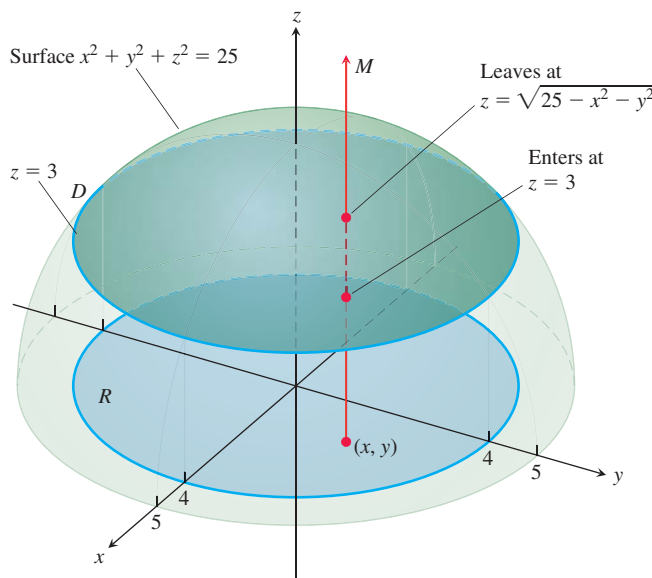

FIGURE 14.31 Finding the limits of integration for evaluating the triple integral of a function defined over the portion of the sphere of radius 5 that lies above the plane $z = 3$ (Example 1).

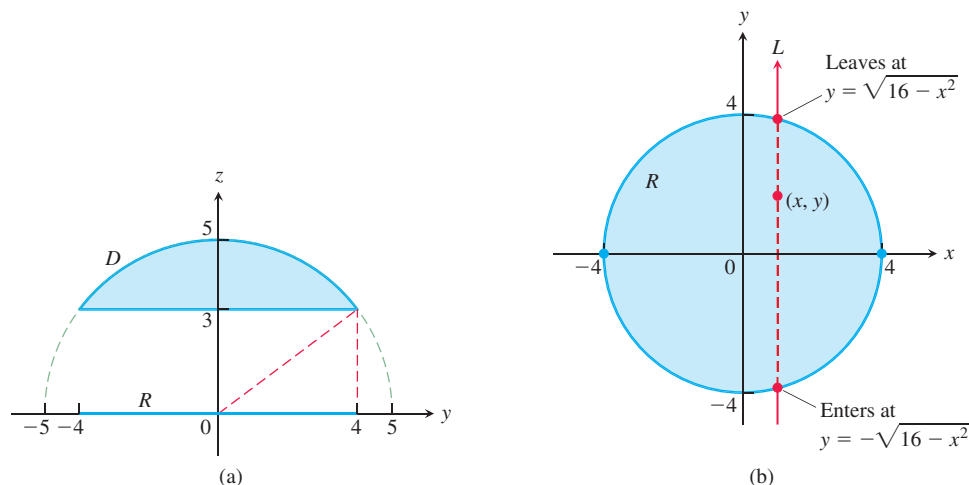

FIGURE 14.32 (a) Side view of the solid region from Example 1, looking down the x -axis. The dashed right triangle has a hypotenuse of length 5 and sides of lengths 3 and 4. In this side view, the shadow region R lies between -4 and 4 on the y -axis. (b) The “shadow region” R shown face-on in the xy -plane.

The region D in Example 1 has a great deal of symmetry, which makes visualization easier. Even without symmetry, the steps in finding the limits of integration are the same, as shown in the next example.

EXAMPLE 2 Set up the limits of integration for evaluating the triple integral of a function $F(x, y, z)$ over the tetrahedron D whose vertices are $O(0, 0, 0)$, $A(1, 1, 0)$, $B(0, 1, 0)$, and $C(0, 1, 1)$. Use the order of integration $dz dy dx$.

Solution The solid region D and its “shadow” R in the xy -plane are shown in Figure 14.33a. The “top” face is contained in the plane through the points O , A , and C . Following the procedure introduced in Example 7 of Section 11.5, we first form a normal vector to that plane:

$$\mathbf{n} = \overrightarrow{OA} \times \overrightarrow{OC} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{vmatrix} = \mathbf{i} - \mathbf{j} + \mathbf{k},$$

and then use this vector and the coordinates of O to set up an equation for the plane:

$$1(x - 0) - 1(y - 0) + 1(z - 0) = 0 \\ x - y + z = 0.$$

The “side” face of D is parallel to the xz -plane, the “back” face lies in the yz -plane, and the “bottom” face is contained in the xy -plane.

To find the z -limits of integration, fix a point (x, y) in the shadow region R , and consider the vertical line M that passes through (x, y) and is parallel to the z -axis. This line enters D at the height $z = 0$, and it exits at height $z = y - x$.

To find the y -limits of integration we again fix a point (x, y) in R , but now we consider a line L that lies in R , passes through (x, y) , and is parallel to the y -axis. This line is shown in Figure 14.33a and also in the face-on view of R that is pictured in Figure 14.33b. The line L enters R when $y = x$ and exits when $y = 1$.

Finally, as L sweeps across R , the value of x varies from $x = 0$ to $x = 1$. Therefore, the triple integral of F over the region D is given by

$$\iiint_D F(x, y, z) dz dy dx = \int_0^1 \int_x^1 \int_0^{y-x} F(x, y, z) dz dy dx. \quad \blacksquare$$

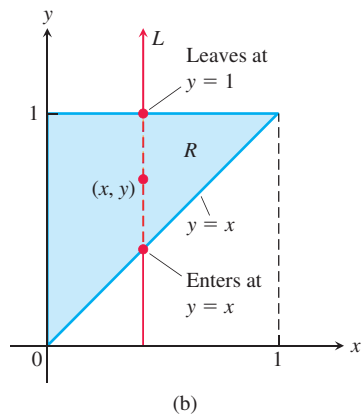

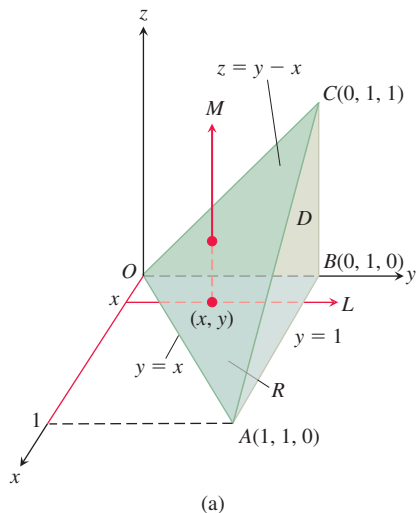

FIGURE 14.33 (a) The tetrahedron in Example 2, showing how the limits of integration are found for the order $dz dy dx$. (b) The “shadow region” R shown face-on in the xy -plane.

In the next example we project the region D onto the xz -plane instead of the xy -plane, to show how to use a different order of integration.

EXAMPLE 3 Find the volume of the tetrahedron D from Example 2 by integrating $F(x, y, z) = 1$ over the region using the order $dz dy dx$. Then do the same calculation using the order $dy dz dx$.

Solution Using the limits of integration that we found in Example 2, we calculate the volume of the tetrahedron as follows:

$$\begin{aligned}
 V &= \int_0^1 \int_x^1 \int_0^{y-x} dz dy dx && \text{Integrand is 1 when} \\
 &= \int_0^1 \int_x^1 (y-x) dy dx && \text{computing volume.} \\
 &= \int_0^1 \left[\frac{1}{2}y^2 - xy \right]_{y=x}^{y=1} dx && \text{Integrate over } z \\
 &= \int_0^1 \left(\frac{1}{2} - x + \frac{1}{2}x^2 \right) dx && \text{and evaluate.} \\
 &= \left[\frac{1}{2}x - \frac{1}{2}x^2 + \frac{1}{6}x^3 \right]_0^1 && \text{Integrate over } y. \\
 &= \frac{1}{6}. && \text{Evaluate.}
 \end{aligned}$$

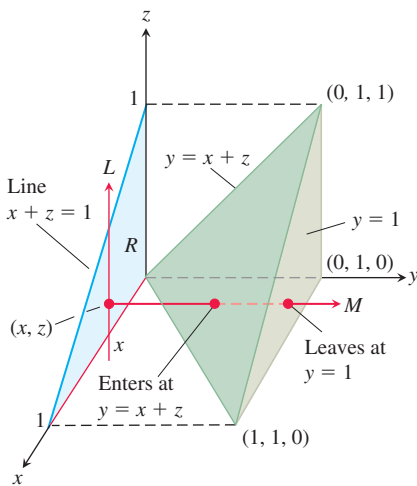

FIGURE 14.34 Finding the limits of integration for evaluating the triple integral of a function defined over the tetrahedron D (Example 3).

Now we will compute the volume using the order of integration $dy dz dx$. The procedure for finding the limits of integration is similar, except that we find the limits for y first, then for z , and then for x . The region D is the same tetrahedron as before, but now the “shadow region” R lies in the xz -plane, as shown in Figure 14.34.

To find the y -limits of integration, we fix a point (x, z) in the shadow R and consider the line M that passes through (x, z) and is parallel to the y -axis. As shown in Figure 14.34, this line enters D when $y = x + z$, and it leaves when $y = 1$.

Next we find the z -limits of integration. The line L that passes through a point (x, z) in R and is parallel to the z -axis enters R when $z = 0$ and exits when $z = 1 - x$ (see Figure 14.34).

Finally, as L sweeps across R , the value of x varies from $x = 0$ to $x = 1$. Therefore, the volume of the tetrahedron is

$$\begin{aligned}
 V &= \int_0^1 \int_0^{1-x} \int_{x+z}^1 dy dz dx \\
 &= \int_0^1 \int_0^{1-x} (1-x-z) dz dx \\
 &= \int_0^1 \left[(1-x)z - \frac{1}{2}z^2 \right]_{z=0}^{z=1-x} dx \\
 &= \int_0^1 \left[(1-x)^2 - \frac{1}{2}(1-x)^2 \right] dx \\
 &= \frac{1}{2} \int_0^1 (1-x)^2 dx \\
 &= -\frac{1}{6}(1-x)^3 \Big|_0^1 = \frac{1}{6}.
 \end{aligned}$$

Next we set up and evaluate a triple integral over a more complicated region.

EXAMPLE 4 Find the volume of the solid region D enclosed by the surfaces $z = x^2 + 3y^2$ and $z = 8 - x^2 - y^2$.

Solution The volume is

$$V = \iiint_D dz \, dy \, dx,$$

the integral of $F(x, y, z) = 1$ over D . To find the limits of integration for evaluating the integral, we first sketch the region. The surfaces (Figure 14.35) intersect on the elliptical cylinder $x^2 + 3y^2 = 8 - x^2 - y^2$ or $x^2 + 2y^2 = 4$, $z > 0$. The boundary of the region R , the projection of D onto the xy -plane, is an ellipse with the same equation: $x^2 + 2y^2 = 4$. The “upper” boundary of R is the curve $y = \sqrt{(4 - x^2)}/2$. The lower boundary is the curve $y = -\sqrt{(4 - x^2)}/2$.

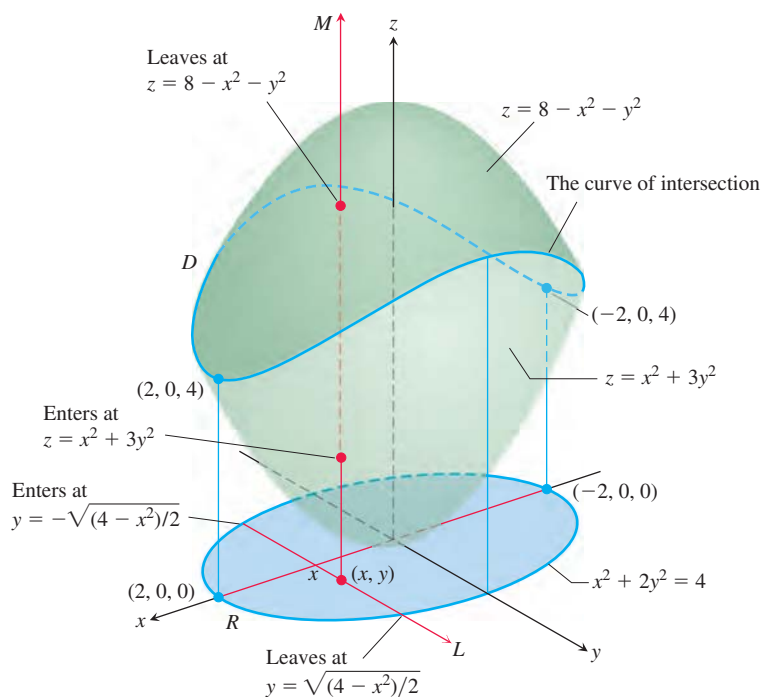

FIGURE 14.35 The volume of the region enclosed by two paraboloids, calculated in Example 4.

Now we find the z -limits of integration. The line M passing through a typical point (x, y) in R parallel to the z -axis enters D at $z = x^2 + 3y^2$ and leaves at $z = 8 - x^2 - y^2$.

Next we find the y -limits of integration. The line L through (x, y) that lies parallel to the y -axis enters the region R when $y = -\sqrt{(4 - x^2)}/2$ and leaves when $y = \sqrt{(4 - x^2)}/2$.

Finally, we find the x -limits of integration. As L sweeps across R , the value of x varies from $x = -2$ at $(-2, 0, 0)$ to $x = 2$ at $(2, 0, 0)$. The volume of D is

$$\begin{aligned} V &= \iiint_D dz \, dy \, dx && \text{Integrand is 1 when computing volume.} \\ &= \int_{-2}^2 \int_{-\sqrt{(4-x^2)}/2}^{\sqrt{(4-x^2)}/2} \int_{x^2+3y^2}^{8-x^2-y^2} dz \, dy \, dx && \text{Form an iterated integral.} \end{aligned}$$

$$\begin{aligned}
&= \int_{-2}^2 \int_{-\sqrt{(4-x^2)/2}}^{\sqrt{(4-x^2)/2}} (8 - 2x^2 - 4y^2) dy dx && \text{Integrate over } z \text{ and evaluate.} \\
&= \int_{-2}^2 \left[(8 - 2x^2)y - \frac{4}{3}y^3 \right]_{y=-\sqrt{(4-x^2)/2}}^{y=\sqrt{(4-x^2)/2}} dx && \text{Integrate over } y. \\
&= \int_{-2}^2 \left(2(8 - 2x^2)\sqrt{\frac{4-x^2}{2}} - \frac{8}{3}\left(\frac{4-x^2}{2}\right)^{3/2} \right) dx && \text{Evaluate.} \\
&= \int_{-2}^2 \left[8\left(\frac{4-x^2}{2}\right)^{3/2} - \frac{8}{3}\left(\frac{4-x^2}{2}\right)^{3/2} \right] dx \\
&= \frac{4\sqrt{2}}{3} \int_{-2}^2 (4-x^2)^{3/2} dx \\
&= 8\pi\sqrt{2}. && \text{After integration with the substitution } x = 2\sin\theta
\end{aligned}$$

Average Value of a Function in Space

The average value of a function F over a solid region D in space is defined by the formula

$$\text{Average value of } F \text{ over } D = \frac{1}{\text{volume of } D} \iiint_D F dV. \quad (2)$$

For example, if $F(x, y, z) = \sqrt{x^2 + y^2 + z^2}$, then the average value of F over D is the average distance of points in D from the origin. If $F(x, y, z)$ is the temperature at (x, y, z) on a solid that occupies a region D in space, then the average value of F over D is the average temperature of the solid.

EXAMPLE 5 Find the average value of $F(x, y, z) = xyz$ throughout the cubical region D bounded by the coordinate planes and the planes $x = 2$, $y = 2$, and $z = 2$ in the first octant.

Solution We sketch the cube with enough detail to show the limits of integration (Figure 14.36). We then use Equation (2) to calculate the average value of F over the cube.

The volume of the region D is $(2)(2)(2) = 8$. The value of the integral of F over the cube is

$$\begin{aligned}
\int_0^2 \int_0^2 \int_0^2 xyz dx dy dz &= \int_0^2 \int_0^2 \left[\frac{x^2}{2} yz \right]_{x=0}^{x=2} dy dz = \int_0^2 \int_0^2 2yz dy dz \\
&= \int_0^2 \left[y^2 z \right]_{y=0}^{y=2} dz = \int_0^2 4z dz = \left[2z^2 \right]_0^2 = 8.
\end{aligned}$$

With these values, Equation (2) gives

$$\text{Average value of } xyz \text{ over the cube} = \frac{1}{\text{volume}_{\text{cube}}} \iiint_{\text{cube}} xyz dV = \left(\frac{1}{8}\right)(8) = 1.$$

In evaluating the integral, we chose the order $dx dy dz$, but any of the other five possible orders would have done as well. ■

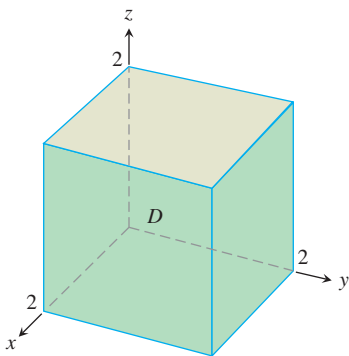

FIGURE 14.36 The region of integration in Example 5.

Properties of Triple Integrals

Triple integrals have the same algebraic properties as double and single integrals. Simply replace the double integrals in the four properties given in Section 14.2, page 864, with triple integrals.

EXERCISES 14.5

Triple Integrals in Different Iteration Orders

- Evaluate the integral in Example 3, taking $F(x, y, z) = 1$ to find the volume of the tetrahedron in the order $dz dx dy$.
- Volume of rectangular solid** Write six different iterated triple integrals for the volume of the rectangular solid in the first octant bounded by the coordinate planes and the planes $x = 1$, $y = 2$, and $z = 3$. Evaluate one of the integrals.
- Volume of tetrahedron** Write six different iterated triple integrals for the volume of the tetrahedron cut from the first octant by the plane $6x + 3y + 2z = 6$. Evaluate one of the integrals.
- Volume of solid** Write six different iterated triple integrals for the volume of the solid region in the first octant enclosed by the cylinder $x^2 + z^2 = 4$ and the plane $y = 3$. Evaluate one of the integrals.
- Volume enclosed by paraboloids** Let D be the solid region bounded by the paraboloids $z = 8 - x^2 - y^2$ and $z = x^2 + y^2$. Write six different triple iterated integrals for the volume of D . Evaluate one of the integrals.
- Volume inside paraboloid beneath a plane** Let D be the solid region bounded by the paraboloid $z = x^2 + y^2$ and the plane $z = 2y$. Write triple iterated integrals in the order $dz dx dy$ and $dz dy dx$ that give the volume of D . Do not evaluate either integral.

Evaluating Triple Iterated Integrals

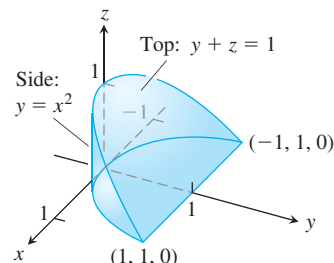

Evaluate the integrals in Exercises 7–20.

- $\int_0^1 \int_0^1 \int_0^1 (x^2 + y^2 + z^2) dz dy dx$
- $\int_0^{\sqrt{2}} \int_0^{3y} \int_{x^2+3y^2}^{8-x^2-y^2} dz dx dy$
- $\int_1^e \int_1^{e^2} \int_1^{e^3} \frac{1}{xyz} dx dy dz$
- $\int_0^1 \int_0^{3-3x} \int_0^{3-3x-y} dz dy dx$
- $\int_0^{\pi/6} \int_0^1 \int_{-2}^3 y \sin z dx dy dz$
- $\int_{-1}^1 \int_0^1 \int_0^2 (x + y + z) dy dx dz$
- $\int_0^3 \int_0^{\sqrt{9-x^2}} \int_0^{\sqrt{9-x^2}} dz dy dx$
- $\int_0^2 \int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}} \int_0^{2x+y} dz dx dy$
- $\int_0^1 \int_0^{2-x} \int_0^{2-x-y} dz dy dx$
- $\int_0^1 \int_0^{1-x^2} \int_3^{4-x^2-y} x dz dy dx$
- $\int_0^{\pi} \int_0^{\pi} \int_0^{\pi} \cos(u + v + w) du dv dw$ (uvw -space)
- $\int_0^1 \int_1^{\sqrt{e}} \int_1^e se^s \ln r \frac{(\ln t)^2}{t} dt dr ds$ (rst -space)
- $\int_0^{\pi/4} \int_0^{\ln \sec v} \int_{-\infty}^{2t} e^x dx dt dv$ (tvx -space)
- $\int_0^7 \int_0^2 \int_0^{\sqrt{4-q^2}} \frac{q}{r+1} dp dq dr$ (pqr -space)

Finding Equivalent Iterated Integrals

21. Here is the region of integration of the integral

$$\int_{-1}^1 \int_{x^2}^1 \int_0^{1-y} dz dy dx.$$

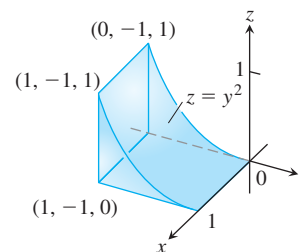

Rewrite the integral as an equivalent iterated integral in the order

- $dy dz dx$
- $dy dx dz$
- $dx dy dz$
- $dx dz dy$
- $dz dx dy$.

22. Here is the region of integration of the integral

$$\int_0^1 \int_{-1}^0 \int_0^{y^2} dz dy dx$$

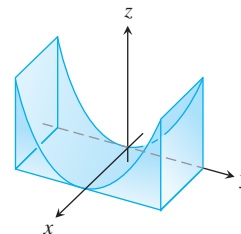

Rewrite the integral as an equivalent iterated integral in the order

- $dy dz dx$
- $dy dx dz$
- $dx dy dz$
- $dx dz dy$
- $dz dx dy$.

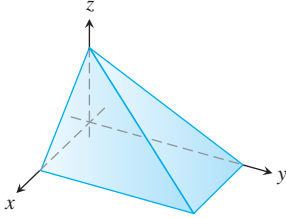

Finding Volumes Using Triple Integrals

Find the volumes of the solid regions in Exercises 23–36.

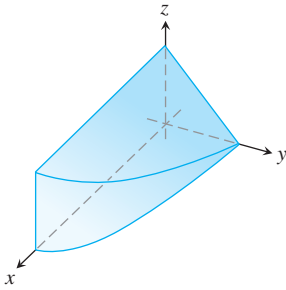

23. The region between the cylinder $z = y^2$ and the xy -plane that is bounded by the planes $x = 0$, $x = 1$, $y = -1$, $y = 1$

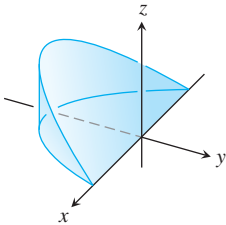

24. The region in the first octant bounded by the coordinate planes and the planes $x + z = 1$, $y + 2z = 2$

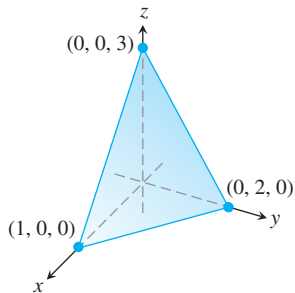

25. The region in the first octant bounded by the coordinate planes, the plane $y + z = 2$, and the cylinder $x = 4 - y^2$

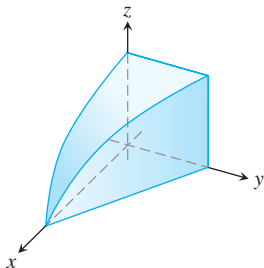

26. The wedge cut from the cylinder $x^2 + y^2 = 1$ with $z \geq 0$ by the planes $z = -y$ and $z = 0$

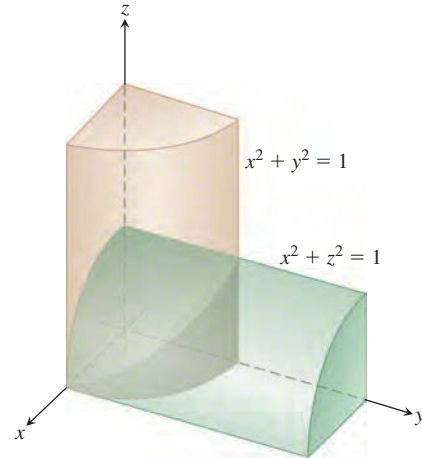

27. The tetrahedron in the first octant bounded by the coordinate planes and the plane passing through $(1, 0, 0)$, $(0, 2, 0)$, and $(0, 0, 3)$

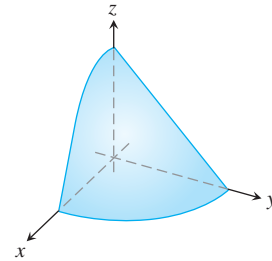

28. The region in the first octant bounded by the coordinate planes, the plane $y = 1 - x$, and the surface $z = \cos(\pi x/2)$, $0 \leq x \leq 1$

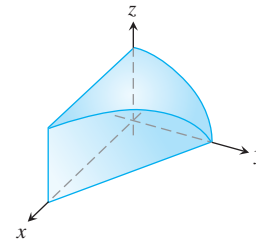

29. The region common to the interiors of the cylinders $x^2 + y^2 = 1$ and $x^2 + z^2 = 1$, one-eighth of which is shown in the accompanying figure

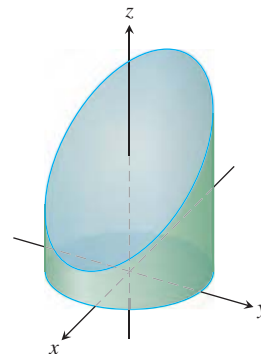

30. The region in the first octant bounded by the coordinate planes and the surface $z = 4 - x^2 - y^2$

31. The region in the first octant bounded by the coordinate planes, the plane $x + y = 4$, and the cylinder $y^2 + 4z^2 = 16$

32. The region cut from the cylinder $x^2 + y^2 = 4$ by the plane $z = 0$ and the plane $x + z = 3$

33. The region between the planes $x + y + 2z = 2$ and $2x + 2y + z = 4$ in the first octant
34. The finite region bounded by the planes $z = x$, $x + z = 8$, $z = y$, $y = 8$, and $z = 0$
35. The region cut from the solid elliptical cylinder $x^2 + 4y^2 \leq 4$ by the xy -plane and the plane $z = x + 2$
36. The region bounded in back by the plane $x = 0$, on the front and sides by the parabolic cylinder $x = 1 - y^2$, on the top by the paraboloid $z = x^2 + y^2$, and on the bottom by the xy -plane

Average Values

In Exercises 37–40, find the average value of $F(x, y, z)$ over the given region.

37. $F(x, y, z) = x^2 + 9$ over the cube in the first octant bounded by the coordinate planes and the planes $x = 2$, $y = 2$, and $z = 2$
38. $F(x, y, z) = x + y - z$ over the rectangular box in the first octant bounded by the coordinate planes and the planes $x = 1$, $y = 1$, and $z = 2$
39. $F(x, y, z) = x^2 + y^2 + z^2$ over the cube in the first octant bounded by the coordinate planes and the planes $x = 1$, $y = 1$, and $z = 1$
40. $F(x, y, z) = xyz$ over the cube in the first octant bounded by the coordinate planes and the planes $x = 2$, $y = 2$, and $z = 2$

Changing the Order of Integration

Evaluate the integrals in Exercises 41–44 by changing the order of integration in an appropriate way.

41. $\int_0^4 \int_0^1 \int_{2y}^2 \frac{4 \cos(x^2)}{2\sqrt{z}} dx dy dz$
42. $\int_0^1 \int_0^1 \int_{x^2}^1 12xze^{zy^2} dy dx dz$
43. $\int_0^1 \int_{\sqrt[3]{z}}^1 \int_0^{\ln 3} \frac{\pi e^{2x} \sin \pi y^2}{y^2} dx dy dz$

$$44. \int_0^2 \int_0^{4-x^2} \int_0^x \frac{\sin 2z}{4-z} dy dz dx$$

Theory and Examples

45. **Finding an upper limit of an iterated integral** Solve for a :

$$\int_0^1 \int_0^{4-a-x^2} \int_a^{4-x^2-y} dz dy dx = \frac{4}{15}.$$

46. **Ellipsoid** For what value of c is the volume of the ellipsoid $x^2 + (y/2)^2 + (z/c)^2 = 1$ equal to 8π ?
47. **Minimizing a triple integral** What domain D in space minimizes the value of the integral

$$\iiint_D (4x^2 + 4y^2 + z^2 - 4) dV?$$

Give reasons for your answer.

48. **Maximizing a triple integral** What domain D in space maximizes the value of the integral

$$\iiint_D (1 - x^2 - y^2 - z^2) dV?$$

Give reasons for your answer.

COMPUTER EXPLORATIONS

In Exercises 49–52, use a CAS integration utility to evaluate the triple integral of the given function over the specified solid region.

49. $F(x, y, z) = x^2 y^2 z$ over the solid cylinder bounded by $x^2 + y^2 = 1$ and the planes $z = 0$ and $z = 1$
50. $F(x, y, z) = |xyz|$ over the solid bounded below by the paraboloid $z = x^2 + y^2$ and above by the plane $z = 1$
51. $F(x, y, z) = \frac{z}{(x^2 + y^2 + z^2)^{3/2}}$ over the solid bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the plane $z = 1$
52. $F(x, y, z) = x^4 + y^2 + z^2$ over the solid sphere $x^2 + y^2 + z^2 \leq 1$

14.6 Applications

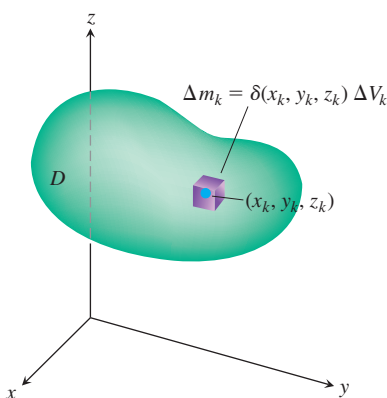

FIGURE 14.37 To define an object's mass, we first imagine it to be partitioned into a finite number of mass elements Δm_k .

This section shows how to calculate the masses and moments of two- and three-dimensional objects in Cartesian coordinates. The definitions and ideas are similar to the single-variable case we studied in Section 6.6, but now we can consider more general situations.

Masses and First Moments

If $\delta(x, y, z)$ is the density (mass per unit volume) of an object occupying a solid region D in space, the integral of δ over D gives the **mass** of the object. To see why, imagine partitioning the object into n mass elements like the one in Figure 14.37. The object's mass is the limit

$$M = \lim_{n \rightarrow \infty} \sum_{k=1}^n \Delta m_k = \lim_{n \rightarrow \infty} \sum_{k=1}^n \delta(x_k, y_k, z_k) \Delta V_k = \iiint_D \delta(x, y, z) dV.$$

The **first moment** of a solid region D about a coordinate plane is defined as the triple integral over D of the (signed) distance from a point (x, y, z) in D to the plane multiplied

by the density of the solid at that point. For instance, the first moment about the yz -plane is the integral

$$M_{yz} = \iiint_D x \delta(x, y, z) dV.$$

The *center of mass* is found from the first moments. For instance, the x -coordinate of the center of mass is $\bar{x} = M_{yz}/M$.

For a two-dimensional object, such as a thin, flat plate, we calculate first moments about the coordinate axes by simply dropping the z -coordinate. So the first moment about the y -axis is the double integral over the region R forming the plate of the (signed) distance from the axis multiplied by the density, or

$$M_y = \iint_R x \delta(x, y) dA.$$

Table 14.1 summarizes the formulas.

TABLE 14.1 Mass and first moment formulas

THREE-DIMENSIONAL SOLID

Mass: $M = \iiint_D \delta dV$ $\delta = \delta(x, y, z)$ is the density at (x, y, z) .

First moments about the coordinate planes:

$$M_{yz} = \iiint_D x \delta dV, \quad M_{xz} = \iiint_D y \delta dV, \quad M_{xy} = \iiint_D z \delta dV$$

Center of mass: $\bar{x} = \frac{M_{yz}}{M}, \quad \bar{y} = \frac{M_{xz}}{M}, \quad \bar{z} = \frac{M_{xy}}{M}$

TWO-DIMENSIONAL PLATE

Mass: $M = \iint_R \delta dA$ $\delta = \delta(x, y)$ is the density at (x, y) .

First moments: $M_y = \iint_R x \delta dA, \quad M_x = \iint_R y \delta dA$

Center of mass: $\bar{x} = \frac{M_y}{M}, \quad \bar{y} = \frac{M_x}{M}$

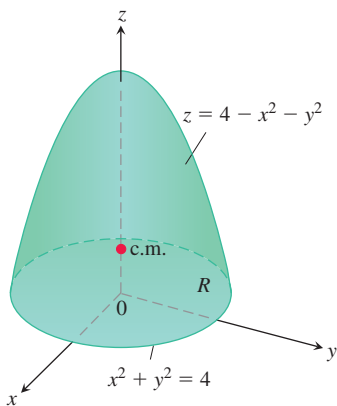

FIGURE 14.38 Finding the center of mass of a solid (Example 1).

EXAMPLE 1 Find the center of mass of a solid of constant density δ bounded below by the disk $R: x^2 + y^2 \leq 4$ in the plane $z = 0$ and above by the paraboloid $z = 4 - x^2 - y^2$ (Figure 14.38).

Solution By symmetry $\bar{x} = \bar{y} = 0$. To find \bar{z} , we first calculate

$$\begin{aligned} M_{xy} &= \iint_R \int_{z=0}^{z=4-x^2-y^2} z \delta dz dy dx = \iint_R \left[\frac{z^2}{2} \right]_{z=0}^{z=4-x^2-y^2} \delta dy dx \\ &= \frac{\delta}{2} \iint_R (4 - x^2 - y^2)^2 dy dx \end{aligned}$$

$$\begin{aligned}
 &= \frac{\delta}{2} \int_0^{2\pi} \int_0^2 (4 - r^2)^2 r \, dr \, d\theta && \text{Polar coordinates simplify the integration.} \\
 &= \frac{\delta}{2} \int_0^{2\pi} \left[-\frac{1}{6} (4 - r^2)^3 \right]_{r=0}^{r=2} d\theta = \frac{16\delta}{3} \int_0^{2\pi} d\theta = \frac{32\pi\delta}{3}.
 \end{aligned}$$

A similar calculation gives the mass:

$$M = \iiint_R \int_0^{4-x^2-y^2} \delta \, dz \, dy \, dx = 8\pi\delta.$$

Therefore, $\bar{z} = (M_{xy}/M) = 4/3$ and the center of mass is $(\bar{x}, \bar{y}, \bar{z}) = (0, 0, 4/3)$. ■

When the density of a solid object or plate is constant (as in Example 1), the center of mass is called the **centroid** of the object. To find a centroid, we set δ equal to 1 and proceed to find \bar{x} , \bar{y} , and \bar{z} as before, by dividing first moments by masses. These calculations are also valid for two-dimensional objects.

EXAMPLE 2 Find the centroid of the region in the first quadrant that is bounded above by the line $y = x$ and below by the parabola $y = x^2$.

Solution We sketch the region and include enough detail to determine the limits of integration (Figure 14.39). We then set δ equal to 1 and evaluate the appropriate formulas from Table 14.1:

$$M = \int_0^1 \int_{x^2}^x 1 \, dy \, dx = \int_0^1 \left[y \right]_{y=x^2}^{y=x} dx = \int_0^1 (x - x^2) dx = \left[\frac{x^2}{2} - \frac{x^3}{3} \right]_0^1 = \frac{1}{6}$$

$$\begin{aligned}
 M_x &= \int_0^1 \int_{x^2}^x y \, dy \, dx = \int_0^1 \left[\frac{y^2}{2} \right]_{y=x^2}^{y=x} dx \\
 &= \int_0^1 \left(\frac{x^2}{2} - \frac{x^4}{2} \right) dx = \left[\frac{x^3}{6} - \frac{x^5}{10} \right]_0^1 = \frac{1}{15}
 \end{aligned}$$

$$M_y = \int_0^1 \int_{x^2}^x x \, dy \, dx = \int_0^1 \left[xy \right]_{y=x^2}^{y=x} dx = \int_0^1 (x^2 - x^3) dx = \left[\frac{x^3}{3} - \frac{x^4}{4} \right]_0^1 = \frac{1}{12}.$$

From these values of M , M_x , and M_y , we find

$$\bar{x} = \frac{M_y}{M} = \frac{1/12}{1/6} = \frac{1}{2} \quad \text{and} \quad \bar{y} = \frac{M_x}{M} = \frac{1/15}{1/6} = \frac{2}{5}.$$

The centroid is the point $(1/2, 2/5)$. ■

Note that each coordinate of the centroid of a region is equal to the average value of the corresponding variable over the region.

Moments of Inertia

An object's first moments (Table 14.1) give us information related to balance and to the torque the object experiences about different axes in a gravitational field. If the object is a rotating shaft, we are interested in how much energy is stored in the shaft and how much energy is generated by a shaft rotating at a particular angular velocity. This is captured by the second moment or moment of inertia.

Think of partitioning the shaft into small blocks of mass Δm_k and let r_k denote the distance from the k th block's center of mass to the axis of rotation (Figure 14.40). If the

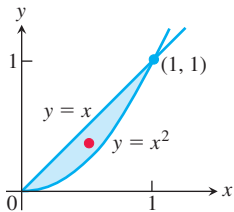

FIGURE 14.39 The centroid of this region is found in Example 2.

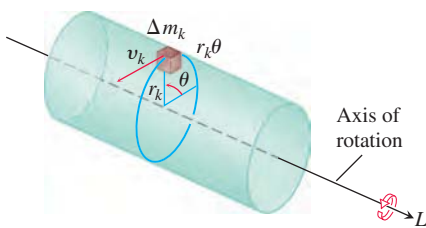

FIGURE 14.40 To find an integral for the amount of energy stored in a rotating shaft, we first imagine the shaft to be partitioned into small blocks. Each block has its own kinetic energy. We add the contributions of the individual blocks to find the kinetic energy of the shaft.

shaft rotates at a constant angular velocity of $\omega = d\theta/dt$ radians per second, the block's center of mass will trace its orbit at a linear speed of

$$v_k = \frac{d}{dt}(r_k\theta) = r_k \frac{d\theta}{dt} = r_k\omega.$$

The block's kinetic energy will be approximately

$$\frac{1}{2}\Delta m_k v_k^2 = \frac{1}{2}\Delta m_k (r_k\omega)^2 = \frac{1}{2}\omega^2 r_k^2 \Delta m_k.$$

The kinetic energy of the shaft will be approximately

$$\sum \frac{1}{2}\omega^2 r_k^2 \Delta m_k.$$

The integral approached by these sums as the shaft is partitioned into smaller and smaller blocks gives the shaft's kinetic energy:

$$\text{KE}_{\text{shaft}} = \int \frac{1}{2}\omega^2 r^2 dm = \frac{1}{2}\omega^2 \int r^2 dm. \quad (1)$$

The factor

$$I = \int r^2 dm$$

is the *moment of inertia* of the shaft about its axis of rotation, and we see from Equation (1) that the shaft's kinetic energy is

$$\text{KE}_{\text{shaft}} = \frac{1}{2}I\omega^2.$$

The moment of inertia of a shaft resembles in some ways the inertial mass of a locomotive. To start a locomotive with mass m moving at a linear velocity v , we need to provide a kinetic energy of $\text{KE} = (1/2)mv^2$. To stop the locomotive we have to remove this amount of energy. To start a shaft with moment of inertia I rotating at an angular velocity ω , we need to provide a kinetic energy of $\text{KE} = (1/2)I\omega^2$. To stop the shaft we have to take this amount of energy back out. The shaft's moment of inertia is analogous to the locomotive's mass. What makes the locomotive hard to start or stop is its mass. What makes the shaft hard to start or stop is its moment of inertia. The moment of inertia depends not only on the mass of the shaft but also on its distribution. Mass that is farther away from the axis of rotation contributes more to the moment of inertia.

We now derive a formula for the moment of inertia for a solid in space. If $r(x, y, z)$ is the distance from the point (x, y, z) in D to a line L , then the moment of inertia of the mass $\Delta m_k = \delta(x_k, y_k, z_k) \Delta V_k$ about the line L (as in Figure 14.40) is approximately $\Delta I_k = r^2(x_k, y_k, z_k) \Delta m_k$. **The moment of inertia about L** of the entire object is

$$I_L = \lim_{n \rightarrow \infty} \sum_{k=1}^n \Delta I_k = \lim_{n \rightarrow \infty} \sum_{k=1}^n r^2(x_k, y_k, z_k) \delta(x_k, y_k, z_k) \Delta V_k = \iiint_D r^2 \delta dV.$$

If L is the x -axis, then $r^2 = y^2 + z^2$ (Figure 14.41) and

$$I_x = \iiint_D (y^2 + z^2) \delta(x, y, z) dV.$$

Similarly, if L is the y -axis or the z -axis, we have

$$I_y = \iiint_D (x^2 + z^2) \delta(x, y, z) dV \quad \text{and} \quad I_z = \iiint_D (x^2 + y^2) \delta(x, y, z) dV.$$

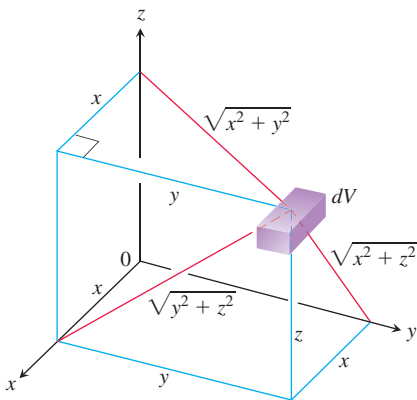

FIGURE 14.41 Distances from dV to the axes.

Table 14.2 summarizes the formulas for these moments of inertia (second moments because they invoke the *squares* of the distances). It shows the definition of the *polar moment* about the origin as well.

TABLE 14.2 Moments of inertia (second moments) formulas

THREE-DIMENSIONAL SOLID

About the x -axis:
$$I_x = \iiint_D (y^2 + z^2) \delta \, dV \quad \delta = \delta(x, y, z)$$

About the y -axis:
$$I_y = \iiint_D (x^2 + z^2) \delta \, dV$$

About the z -axis:
$$I_z = \iiint_D (x^2 + y^2) \delta \, dV$$

About a line L :
$$I_L = \iiint_D r^2(x, y, z) \delta \, dV \quad r(x, y, z) = \text{distance from the point } (x, y, z) \text{ to line } L$$

TWO-DIMENSIONAL PLATE

About the x -axis:
$$I_x = \iint_R y^2 \delta \, dA \quad \delta = \delta(x, y)$$

About the y -axis:
$$I_y = \iint_R x^2 \delta \, dA$$

About a line L :
$$I_L = \iint_R r^2(x, y) \delta \, dA \quad r(x, y) = \text{distance from } (x, y) \text{ to } L$$

About the origin (polar moment):
$$I_0 = \iint_R (x^2 + y^2) \delta \, dA = I_x + I_y$$

EXAMPLE 3 Find I_x , I_y , I_z for the rectangular solid of constant density δ shown in Figure 14.42.

Solution The formula for I_x gives

$$I_x = \int_{-c/2}^{c/2} \int_{-b/2}^{b/2} \int_{-a/2}^{a/2} (y^2 + z^2) \delta \, dx \, dy \, dz.$$

We can avoid some of the work of integration by observing that $(y^2 + z^2)\delta$ is an even function of x , y , and z since δ is constant. The rectangular solid consists of eight symmetric pieces, one in each octant. We can evaluate the integral on one of these pieces and then multiply by 8 to get the total value:

$$\begin{aligned} I_x &= 8 \int_0^{c/2} \int_0^{b/2} \int_0^{a/2} (y^2 + z^2) \delta \, dx \, dy \, dz = 4a\delta \int_0^{c/2} \int_0^{b/2} (y^2 + z^2) \, dy \, dz \\ &= 4a\delta \int_0^{c/2} \left[\frac{y^3}{3} + z^2 y \right]_{y=0}^{y=b/2} dz \\ &= 4a\delta \int_0^{c/2} \left(\frac{b^3}{24} + \frac{z^2 b}{2} \right) dz \end{aligned}$$

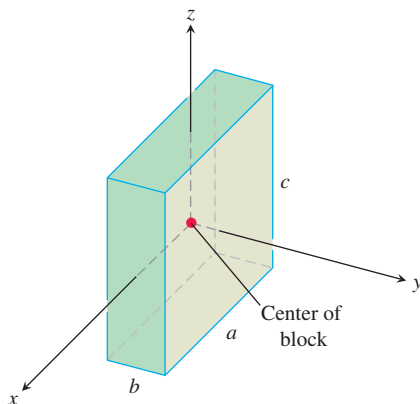

FIGURE 14.42 Finding I_x , I_y , and I_z for the block shown here. The origin lies at the center of the block (Example 3).

$$= 4a\delta\left(\frac{b^3c}{48} + \frac{c^3b}{48}\right) = \frac{abc\delta}{12}(b^2 + c^2) = \frac{M}{12}(b^2 + c^2). \quad M = abc\delta$$

Similarly,

$$I_y = \frac{M}{12}(a^2 + c^2) \quad \text{and} \quad I_z = \frac{M}{12}(a^2 + b^2). \quad \blacksquare$$

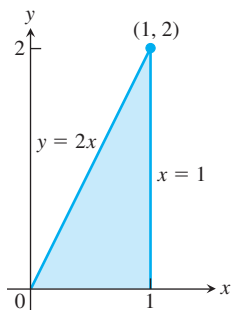

FIGURE 14.43 The triangular region covered by the plate in Example 4.

EXAMPLE 4 A thin plate covers the triangular region bounded by the x -axis and the lines $x = 1$ and $y = 2x$ in the first quadrant. The plate's density at the point (x, y) is $\delta(x, y) = 6x + 6y + 6$. Find the plate's moments of inertia about the coordinate axes and the origin.

Solution We sketch the plate and put in enough detail to determine the limits of integration for the integrals we have to evaluate (Figure 14.43). The moment of inertia about the x -axis is

$$\begin{aligned} I_x &= \int_0^1 \int_0^{2x} y^2 \delta(x, y) dy dx = \int_0^1 \int_0^{2x} (6xy^2 + 6y^3 + 6y^2) dy dx \\ &= \int_0^1 \left[2xy^3 + \frac{3}{2}y^4 + 2y^3 \right]_{y=0}^{y=2x} dx = \int_0^1 (40x^4 + 16x^3) dx \\ &= \left[8x^5 + 4x^4 \right]_0^1 = 12. \end{aligned}$$

Similarly, the moment of inertia about the y -axis is

$$I_y = \int_0^1 \int_0^{2x} x^2 \delta(x, y) dy dx = \frac{39}{5}.$$

Notice that we integrate y^2 times density in calculating I_x , and x^2 times density to find I_y .

Since we know I_x and I_y , we do not need to evaluate an integral to find I_0 ; we can use the equation $I_0 = I_x + I_y$ from Table 14.2 instead:

$$I_0 = 12 + \frac{39}{5} = \frac{60 + 39}{5} = \frac{99}{5}. \quad \blacksquare$$

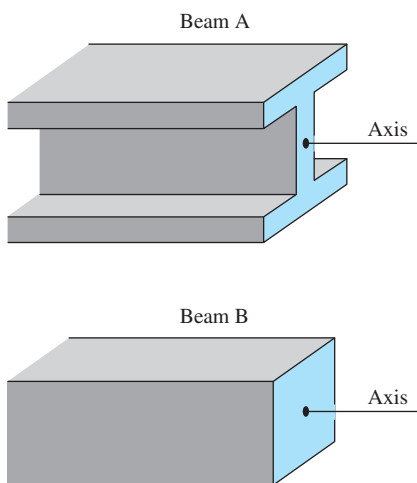

FIGURE 14.44 The greater the polar moment of inertia of the cross-section of a beam about the beam's longitudinal axis, the stiffer the beam. Beams A and B have the same cross-sectional area, but A is stiffer.

The moment of inertia also plays a role in determining how much a horizontal metal beam will bend under a load. The stiffness of the beam is a constant times I , the moment of inertia of a typical cross-section of the beam about the beam's longitudinal axis. The greater the value of I , the stiffer the beam and the less it will bend under a given load. That is why we use I-beams instead of beams whose cross-sections are square. The flanges at the top and bottom of the beam hold most of the beam's mass away from the longitudinal axis to increase the value of I (Figure 14.44).

Probability

The probability that a continuous random variable X takes values between a and b is found by integrating a probability density function f (Appendix A.8),

$$P(a \leq X \leq b) = \int_a^b f(x) dx.$$

A similar process applies to probabilities involving two continuous random variables. The probability that a pair of random variables (X, Y) takes values lying within a particular

region is determined by a *joint probability density function* f . Integrating the joint probability density function over a region R in the plane gives the probability that the pair of random variables take values in that region:

$$P((X, Y) \in R) = \iint_R f(x, y) dx dy.$$

If the region is a rectangle, then this expression has the simple form

$$P(a \leq X \leq b \text{ and } c \leq Y \leq d) = \int_c^d \int_a^b f(x, y) dx dy.$$

A joint probability density function f is defined by three basic properties. The first property ensures that there are no negative probabilities, and the second implies that the total probability of all possible outcomes is one. The final property describes the connection of f to probabilities.

DEFINITION A **joint probability density function** f is a function that satisfies three conditions:

1. $f(x, y) \geq 0$
2. $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) dx dy = 1$
3. $P((X, Y) \in R) = \iint_R f(x, y) dx dy.$

A pair of random variables has a *uniform* distribution on a region R with finite area A if $f(x, y) = 1/A$ for any $(x, y) \in R$, and $f(x, y) = 0$ otherwise.

EXAMPLE 5 A random number generator is used to generate two random real numbers X and Y in succession. The first number X is chosen between 0 and 10, and the second number Y is chosen between 0 and 5. The random number generation is done by a process that gives a uniform distribution. Find the joint probability density function f for the pair of numbers (X, Y) and use it to compute the probability that X is larger than Y .

Solution The joint probability density function f is constant on the rectangle $0 \leq x \leq 10$, $0 \leq y \leq 5$, because (X, Y) is uniformly distributed. The area of the rectangle is 50, so f takes the value $1/50$ inside this rectangle:

$$f(x, y) = \begin{cases} 1/50, & \text{if } 0 \leq x \leq 10 \text{ and } 0 \leq y \leq 5, \\ 0, & \text{otherwise.} \end{cases}$$

To compute the probability that $X > Y$, we integrate the joint probability density function f over the region in the rectangle where $X > Y$. This region is bounded on the left by the line $x = y$ and on the right by the line $x = 10$. An integral over this region has limits of integration given by $y \leq x \leq 10$, $0 \leq y \leq 5$ (see Figure 14.45). The probability is given by

$$P(X > Y) = \int_0^5 \int_y^{10} \frac{1}{50} dx dy = \frac{3}{4}.$$

There is a 75% probability that the first number is larger than the second. ■

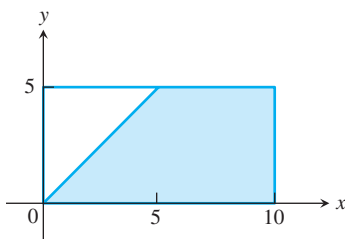

FIGURE 14.45 The pair of random variables X and Y take values anywhere in this rectangle with equal probability. In the shaded region we have $X > Y$.

EXAMPLE 6 Using the joint probability density function

$$f(x, y) = \begin{cases} e^{-(x+y)}, & \text{if } 0 < x \text{ and } 0 < y \\ 0, & \text{otherwise} \end{cases}$$

find the probability that $1 < X < 2$ and $2 < Y < 3$.

Solution

$$P(1 < X < 2, 2 < Y < 3) = \int_2^3 \int_1^2 e^{-(x+y)} dx dy = e^{-5} + e^{-3} - 2e^{-4} \approx 0.01989.$$

There is slightly less than a 2% probability that X and Y fall within these bounds. ■

Means and Expected Values

The mean, or expected value, of a random variable is (Appendix A.8)

$$\mu = \int_{-\infty}^{\infty} x f(x) dx.$$

When X and Y have joint probability density function f , the expected value of X and the expected value of Y are

$$\mu_X = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x f(x, y) dx dy \quad \text{and} \quad \mu_Y = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} y f(x, y) dx dy.$$

These indicate the average value expected for each of X and Y . The expected values μ_X and μ_Y are sometimes called the first moments of the distribution, because their defining formulas have the same form as those seen in Table 14.1 for the moments of a two-dimensional plate. The joint probability density function plays the role in computing μ_X that the mass density function plays in computing the x -coordinate \bar{x} of the center of mass, and the same applies to μ_Y and \bar{y} . One can roughly think of the joint probability density function as measuring the probability concentration per unit area on the plane, just as density measures the mass per unit area for a plate.

EXAMPLE 7 Find the expected values μ_X and μ_Y for the joint probability density function in Example 5.

Solution For the joint probability density function in Example 5, we compute

$$\mu_X = \int_0^5 \int_0^{10} x(1/50) dx dy = 5$$

and

$$\mu_Y = \int_0^5 \int_0^{10} y(1/50) dx dy = 2.5.$$

The expected value of X is 5 and that of Y is 2.5. ■

EXERCISES 14.6

Plates of Constant Density

- Finding a center of mass** Find the center of mass of a thin plate of density $\delta = 3$ bounded by the lines $x = 0$, $y = x$, and the parabola $y = 2 - x^2$ in the first quadrant.
- Finding moments of inertia** Find the moments of inertia about the coordinate axes of a thin rectangular plate of constant density

δ gm/cm² bounded by the lines $x = 3$ and $y = 3$ in the first quadrant.

- Finding a centroid** Find the centroid of the region in the first quadrant bounded by the x -axis, the parabola $y^2 = 2x$, and the line $x + y = 4$.

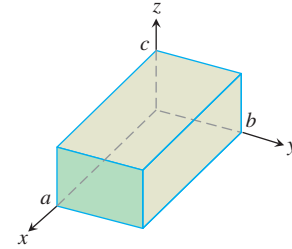

4. **Finding a centroid** Find the centroid of the triangular region cut from the first quadrant by the line $x + y = 3$.
5. **Finding a centroid** Find the centroid of the region cut from the first quadrant by the circle $x^2 + y^2 = a^2$.
6. **Finding a centroid** Find the centroid of the region between the x -axis and the arch $y = \sin x$, $0 \leq x \leq \pi$.
7. **Finding moments of inertia** Find the moment of inertia about the x -axis of a thin plate of density $\delta = 1 \text{ gm/cm}^2$ bounded by the circle $x^2 + y^2 = 4$. Then use your result to find I_y and I_0 for the plate.
8. **Finding a moment of inertia** Find the moment of inertia with respect to the y -axis of a thin sheet of constant density $\delta = 1 \text{ gm/cm}^2$ bounded by the curve $y = (\sin^2 x)/x^2$ and the interval $\pi \leq x \leq 2\pi$ of the x -axis.
9. **The centroid of an infinite region** Find the centroid of the infinite region in the second quadrant enclosed by the coordinate axes and the curve $y = e^x$. (Use improper integrals in the mass-moment formulas.)
10. **The first moment of an infinite plate** Find the first moment about the y -axis of a thin plate of density $\delta(x, y) = 1$ covering the infinite region under the curve $y = e^{-x^2/2}$ in the first quadrant.

Plates with Varying Density

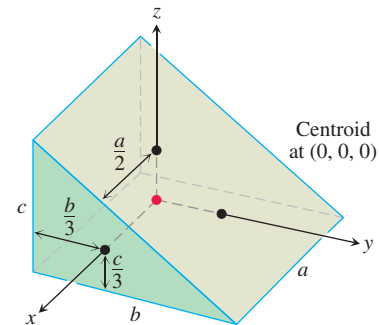

11. **Finding a moment of inertia** Find the moment of inertia about the x -axis of a thin plate bounded by the parabola $x = y - y^2$ and the line $x + y = 0$ if $\delta(x, y) = x + y$.
12. **Finding mass** Find the mass of a thin plate occupying the smaller region cut from the ellipse $x^2 + 4y^2 = 12$ by the parabola $x = 4y^2$ if $\delta(x, y) = 5x \text{ kg/m}^2$.
13. **Finding a center of mass** Find the center of mass of a thin triangular plate bounded by the y -axis and the lines $y = x$ and $y = 2 - x$ if $\delta(x, y) = 6x + 3y + 3$.
14. **Finding a center of mass and moment of inertia** Find the center of mass and moment of inertia about the x -axis of a thin plate bounded by the curves $x = y^2$ and $x = 2y - y^2$ if the density at the point (x, y) is $\delta(x, y) = y + 1$.
15. **Center of mass, moment of inertia** Find the center of mass and the moment of inertia about the y -axis of a thin rectangular plate cut from the first quadrant by the lines $x = 6$ and $y = 1$ if $\delta(x, y) = x + y + 1$.
16. **Center of mass, moment of inertia** Find the center of mass and the moment of inertia about the y -axis of a thin plate bounded by the line $y = 1$ and the parabola $y = x^2$ if the density is $\delta(x, y) = y + 1$.
17. **Center of mass, moment of inertia** Find the center of mass and the moment of inertia about the y -axis of a thin plate bounded by the x -axis, the lines $x = \pm 1$, and the parabola $y = x^2$ if $\delta(x, y) = 7y + 1$.
18. **Center of mass, moments of inertia** Find the center of mass and the moments of inertia about the x -axis of a thin rectangular plate bounded by the lines $x = 0$, $x = 20$, $y = -1$, and $y = 1$ if $\delta(x, y) = 1 + (x/20)$.
19. **Center of mass, moments of inertia** Find the center of mass, the moment of inertia about the coordinate axes, and the polar moment of inertia of a thin triangular plate bounded by the lines $y = x$, $y = -x$, and $y = 1$ if $\delta(x, y) = y + 1 \text{ kg/m}^2$.
20. **Center of mass, moments of inertia** Repeat Exercise 19 for $\delta(x, y) = 3x^2 + 1 \text{ kg/m}^2$.

Solids with Constant Density

21. **Moments of inertia** Find the moments of inertia of the rectangular box of constant density $\delta(x, y, z) = 1$ shown here with respect to its edges by calculating I_x , I_y , and I_z .

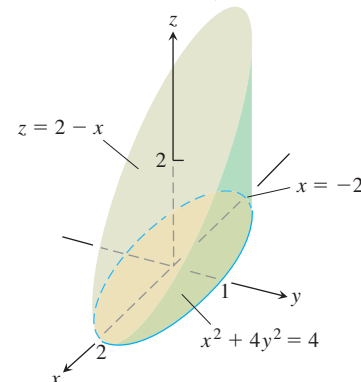

22. **Moments of inertia** The coordinate axes in the figure run through the centroid of a solid wedge parallel to the labeled edges. Find I_x , I_y , and I_z if $a = b = 6$, $c = 4$, and the density is $\delta(x, y, z) = 1$.

23. **Center of mass and moments of inertia** A solid “trough” of constant density $\delta(x, y, z) = 1$ is bounded below by the surface $z = 4y^2$, above by the plane $z = 4$, and on the ends by the planes $x = 1$ and $x = -1$. Find the center of mass and the moments of inertia with respect to the three axes.
24. **Center of mass** A solid of constant density is bounded below by the plane $z = 0$, on the sides by the elliptical cylinder $x^2 + 4y^2 = 4$, and above by the plane $z = 2 - x$ (see the accompanying figure).
 - a. Find \bar{x} and \bar{y} .
 - b. Evaluate the integral

$$M_{xy} = \int_{-2}^2 \int_{-(1/2)\sqrt{4-x^2}}^{(1/2)\sqrt{4-x^2}} \int_0^{2-x} z \, dz \, dy \, dx,$$

using integral tables to carry out the final integration with respect to x . Then divide M_{xy} by M to verify that $\bar{z} = 5/4$.

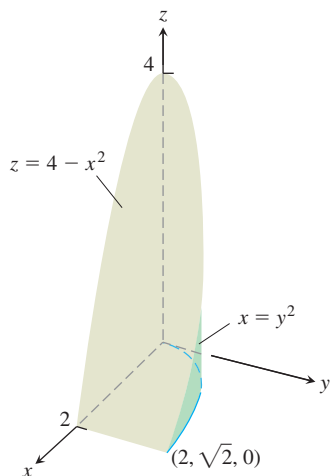

- 25. a. Center of mass** Find the center of mass of a solid of constant density bounded below by the paraboloid $z = x^2 + y^2$ and above by the plane $z = 4$.
- b.** Find the plane $z = c$ that divides the solid into two parts of equal volume. This plane does not pass through the center of mass.
- 26. Moments** A solid cube of constant density $\delta(x, y, z) = 1$, 2 units on a side, is bounded by the planes $x = \pm 1$, $z = \pm 1$, $y = 3$, and $y = 5$. Find the center of mass and the moments of inertia about the coordinate axes.
- 27. Moment of inertia about a line** A wedge like the one in Exercise 22 has $a = 4$, $b = 6$, $c = 3$, and a constant density $\delta(x, y, z) = 1$. Make a quick sketch to check for yourself that the square of the distance from a typical point (x, y, z) of the wedge to the line $L: z = 0, y = 6$ is $r^2 = (y - 6)^2 + z^2$. Then calculate the moment of inertia of the wedge about L .
- 28. Moment of inertia about a line** A wedge like the one in Exercise 22 has $a = 4$, $b = 6$, $c = 3$, and a constant density $\delta(x, y, z) = 1$. Make a quick sketch to check for yourself that the square of the distance from a typical point (x, y, z) of the wedge to the line $L: x = 4, y = 0$ is $r^2 = (x - 4)^2 + y^2$. Then calculate the moment of inertia of the wedge about L .

Solids with Varying Density

In Exercises 29 and 30, find

- a.** the mass of the solid. **b.** the center of mass.
- 29.** A solid region in the first octant is bounded by the coordinate planes and the plane $x + y + z = 2$. The density of the solid is $\delta(x, y, z) = 2x \text{ gm/cm}^3$.
- 30.** A solid in the first octant is bounded by the planes $y = 0$ and $z = 0$ and by the surfaces $z = 4 - x^2$ and $x = y^2$ (see the accompanying figure). Its density function is $\delta(x, y, z) = kxy$, k a constant.

In Exercises 31 and 32, find

- a.** the mass of the solid.
b. the center of mass.
c. the moments of inertia about the coordinate axes.

- 31.** A solid cube in the first octant is bounded by the coordinate planes and by the planes $x = 1$, $y = 1$, and $z = 1$. The density of the cube is $\delta(x, y, z) = x + y + z + 1$.
- 32.** A wedge like the one in Exercise 22 has dimensions $a = 2$, $b = 6$, and $c = 3$. The density is $\delta(x, y, z) = x + 1$. Notice that if the density is constant, the center of mass will be $(0, 0, 0)$.
- 33. Mass** Find the mass of the solid bounded by the planes $x + z = 1$, $x - z = -1$, $y = 0$, and the surface $y = \sqrt{z}$. The density of the solid is $\delta(x, y, z) = 2y + 5 \text{ kg/m}^3$.
- 34. Mass** Find the mass of the solid region bounded by the parabolic surfaces $z = 16 - 2x^2 - 2y^2$ and $z = 2x^2 + 2y^2$ if the density of the solid is $\delta(x, y, z) = \sqrt{x^2 + y^2}$.

Theory and Examples

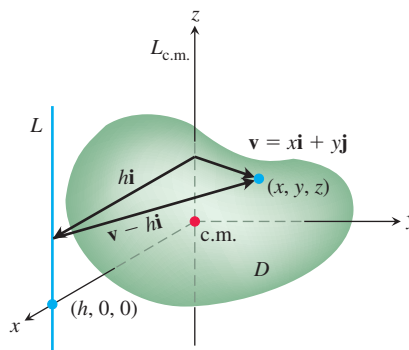

The Parallel Axis Theorem Let $L_{c.m.}$ be a line through the center of mass of a body of mass m and let L be a parallel line h units away from $L_{c.m.}$. The *Parallel Axis Theorem* says that the moments of inertia $I_{c.m.}$ and I_L of the body about $L_{c.m.}$ and L satisfy the equation

$$I_L = I_{c.m.} + mh^2. \quad (2)$$

As in the two-dimensional case, the theorem gives a quick way to calculate one moment when the other moment and the mass are known.

35. Proof of the Parallel Axis Theorem

- a.** Show that the first moment of a body in space about any plane through the body's center of mass is zero. (*Hint:* Place the body's center of mass at the origin and let the plane be the yz -plane. What does the formula $\bar{x} = M_{yz}/M$ then tell you?)

- b.** To prove the Parallel Axis Theorem, place the body with its center of mass at the origin, with the line $L_{c.m.}$ along the z -axis and the line L perpendicular to the xy -plane at the point $(h, 0, 0)$. Let D be the region of space occupied by the body. Then, in the notation of the figure,

$$I_L = \iiint_D |\mathbf{v} - h\mathbf{i}|^2 dm.$$

Expand the integrand in this integral and complete the proof.

- 36.** The moment of inertia about a diameter of a solid sphere of constant density and radius a is $(2/5)ma^2$, where m is the mass of the sphere. Find the moment of inertia about a line tangent to the sphere.
- 37.** The moment of inertia of the solid in Exercise 21 about the z -axis is $I_z = abc(a^2 + b^2)/3$.
- a.** Use Equation (2) to find the moment of inertia of the solid about the line parallel to the z -axis through the solid's center of mass.

b. Use Equation (2) and the result in part (a) to find the moment of inertia of the solid about the line $x = 0$, $y = 2b$.

38. If $a = b = 6$ and $c = 4$, the moment of inertia of the solid wedge in Exercise 22 about the x -axis is $I_x = 208$. Find the moment of inertia of the wedge about the line $y = 4$, $z = -4/3$ (the edge of the wedge's narrow end).

Joint Probability Density Functions

For Exercises 39–42, verify that f gives a joint probability density function. Then find the expected values μ_x and μ_y .

39. $f(x, y) = \begin{cases} x + y, & \text{if } 0 \leq x \leq 1 \text{ and } 0 \leq y \leq 1, \\ 0, & \text{otherwise.} \end{cases}$

40. $f(x, y) = \begin{cases} 4xy, & \text{if } 0 \leq x \leq 1 \text{ and } 0 \leq y \leq 1, \\ 0, & \text{otherwise.} \end{cases}$

41. $f(x, y) = \begin{cases} 6x^2y, & \text{if } 0 \leq x \leq 1 \text{ and } 0 \leq y \leq 1, \\ 0, & \text{otherwise.} \end{cases}$

42. $f(x, y) = \begin{cases} \frac{3}{2}(x^2 + y^2), & \text{if } 0 \leq x \leq 1 \text{ and } 0 \leq y \leq 1, \\ 0, & \text{otherwise.} \end{cases}$

43. Suppose that f is a uniform joint probability density function on $0 \leq x < 2$, $0 \leq y < 3$. What is the formula for f ? What is the probability that $X < Y$?

44. The following formula defines a joint probability density function. What is the value of C ? What are the expected values μ_x and μ_y ?

$$f(x, y) = \begin{cases} Cxy, & \text{if } 0 \leq x \leq 2 \text{ and } 0 \leq y \leq 3, \\ 0, & \text{otherwise.} \end{cases}$$

14.7 Triple Integrals in Cylindrical and Spherical Coordinates

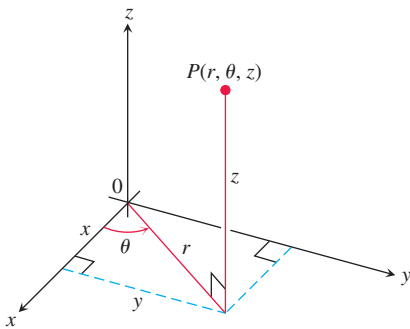

FIGURE 14.46 The cylindrical coordinates of a point in space are r , θ , and z .

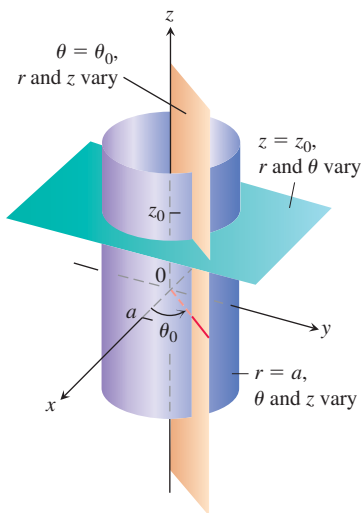

FIGURE 14.47 Constant-coordinate equations in cylindrical coordinates yield cylinders and planes.

When a calculation in physics, engineering, or geometry involves a cylinder, cone, or sphere, we can often simplify our work by using cylindrical or spherical coordinates, which are introduced in this section. The procedure for transforming to these coordinates and evaluating the resulting triple integrals is similar to the transformation to polar coordinates in the plane discussed in Section 14.4.

Integration in Cylindrical Coordinates

We obtain cylindrical coordinates for space by combining polar coordinates in the xy -plane with the usual z -axis. This assigns to every point in space coordinate triples of the form (r, θ, z) , as shown in Figure 14.46. Here we require $r \geq 0$.

DEFINITION Cylindrical coordinates represent a point P in space by ordered triples (r, θ, z) in which

1. r and θ are polar coordinates for the vertical projection of P on the xy -plane, with $r \geq 0$, and
2. z is the rectangular vertical coordinate.

The values of x , y , r , and θ in rectangular and cylindrical coordinates are related by the usual equations.

Equations Relating Rectangular (x, y, z) and Cylindrical (r, θ, z) Coordinates

$$\begin{aligned} x &= r \cos \theta, & y &= r \sin \theta, & z &= z, \\ r^2 &= x^2 + y^2, & \tan \theta &= y/x \end{aligned}$$

In cylindrical coordinates, the equation $r = a$ describes not just a circle in the xy -plane but an entire cylinder about the z -axis (Figure 14.47). The z -axis is given by $r = 0$. The equation $\theta = \theta_0$ describes the half-plane that contains the z -axis and makes an angle θ_0 with the positive x -axis. And, just as in rectangular coordinates, the equation $z = z_0$ describes a plane perpendicular to the z -axis.

Cylindrical coordinates are good for describing cylinders whose axes run along the z -axis and planes that either contain the z -axis or lie perpendicular to the z -axis. Surfaces like these have equations of constant coordinate value:

$$r = 4 \quad \text{Cylinder, radius 4, axis the } z\text{-axis}$$

$$\theta = \frac{\pi}{3} \quad \text{Half-plane containing the } z\text{-axis}$$

$$z = 2. \quad \text{Plane perpendicular to the } z\text{-axis}$$

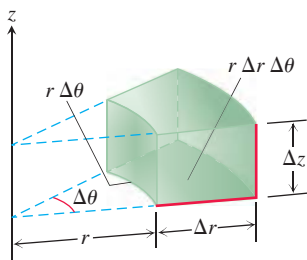

FIGURE 14.48 In cylindrical coordinates the volume of the wedge is approximated by the product $\Delta V = r \Delta z \Delta r \Delta \theta$.

When computing triple integrals over a solid region D in cylindrical coordinates, we partition the region into n small cylindrical wedges, rather than into rectangular boxes. In the k th cylindrical wedge, r , θ , and z change by Δr_k , $\Delta \theta_k$, and Δz_k , and the largest of these numbers among all the cylindrical wedges is called the **norm** of the partition. We express the triple integral as a limit of Riemann sums using these wedges. The volume of such a cylindrical wedge ΔV_k is obtained by taking the area ΔA_k of its base in the $r\theta$ -plane and multiplying by the height Δz_k (Figure 14.48).

For a point (r_k, θ_k, z_k) in the center of the k th wedge, we calculated in polar coordinates that $\Delta A_k = r_k \Delta r_k \Delta \theta_k$. So $\Delta V_k = \Delta z_k r_k \Delta r_k \Delta \theta_k = r_k \Delta z_k \Delta r_k \Delta \theta_k$, and a Riemann sum for f over D has the form

$$S_n = \sum_{k=1}^n f(r_k, \theta_k, z_k) r_k \Delta z_k \Delta r_k \Delta \theta_k.$$

The triple integral of a function f over D is obtained by taking a limit of such Riemann sums with partitions whose norms approach zero:

Volume Differential in Cylindrical Coordinates

$$dV = r \, dz \, dr \, d\theta$$

$$\lim_{n \rightarrow \infty} S_n = \iiint_D f \, dV = \iiint_D f \, r \, dz \, dr \, d\theta.$$

Triple integrals in cylindrical coordinates are then evaluated as iterated integrals, as in the following example. Although the definition of cylindrical coordinates makes sense without any restrictions on θ , in most situations when integrating, we will need to restrict θ to an interval of length 2π . So we impose the requirement that $\alpha \leq \theta \leq \beta$, where $0 \leq \beta - \alpha \leq 2\pi$.

EXAMPLE 1 Find the limits of integration in cylindrical coordinates for integrating a function $f(r, \theta, z)$ over the solid region D bounded below by the plane $z = 0$, laterally by the circular cylinder $x^2 + (y - 1)^2 = 1$, and above by the paraboloid $z = x^2 + y^2$.

Solution The base of D is also the region's projection R on the xy -plane. The boundary of R is the circle $x^2 + (y - 1)^2 = 1$. Its polar coordinate equation is

$$\begin{aligned} x^2 + (y - 1)^2 &= 1 \\ x^2 + y^2 - 2y + 1 &= 1 \\ r^2 - 2r \sin \theta &= 0 \\ r &= 2 \sin \theta. \end{aligned}$$

The region is sketched in Figure 14.49.

We find the limits of integration, starting with the z -limits. A line M through a typical point (r, θ) in R parallel to the z -axis enters D at $z = 0$ and leaves at $z = x^2 + y^2 = r^2$.

Next we find the r -limits of integration. A ray L through (r, θ) from the origin enters R at $r = 0$ and leaves at $r = 2 \sin \theta$.

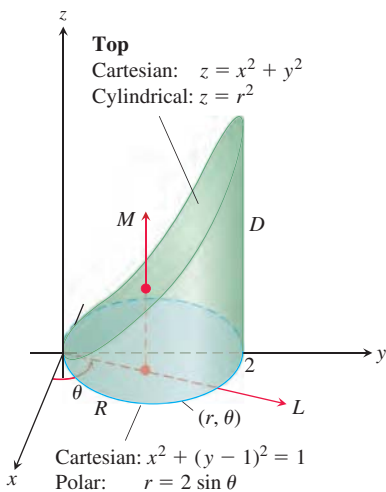

FIGURE 14.49 Finding the limits of integration for evaluating an integral in cylindrical coordinates (Example 1).

Finally, we find the θ -limits of integration. As L sweeps across R , the angle θ it makes with the positive x -axis runs from $\theta = 0$ to $\theta = \pi$. The integral is

$$\iiint_D f(r, \theta, z) dV = \int_0^\pi \int_0^{2 \sin \theta} \int_0^{r^2} f(r, \theta, z) r dz dr d\theta. \quad \blacksquare$$

Example 1 illustrates a good procedure for finding limits of integration in cylindrical coordinates. The procedure is summarized as follows.

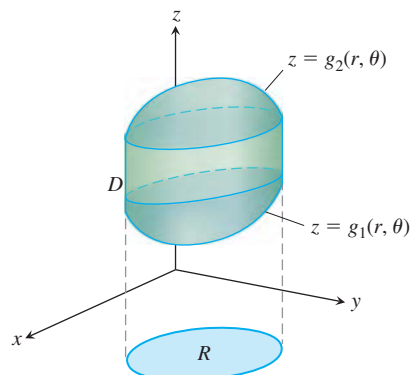

How to Integrate in Cylindrical Coordinates

To evaluate

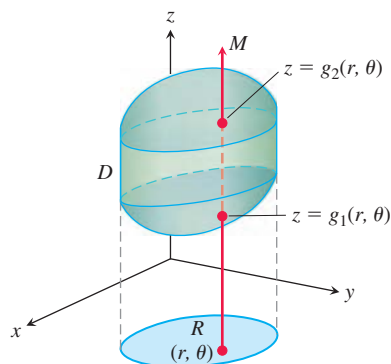

$$\iiint_D f(r, \theta, z) dV$$

over a solid region D in space in cylindrical coordinates, integrating first with respect to z , then with respect to r , and finally with respect to θ , take the following steps.

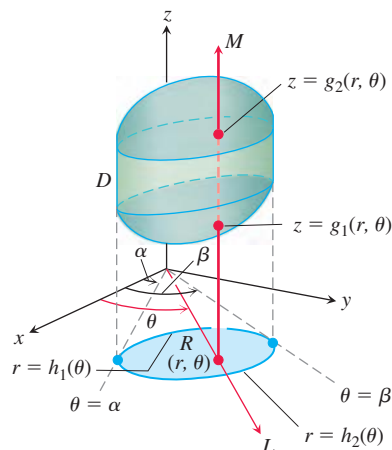

1. *Sketch.* Sketch the solid region D along with its projection R on the xy -plane. Label the surfaces and curves that bound D and R .

2. *Find the z -limits of integration.* Draw a line M through a typical point (r, θ) of R parallel to the z -axis. As z increases, M enters D at $z = g_1(r, \theta)$ and leaves at $z = g_2(r, \theta)$. These are the z -limits of integration.

3. Find the r -limits of integration. Draw a ray L through (r, θ) from the origin. The ray enters R at $r = h_1(\theta)$ and leaves at $r = h_2(\theta)$. These are the r -limits of integration.

4. Find the θ -limits of integration. As L sweeps across R , the angle θ it makes with the positive x -axis runs from $\theta = \alpha$ to $\theta = \beta$. These are the θ -limits of integration. The integral is

$$\iiint_D f(r, \theta, z) dV = \int_{\theta=\alpha}^{\theta=\beta} \int_{r=h_1(\theta)}^{r=h_2(\theta)} \int_{z=g_1(r, \theta)}^{z=g_2(r, \theta)} f(r, \theta, z) r dz dr d\theta.$$

EXAMPLE 2 Find the centroid ($\delta = 1$) of the solid enclosed by the cylinder $x^2 + y^2 = 4$, bounded above by the paraboloid $z = x^2 + y^2$, and bounded below by the xy -plane.

Solution We sketch the solid, bounded above by the paraboloid $z = r^2$ and below by the plane $z = 0$ (Figure 14.50). Its base R is the disk $0 \leq r \leq 2$ in the xy -plane.

The solid's centroid $(\bar{x}, \bar{y}, \bar{z})$ lies on its axis of symmetry, here the z -axis. This makes $\bar{x} = \bar{y} = 0$. To find \bar{z} , we divide the first moment M_{xy} by the mass M .

To find the limits of integration for the mass and moment integrals, we continue with the four basic steps. We completed our initial sketch. The remaining steps give the limits of integration.

The z -limits. A line M through a typical point (r, θ) in the base parallel to the z -axis enters the solid at $z = 0$ and leaves at $z = r^2$.

The r -limits. A ray L through (r, θ) from the origin enters R at $r = 0$ and leaves at $r = 2$.

The θ -limits. As L sweeps over the base like a clock hand, the angle θ it makes with the positive x -axis runs from $\theta = 0$ to $\theta = 2\pi$. The value of M_{xy} is

$$\begin{aligned} M_{xy} &= \int_0^{2\pi} \int_0^2 \int_0^{r^2} z r dz dr d\theta = \int_0^{2\pi} \int_0^2 \left[\frac{z^2}{2} \right]_{z=0}^{z=r^2} r dr d\theta \\ &= \int_0^{2\pi} \int_0^2 \frac{r^5}{2} dr d\theta = \int_0^{2\pi} \left[\frac{r^6}{12} \right]_{r=0}^{r=2} d\theta = \int_0^{2\pi} \frac{16}{3} d\theta = \frac{32\pi}{3}. \end{aligned}$$

The value of M is

$$\begin{aligned} M &= \int_0^{2\pi} \int_0^2 \int_0^{r^2} r dz dr d\theta = \int_0^{2\pi} \int_0^2 \left[z \right]_{z=0}^{z=r^2} r dr d\theta \\ &= \int_0^{2\pi} \int_0^2 r^3 dr d\theta = \int_0^{2\pi} \left[\frac{r^4}{4} \right]_{r=0}^{r=2} d\theta = \int_0^{2\pi} 4 d\theta = 8\pi. \end{aligned}$$

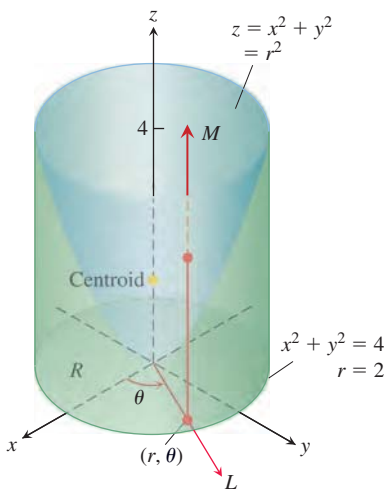

FIGURE 14.50 Example 2 shows how to find the centroid of this solid.

Therefore,

$$\bar{z} = \frac{M_{xy}}{M} = \frac{32\pi}{3} \frac{1}{8\pi} = \frac{4}{3},$$

and the centroid is $(0, 0, 4/3)$. Notice that the centroid lies on the z -axis, outside the solid. ■

Spherical Coordinates and Integration

Spherical coordinates locate points in space with two angles and one distance, as shown in Figure 14.51. The first coordinate, $\rho = |\overline{OP}|$, is the point's distance from the origin and is never negative. The second coordinate, ϕ , is the angle \overline{OP} makes with the positive z -axis. It is required to lie in the interval $[0, \pi]$. The third coordinate is the angle θ as measured in cylindrical coordinates.

ϕ is the Greek letter phi, pronounced “fee.”

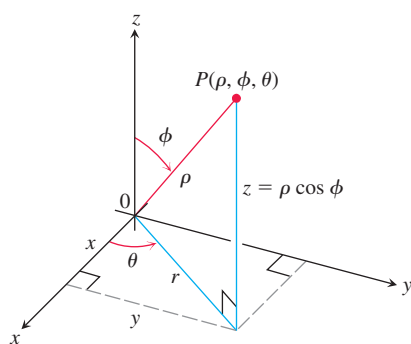

FIGURE 14.51 The spherical coordinates ρ , ϕ , and θ and their relation to x , y , z , and r .

DEFINITION Spherical coordinates represent a point P in space by ordered triples (ρ, ϕ, θ) in which

1. ρ is the distance from P to the origin ($\rho \geq 0$).
2. ϕ is the angle \overline{OP} makes with the positive z -axis ($0 \leq \phi \leq \pi$).
3. θ is the angle from cylindrical coordinates.

On maps of Earth, θ is related to the longitude of a point on the planet and ϕ to its latitude, while ρ is related to elevation above Earth's surface.

The equation $\rho = a$ describes the sphere of radius a centered at the origin (Figure 14.52). The equation $\phi = \phi_0$ describes a single cone whose vertex lies at the origin and whose axis lies along the z -axis. (We broaden our interpretation to include the xy -plane as the cone $\phi = \pi/2$.) If ϕ_0 is greater than $\pi/2$, the cone $\phi = \phi_0$ opens downward. The equation $\theta = \theta_0$ describes the half-plane that contains the z -axis and makes an angle θ_0 with the positive x -axis.

Equations Relating Spherical Coordinates to Cartesian and Cylindrical Coordinates

$$\begin{aligned} r &= \rho \sin \phi, & x &= r \cos \theta = \rho \sin \phi \cos \theta, \\ z &= \rho \cos \phi, & y &= r \sin \theta = \rho \sin \phi \sin \theta, \\ \rho &= \sqrt{x^2 + y^2 + z^2} = \sqrt{r^2 + z^2}. \end{aligned} \quad (1)$$

EXAMPLE 3 Find a spherical coordinate equation for the sphere $x^2 + y^2 + (z - 1)^2 = 1$.

Solution We use Equations (1) to substitute for x , y , and z :

$$\begin{aligned} x^2 + y^2 + (z - 1)^2 &= 1 \\ \rho^2 \sin^2 \phi \cos^2 \theta + \rho^2 \sin^2 \phi \sin^2 \theta + (\rho \cos \phi - 1)^2 &= 1 && \text{Eqs. (1)} \\ \rho^2 \sin^2 \phi (\underbrace{\cos^2 \theta + \sin^2 \theta}_1) + \rho^2 \cos^2 \phi - 2\rho \cos \phi + 1 &= 1 \\ \rho^2 (\underbrace{\sin^2 \phi + \cos^2 \phi}_1) &= 2\rho \cos \phi \end{aligned}$$

$$\begin{aligned} \rho^2 &= 2\rho \cos \phi \\ \rho &= 2 \cos \phi. \quad \text{Includes } \rho = 0 \end{aligned}$$

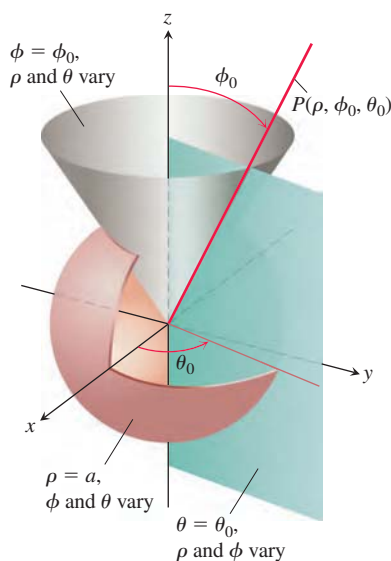

FIGURE 14.52 Constant-coordinate equations in spherical coordinates yield spheres, single cones, and half-planes.

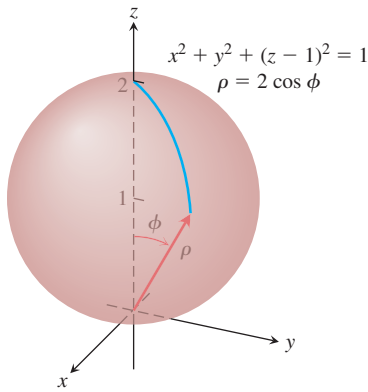

FIGURE 14.53 The sphere in Example 3.

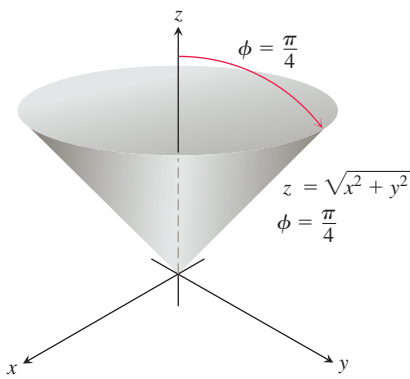

FIGURE 14.54 The cone in Example 4.

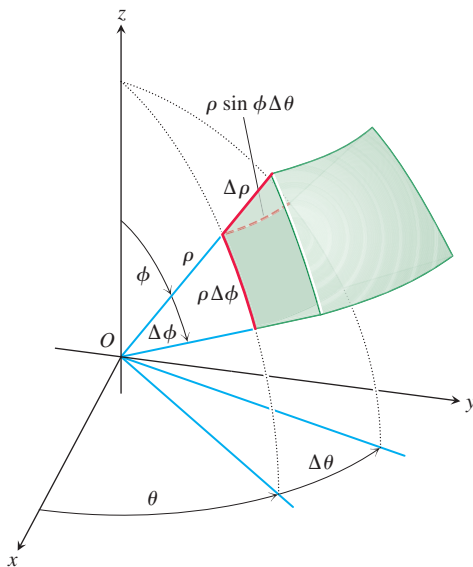

FIGURE 14.55 In spherical coordinates we use the volume of a spherical wedge, which closely approximates that of a rectangular box.

Volume Differential in Spherical Coordinates

$$dV = \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$$

The angle ϕ varies from 0 at the north pole of the sphere to $\pi/2$ at the south pole; the angle θ does not appear in the expression for ρ , reflecting the symmetry about the z -axis (see Figure 14.53). ■

EXAMPLE 4 Find a spherical coordinate equation for the cone $z = \sqrt{x^2 + y^2}$.

Solution 1 Use geometry. The cone is symmetric with respect to the z -axis and cuts the first quadrant of the yz -plane along the line $z = y$. The angle between the cone and the positive z -axis is therefore $\pi/4$ radians. The cone consists of the points whose spherical coordinates have ϕ equal to $\pi/4$, so its equation is $\phi = \pi/4$. (See Figure 14.54.)

Solution 2 Use algebra. If we use Equations (1) to substitute for x , y , and z , we obtain the same result:

$$\begin{aligned} z &= \sqrt{x^2 + y^2} \\ \rho \cos \phi &= \sqrt{\rho^2 \sin^2 \phi} && \text{Example 3} \\ \rho \cos \phi &= \rho \sin \phi && \rho \geq 0, \sin \phi \geq 0 \\ \cos \phi &= \sin \phi && \text{Includes } \rho = 0 \text{ (the origin)} \\ \phi &= \frac{\pi}{4}. && 0 \leq \phi \leq \pi \end{aligned}$$

Spherical coordinates are useful for describing spheres centered at the origin, half-planes hinged along the z -axis, and cones whose vertices lie at the origin and whose axes lie along the z -axis. Surfaces like these have equations of constant coordinate value:

$$\begin{aligned} \rho &= 4 && \text{Sphere, radius 4, center at origin} \\ \phi &= \frac{2\pi}{3} && \text{Cone opening down from the origin, making an} \\ &&& \text{angle of } 2\pi/3 \text{ radians with the positive } z\text{-axis} \\ \theta &= \frac{\pi}{3}. && \text{Half-plane, hinged along the } z\text{-axis, making an} \\ &&& \text{angle of } \pi/3 \text{ radians with the positive } x\text{-axis} \end{aligned}$$

When computing triple integrals over a solid region D in spherical coordinates, we partition the region into n spherical wedges. The size of the k th spherical wedge, which contains a point $(\rho_k, \phi_k, \theta_k)$, is given by the changes $\Delta\rho_k$, $\Delta\phi_k$, and $\Delta\theta_k$ in ρ , ϕ , and θ . Such a spherical wedge has one edge a circular arc of length $\rho_k \Delta\phi_k$, another edge a circular arc of length $\rho_k \sin \phi_k \Delta\theta_k$, and thickness $\Delta\rho_k$. The spherical wedge closely approximates a rectangular box of these dimensions when $\Delta\rho_k$, $\Delta\phi_k$, and $\Delta\theta_k$ are all small (Figure 14.55). It can be shown that the volume of this spherical wedge ΔV_k is $\Delta V_k = \rho_k^2 \sin \phi_k \Delta\rho_k \Delta\phi_k \Delta\theta_k$ for $(\rho_k, \phi_k, \theta_k)$, a point chosen inside the wedge.

The corresponding Riemann sum for a function $f(\rho, \phi, \theta)$ is

$$S_n = \sum_{k=1}^n f(\rho_k, \phi_k, \theta_k) \rho_k^2 \sin \phi_k \Delta\rho_k \Delta\phi_k \Delta\theta_k.$$

As the norm of a partition approaches zero, and the spherical wedges get smaller, the limit of the Riemann sums is the triple integral:

$$\lim_{n \rightarrow \infty} S_n = \iiint_D f(\rho, \phi, \theta) \, dV = \iiint_D f(\rho, \phi, \theta) \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta.$$

To evaluate integrals in spherical coordinates, we usually integrate first with respect to ρ . The procedure for finding the limits of integration is as follows. As with cylindrical coordinates, we restrict θ in the form $\alpha \leq \theta \leq \beta$ and $0 \leq \beta - \alpha \leq 2\pi$.

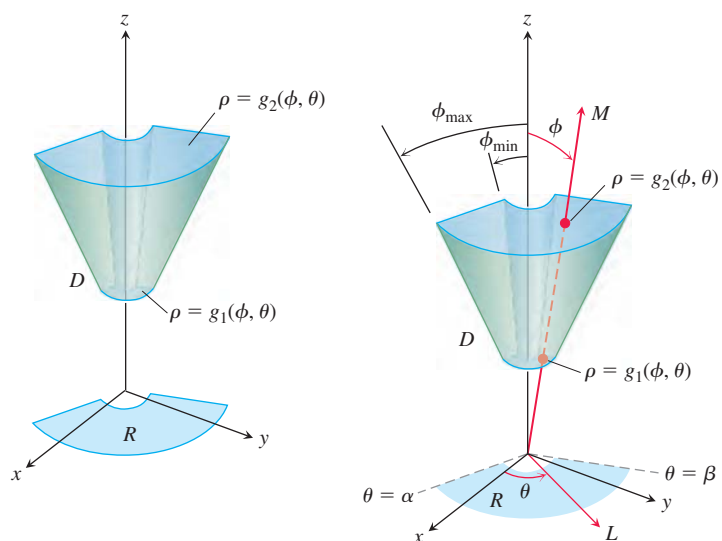

How to Integrate in Spherical Coordinates

To evaluate

$$\iiint_D f(\rho, \phi, \theta) dV$$

over a solid region D in space in spherical coordinates, integrating first with respect to ρ , then with respect to ϕ , and finally with respect to θ , take the following steps.

1. *Sketch.* Sketch the solid region D along with its projection R on the xy -plane. Label the surfaces that bound D .

2. *Find the ρ -limits of integration.* Draw a ray M from the origin through D , making an angle ϕ with the positive z -axis. Also draw the projection of M on the xy -plane (call the projection L). The ray L makes an angle θ with the positive x -axis. As ρ increases, M enters D at $\rho = g_1(\phi, \theta)$ and leaves at $\rho = g_2(\phi, \theta)$. These are the ρ -limits of integration shown in the above figure.
3. *Find the ϕ -limits of integration.* For any given θ , the angle ϕ that M makes with the positive z -axis runs from $\phi = \phi_{\min}$ to $\phi = \phi_{\max}$. The ϕ -limits of integration may depend on θ , but they are often constant.
4. *Find the θ -limits of integration.* The ray L sweeps over R as θ runs from α to β . These are the θ -limits of integration. The integral is

$$\iiint_D f(\rho, \phi, \theta) dV = \int_{\theta=\alpha}^{\theta=\beta} \int_{\phi=\phi_{\min}}^{\phi=\phi_{\max}} \int_{\rho=g_1(\phi, \theta)}^{\rho=g_2(\phi, \theta)} f(\rho, \phi, \theta) \rho^2 \sin \phi d\rho d\phi d\theta.$$

EXAMPLE 5 Find the volume of the “ice cream cone” D bounded above by the sphere $\rho = 1$ and bounded below by the cone $\phi = \pi/3$.

Solution The volume is $V = \iiint_D \rho^2 \sin \phi d\rho d\phi d\theta$, the integral of $f(\rho, \phi, \theta) = 1$ over D .

To find the limits of integration for evaluating the integral, we begin by sketching D and its projection R on the xy -plane (Figure 14.56).

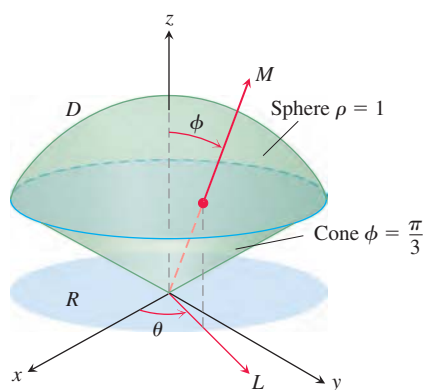

FIGURE 14.56 The ice cream cone in Example 5.

The ρ -limits of integration. We draw a ray M from the origin through D , making an angle ϕ with the positive z -axis. We also draw L , the projection of M on the xy -plane, along with the angle θ that L makes with the positive x -axis. Ray M enters D at $\rho = 0$ and leaves at $\rho = 1$.

The ϕ -limits of integration. The cone $\phi = \pi/3$ makes an angle of $\pi/3$ with the positive z -axis. For any given θ , the angle ϕ can run from $\phi = 0$ to $\phi = \pi/3$.

The θ -limits of integration. The ray L sweeps over R as θ runs from 0 to 2π . The volume is

$$\begin{aligned} V &= \iiint_D \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \int_0^1 \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta \\ &= \int_0^{2\pi} \int_0^{\pi/3} \left[\frac{\rho^3}{3} \right]_{\rho=0}^{\rho=1} \sin \phi \, d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \frac{1}{3} \sin \phi \, d\phi \, d\theta \\ &= \int_0^{2\pi} \left[-\frac{1}{3} \cos \phi \right]_{\phi=0}^{\phi=\pi/3} d\theta = \int_0^{2\pi} \left(-\frac{1}{6} + \frac{1}{3} \right) d\theta = \frac{1}{6} (2\pi) = \frac{\pi}{3}. \quad \blacksquare \end{aligned}$$

EXAMPLE 6 A solid of constant density $\delta = 1$ occupies the solid region D in Example 5. Find the solid's moment of inertia about the z -axis.

Solution In rectangular coordinates, the moment is

$$I_z = \iiint_D (x^2 + y^2) \, dV.$$

In spherical coordinates, $x^2 + y^2 = (\rho \sin \phi \cos \theta)^2 + (\rho \sin \phi \sin \theta)^2 = \rho^2 \sin^2 \phi$. Hence,

$$I_z = \iiint_D (\rho^2 \sin^2 \phi) \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta = \iiint_D \rho^4 \sin^3 \phi \, d\rho \, d\phi \, d\theta.$$

For the region D in Example 5, this becomes

$$\begin{aligned} I_z &= \int_0^{2\pi} \int_0^{\pi/3} \int_0^1 \rho^4 \sin^3 \phi \, d\rho \, d\phi \, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \left[\frac{\rho^5}{5} \right]_{\rho=0}^{\rho=1} \sin^3 \phi \, d\phi \, d\theta \\ &= \frac{1}{5} \int_0^{2\pi} \int_0^{\pi/3} (1 - \cos^2 \phi) \sin \phi \, d\phi \, d\theta = \frac{1}{5} \int_0^{2\pi} \left[-\cos \phi + \frac{\cos^3 \phi}{3} \right]_{\phi=0}^{\phi=\pi/3} d\theta \\ &= \frac{1}{5} \int_0^{2\pi} \left(-\frac{1}{2} + \frac{1}{24} + 1 - \frac{1}{3} \right) d\theta = \frac{1}{5} \int_0^{2\pi} \frac{5}{24} d\theta = \frac{1}{24} (2\pi) = \frac{\pi}{12}. \quad \blacksquare \end{aligned}$$

Coordinate Conversion Formulas

CYLINDRICAL TO RECTANGULAR

$$x = r \cos \theta$$

$$y = r \sin \theta$$

$$z = z$$

SPHERICAL TO RECTANGULAR

$$x = \rho \sin \phi \cos \theta$$

$$y = \rho \sin \phi \sin \theta$$

$$z = \rho \cos \phi$$

SPHERICAL TO CYLINDRICAL

$$r = \rho \sin \phi$$

$$z = \rho \cos \phi$$

$$\theta = \theta$$

Corresponding formulas for dV in triple integrals:

$$dV = dx \, dy \, dz$$

$$= r \, dz \, dr \, d\theta$$

$$= \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$$

In the next section we offer a more general procedure for determining dV in cylindrical and spherical coordinates. The results, of course, will be the same.

EXERCISES 14.7

In Exercises 1–12, sketch the region described by the following cylindrical coordinates in three-dimensional space.

1. $r = 2$
2. $\theta = \frac{\pi}{4}$
3. $z = -1$
4. $z = r$
5. $r = \theta$
6. $z = r \sin \theta$
7. $r^2 + z^2 = 4$
8. $1 \leq r \leq 2, 0 \leq \theta \leq \frac{\pi}{3}$
9. $r \leq z \leq \sqrt{9 - r^2}$
10. $0 \leq r \leq 2 \sin \theta, 1 \leq z \leq 3$
11. $0 \leq r \leq 4 \cos \theta, 0 \leq \theta \leq \frac{\pi}{2}, 0 \leq z \leq 5$
12. $0 \leq r \leq 3, \frac{-\pi}{2} \leq \theta \leq \frac{\pi}{2}, 0 \leq z \leq r \cos \theta$

In Exercises 13–22, sketch the region described by the following spherical coordinates in three-dimensional space.

13. $\rho = 3$
14. $\phi = \frac{\pi}{6}$
15. $\theta = \frac{2}{3}\pi$
16. $\rho = \csc \phi$
17. $\rho \cos \phi = 4$
18. $1 \leq \rho \leq 2 \sec \phi, 0 \leq \phi \leq \frac{\pi}{4}$
19. $0 \leq \rho \leq 3 \csc \phi$
20. $0 \leq \rho \leq 1, \frac{\pi}{2} \leq \phi \leq \pi, 0 \leq \theta \leq \pi$
21. $0 \leq \rho \cos \theta \sin \phi \leq 2, 0 \leq \rho \sin \theta \sin \phi \leq 3, 0 \leq \rho \cos \phi \leq 4$
22. $4 \sec \phi \leq \rho \leq 5, 0 \leq \phi \leq \frac{\pi}{2}$

Evaluating Integrals in Cylindrical Coordinates

Evaluate the cylindrical coordinate integrals in Exercises 23–28.

23. $\int_0^{2\pi} \int_0^1 \int_r^{\sqrt{2-r^2}} r \, dz \, dr \, d\theta$
24. $\int_0^{2\pi} \int_0^3 \int_{r^2/3}^{\sqrt{18-r^2}} r \, dz \, dr \, d\theta$
25. $\int_0^{2\pi} \int_0^{\theta/2\pi} \int_0^{3+24r^2} r \, dz \, dr \, d\theta$
26. $\int_0^\pi \int_0^{\theta/\pi} \int_{-\sqrt{4-r^2}}^{3\sqrt{4-r^2}} z \, dz \, dr \, d\theta$
27. $\int_0^{2\pi} \int_0^1 \int_r^{1/\sqrt{2-r^2}} 3r \, dz \, dr \, d\theta$
28. $\int_0^{2\pi} \int_0^1 \int_{-1/2}^{1/2} (r^2 \sin^2 \theta + z^2) r \, dz \, dr \, d\theta$

Changing the Order of Integration in Cylindrical Coordinates

The integrals we have seen so far suggest that there are preferred orders of integration for cylindrical coordinates, but other orders usually work well and are occasionally easier to evaluate. Evaluate the integrals in Exercises 29–32.

29. $\int_0^{2\pi} \int_0^3 \int_0^{z/3} r^3 \, dr \, dz \, d\theta$
30. $\int_{-1}^1 \int_0^{2\pi} \int_0^{1+\cos \theta} 4r \, dr \, d\theta \, dz$
31. $\int_0^1 \int_0^{\sqrt{z}} \int_0^{2\pi} (r^2 \cos^2 \theta + z^2) r \, d\theta \, dr \, dz$
32. $\int_0^2 \int_{r-2}^{\sqrt{4-r^2}} \int_0^{2\pi} (r \sin \theta + 1) r \, d\theta \, dz \, dr$
33. Let D be the solid region bounded below by the plane $z = 0$, above by the sphere $x^2 + y^2 + z^2 = 4$, and on the sides by the cylinder $x^2 + y^2 = 1$. Set up the triple integrals in cylindrical coordinates that give the volume of D using the following orders of integration.
 - a. $dz \, dr \, d\theta$
 - b. $dr \, dz \, d\theta$
 - c. $d\theta \, dz \, dr$
34. Let D be the solid region bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the paraboloid $z = 2 - x^2 - y^2$. Set up the triple integrals in cylindrical coordinates that give the volume of D using the following orders of integration.
 - a. $dz \, dr \, d\theta$
 - b. $dr \, dz \, d\theta$
 - c. $d\theta \, dz \, dr$

Finding Iterated Integrals in Cylindrical Coordinates

35. Give the limits of integration for evaluating the integral

$$\iiint_D f(r, \theta, z) r \, dz \, dr \, d\theta$$

as an iterated integral over the solid region D that is bounded below by the plane $z = 0$, on the side by the cylinder $r = \cos \theta$, and on top by the paraboloid $z = 3r^2$.

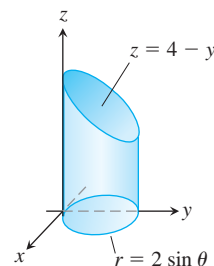

36. Convert the integral

$$\int_{-1}^1 \int_0^{\sqrt{1-y^2}} \int_0^x (x^2 + y^2) \, dz \, dx \, dy$$

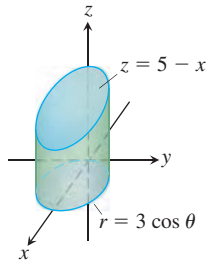

to an equivalent integral in cylindrical coordinates and evaluate the result.

In Exercises 37–42, set up the iterated integral for evaluating $\iiint_D f(r, \theta, z) r \, dz \, dr \, d\theta$ over the given solid region D .

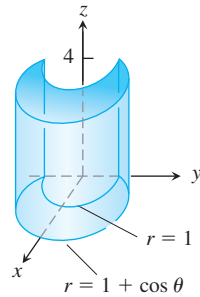

37. D is the right circular cylinder whose base is the circle $r = 2 \sin \theta$ in the xy -plane and whose top lies in the plane $z = 4 - y$.

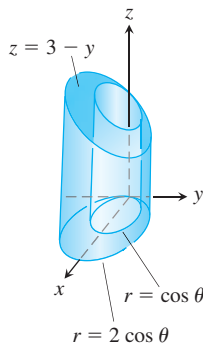

38. D is the right circular cylinder whose base is the circle $r = 3 \cos \theta$ and whose top lies in the plane $z = 5 - x$.

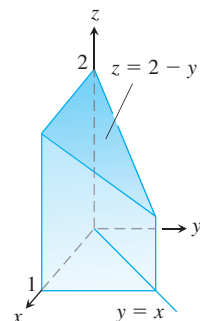

39. D is the solid right cylinder whose base is the region in the xy -plane that lies inside the cardioid $r = 1 + \cos \theta$ and outside the circle $r = 1$ and whose top lies in the plane $z = 4$.

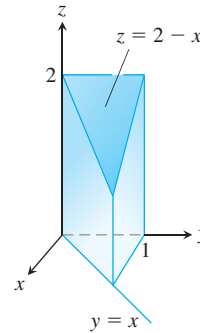

40. D is the solid right cylinder whose base is the region between the circles $r = \cos \theta$ and $r = 2 \cos \theta$ and whose top lies in the plane $z = 3 - y$.

41. D is the right prism whose base is the triangle in the xy -plane bounded by the x -axis and the lines $y = x$ and $x = 1$ and whose top lies in the plane $z = 2 - y$.

42. D is the right prism whose base is the triangle in the xy -plane bounded by the y -axis and the lines $y = x$ and $y = 1$ and whose top lies in the plane $z = 2 - x$.

Evaluating Integrals in Spherical Coordinates

Evaluate the spherical coordinate integrals in Exercises 43–48.

43. $\int_0^\pi \int_0^\pi \int_0^{2 \sin \phi} \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$
44. $\int_0^{2\pi} \int_0^{\pi/4} \int_0^2 (\rho \cos \phi) \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$
45. $\int_0^{2\pi} \int_0^\pi \int_0^{(1-\cos \phi)/2} \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$
46. $\int_0^{3\pi/2} \int_0^\pi \int_0^1 5\rho^3 \sin^3 \phi \, d\rho \, d\phi \, d\theta$
47. $\int_0^{2\pi} \int_0^{\pi/3} \int_{\sec \phi}^2 3\rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$
48. $\int_0^{2\pi} \int_0^{\pi/4} \int_0^{\sec \phi} (\rho \cos \phi) \rho^2 \sin \phi \, d\rho \, d\phi \, d\theta$

Changing the Order of Integration in Spherical Coordinates

The previous integrals suggest there are preferred orders of integration for spherical coordinates, but other orders give the same value and are occasionally easier to evaluate. Evaluate the integrals in Exercises 49–52.

49. $\int_0^2 \int_{-\pi}^0 \int_{\pi/4}^{\pi/2} \rho^3 \sin 2\phi \, d\phi \, d\theta \, d\rho$
50. $\int_{\pi/6}^{\pi/3} \int_{\csc \phi}^{2 \csc \phi} \int_0^{2\pi} \rho^2 \sin \phi \, d\theta \, d\rho \, d\phi$
51. $\int_0^1 \int_0^\pi \int_0^{\pi/4} 12\rho \sin^3 \phi \, d\phi \, d\theta \, d\rho$
52. $\int_{\pi/6}^{\pi/2} \int_{-\pi/2}^{\pi/2} \int_{\csc \phi}^2 5\rho^4 \sin^3 \phi \, d\rho \, d\theta \, d\phi$

53. Let D be the region in Exercise 33. Set up the triple integrals in spherical coordinates that give the volume of D using the following orders of integration.

- a. $d\rho \, d\phi \, d\theta$
b. $d\phi \, d\rho \, d\theta$

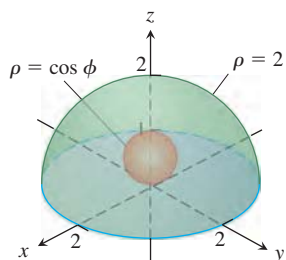

54. Let D be the solid region bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the plane $z = 1$. Set up the triple integrals in spherical coordinates that give the volume of D using the following orders of integration.

a. $d\rho \, d\phi \, d\theta$ b. $d\phi \, d\rho \, d\theta$

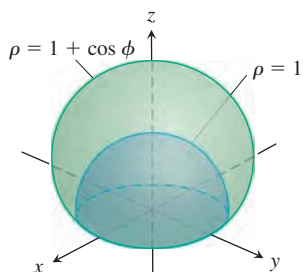

Finding Iterated Integrals in Spherical Coordinates

In Exercises 55–60, (a) find the spherical coordinate limits for the integral that calculates the volume of the given solid and then (b) evaluate the integral.

55. The solid between the sphere $\rho = \cos \phi$ and the hemisphere $\rho = 2, z \geq 0$

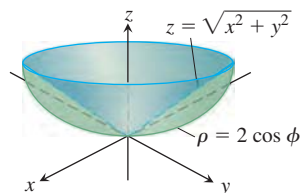

56. The solid bounded below by the hemisphere $\rho = 1, z \geq 0$, and above by the surface $\rho = 1 + \cos \phi$

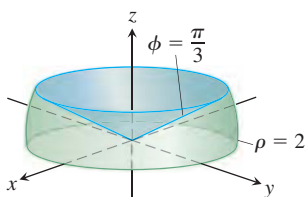

57. The solid enclosed by the surface $\rho = 1 - \cos \phi$

58. The upper portion cut from the solid in Exercise 57 by the xy -plane

59. The solid bounded below by the sphere $\rho = 2 \cos \phi$ and above by the cone $z = \sqrt{x^2 + y^2}$

60. The solid bounded below by the xy -plane, on the sides by the sphere $\rho = 2$, and above by the cone $\phi = \pi/3$

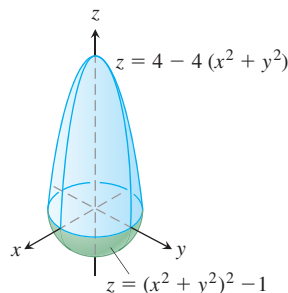

Finding Triple Integrals

61. Set up triple integrals for the volume of the sphere $\rho = 2$ in (a) spherical, (b) cylindrical, and (c) rectangular coordinates.
62. Let D be the solid region in the first octant that is bounded below by the cone $\phi = \pi/4$ and above by the sphere $\rho = 3$. Express the volume of D as an iterated triple integral in (a) cylindrical and (b) spherical coordinates. Then (c) find the volume.
63. Let D be the smaller cap cut from a solid ball of radius 2 units by a plane 1 unit from the center of the sphere. Express the volume of D as an iterated triple integral in (a) spherical, (b) cylindrical, and (c) rectangular coordinates. Then (d) find the volume by evaluating one of the three triple integrals.
64. Let D be the solid hemisphere $x^2 + y^2 + z^2 \leq 1, z \geq 0$. If the density is $\delta(x, y, z) = 1$, express the moment of inertia I_z as an iterated integral in (a) cylindrical and (b) spherical coordinates. Then (c) find I_z .

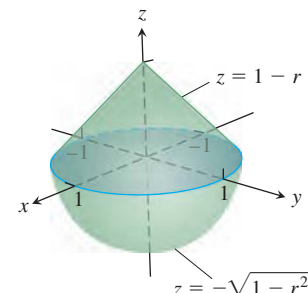

Volumes

Find the volumes of the solids in Exercises 65–70.

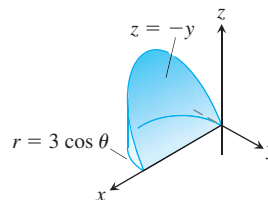

65.

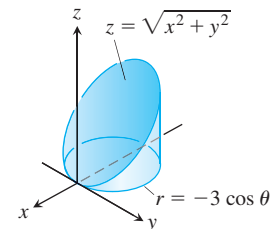

66.

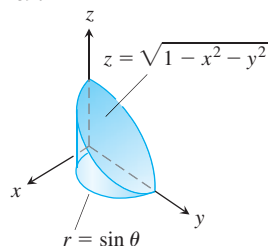

67.

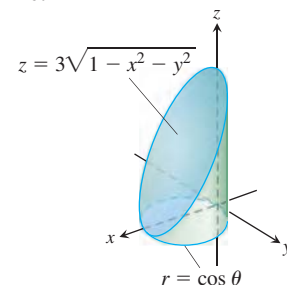

68.

69.

70.

71. **Ball and cones** Find the volume of the portion of the ball $\rho \leq a$ that lies between the cones $\phi = \pi/3$ and $\phi = 2\pi/3$.

72. **Ball and half-planes** Find the volume of the region cut from the ball $\rho \leq a$ by the half-planes $\theta = 0$ and $\theta = \pi/6$ in the first octant.

- 73. Ball and plane** Find the volume of the smaller region cut from the ball $\rho \leq \sqrt{2}$ by the plane $z = 1$.
- 74. Cone and planes** Find the volume of the solid enclosed by the cone $z = \sqrt{x^2 + y^2}$ between the planes $z = 1$ and $z = 2$.
- 75. Cylinder and paraboloid** Find the volume of the solid region bounded below by the plane $z = 0$, laterally by the cylinder $x^2 + y^2 = 1$, and above by the paraboloid $z = x^2 + y^2$.
- 76. Cylinder and paraboloids** Find the volume of the solid region bounded below by the paraboloid $z = x^2 + y^2$, laterally by the cylinder $x^2 + y^2 = 1$, and above by the paraboloid $z = x^2 + y^2 + 1$.
- 77. Cylinder and cones** Find the volume of the solid cut from the thick-walled cylinder $1 \leq x^2 + y^2 \leq 2$ by the cones $z = \pm\sqrt{x^2 + y^2}$.
- 78. Sphere and cylinder** Find the volume of the solid region that lies inside the sphere $x^2 + y^2 + z^2 = 2$ and outside the cylinder $x^2 + y^2 = 1$.
- 79. Cylinder and planes** Find the volume of the solid region enclosed by the cylinder $x^2 + y^2 = 4$ and the planes $z = 0$ and $y + z = 4$.
- 80. Cylinder and planes** Find the volume of the solid region enclosed by the cylinder $x^2 + y^2 = 4$ and the planes $z = 0$ and $x + y + z = 4$.
- 81. Region trapped by paraboloids** Find the volume of the solid region bounded above by the paraboloid $z = 5 - x^2 - y^2$ and below by the paraboloid $z = 4x^2 + 4y^2$.
- 82. Paraboloid and cylinder** Find the volume of the solid region bounded above by the paraboloid $z = 9 - x^2 - y^2$, bounded below by the xy -plane, and lying *outside* the cylinder $x^2 + y^2 = 1$.
- 83. Cylinder and sphere** Find the volume of the region cut from the solid cylinder $x^2 + y^2 \leq 1$ by the sphere $x^2 + y^2 + z^2 = 4$.
- 84. Sphere and paraboloid** Find the volume of the solid region bounded above by the sphere $x^2 + y^2 + z^2 = 2$ and below by the paraboloid $z = x^2 + y^2$.

Average Values

- 85.** Find the average value of the function $f(r, \theta, z) = r$ over the solid region bounded by the cylinder $r = 1$ between the planes $z = -1$ and $z = 1$.
- 86.** Find the average value of the function $f(r, \theta, z) = r$ over the solid ball bounded by the sphere $r^2 + z^2 = 1$. (This is the sphere $x^2 + y^2 + z^2 = 1$.)
- 87.** Find the average value of the function $f(\rho, \phi, \theta) = \rho$ over the solid ball $\rho \leq 1$.
- 88.** Find the average value of the function $f(\rho, \phi, \theta) = \rho \cos \phi$ over the upper half of the solid ball $\rho \leq 1$, $0 \leq \phi \leq \pi/2$.

Masses, Moments, and Centroids

- 89. Center of mass** A solid of constant density is bounded below by the plane $z = 0$, above by the cone $z = r$, $r \geq 0$, and on the sides by the cylinder $r = 1$. Find the center of mass.
- 90. Centroid** Find the centroid of the solid region in the first octant that is bounded above by the cone $z = \sqrt{x^2 + y^2}$, below by the plane $z = 0$, and on the sides by the cylinder $x^2 + y^2 = 4$ and the planes $x = 0$ and $y = 0$.
- 91. Centroid** Find the centroid of the solid in Exercise 60.
- 92. Centroid** Find the centroid of the solid bounded above by the sphere $\rho = a$ and below by the cone $\phi = \pi/4$.
- 93. Centroid** Find the centroid of the solid region that is bounded above by the surface $z = \sqrt{r}$, on the sides by the cylinder $r = 4$, and below by the xy -plane.
- 94. Centroid** Find the centroid of the region cut from the solid ball $r^2 + z^2 \leq 1$ by the half-planes $\theta = -\pi/3$, $r \geq 0$, and $\theta = \pi/3$, $r \geq 0$.
- 95. Moment of inertia of solid cone** Find the moment of inertia of a solid right circular cone of base radius 1 and height 1 about an axis through the vertex parallel to the base if the density is $\delta = 1$.
- 96. Moment of inertia of ball** Find the moment of inertia of a ball of radius a about a diameter if the density is $\delta = 1$.
- 97. Moment of inertia of solid cone** Find the moment of inertia of a solid right circular cone of base radius a and height h about its axis if the density is $\delta = 1$. (*Hint:* Place the cone with its vertex at the origin and its axis along the z -axis.)
- 98. Variable density** A solid is bounded on the top by the paraboloid $z = r^2$, on the bottom by the plane $z = 0$, and on the sides by the cylinder $r = 1$. Find the center of mass and the moment of inertia about the z -axis if the density is
- $\delta(r, \theta, z) = z$
 - $\delta(r, \theta, z) = r$.
- 99. Variable density** A solid is bounded below by the cone $z = \sqrt{x^2 + y^2}$ and above by the plane $z = 1$. Find the center of mass and the moment of inertia about the z -axis if the density is
- $\delta(r, \theta, z) = z$
 - $\delta(r, \theta, z) = z^2$.
- 100. Variable density** A solid ball is bounded by the sphere $\rho = a$. Find the moment of inertia about the z -axis if the density is
- $\delta(\rho, \phi, \theta) = \rho^2$
 - $\delta(\rho, \phi, \theta) = r = \rho \sin \phi$.
- 101. Centroid of solid semi-ellipsoid** Show that the centroid of the solid semi-ellipsoid of revolution $(r^2/a^2) + (z^2/h^2) \leq 1$, $z \geq 0$, lies on the z -axis three-eighths of the way from the base to the top. The special case $h = a$ gives a solid hemisphere. Thus, the centroid of a solid hemisphere lies on the axis of symmetry three-eighths of the way from the base to the top.
- 102. Centroid of solid cone** Show that the centroid of a solid right circular cone is one-fourth of the way from the base to the vertex. (In general, the centroid of a solid cone or pyramid is one-fourth of the way from the centroid of the base to the vertex.)
- 103. Density of center of a planet** A planet is in the shape of a sphere of radius R and total mass M with spherically symmetric density distribution that increases linearly as one approaches its center. What is the density at the center of this planet if the density at its edge (surface) is taken to be zero?
- 104. Mass of planet's atmosphere** A spherical planet of radius R has an atmosphere whose density is $\mu = \mu_0 e^{-ch}$, where h is the altitude above the surface of the planet, μ_0 is the density at sea level, and c is a positive constant. Find the mass of the planet's atmosphere.

Theory and Examples

105. Vertical planes in cylindrical coordinates

- Show that planes perpendicular to the x -axis have equations of the form $r = a \sec \theta$ in cylindrical coordinates.
- Show that planes perpendicular to the y -axis have equations of the form $r = b \csc \theta$.

106. (Continuation of Exercise 105.) Find an equation of the form $r = f(\theta)$ in cylindrical coordinates for the plane $ax + by = c$, $c \neq 0$.

107. **Symmetry** What symmetry will you find in a surface that has an equation of the form $r = f(z)$ in cylindrical coordinates? Give reasons for your answer.

108. **Symmetry** What symmetry will you find in a surface that has an equation of the form $\rho = f(\phi)$ in spherical coordinates? Give reasons for your answer.

14.8 Substitutions in Multiple Integrals

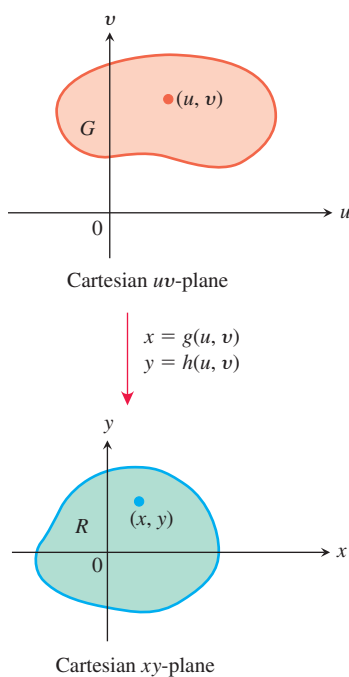

FIGURE 14.57 The equations $x = g(u, v)$ and $y = h(u, v)$ allow us to change an integral over a region R in the xy -plane into an integral over a region G in the uv -plane.

HISTORICAL BIOGRAPHY

Carl Gustav Jacob Jacobi
(1804–1851)

Jacobi, one of nineteenth-century Germany's most accomplished scientists, developed the theory of determinants and transformations into a powerful tool for evaluating multiple integrals and solving differential equations. He also applied transformation methods to study integrals like the ones that arise in the calculation of arc length.

To know more, visit the companion Website.

This section introduces the ideas involved in coordinate transformations to evaluate multiple integrals by substitution. The method replaces complicated integrals by ones that are easier to evaluate. Substitutions accomplish this by simplifying the integrand, the limits of integration, or both. A thorough discussion of multivariable transformations and substitutions is best left to a more advanced course, but our introduction here shows how the substitutions just studied reflect the general idea derived for single integral calculus.

Substitutions in Double Integrals

The polar coordinate substitution of Section 14.4 is a special case of a more general substitution method for double integrals, a method that pictures changes in variables as transformations of regions.

Suppose that a region G in the uv -plane is transformed into the region R in the xy -plane by equations of the form

$$x = g(u, v), \quad y = h(u, v),$$

as suggested in Figure 14.57. We assume the transformation is one-to-one on the interior of G . We call R the **image** of G under the transformation, and G the **preimage** of R . Any function $f(x, y)$ defined on R can be thought of as a function $f(g(u, v), h(u, v))$ defined on G as well. How is the integral of $f(x, y)$ over R related to the integral of $f(g(u, v), h(u, v))$ over G ?

To gain some insight into the question, we look again at the single variable case. To be consistent with how we are using them now, we interchange the variables x and u used in the substitution method for single integrals in Chapter 5, so the equation is

$$\int_{g(a)}^{g(b)} f(x) dx = \int_a^b f(g(u)) g'(u) du. \quad x = g(u), dx = g'(u) du$$

To propose an analogue for substitution in a double integral $\iint_R f(x, y) dx dy$, we need a derivative factor like $g'(u)$ as a multiplier that transforms the area element $du dv$ in the region G to its corresponding area element $dx dy$ in the region R . We denote this factor by J . In continuing with our analogy, it is reasonable to assume that J is a function of both variables u and v , just as g' is a function of the single variable u . Moreover, J should register instantaneous change, so partial derivatives are going to be involved in its expression. Since four partial derivatives are associated with the transforming equations $x = g(u, v)$ and $y = h(u, v)$, it is also reasonable to assume that the factor $J(u, v)$ we seek includes them all. These features are captured in the following definition, which is constructed from the partial derivatives and is named after the German mathematician Carl Jacobi.

DEFINITION The **Jacobian determinant** or **Jacobian** of the coordinate transformation $x = g(u, v)$, $y = h(u, v)$ is

$$J(u, v) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \frac{\partial x}{\partial u} \frac{\partial y}{\partial v} - \frac{\partial y}{\partial u} \frac{\partial x}{\partial v}. \quad (1)$$

The Jacobian can also be denoted by

$$J(u, v) = \frac{\partial(x, y)}{\partial(u, v)}$$

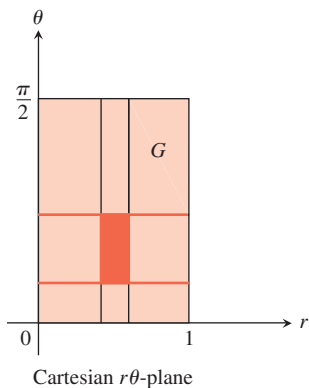

to help us remember how the determinant in Equation (1) is constructed from the partial derivatives of x and y . The array of partial derivatives in Equation (1) behaves just like the derivative g' in the single variable situation. The Jacobian measures how much the transformation is expanding or contracting the area around the point (u, v) . Effectively, the factor $|J|$ converts the area of the differential rectangle $du dv$ in G to match its corresponding differential area $dx dy$ in R . We note that, in general, the value of the scaling factor $|J|$ depends on the point (u, v) in G ; that is, the scaling changes as the point (u, v) varies through the region G . Our examples to follow will show how it scales the differential area $du dv$ for specific transformations.

Now we can answer our original question concerning the relationship of the integral of $f(x, y)$ over the region R to the integral of $f(g(u, v), h(u, v))$ over G .

Differential Area Change Substituting

$$x = g(u, v), y = h(u, v)$$

$$dx dy = \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv$$

$$\begin{aligned} x &= r \cos \theta \\ y &= r \sin \theta \end{aligned}$$

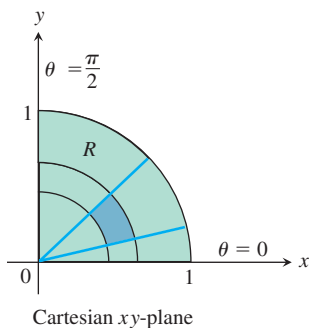

FIGURE 14.58 The equations $x = r \cos \theta$, $y = r \sin \theta$ transform G into R . The Jacobian factor r , calculated in Example 1, scales the differential rectangle $dr d\theta$ in G to match the differential area element $dx dy$ in R .

THEOREM 3—Substitution for Double Integrals

Suppose that $f(x, y)$ is continuous over the region R . Let G be the preimage of R under the transformation $x = g(u, v)$, $y = h(u, v)$, which is assumed to be one-to-one on the interior of G . If the functions g and h have continuous first partial derivatives within the interior of G , then

$$\iint_R f(x, y) dx dy = \iint_G f(g(u, v), h(u, v)) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du dv. \quad (2)$$

The derivation of Equation (2) is intricate and properly belongs to a course in advanced calculus, so we do not include it here. We now present examples illustrating the substitution method defined by the equation.

EXAMPLE 1 Find the Jacobian for the polar coordinate transformation $x = r \cos \theta$, $y = r \sin \theta$, and use Equation (2) to write the Cartesian integral $\iint_R f(x, y) dx dy$ as a polar integral.

Solution Figure 14.58 shows how the equations $x = r \cos \theta$, $y = r \sin \theta$ transform the rectangle $G: 0 \leq r \leq 1$, $0 \leq \theta \leq \pi/2$, into the quarter of a circular disk R bounded by $x^2 + y^2 = 1$ in the first quadrant of the xy -plane.

For polar coordinates, we have r and θ in place of u and v . With $x = r \cos \theta$ and $y = r \sin \theta$, the Jacobian is

$$J(r, \theta) = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{vmatrix} = r(\cos^2 \theta + \sin^2 \theta) = r.$$

Since we assume $r \geq 0$ when integrating in polar coordinates, $|J(r, \theta)| = |r| = r$ so that Equation (2) gives

$$\iint_R f(x, y) dx dy = \iint_G f(r \cos \theta, r \sin \theta) r dr d\theta. \quad (3)$$

This is the same formula we derived independently using a geometric argument for polar area in Section 14.4. ■

Here is an example of a substitution in which the image of a rectangle under the coordinate transformation is a trapezoid. Transformations like this one are called **linear transformations**, and their Jacobians are constant throughout G .

EXAMPLE 2 Evaluate

$$\int_0^4 \int_{x=y/2}^{x=(y/2)+1} \frac{2x-y}{2} dx dy$$

by applying the transformation

$$u = \frac{2x-y}{2}, \quad v = \frac{y}{2} \quad (4)$$

and integrating over an appropriate region in the uv -plane.

Solution We sketch the region R of integration in the xy -plane and identify its boundaries (Figure 14.59).

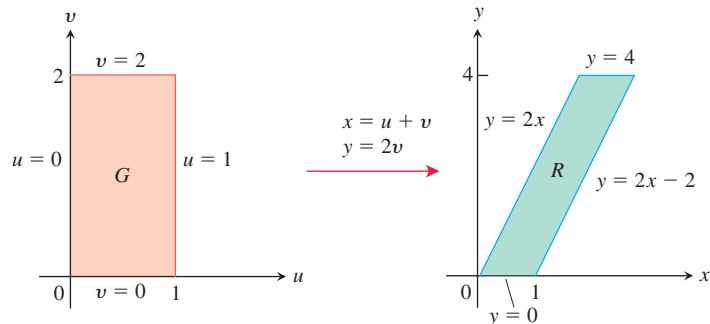

FIGURE 14.59 The equations $x = u + v$ and $y = 2v$ transform G into R . Reversing the transformation by the equations $u = (2x - y)/2$ and $v = y/2$ transforms R into G (Example 2).

To apply Equation (2), we need to find the corresponding uv -region G and the Jacobian of the transformation. To find them, we first solve Equations (4) for x and y in terms of u and v . From those equations it is easy to find algebraically that

$$x = u + v, \quad y = 2v. \quad (5)$$

We then find the boundaries of G by substituting these expressions into the equations for the boundaries of R (Figure 14.59)

xy-equations for the boundary of R	Corresponding uv-equations for the boundary of G	Simplified uv-equations
$x = y/2$	$u + v = 2v/2 = v$	$u = 0$
$x = (y/2) + 1$	$u + v = (2v/2) + 1 = v + 1$	$u = 1$
$y = 0$	$2v = 0$	$v = 0$
$y = 4$	$2v = 4$	$v = 2$

From Equations (5) the Jacobian of the transformation is

$$J(u, v) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{\partial}{\partial u}(u+v) & \frac{\partial}{\partial v}(u+v) \\ \frac{\partial}{\partial u}(2v) & \frac{\partial}{\partial v}(2v) \end{vmatrix} = \begin{vmatrix} 1 & 1 \\ 0 & 2 \end{vmatrix} = 2.$$

We now have everything we need to apply Equation (2):

$$\begin{aligned} \int_0^4 \int_{x=y/2}^{x=(y/2)+1} \frac{2x-y}{2} dx dy &= \int_{v=0}^{v=2} \int_{u=0}^{u=1} u |J(u, v)| du dv \\ &= \int_0^2 \int_0^1 (u)(2) du dv = \int_0^2 \left[u^2 \right]_{u=0}^{u=1} dv = \int_0^2 dv = 2. \end{aligned}$$

EXAMPLE 3 Evaluate

$$\int_0^1 \int_0^{1-x} \sqrt{x+y} (y-2x)^2 dy dx.$$

Solution We sketch the region R of integration in the xy -plane and identify its boundaries (Figure 14.60). The integrand suggests the transformation $u = x + y$ and $v = y - 2x$. Routine algebra produces x and y as functions of u and v :

$$x = \frac{u}{3} - \frac{v}{3}, \quad y = \frac{2u}{3} + \frac{v}{3}. \quad (6)$$

From Equations (6), we can find the boundaries of the uv -region G (Figure 14.60).

xy -equations for the boundary of R	Corresponding uv -equations for the boundary of G	Simplified uv -equations
$x + y = 1$	$\left(\frac{u}{3} - \frac{v}{3}\right) + \left(\frac{2u}{3} + \frac{v}{3}\right) = 1$	$u = 1$
$x = 0$	$\frac{u}{3} - \frac{v}{3} = 0$	$v = u$
$y = 0$	$\frac{2u}{3} + \frac{v}{3} = 0$	$v = -2u$

The Jacobian of the transformation in Equations (6) is

$$J(u, v) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & -\frac{1}{3} \\ \frac{2}{3} & \frac{1}{3} \end{vmatrix} = \frac{1}{3}.$$

Applying Equation (2), we evaluate the integral:

$$\begin{aligned} \int_0^1 \int_0^{1-x} \sqrt{x+y} (y-2x)^2 dy dx &= \int_{u=0}^{u=1} \int_{v=-2u}^{v=u} u^{1/2} v^2 |J(u, v)| dv du \\ &= \int_0^1 \int_{-2u}^u u^{1/2} v^2 \left(\frac{1}{3}\right) dv du = \frac{1}{3} \int_0^1 u^{1/2} \left[\frac{1}{3} v^3 \right]_{v=-2u}^{v=u} du \\ &= \frac{1}{9} \int_0^1 u^{1/2} (u^3 + 8u^3) du = \int_0^1 u^{7/2} du = \frac{2}{9} u^{9/2} \Big|_0^1 = \frac{2}{9}. \end{aligned}$$

In the next example we illustrate a nonlinear transformation of coordinates resulting from simplifying the form of the integrand. Like the polar coordinates' transformation, nonlinear transformations can map a straight-line boundary of a region into a curved

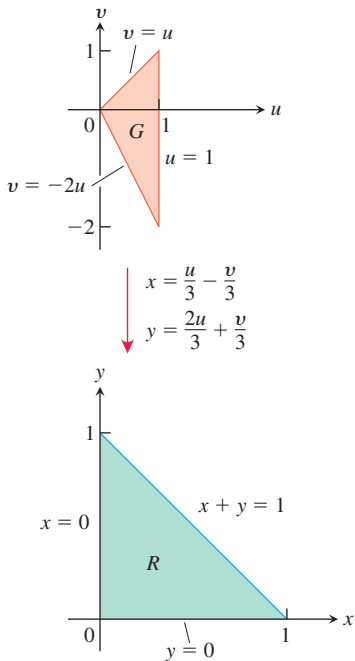

FIGURE 14.60 The equations $x = (u/3) - (v/3)$ and $y = (2u/3) + (v/3)$ transform G into R . Reversing the transformation by the equations $u = x + y$ and $v = y - 2x$ transforms R into G (Example 3).

boundary (or vice versa with the inverse transformation). In general, nonlinear transformations are more complex to analyze than linear ones, and a complete treatment is left to a more advanced course.

EXAMPLE 4 Evaluate the integral

$$\int_1^2 \int_{1/y}^y \sqrt{\frac{y}{x}} e^{\sqrt{xy}} dx dy.$$

Solution The square root terms in the integrand suggest that we might simplify the integration by substituting $u = \sqrt{xy}$ and $v = \sqrt{y/x}$. Squaring these equations gives $u^2 = xy$ and $v^2 = y/x$, which imply that $u^2 v^2 = y^2$ and $u^2/v^2 = x^2$. So we obtain the transformation (in the same ordering of the variables as discussed before)

$$x = \frac{u}{v} \quad \text{and} \quad y = uv,$$

with $u > 0$ and $v > 0$. Let's first see what happens to the integrand itself under this transformation. The Jacobian of the transformation is not constant:

$$J(u, v) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} \end{vmatrix} = \begin{vmatrix} \frac{1}{v} & -\frac{u}{v^2} \\ v & u \end{vmatrix} = \frac{2u}{v}.$$

If G is the region of integration in the uv -plane, then by Equation (2) the transformed double integral under the substitution is

$$\iint_R \sqrt{\frac{y}{x}} e^{\sqrt{xy}} dx dy = \iint_G ve^u |J(u, v)| du dv = \iint_G ve^u \frac{2u}{v} du dv = \iint_G 2ue^u du dv.$$

The transformed integrand function is easier to integrate than the original one, so we proceed to determine the limits of integration for the transformed integral.

The region of integration R of the original integral in the xy -plane is shown in Figure 14.61. From the substitution equations $u = \sqrt{xy}$ and $v = \sqrt{y/x}$, we see that the image of the left-hand boundary $xy = 1$ for R is the vertical line segment $u = 1$, $2 \geq v \geq 1$, in G (see Figure 14.62). Likewise, the right-hand boundary $y = x$ of R maps to the horizontal line segment $v = 1$, $1 \leq u \leq 2$, in G . Finally, the horizontal top boundary $y = 2$ of R maps to $uv = 2$, $1 \leq v \leq 2$, in G . As we move counterclockwise around the boundary of the region R , we also move counterclockwise around the boundary of G , as shown in Figure 14.62. Knowing the region of integration G in the uv -plane, we can now write equivalent iterated integrals:

$$\int_1^2 \int_{1/y}^y \sqrt{\frac{y}{x}} e^{\sqrt{xy}} dx dy = \int_1^2 \int_1^{2/u} 2ue^u dv du. \quad \text{Note the order of integration.}$$

We now evaluate the transformed integral on the right-hand side:

$$\begin{aligned} \int_1^2 \int_1^{2/u} 2ue^u dv du &= 2 \int_1^2 \left[v u e^u \right]_{v=1}^{v=2/u} du \\ &= 2 \int_1^2 (2e^u - u e^u) du \\ &= 2 \int_1^2 (2 - u) e^u du \\ &= 2 \left[(2 - u) e^u + e^u \right]_{u=1}^{u=2} \\ &= 2(e^2 - (e + e)) = 2e(e - 2). \end{aligned}$$

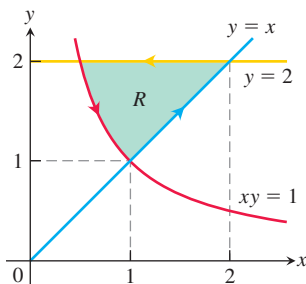

FIGURE 14.61 The region of integration R in Example 4.

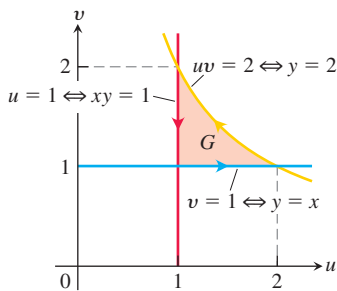

FIGURE 14.62 The boundaries of the region G correspond to those of region R in Figure 14.61. Notice that as we move counterclockwise around the region R , we move counterclockwise around the region G as well. The inverse transformation equations $u = \sqrt{xy}$, $v = \sqrt{y/x}$ produce the region G from the region R .

Substitutions in Triple Integrals

The cylindrical and spherical coordinate substitutions in Section 14.7 are special cases of a substitution method that pictures changes of variables in triple integrals as transformations of solid regions. The method is like the method for double integrals given by Equation (2) except that now we work in three dimensions instead of two.

Suppose that a solid region G in uvw -space is transformed one-to-one into the solid region D in xyz -space by differentiable equations of the form

$$x = g(u, v, w), \quad y = h(u, v, w), \quad z = k(u, v, w),$$

as suggested in Figure 14.63. Then any function $F(x, y, z)$ defined on D can be thought of as a function

$$F(g(u, v, w), h(u, v, w), k(u, v, w)) = H(u, v, w)$$

defined on G . If g , h , and k have continuous first partial derivatives, then the integral of $F(x, y, z)$ over D is related to the integral of $H(u, v, w)$ over G by the equation

$$\iiint_D F(x, y, z) \, dx \, dy \, dz = \iiint_G H(u, v, w) |J(u, v, w)| \, du \, dv \, dw. \quad (7)$$

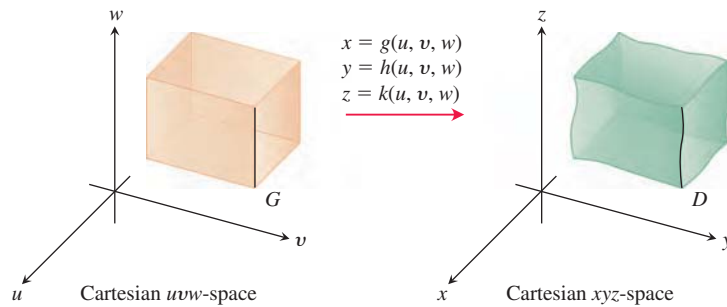

FIGURE 14.63 The equations $x = g(u, v, w)$, $y = h(u, v, w)$, and $z = k(u, v, w)$ allow us to change an integral over a region D in Cartesian xyz -space into an integral over a region G in Cartesian uvw -space using Equation (7).

Determinants

2×2 and 3×3 determinants are evaluated as follows:

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = a_1 \begin{vmatrix} b_2 & b_3 \\ c_2 & c_3 \end{vmatrix} - a_2 \begin{vmatrix} b_1 & b_3 \\ c_1 & c_3 \end{vmatrix} + a_3 \begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix}$$

The factor $J(u, v, w)$, whose absolute value appears in this equation, is the **Jacobian determinant**

$$J(u, v, w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \frac{\partial(x, y, z)}{\partial(u, v, w)}.$$

This determinant measures how much the volume near a point in G is being expanded or contracted by the transformation from (u, v, w) to (x, y, z) coordinates. As in the two-dimensional case, the derivation of the change-of-variable formula in Equation (7) is omitted.

For cylindrical coordinates, r , θ , and z take the place of u , v , and w . The transformation from Cartesian $r\theta z$ -space to Cartesian xyz -space is given by the equations

$$x = r \cos \theta, \quad y = r \sin \theta, \quad z = z$$

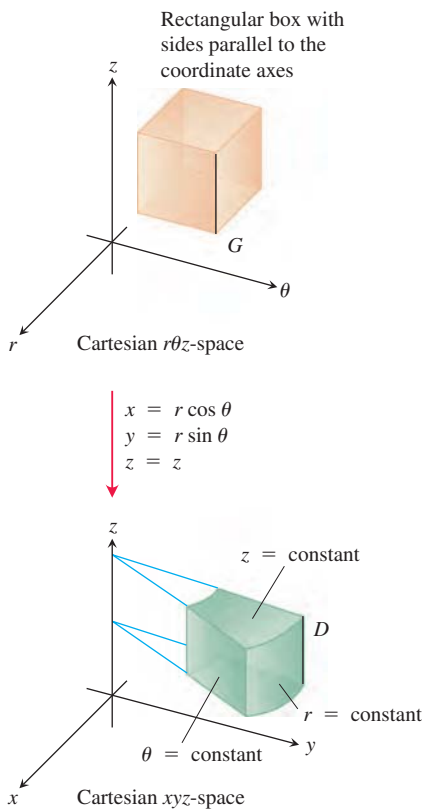

FIGURE 14.64 The equations $x = r \cos \theta$, $y = r \sin \theta$, and $z = z$ transform the rectangular box G into a cylindrical wedge D .

(Figure 14.64). The Jacobian of the transformation is

$$J(r, \theta, z) = \begin{vmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} & \frac{\partial x}{\partial z} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} & \frac{\partial y}{\partial z} \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial \theta} & \frac{\partial z}{\partial z} \end{vmatrix} = \begin{vmatrix} \cos \theta & -r \sin \theta & 0 \\ \sin \theta & r \cos \theta & 0 \\ 0 & 0 & 1 \end{vmatrix} = r \cos^2 \theta + r \sin^2 \theta = r.$$

The corresponding version of Equation (7) is

$$\iiint_D F(x, y, z) dx dy dz = \iiint_G H(r, \theta, z) |r| dr d\theta dz.$$

We can drop the absolute value signs because $r \geq 0$.

For spherical coordinates, ρ , ϕ , and θ take the place of u , v , and w . The transformation from Cartesian $\rho\phi\theta$ -space to Cartesian xyz -space is given by

$$x = \rho \sin \phi \cos \theta, \quad y = \rho \sin \phi \sin \theta, \quad z = \rho \cos \phi$$

(Figure 14.65). The Jacobian of the transformation (see Exercise 23) is

$$J(\rho, \phi, \theta) = \begin{vmatrix} \frac{\partial x}{\partial \rho} & \frac{\partial x}{\partial \phi} & \frac{\partial x}{\partial \theta} \\ \frac{\partial y}{\partial \rho} & \frac{\partial y}{\partial \phi} & \frac{\partial y}{\partial \theta} \\ \frac{\partial z}{\partial \rho} & \frac{\partial z}{\partial \phi} & \frac{\partial z}{\partial \theta} \end{vmatrix} = \rho^2 \sin \phi.$$

The corresponding version of Equation (7) is

$$\iiint_D F(x, y, z) dx dy dz = \iiint_G H(\rho, \phi, \theta) |\rho^2 \sin \phi| d\rho d\phi d\theta.$$

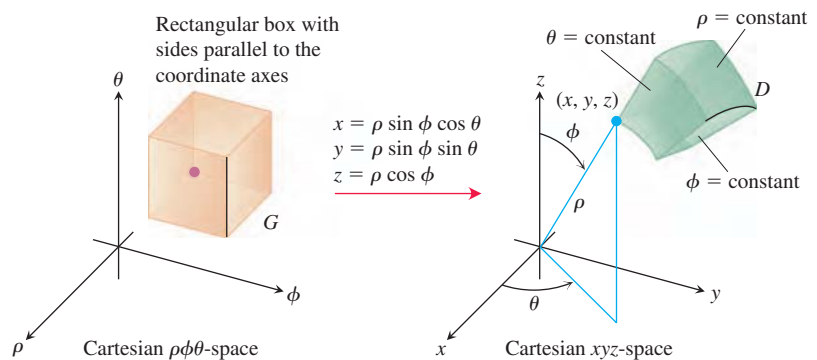

FIGURE 14.65 The equations $x = \rho \sin \phi \cos \theta$, $y = \rho \sin \phi \sin \theta$, and $z = \rho \cos \phi$ transform the rectangular box G into the spherical wedge D .

We can drop the absolute value signs because $\sin \phi$ is never negative for $0 \leq \phi \leq \pi$. Note that this is the same result we obtained in Section 14.7.

Here is an example of another substitution. Although we could evaluate the integral in this example directly, we have chosen it to illustrate the substitution method in a simple (and fairly intuitive) setting.

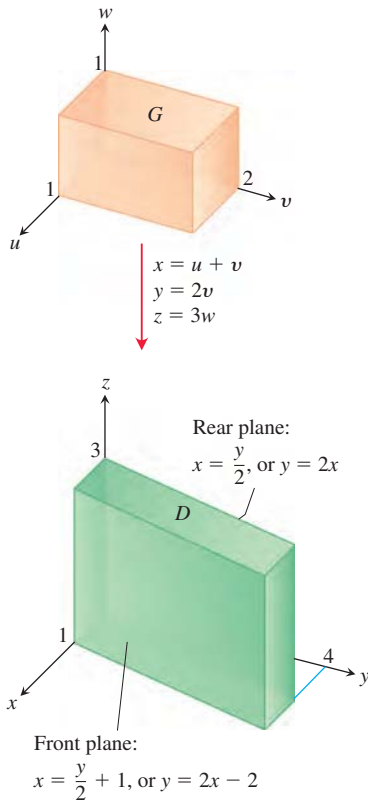

FIGURE 14.66 The equations $x = u + v$, $y = 2v$, and $z = 3w$ transform G into D . Reversing the transformation by the equations $u = (2x - y)/2$, $v = y/2$, and $w = z/3$ transforms D into G (Example 5).

EXAMPLE 5 Evaluate

$$\int_0^3 \int_0^4 \int_{x=y/2}^{x=(y/2)+1} \left(\frac{2x-y}{2} + \frac{z}{3} \right) dx dy dz$$

by applying the transformation

$$u = (2x - y)/2, \quad v = y/2, \quad w = z/3 \quad (8)$$

and integrating over an appropriate region in uvw -space.

Solution We sketch the solid region D of integration in xyz -space and identify its boundaries (Figure 14.66). In this case, the bounding surfaces are planes.

To apply Equation (7), we need to find the corresponding uvw -region G and the Jacobian of the transformation. To find them, we first solve Equations (8) for x , y , and z in terms of u , v , and w . Routine algebra gives

$$x = u + v, \quad y = 2v, \quad z = 3w. \quad (9)$$

We then find the boundaries of G by substituting these expressions into the equations for the boundaries of D .

xyz -equations for the boundary of D	Corresponding uvw -equations for the boundary of G	Simplified uvw -equations
$x = y/2$	$u + v = 2v/2 = v$	$u = 0$
$x = (y/2) + 1$	$u + v = (2v/2) + 1 = v + 1$	$u = 1$
$y = 0$	$2v = 0$	$v = 0$
$y = 4$	$2v = 4$	$v = 2$
$z = 0$	$3w = 0$	$w = 0$
$z = 3$	$3w = 3$	$w = 1$

The Jacobian of the transformation, again from Equations (9), is

$$J(u, v, w) = \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial x}{\partial v} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial u} & \frac{\partial y}{\partial v} & \frac{\partial y}{\partial w} \\ \frac{\partial z}{\partial u} & \frac{\partial z}{\partial v} & \frac{\partial z}{\partial w} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{vmatrix} = 6.$$

We now have everything we need to apply Equation (7):

$$\begin{aligned} & \int_0^3 \int_0^4 \int_{x=y/2}^{x=(y/2)+1} \left(\frac{2x-y}{2} + \frac{z}{3} \right) dx dy dz \\ &= \int_0^1 \int_0^2 \int_0^1 (u + w) |J(u, v, w)| du dv dw \\ &= \int_0^1 \int_0^2 \int_0^1 (u + w)(6) du dv dw = 6 \int_0^1 \int_0^2 \left[\frac{u^2}{2} + uw \right]_{u=0}^{u=1} dv dw \\ &= 6 \int_0^1 \int_0^2 \left(\frac{1}{2} + w \right) dv dw = 6 \int_0^1 \left[\frac{v}{2} + vw \right]_{v=0}^{v=2} dw = 6 \int_0^1 (1 + 2w) dw \\ &= 6 \left[w + w^2 \right]_0^1 = 6(2) = 12. \end{aligned}$$

EXERCISES 14.8

Jacobians and Transformed Regions in the Plane

1. a. Solve the system

$$u = x - y, \quad v = 2x + y$$

for x and y in terms of u and v . Then find the value of the Jacobian $\partial(x, y)/\partial(u, v)$.

- b. Find the image under the transformation $u = x - y$, $v = 2x + y$ of the triangular region with vertices $(0, 0)$, $(1, 1)$, and $(1, -2)$ in the xy -plane. Sketch the transformed region in the uv -plane.

2. a. Solve the system

$$u = x + 2y, \quad v = x - y$$

for x and y in terms of u and v . Then find the value of the Jacobian $\partial(x, y)/\partial(u, v)$.

- b. Find the image under the transformation $u = x + 2y$, $v = x - y$ of the triangular region in the xy -plane bounded by the lines $y = 0$, $y = x$, and $x + 2y = 2$. Sketch the transformed region in the uv -plane.

3. a. Solve the system

$$u = 3x + 2y, \quad v = x + 4y$$

for x and y in terms of u and v . Then find the value of the Jacobian $\partial(x, y)/\partial(u, v)$.

- b. Find the image under the transformation $u = 3x + 2y$, $v = x + 4y$ of the triangular region in the xy -plane bounded by the x -axis, the y -axis, and the line $x + y = 1$. Sketch the transformed region in the uv -plane.

4. a. Solve the system

$$u = 2x - 3y, \quad v = -x + y$$

for x and y in terms of u and v . Then find the value of the Jacobian $\partial(x, y)/\partial(u, v)$.

- b. Find the image under the transformation $u = 2x - 3y$, $v = -x + y$ of the parallelogram R in the xy -plane with boundaries $x = -3$, $x = 0$, $y = x$, and $y = x + 1$. Sketch the transformed region in the uv -plane.

Substitutions in Double Integrals

5. Evaluate the integral

$$\int_0^4 \int_{x=y/2}^{x=(y/2)+1} \frac{2x-y}{2} dx dy$$

from Example 1 directly by integration with respect to x and y to confirm that its value is 2.

6. Use the transformation in Exercise 1 to evaluate the integral

$$\iint_R (2x^2 - xy - y^2) dx dy$$

for the region R in the first quadrant bounded by the lines $y = -2x + 4$, $y = -2x + 7$, $y = x - 2$, and $y = x + 1$.

7. Use the transformation in Exercise 3 to evaluate the integral

$$\iint_R (3x^2 + 14xy + 8y^2) dx dy$$

for the region R bounded by the lines $y = -(3/2)x + 1$, $y = -(3/2)x + 3$, $y = -(1/4)x$, and $y = -(1/4)x + 1$.

8. Use the transformation and parallelogram R in Exercise 4 to evaluate the integral

$$\iint_R 2(x-y) dx dy.$$

9. Let R be the region in the first quadrant of the xy -plane bounded by the hyperbolas $xy = 1$, $xy = 9$ and the lines $y = x$, $y = 4x$. Use the transformation $x = u/v$, $y = uv$ with $u > 0$ and $v > 0$ to rewrite

$$\iint_R \left(\sqrt{\frac{y}{x}} + \sqrt{xy} \right) dx dy$$

as an integral over an appropriate region G in the uv -plane. Then evaluate the uv -integral over G .

10. a. Find the Jacobian of the transformation $x = u$, $y = uv$ and sketch the region $G: 1 \leq u \leq 2$, $1 \leq uv \leq 2$, in the uv -plane.

- b. Then use Equation (2) to transform the integral

$$\int_1^2 \int_1^{2^2} \frac{y}{x} dy dx$$

into an integral over G , and evaluate both integrals.

11. **Polar moment of inertia of an elliptical plate** A thin plate of constant density covers the region bounded by the ellipse $x^2/a^2 + y^2/b^2 = 1$, $a > 0$, $b > 0$, in the xy -plane. Find the first moment of the plate about the origin. (*Hint*: Use the transformation $x = ar \cos \theta$, $y = br \sin \theta$.)

12. **The area of an ellipse** The area πab of the ellipse $x^2/a^2 + y^2/b^2 = 1$ can be found by integrating the function $f(x, y) = 1$ over the region bounded by the ellipse in the xy -plane. Evaluating the integral directly requires a trigonometric substitution. An easier way to evaluate the integral is to use the transformation $x = au$, $y = bv$ and evaluate the transformed integral over the disk $G: u^2 + v^2 \leq 1$ in the uv -plane. Find the area this way.

13. Use the transformation in Exercise 2 to evaluate the integral

$$\int_0^{2/3} \int_y^{2-2y} (x+2y) e^{(y-x)} dx dy$$

by first writing it as an integral over a region G in the uv -plane.

14. Use the transformation $x = u + (1/2)v$, $y = v$ to evaluate the integral

$$\int_0^2 \int_{y/2}^{(y+4)/2} y^3 (2x-y) e^{(2x-y)^2} dx dy$$

by first writing it as an integral over a region G in the uv -plane.

15. Use the transformation $x = u/v$, $y = uv$ to evaluate the integral sum

$$\int_1^2 \int_{1/y}^y (x^2 + y^2) dx dy + \int_2^4 \int_{y/4}^{4/y} (x^2 + y^2) dx dy.$$

16. Use the transformation $x = u^2 - v^2$, $y = 2uv$ to evaluate the integral

$$\int_0^1 \int_0^{2\sqrt{1-x}} \sqrt{x^2 + y^2} dy dx.$$

(*Hint*: Show that the image of the triangular region G with vertices $(0, 0)$, $(1, 0)$, $(1, 1)$ in the uv -plane is the region of integration R in the xy -plane defined by the limits of integration.)

Substitutions in Triple Integrals

17. Evaluate the integral in Example 5 by integrating with respect to x , y , and z .

18. **Volume of a solid ellipsoid** Find the volume of the solid ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \leq 1.$$

(Hint: Let $x = au$, $y = bv$, and $z = cw$. Then find the volume of an appropriate region in uvw -space.)

19. Evaluate

$$\iiint_D |xyz| \, dx \, dy \, dz$$

over the solid ellipsoid D ,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \leq 1.$$

(Hint: Let $x = au$, $y = bv$, and $z = cw$. Then integrate over an appropriate region in uvw -space.)

20. Let D be the solid region in xyz -space defined by the inequalities

$$1 \leq x \leq 2, \quad 0 \leq xy \leq 2, \quad 0 \leq z \leq 1.$$

Evaluate

$$\iiint_D (x^2y + 3xyz) \, dx \, dy \, dz$$

by applying the transformation

$$u = x, \quad v = xy, \quad w = 3z$$

and integrating over an appropriate region G in uvw -space.

Theory and Examples

21. Find the Jacobian $\partial(x, y)/\partial(u, v)$ of the transformation

a. $x = u \cos v, \quad y = u \sin v$

b. $x = u \sin v, \quad y = u \cos v$

22. Find the Jacobian $\partial(x, y, z)/\partial(u, v, w)$ of the transformation

a. $x = u \cos v, \quad y = u \sin v, \quad z = w$

b. $x = 2u - 1, \quad y = 3v - 4, \quad z = (1/2)(w - 4)$.

23. Evaluate the appropriate determinant to show that the Jacobian of the transformation from Cartesian $\rho\phi\theta$ -space to Cartesian xyz -space is $\rho^2 \sin \phi$.

24. **Substitutions in single integrals** How can substitutions in single definite integrals be viewed as transformations of regions? What is the Jacobian in such a case? Illustrate with an example.

25. **Centroid of a solid semi-ellipsoid** Assuming the result that the centroid of a solid hemisphere lies on the axis of symmetry three-eighths of the way from the base toward the top, show, by transforming the appropriate integrals, that the center of mass of a solid semi-ellipsoid $(x^2/a^2) + (y^2/b^2) + (z^2/c^2) \leq 1, z \geq 0$, lies on the z -axis three-eighths of the way from the base toward the top. (You can do this without evaluating any of the integrals.)

26. **Cylindrical shells** In Section 6.2, we learned how to find the volume of a solid of revolution using the shell method. Specifically, if the region between the curve $y = f(x)$ and the x -axis from a to b ($0 < a < b$) is revolved about the y -axis, the volume of the resulting solid is $\int_a^b 2\pi x f(x) \, dx$. Prove that finding volumes by using triple integrals gives the same result. (Hint: Use cylindrical coordinates with the roles of y and z changed.)

27. **Inverse transform** The equations $x = g(u, v), y = h(u, v)$ in Figure 14.57 transform the region G in the uv -plane into the region R in the xy -plane. Since the substitution transformation is one-to-one with continuous first partial derivatives, it has an inverse transformation, and there are equations $u = \alpha(x, y), v = \beta(x, y)$ with continuous first partial derivatives transforming R back into G . Moreover, the Jacobian determinants of the transformations are related reciprocally by

$$\frac{\partial(x, y)}{\partial(u, v)} = \left(\frac{\partial(u, v)}{\partial(x, y)} \right)^{-1}. \quad (10)$$

Equation (10) is proved in advanced calculus. Use it to find the area of the region R in the first quadrant of the xy -plane bounded by the lines $y = 2x, 2y = x$, and the curves $xy = 2, 2xy = 1$ for $u = xy$ and $v = y/x$.

28. (Continuation of Exercise 27.) For the region R described in Exercise 27, evaluate the integral $\iint_R y^2 \, dA$.

CHAPTER 14 Questions to Guide Your Review

1. Define the double integral of a function of two variables over a bounded region in the coordinate plane.
2. How are double integrals evaluated as iterated integrals? Does the order of integration matter? How are the limits of integration determined? Give examples.
3. How are double integrals used to calculate areas and average values. Give examples.
4. How can you change a double integral in rectangular coordinates into a double integral in polar coordinates? Why might it be worthwhile to do so? Give an example.
5. Define the triple integral of a function $f(x, y, z)$ over a bounded solid region in space.
6. How are triple integrals in rectangular coordinates evaluated? How are the limits of integration determined? Give an example.

7. How are double and triple integrals in rectangular coordinates used to calculate volumes, average values, masses, moments, and centers of mass? Give examples.
8. How are triple integrals defined in cylindrical and spherical coordinates? Why might one prefer working in one of these coordinate systems to working in rectangular coordinates?
9. How are triple integrals in cylindrical and spherical coordinates evaluated? How are the limits of integration found? Give examples.
10. How are substitutions in double integrals pictured as transformations of regions in the plane? Give a sample calculation.
11. How are substitutions in triple integrals pictured as transformations of solid regions? Give a sample calculation.

CHAPTER 14 Practice Exercises

Evaluating Double Iterated Integrals

In Exercises 1–4, sketch the region of integration and evaluate the double integral.

$$1. \int_1^{10} \int_0^{1/y} y e^{xy} dx dy \quad 2. \int_0^1 \int_0^{x^3} e^{y/x} dy dx$$

$$3. \int_0^{3/2} \int_{-\sqrt{9-4t^2}}^{\sqrt{9-4t^2}} t ds dt \quad 4. \int_0^1 \int_{\sqrt{y}}^{2-\sqrt{y}} xy dx dy$$

In Exercises 5–8, sketch the region of integration and write an equivalent integral with the order of integration reversed. Then evaluate both integrals.

$$5. \int_0^4 \int_{-\sqrt{4-y}}^{(y-4)/2} dx dy \quad 6. \int_0^1 \int_{x^2}^x \sqrt{x} dy dx$$

$$7. \int_0^{3/2} \int_{-\sqrt{9-4y^2}}^{\sqrt{9-4y^2}} y dx dy \quad 8. \int_0^2 \int_0^{4-x^2} 2x dy dx$$

Evaluate the integrals in Exercises 9–12.

$$9. \int_0^1 \int_{2y}^2 4 \cos(x^2) dx dy \quad 10. \int_0^2 \int_{y/2}^1 e^{x^2} dx dy$$

$$11. \int_0^8 \int_{\sqrt[3]{x}}^2 \frac{dy dx}{y^4 + 1} \quad 12. \int_0^1 \int_{\sqrt[3]{y}}^1 \frac{2\pi \sin \pi x^2}{x^2} dx dy$$

Areas and Volumes Using Double Integrals

- 13. Area between line and parabola** Find the area of the region enclosed by the line $y = 2x + 4$ and the parabola $y = 4 - x^2$ in the xy -plane.
- 14. Area bounded by lines and parabola** Find the area of the “triangular” region in the xy -plane that is bounded on the right by the parabola $y = x^2$, on the left by the line $x + y = 2$, and above by the line $y = 4$.
- 15. Volume of the region under a paraboloid** Find the volume under the paraboloid $z = x^2 + y^2$ above the triangle enclosed by the lines $y = x$, $x = 0$, and $x + y = 2$ in the xy -plane.
- 16. Volume of the region under a parabolic cylinder** Find the volume under the parabolic cylinder $z = x^2$ above the region enclosed by the parabola $y = 6 - x^2$ and the line $y = x$ in the xy -plane.

Average Values

Find the average value of $f(x, y) = xy$ over the regions in Exercises 17 and 18.

- 17.** The square bounded by the lines $x = 1$, $y = 1$ in the first quadrant
- 18.** The quarter circle $x^2 + y^2 \leq 1$ in the first quadrant

Polar Coordinates

Evaluate the integrals in Exercises 19 and 20 by changing to polar coordinates.

$$19. \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{2 dy dx}{(1+x^2+y^2)^2}$$

$$20. \int_{-1}^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} \ln(x^2 + y^2 + 1) dx dy$$

- 21. Integrating over a lemniscate** Integrate the function $f(x, y) = 1/(1 + x^2 + y^2)^2$ over the region enclosed by one loop of the lemniscate $(x^2 + y^2)^2 - (x^2 - y^2) = 0$.
- 22.** Integrate $f(x, y) = 1/(1 + x^2 + y^2)^2$ over
- a. Triangular region** The triangle with vertices $(0, 0)$, $(1, 0)$, and $(1, \sqrt{3})$.
- b. First quadrant** The first quadrant of the xy -plane.

Evaluating Triple Iterated Integrals

Evaluate the integrals in Exercises 23–26.

$$23. \int_0^\pi \int_0^\pi \int_0^\pi \cos(x + y + z) dx dy dz$$

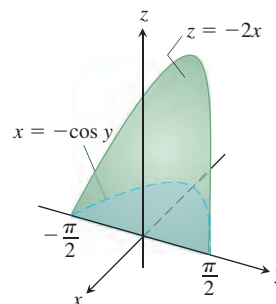

$$24. \int_{\ln 6}^{\ln 7} \int_0^{\ln 2} \int_{\ln 4}^{\ln 5} e^{(x+y+z)} dz dy dx$$

$$25. \int_0^1 \int_0^{x^2} \int_0^{x+y} (2x - y - z) dz dy dx$$

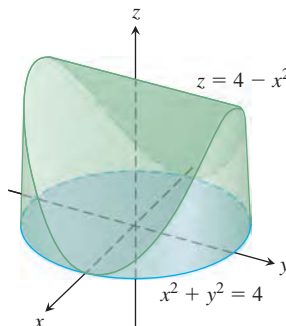

$$26. \int_1^e \int_1^x \int_0^z \frac{2y}{z^3} dy dz dx$$

Volumes and Average Values Using Triple Integrals

- 27. Volume** Find the volume of the wedge-shaped solid region enclosed on the side by the cylinder $x = -\cos y$, $-\pi/2 \leq y \leq \pi/2$, on the top by the plane $z = -2x$, and below by the xy -plane.

- 28. Volume** Find the volume of the solid that is bounded above by the cylinder $z = 4 - x^2$, on the sides by the cylinder $x^2 + y^2 = 4$, and below by the xy -plane.

- 29. Average value** Find the average value of $f(x, y, z) = 30xz\sqrt{x^2 + y}$ over the rectangular solid in the first octant bounded by the coordinate planes and the planes $x = 1$, $y = 3$, $z = 1$.

- 30. Average value** Find the average value of ρ over the ball $\rho \leq a$ (spherical coordinates).

Cylindrical and Spherical Coordinates

- 31. Cylindrical to rectangular coordinates** Convert

$$\int_0^{2\pi} \int_0^{\sqrt{2}} \int_r^{\sqrt{4-r^2}} 3r \, dz \, dr \, d\theta, \quad r \geq 0$$

to (a) rectangular coordinates with the order of integration $dz \, dx \, dy$ and (b) spherical coordinates. Then (c) evaluate one of the integrals.

- 32. Rectangular to cylindrical coordinates** (a) Convert to cylindrical coordinates. Then (b) evaluate the new integral.

$$\int_0^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{-(x^2+y^2)}^{(x^2+y^2)} 21xy^2 \, dz \, dy \, dx$$

- 33. Rectangular to spherical coordinates** (a) Convert to spherical coordinates. Then (b) evaluate the new integral.

$$\int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \int_{\sqrt{x^2+y^2}}^1 dz \, dy \, dx$$

- 34. Rectangular, cylindrical, and spherical coordinates** Write an iterated triple integral for the integral of $f(x, y, z) = 6 + 4y$ over the region in the first octant bounded by the cone $z = \sqrt{x^2 + y^2}$, the cylinder $x^2 + y^2 = 1$, and the coordinate planes in (a) rectangular coordinates, (b) cylindrical coordinates, and (c) spherical coordinates. Then (d) find the integral of f by evaluating one of the triple integrals.

- 35. Cylindrical to rectangular coordinates** Set up an integral in rectangular coordinates equivalent to the integral

$$\int_0^{\pi/2} \int_1^{\sqrt{3}} \int_1^{\sqrt{4-r^2}} r^3 (\sin \theta \cos \theta) z^2 \, dz \, dr \, d\theta.$$

Arrange the order of integration to be z first, then y , then x .

- 36. Rectangular to cylindrical coordinates** The volume of a solid is

$$\int_0^2 \int_0^{\sqrt{2x-x^2}} \int_{-\sqrt{4-x^2-y^2}}^{\sqrt{4-x^2-y^2}} dz \, dy \, dx.$$

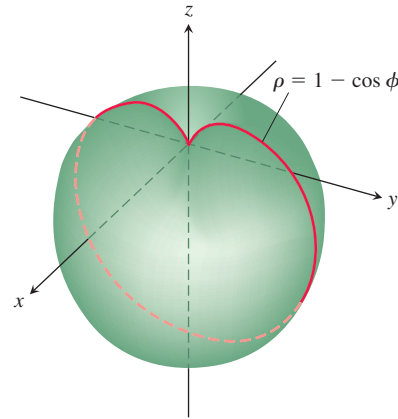

- a. Describe the solid by giving equations for the surfaces that form its boundary.
 b. Convert the integral to cylindrical coordinates, but do not evaluate the integral.
- 37. Spherical versus cylindrical coordinates** Triple integrals involving spherical shapes do not always require spherical coordinates for convenient evaluation. Some calculations may be accomplished more easily with cylindrical coordinates. As a case in point, find the volume of the solid region bounded above by the sphere $x^2 + y^2 + z^2 = 8$ and below by the plane $z = 2$ by using (a) cylindrical coordinates and (b) spherical coordinates.

Masses and Moments

- 38. Finding I_z in spherical coordinates** Find the moment of inertia about the z -axis of a solid of constant density $\delta = 1$ that is bounded above by the sphere $\rho = 2$ and below by the cone $\phi = \pi/3$ (spherical coordinates).

- 39. Moment of inertia of a “thick” sphere** Find the moment of inertia of a solid of constant density δ bounded by two concentric spheres of radii a and b ($a < b$) about a diameter.

- 40. Moment of inertia of an apple** Find the moment of inertia about the z -axis of a solid of density $\delta = 1$ enclosed by the spherical coordinate surface $\rho = 1 - \cos \phi$. The solid is the red curve rotated about the z -axis in the accompanying figure.

- 41. Centroid** Find the centroid of the “triangular” region bounded by the lines $x = 2$, $y = 2$ and the hyperbola $xy = 2$ in the xy -plane.
- 42. Centroid** Find the centroid of the region between the parabola $x + y^2 - 2y = 0$ and the line $x + 2y = 0$ in the xy -plane.
- 43. Polar moment** Find the polar moment of inertia about the origin of a thin triangular plate of constant density $\delta = 3$ bounded by the y -axis and the lines $y = 2x$ and $y = 4$ in the xy -plane.
- 44. Polar moment** Find the polar moment of inertia about the center of a thin rectangular sheet of constant density $\delta = 1$ bounded by the lines
- a. $x = \pm 2$, $y = \pm 1$ in the xy -plane
 b. $x = \pm a$, $y = \pm b$ in the xy -plane.
 (Hint: Find I_x . Then use the formula for I_x to find I_y , and add the two to find I_0 .)
- 45. Inertial moment** Find the moment of inertia about the x -axis of a thin plate of constant density δ covering the triangle with vertices $(0, 0)$, $(3, 0)$, and $(3, 2)$ in the xy -plane.
- 46. Plate with variable density** Find the center of mass and the moments of inertia about the coordinate axes of a thin plate bounded by the line $y = x$ and the parabola $y = x^2$ in the xy -plane if the density is $\delta(x, y) = x + 1$.
- 47. Plate with variable density** Find the mass and first moments about the coordinate axes of a thin square plate bounded by the lines $x = \pm 1$, $y = \pm 1$ in the xy -plane if the density is $\delta(x, y) = x^2 + y^2 + 1/3$.
- 48. Triangles with same inertial moment** Find the moment of inertia about the x -axis of a thin triangular plate of constant density δ whose base lies along the interval $[0, b]$ on the x -axis and whose vertex lies on the line $y = h$ above the x -axis. As you will see, it does not matter where on the line this vertex lies. All such triangles have the same moment of inertia about the x -axis.

49. **Centroid** Find the centroid of the region in the polar coordinate plane defined by the inequalities $0 \leq r \leq 3$, $-\pi/3 \leq \theta \leq \pi/3$.
50. **Centroid** Find the centroid of the region in the first quadrant bounded by the rays $\theta = 0$ and $\theta = \pi/2$ and the circles $r = 1$ and $r = 3$.
51. **a. Centroid** Find the centroid of the region in the polar coordinate plane that lies inside the cardioid $r = 1 + \cos \theta$ and outside the circle $r = 1$.
- b.** Sketch the region and show the centroid in your sketch.
52. **a. Centroid** Find the centroid of the plane region defined by the polar coordinate inequalities $0 \leq r \leq a$, $-\alpha \leq \theta \leq \alpha$ ($0 < \alpha \leq \pi$). How does the centroid move as $\alpha \rightarrow \pi^-$?
- b.** Sketch the region for $\alpha = 5\pi/6$ and show the centroid in your sketch.

Substitutions

53. Show that if $u = x - y$ and $v = y$, then for any continuous f ,
- $$\int_0^{\infty} \int_0^x e^{-sx} f(x - y, y) dy dx = \int_0^{\infty} \int_0^{\infty} e^{-s(u+v)} f(u, v) du dv.$$

54. What relationship must hold between the constants a , b , and c to make

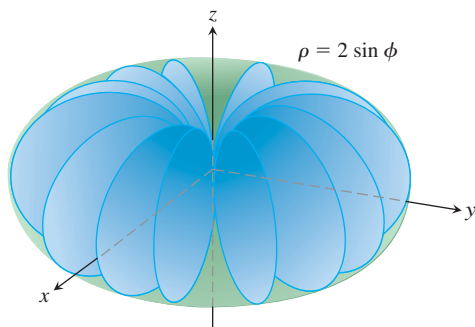

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-(ax^2 + 2bxy + cy^2)} dx dy = 1?$$

(Hint: Let $s = \alpha x + \beta y$ and $t = \gamma x + \delta y$, where $(\alpha\delta - \beta\gamma)^2 = ac - b^2$. Then $ax^2 + 2bxy + cy^2 = s^2 + t^2$.)

CHAPTER 14 Additional and Advanced Exercises

Volumes

1. **Sand pile: double and triple integrals** The base of a sand pile covers the region in the xy -plane that is bounded by the parabola $x^2 + y = 6$ and the line $y = x$. The height of the sand above the point (x, y) is x^2 . Express the volume of sand as (a) a double integral and (b) a triple integral. Then (c) find the volume.
2. **Water in a hemispherical bowl** A hemispherical bowl of radius 5 cm is filled with water to within 3 cm of the top. Find the volume of water in the bowl.
3. **Solid cylindrical region between two planes** Find the volume of the portion of the solid cylinder $x^2 + y^2 \leq 1$ that lies between the planes $z = 0$ and $x + y + z = 2$.
4. **Sphere and paraboloid** Find the volume of the solid region bounded above by the sphere $x^2 + y^2 + z^2 = 2$ and below by the paraboloid $z = x^2 + y^2$.
5. **Two paraboloids** Find the volume of the solid region bounded above by the paraboloid $z = 3 - x^2 - y^2$ and below by the paraboloid $z = 2x^2 + 2y^2$.
6. **Spherical coordinates** Find the volume of the solid region enclosed by the spherical coordinate surface $\rho = 2 \sin \phi$ (see accompanying figure).

7. **Hole in solid ball** A circular cylindrical hole is bored through a ball, the axis of the hole being a diameter of the sphere. The volume of the remaining solid is

$$V = 2 \int_0^{2\pi} \int_0^{\sqrt{3}} \int_1^{\sqrt{4-z^2}} r dr dz d\theta.$$

- a.** Find the radius of the hole and the radius of the sphere.
- b.** Evaluate the integral.
8. **Ball and cylinder** Find the volume of material cut from the ball $r^2 + z^2 \leq 9$ by the cylinder $r = 3 \sin \theta$.
9. **Two paraboloids** Find the volume of the solid region enclosed by the surfaces $z = x^2 + y^2$ and $z = (x^2 + y^2 + 1)/2$.
10. **Cylinder and surface $z = xy$** Find the volume of the solid region in the first octant that lies between the cylinders $r = 1$ and $r = 2$ and is bounded below by the xy -plane and above by the surface $z = xy$.

Changing the Order of Integration

11. Evaluate the integral

$$\int_0^{\infty} \frac{e^{-ax} - e^{-bx}}{x} dx.$$

(Hint: Use the relation

$$\frac{e^{-ax} - e^{-bx}}{x} = \int_a^b e^{-xy} dy$$

to form a double integral, and evaluate the integral by changing the order of integration.)

12. **a. Polar coordinates** Show, by changing to polar coordinates, that

$$\int_0^{a \sin \beta} \int_{y \cot \beta}^{\sqrt{a^2 - y^2}} \ln(x^2 + y^2) dx dy = a^2 \beta \left(\ln a - \frac{1}{2} \right),$$

where $a > 0$ and $0 < \beta < \pi/2$.

b. Rewrite the Cartesian integral with the order of integration reversed.

- 13. Reducing a double to a single integral** By changing the order of integration, show that the following double integral can be reduced to a single integral:

$$\int_0^x \int_0^u e^{m(x-t)} f(t) dt du = \int_0^x (x-t)e^{m(x-t)} f(t) dt.$$

Similarly, it can be shown that

$$\int_0^x \int_0^v \int_0^u e^{m(x-t)} f(t) dt du dv = \int_0^x \frac{(x-t)^2}{2} e^{m(x-t)} f(t) dt.$$

- 14. Transforming a double integral to obtain constant limits** Sometimes a multiple integral with variable limits can be changed into one with constant limits. By changing the order of integration, show that

$$\begin{aligned} \int_0^1 f(x) \left(\int_0^x g(x-y) f(y) dy \right) dx \\ &= \int_0^1 f(y) \left(\int_y^1 g(x-y) f(x) dx \right) dy \\ &= \frac{1}{2} \int_0^1 \int_0^1 g(|x-y|) f(x) f(y) dx dy. \end{aligned}$$

Masses and Moments

- 15. Minimizing polar inertia** A thin plate of constant density is to occupy the triangular region in the first quadrant of the xy -plane having vertices $(0, 0)$, $(a, 0)$, and $(a, 1/a)$. What value of a will minimize the plate's polar moment of inertia about the origin?
- 16. Polar inertia of triangular plate** Find the polar moment of inertia about the origin of a thin triangular plate of constant density $\delta = 3$ bounded by the y -axis and the lines $y = 2x$ and $y = 4$ in the xy -plane.
- 17. Mass and polar inertia of a counterweight** The counterweight of a flywheel of constant density 1 has the form of the smaller segment cut from a circle of radius a by a chord at a distance b from the center ($b < a$). Find the mass of the counterweight and its polar moment of inertia about the center of the wheel.
- 18. Centroid of a boomerang** Find the centroid of the boomerang-shaped region between the parabolas $y^2 = -4(x-1)$ and $y^2 = -2(x-2)$ in the xy -plane.

Theory and Examples

- 19. Evaluate**

$$\int_0^a \int_0^b e^{\max(b^2x^2, a^2y^2)} dy dx,$$

where a and b are positive numbers and

$$\max(b^2x^2, a^2y^2) = \begin{cases} b^2x^2 & \text{if } b^2x^2 \geq a^2y^2 \\ a^2y^2 & \text{if } b^2x^2 < a^2y^2. \end{cases}$$

- 20. Show that**

$$\iint \frac{\partial^2 F(x, y)}{\partial x \partial y} dx dy$$

over the rectangle $x_0 \leq x \leq x_1$, $y_0 \leq y \leq y_1$ is

$$F(x_1, y_1) - F(x_0, y_1) - F(x_1, y_0) + F(x_0, y_0).$$

- 21. Suppose that $f(x, y)$ can be written as a product $f(x, y) = F(x)G(y)$ of a function of x and a function of y . Then the integral of f over the rectangle $R: a \leq x \leq b$, $c \leq y \leq d$ can be evaluated as a product as well, by the formula**

$$\iint_R f(x, y) dA = \left(\int_a^b F(x) dx \right) \left(\int_c^d G(y) dy \right). \quad (1)$$

The argument is that

$$\iint_R f(x, y) dA = \int_c^d \left(\int_a^b F(x) G(y) dx \right) dy \quad (i)$$

$$= \int_c^d \left(G(y) \int_a^b F(x) dx \right) dy \quad (ii)$$

$$= \int_c^d \left(\int_a^b F(x) dx \right) G(y) dy \quad (iii)$$

$$= \left(\int_a^b F(x) dx \right) \int_c^d G(y) dy. \quad (iv)$$

- a. Give reasons for Steps (i) through (iv).

When it applies, Equation (1) can be a time-saver. Use it to evaluate the following integrals.

$$\text{b. } \int_0^{\ln 2} \int_0^{\pi/2} e^x \cos y dy dx \quad \text{c. } \int_1^2 \int_{-1}^1 \frac{x}{y^2} dx dy$$

- 22. Let $D_{\mathbf{u}}f$ denote the derivative of $f(x, y) = (x^2 + y^2)/2$ in the direction of the unit vector $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j}$.**
- a. **Finding average value** Find the average value of $D_{\mathbf{u}}f$ over the triangular region cut from the first quadrant by the line $x + y = 1$.
- b. **Average value and centroid** Show in general that the average value of $D_{\mathbf{u}}f$ over a region in the xy -plane is the value of $D_{\mathbf{u}}f$ at the centroid of the region.
- 23. The value of $\Gamma(1/2)$** The gamma function,

$$\Gamma(x) = \int_0^{\infty} t^{x-1} e^{-t} dt,$$

extends the factorial function from the nonnegative integers to other real values. Of particular interest in the theory of differential equations is the number

$$\Gamma\left(\frac{1}{2}\right) = \int_0^{\infty} t^{(1/2)-1} e^{-t} dt = \int_0^{\infty} \frac{e^{-t}}{\sqrt{t}} dt. \quad (2)$$

- a. If you have not yet done Exercise 41 in Section 14.4, do it now to show that

$$I = \int_0^{\infty} e^{-y^2} dy = \frac{\sqrt{\pi}}{2}.$$

- b. Substitute $y = \sqrt{t}$ in Equation (2) to show that $\Gamma(1/2) = 2I = \sqrt{\pi}$.

- 24. Total electrical charge over circular plate** The electrical charge distribution on a circular plate of radius R meters is $\sigma(r, \theta) = kr(1 - \sin \theta)$ coulomb/m² (k a constant). Integrate σ over the plate to find the total charge Q .

- 25. A parabolic rain gauge** A bowl is in the shape of the graph of $z = x^2 + y^2$ from $z = 0$ to $z = 30$ cm. You plan to calibrate the bowl to make it into a rain gauge. What height in the bowl would correspond to 3 cm of rain? 9 cm of rain?
- 26. Water in a satellite dish** A parabolic satellite dish is 2 m wide and $1/2$ m deep. Its axis of symmetry is tilted 30 degrees from the vertical.
- Set up, but do not evaluate, a triple integral in rectangular coordinates that gives the amount of water the satellite dish will hold. (*Hint:* Put your coordinate system so that the satellite dish is in “standard position” and the plane of the water level is slanted.) (*Caution:* The limits of integration are not “nice.”)
 - What would be the smallest tilt of the satellite dish so that it holds no water?
- 27. An infinite half-cylinder** Let D be the interior of the infinite right circular half-cylinder of radius 1 with its single-end face

suspended 1 unit above the origin and its axis the ray from $(0, 0, 1)$ to ∞ . Use cylindrical coordinates to evaluate

$$\iiint_D z(r^2 + z^2)^{-5/2} dV.$$

- 28. Hypervolume** We have learned that $\int_a^b 1 dx$ is the length of the interval $[a, b]$ on the number line (one-dimensional space), $\iint_R 1 dA$ is the area of region R in the xy -plane (two-dimensional space), and $\iiint_D 1 dV$ is the volume of the region D in three-dimensional space (xyz -space). We could continue: If Q is a region in 4-space ($xyzw$ -space), then $\iiiii_Q 1 dV$ is the “hyper-volume” of Q . Use your generalizing abilities and a Cartesian coordinate system of 4-space to find the hypervolume inside the unit four-dimensional sphere $x^2 + y^2 + z^2 + w^2 = 1$.

CHAPTER 14 Technology Application Projects

Mathematica/Maple Projects

Projects can be found within MyLab Math.

- **Take Your Chances: Try the Monte Carlo Technique for Numerical Integration in Three Dimensions**
Use the Monte Carlo technique to integrate numerically in three dimensions.
- **Means and Moments and Exploring New Plotting Techniques, Part II**
Use the method of moments in a form that makes use of geometric symmetry as well as multiple integration.

15

Integrals and Vector Fields

OVERVIEW In this chapter we extend the theory of integration to functions whose domains are curves and surfaces in space. The resulting line and surface integrals give powerful mathematical tools for science and engineering. Line integrals are used to find the work done by a force in moving an object along a path and to find the mass of a curved wire with variable density. Surface integrals are used to find the rate of flow of a fluid across a surface and to describe the interactions of electric and magnetic forces. We present the fundamental theorems of vector integral calculus and discuss their mathematical consequences and physical applications. The theorems of vector calculus are then shown to be generalized versions of the Fundamental Theorem of Calculus.

15.1 Line Integrals of Scalar Functions

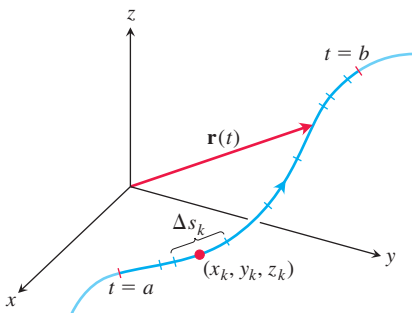

FIGURE 15.1 The curve $\mathbf{r}(t)$ partitioned into small arcs from $t = a$ to $t = b$. The length of a typical subarc is Δs_k .

To calculate the total mass of a wire lying along a curve in space, or to find the work done by a variable force acting along such a curve, we need a more general notion of integral than was defined in Chapter 5. We need to integrate over a curve C rather than over an interval $[a, b]$. These more general integrals are called *line integrals* (although *path integrals* might be more descriptive). We make our definitions for space curves, with curves in the xy -plane being the special case with z -coordinate identically zero.

Suppose that $f(x, y, z)$ is a real-valued function we wish to integrate over the curve C lying within the domain of f and parametrized by $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$, $a \leq t \leq b$. The values of f along the curve are given by the composite function $f(g(t), h(t), k(t))$. We are going to integrate this composition with respect to arc length from $t = a$ to $t = b$. To begin, we first partition the curve C into a finite number n of subarcs (Figure 15.1). The typical subarc has length Δs_k . In each subarc we choose a point (x_k, y_k, z_k) and form the sum

$$S_n = \sum_{k=1}^n \underbrace{f(x_k, y_k, z_k)}_{\text{value of } f \text{ at a point on the subarc}} \underbrace{\Delta s_k}_{\text{length of a small subarc of the curve}},$$

which is similar to a Riemann sum. Depending on how we partition the curve C and pick (x_k, y_k, z_k) in the k th subarc, we may get different values for S_n . If f is continuous and the functions g , h , and k have continuous first derivatives, then these sums approach a limit as n increases and the lengths Δs_k approach zero. This leads to the following definition, which is similar to that for a single integral. In the definition, we assume that the norm of the partition approaches zero as $n \rightarrow \infty$, so that the length of the longest subarc approaches zero.

DEFINITION If f is defined on a curve C given parametrically by $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$, $a \leq t \leq b$, then the **line integral of f over C** is

$$\int_C f(x, y, z) ds = \lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k, y_k, z_k) \Delta s_k, \quad (1)$$

provided this limit exists.

If the curve C is smooth for $a \leq t \leq b$ (so $\mathbf{v} = d\mathbf{r}/dt$ is continuous and never $\mathbf{0}$) and the function f is continuous on C , then the limit in Equation (1) can be shown to exist. We can then apply the Fundamental Theorem of Calculus to differentiate the arc length equation,

$$s(t) = \int_a^t |\mathbf{v}(\tau)| d\tau, \quad \begin{array}{l} \text{Eq. (3) of Section 12.3} \\ \text{with } t_0 = a \end{array}$$

to express ds in Equation (1) as $ds = |\mathbf{v}(t)| dt$ and evaluate the integral of f over C as

$$\int_C f(x, y, z) ds = \int_a^b f(g(t), h(t), k(t)) |\mathbf{v}(t)| dt. \quad (2)$$

The integral on the right side of Equation (2) is just an ordinary definite integral, as defined in Chapter 5, where we are integrating with respect to the parameter t . The formula evaluates the line integral on the left side correctly no matter what smooth parametrization is used. Note that the parameter t defines a direction along the path. The starting point on C is the position $\mathbf{r}(a)$, and movement along the path is in the direction of increasing t (see Figure 15.1).

$$\frac{ds}{dt} = |\mathbf{v}| = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}$$

$$f(\mathbf{r}(t)) = f(g(t), h(t), k(t))$$

How to Evaluate a Line Integral

To integrate a continuous function $f(x, y, z)$ over a curve C :

1. Find a smooth parametrization of C ,

$$\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}, \quad a \leq t \leq b.$$

2. Evaluate the integral as

$$\int_C f(x, y, z) ds = \int_a^b f(g(t), h(t), k(t)) |\mathbf{v}(t)| dt.$$

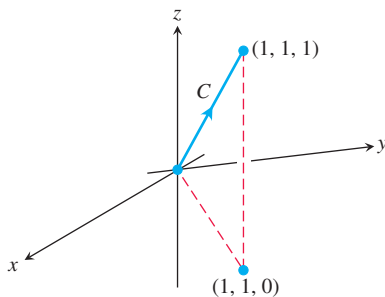

FIGURE 15.2 The integration path in Example 1.

If f has the constant value 1, then the integral of f over C gives the length of C from $t = a$ to $t = b$. We also write $f(\mathbf{r}(t))$ for the evaluation $f(g(t), h(t), k(t))$ along the curve \mathbf{r} .

EXAMPLE 1 Integrate $f(x, y, z) = x - 3y^2 + z$ over the line segment C joining the origin to the point $(1, 1, 1)$ (Figure 15.2).

Solution Since any choice of parametrization will give the same answer, we choose the simplest parametrization we can think of:

$$\mathbf{r}(t) = t\mathbf{i} + t\mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq 1.$$

The components have continuous first derivatives, and $|\mathbf{v}(t)| = |\mathbf{i} + \mathbf{j} + \mathbf{k}| = \sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$ is never 0, so the parametrization is smooth. The integral of f over C is

$$\begin{aligned}\int_C f(x, y, z) ds &= \int_0^1 f(t, t, t) \sqrt{3} dt && \text{Eq. (2), } ds = |\mathbf{v}(t)| dt = \sqrt{3} dt \\ &= \int_0^1 (t - 3t^2 + t) \sqrt{3} dt \\ &= \sqrt{3} \int_0^1 (2t - 3t^2) dt = \sqrt{3} \left[t^2 - t^3 \right]_0^1 = 0. \quad \blacksquare\end{aligned}$$

Additivity

Line integrals have the useful property that if a piecewise smooth curve C is made by joining a finite number of smooth curves C_1, C_2, \dots, C_n end to end (Section 12.1), then the integral of a function over C is the sum of the integrals over the curves that make it up:

$$\int_C f ds = \int_{C_1} f ds + \int_{C_2} f ds + \dots + \int_{C_n} f ds. \quad (3)$$

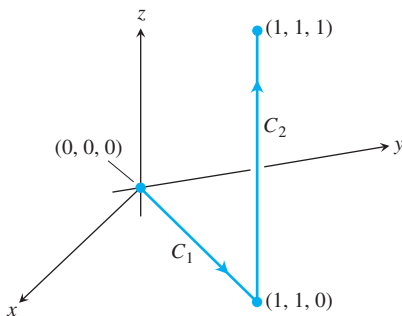

FIGURE 15.3 The path of integration in Example 2.

EXAMPLE 2 Figure 15.3 shows another path from the origin to $(1, 1, 1)$, formed from two line segments C_1 and C_2 . Integrate $f(x, y, z) = x - 3y^2 + z$ over $C_1 \cup C_2$.

Solution We choose the simplest parametrizations for C_1 and C_2 we can find, calculating the lengths of the velocity vectors as we go along:

$$\begin{aligned}C_1: \mathbf{r}(t) &= t\mathbf{i} + t\mathbf{j}, \quad 0 \leq t \leq 1; \quad |\mathbf{v}| = \sqrt{1^2 + 1^2} = \sqrt{2} \\ C_2: \mathbf{r}(t) &= \mathbf{i} + \mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq 1; \quad |\mathbf{v}| = \sqrt{0^2 + 0^2 + 1^2} = 1.\end{aligned}$$

With these parametrizations we find that

$$\begin{aligned}\int_{C_1 \cup C_2} f(x, y, z) ds &= \int_{C_1} f(x, y, z) ds + \int_{C_2} f(x, y, z) ds && \text{Eq. (3)} \\ &= \int_0^1 f(t, t, 0) \sqrt{2} dt + \int_0^1 f(1, 1, t) (1) dt && \text{Eq. (2)} \\ &= \int_0^1 (t - 3t^2 + 0) \sqrt{2} dt + \int_0^1 (1 - 3 + t) (1) dt \\ &= \sqrt{2} \left[\frac{t^2}{2} - t^3 \right]_0^1 + \left[\frac{t^2}{2} - 2t \right]_0^1 = -\frac{\sqrt{2}}{2} - \frac{3}{2}. \quad \blacksquare\end{aligned}$$

Notice three things about the integrations in Examples 1 and 2. First, as soon as the components of the appropriate curve were substituted into the formula for f , the integration became a standard integration with respect to t . Second, the integral of f over $C_1 \cup C_2$ was obtained by integrating f over each section of the path and adding the results. Third, the integrals of f over C and $C_1 \cup C_2$ had different values. We investigate this third observation in Section 15.3.

The value of a line integral along a path joining two points can change if you change the path between them.

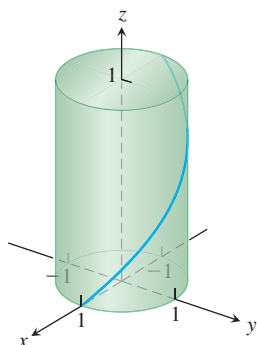

FIGURE 15.4 A line integral is taken over a curve such as this helix from Example 3.

EXAMPLE 3 Find the line integral of $f(x, y, z) = 2xy + \sqrt{z}$ over the helix $\mathbf{r}(t) = \cos t \mathbf{i} + \sin t \mathbf{j} + t \mathbf{k}$, $0 \leq t \leq \pi$.

Solution For the helix (Figure 15.4) we find $\mathbf{v}(t) = \mathbf{r}'(t) = -\sin t \mathbf{i} + \cos t \mathbf{j} + \mathbf{k}$ and $|\mathbf{v}(t)| = \sqrt{(-\sin t)^2 + (\cos t)^2 + 1} = \sqrt{2}$. Evaluating the function f at the point $\mathbf{r}(t)$, we obtain

$$f(\mathbf{r}(t)) = f(\cos t, \sin t, t) = 2 \cos t \sin t + \sqrt{t} = \sin 2t + \sqrt{t}.$$

The line integral is given by

$$\begin{aligned} \int_C f(x, y, z) ds &= \int_0^\pi (\sin 2t + \sqrt{t}) \sqrt{2} dt \\ &= \sqrt{2} \left[-\frac{1}{2} \cos 2t + \frac{2}{3} t^{3/2} \right]_0^\pi \\ &= \frac{2\sqrt{2}}{3} \pi^{3/2} \approx 5.25. \end{aligned}$$

Mass and Moment Calculations

We treat coil springs and wires as masses distributed along smooth curves in space. The distribution is described by a continuous density function $\delta(x, y, z)$ representing mass per unit length. When a curve C is parametrized by $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$, $a \leq t \leq b$, then x , y , and z are functions of the parameter t , the density is the function $\delta(x(t), y(t), z(t))$, and the arc length differential is given by

$$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} dt.$$

(See Section 12.3.) The spring's or wire's mass, center of mass, and moments are then calculated using the formulas in Table 15.1, with the integrations in terms of the parameter t over the interval $[a, b]$. For example, the formula for mass becomes

$$M = \int_a^b \delta(x(t), y(t), z(t)) \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} dt.$$

These formulas also apply to thin rods, and their derivations are similar to those in Section 6.6. Notice how similar the formulas are to those in Tables 15.1 and 15.2 for double and triple integrals. The double integrals for planar regions, and the triple integrals for solids, become line integrals for coil springs, wires, and thin rods.

Notice that the element of mass dm is equal to δds in the table, rather than to δdV as in Table 15.1, and that the integrals are taken over the curve C .

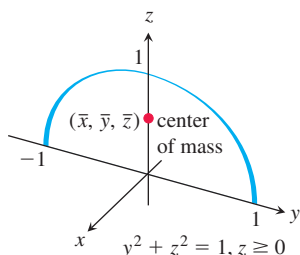

FIGURE 15.5 Example 4 shows how to find the center of mass of a circular arch of variable density.

EXAMPLE 4 A slender metal arch, denser at the bottom than at the top, lies along the semicircle $y^2 + z^2 = 1$, $z \geq 0$, in the yz -plane (Figure 15.5). Find the center of the arch's mass if the density at the point (x, y, z) on the arch is $\delta(x, y, z) = 2 - z$.

Solution We know that $\bar{x} = 0$ and $\bar{y} = 0$ because the arch lies in the yz -plane with its mass distributed symmetrically about the z -axis. To find \bar{z} , we parametrize the circle as

$$\mathbf{r}(t) = (\cos t)\mathbf{j} + (\sin t)\mathbf{k}, \quad 0 \leq t \leq \pi.$$

TABLE 15.1 Mass and moment formulas for coil springs, wires, and thin rods lying along a smooth curve C in space

Mass: $M = \int_C \delta \, ds$ $\delta = \delta(x, y, z)$ is the density at (x, y, z) .

First moments about the coordinate planes:

$$M_{yz} = \int_C x \delta \, ds, \quad M_{xz} = \int_C y \delta \, ds, \quad M_{xy} = \int_C z \delta \, ds$$

Coordinates of the center of mass:

$$\bar{x} = M_{yz}/M, \quad \bar{y} = M_{xz}/M, \quad \bar{z} = M_{xy}/M$$

Moments of inertia about axes and other lines:

$$I_x = \int_C (y^2 + z^2) \delta \, ds, \quad I_y = \int_C (x^2 + z^2) \delta \, ds, \quad I_z = \int_C (x^2 + y^2) \delta \, ds,$$

$$I_L = \int_C r^2 \delta \, ds \quad r = r(x, y, z) \text{ is the distance from the point } (x, y, z) \text{ to line } L.$$

For this parametrization,

$$|\mathbf{v}(t)| = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{(0)^2 + (-\sin t)^2 + (\cos t)^2} = 1,$$

so $ds = |\mathbf{v}| \, dt = dt$.

The formulas in Table 15.1 then give

$$M = \int_C \delta \, ds = \int_C (2 - z) \, ds = \int_0^\pi (2 - \sin t) \, dt = 2\pi - 2$$

$$\begin{aligned} M_{xy} &= \int_C z \delta \, ds = \int_C z(2 - z) \, ds = \int_0^\pi (\sin t)(2 - \sin t) \, dt \\ &= \int_0^\pi (2 \sin t - \sin^2 t) \, dt = \frac{8 - \pi}{2} \quad \text{Routine integration} \end{aligned}$$

$$\bar{z} = \frac{M_{xy}}{M} = \frac{8 - \pi}{2} \cdot \frac{1}{2\pi - 2} = \frac{8 - \pi}{4\pi - 4} \approx 0.57.$$

With \bar{z} to the nearest hundredth, the center of mass is $(0, 0, 0.57)$. ■

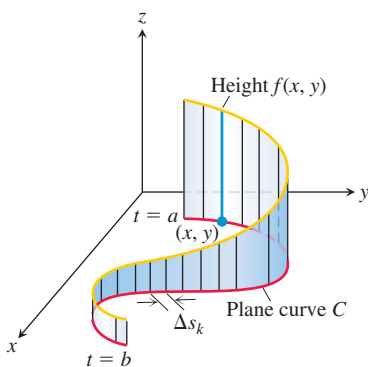

FIGURE 15.6 The line integral $\int_C f \, ds$ gives the area of the portion of the cylindrical surface or “wall” beneath the surface $z = f(x, y) \geq 0$.

Line Integrals in the Plane

Line integrals for curves in the plane have a natural geometric interpretation. If C is a smooth curve in the xy -plane parametrized by $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j}$, $a \leq t \leq b$, we generate a cylindrical surface by moving a straight line along C perpendicular to the plane, holding the line parallel to the z -axis, as in Figure 15.6. If $z = f(x, y)$ is a nonnegative continuous function over a region in the plane containing the curve C , then the graph of f is a surface that lies above the plane. The cylinder cuts through this surface, forming a curve on it that lies above the curve C and follows its winding nature. The part of the cylindrical surface that lies beneath the surface curve and above the xy -plane forms a “curved

wall” or “fence” standing on the curve C and orthogonal to the plane. At any point (x, y) along the curve, the height of the wall is $f(x, y)$. From the definition

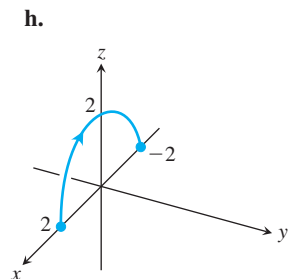

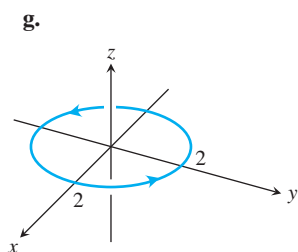

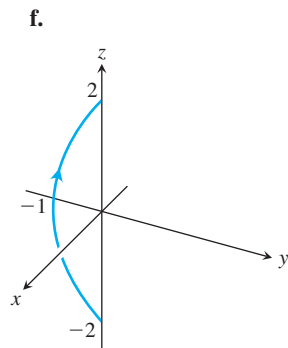

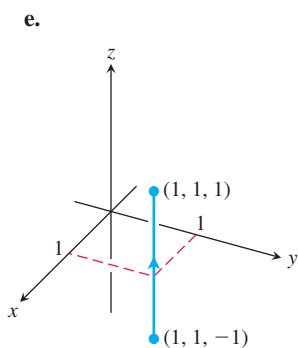

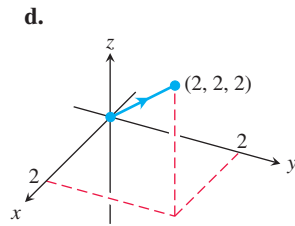

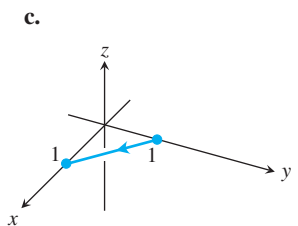

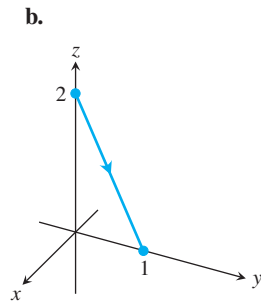

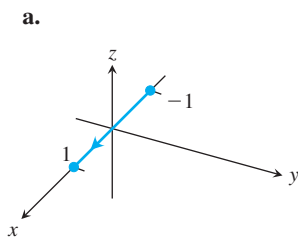

$$\int_C f \, ds = \lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k, y_k) \Delta s_k,$$

where $\Delta s_k \rightarrow 0$ as $n \rightarrow \infty$, we see that the line integral $\int_C f \, ds$ is the area of the wall shown in the figure.

EXERCISES 15.1

Graphs of Vector Equations

Match the vector equations in Exercises 1–8 with the graphs (a)–(h) given here.

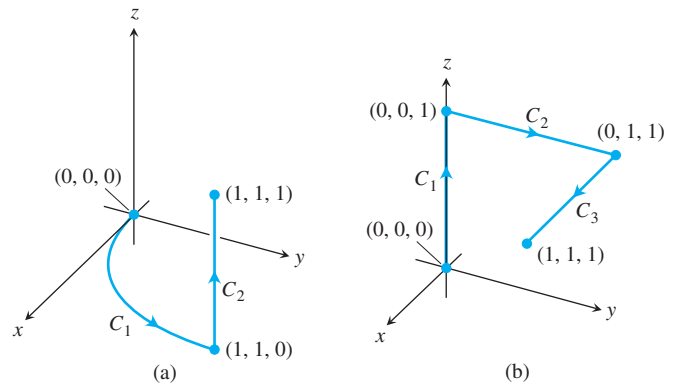

1. $\mathbf{r}(t) = t\mathbf{i} + (1-t)\mathbf{j}$, $0 \leq t \leq 1$
2. $\mathbf{r}(t) = \mathbf{i} + \mathbf{j} + t\mathbf{k}$, $-1 \leq t \leq 1$
3. $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$
4. $\mathbf{r}(t) = t\mathbf{i}$, $-1 \leq t \leq 1$
5. $\mathbf{r}(t) = t\mathbf{i} + t\mathbf{j} + t\mathbf{k}$, $0 \leq t \leq 2$
6. $\mathbf{r}(t) = t\mathbf{j} + (2-2t)\mathbf{k}$, $0 \leq t \leq 1$
7. $\mathbf{r}(t) = (t^2-1)\mathbf{j} + 2t\mathbf{k}$, $-1 \leq t \leq 1$
8. $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{k}$, $0 \leq t \leq \pi$

Evaluating Line Integrals over Space Curves

9. Evaluate $\int_C (x+y) \, ds$, where C is the straight-line segment $x = t$, $y = (1-t)$, $z = 0$, from $(0, 1, 0)$ to $(1, 0, 0)$.
10. Evaluate $\int_C (x-y+z-2) \, ds$, where C is the straight-line segment $x = t$, $y = (1-t)$, $z = 1$, from $(0, 1, 1)$ to $(1, 0, 1)$.
11. Evaluate $\int_C (xy + y + z) \, ds$ along the curve $\mathbf{r}(t) = 2t\mathbf{i} + t\mathbf{j} + (2-2t)\mathbf{k}$, $0 \leq t \leq 1$.
12. Evaluate $\int_C \sqrt{x^2 + y^2} \, ds$ along the curve $\mathbf{r}(t) = (4 \cos t)\mathbf{i} + (4 \sin t)\mathbf{j} + 3t\mathbf{k}$, $-2\pi \leq t \leq 2\pi$.
13. Find the line integral of $f(x, y, z) = x + y + z$ over the straight-line segment from $(1, 2, 3)$ to $(0, -1, 1)$.
14. Find the line integral of $f(x, y, z) = \sqrt{3}/(x^2 + y^2 + z^2)$ over the curve $\mathbf{r}(t) = t\mathbf{i} + t\mathbf{j} + t\mathbf{k}$, $1 \leq t < \infty$.
15. Integrate $f(x, y, z) = x + \sqrt{y} - z^2$ over the path C_1 followed by C_2 from $(0, 0, 0)$ to $(1, 1, 1)$ (see accompanying figure) given by

$$C_1: \mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j}, \quad 0 \leq t \leq 1$$

$$C_2: \mathbf{r}(t) = \mathbf{i} + \mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq 1.$$

The paths of integration for Exercises 15 and 15.

16. Integrate $f(x, y, z) = x + \sqrt{y} - z^2$ over the path C_1 followed by C_2 followed by C_3 from $(0, 0, 0)$ to $(1, 1, 1)$ (see accompanying figure) given by

$$C_1: \mathbf{r}(t) = t\mathbf{k}, \quad 0 \leq t \leq 1$$

$$C_2: \mathbf{r}(t) = t\mathbf{j} + \mathbf{k}, \quad 0 \leq t \leq 1$$

$$C_3: \mathbf{r}(t) = t\mathbf{i} + \mathbf{j} + \mathbf{k}, \quad 0 \leq t \leq 1.$$

17. Integrate $f(x, y, z) = (x + y + z)/(x^2 + y^2 + z^2)$ over the path $\mathbf{r}(t) = t\mathbf{i} + t\mathbf{j} + t\mathbf{k}$, $0 < a \leq t \leq b$.

18. Integrate $f(x, y, z) = -\sqrt{x^2 + z^2}$ over the circle

$$\mathbf{r}(t) = (a \cos t)\mathbf{j} + (a \sin t)\mathbf{k}, \quad 0 \leq t \leq 2\pi.$$

Line Integrals over Plane Curves

19. Evaluate $\int_C x \, ds$, where C is

a. the straight-line segment $x = t$, $y = t/2$, from $(0, 0)$ to $(4, 2)$.

b. the parabolic curve $x = t$, $y = t^2$, from $(0, 0)$ to $(2, 4)$.

20. Evaluate $\int_C \sqrt{x + 2y} \, ds$, where C is

a. the straight-line segment $x = t$, $y = 4t$, from $(0, 0)$ to $(1, 4)$.

b. $C_1 \cup C_2$; C_1 is the line segment from $(0, 0)$ to $(1, 0)$ and C_2 is the line segment from $(1, 0)$ to $(1, 2)$.

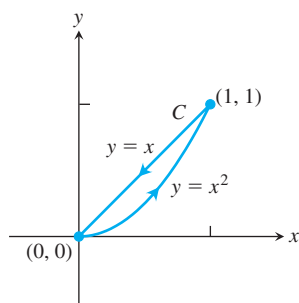

21. Find the line integral of $f(x, y) = ye^{x^2}$ along the curve $\mathbf{r}(t) = 4t\mathbf{i} - 3t\mathbf{j}$, $-1 \leq t \leq 2$.

22. Find the line integral of $f(x, y) = x - y + 3$ along the curve $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$.

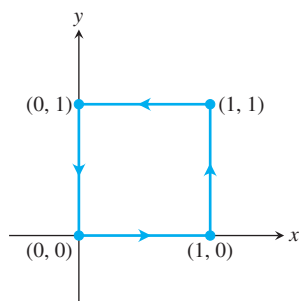

23. Evaluate $\int_C \frac{x^2}{y^{4/3}} \, ds$, where C is the curve $x = t^2$, $y = t^3$, for $1 \leq t \leq 2$.

24. Find the line integral of $f(x, y) = \sqrt{y}/x$ along the curve $\mathbf{r}(t) = t^3\mathbf{i} + t^4\mathbf{j}$, $1/2 \leq t \leq 1$.

25. Evaluate $\int_C (x + \sqrt{y}) \, ds$, where C is given in the accompanying figure.

26. Evaluate $\int_C \frac{1}{x^2 + y^2 + 1} \, ds$, where C is given in the accompanying figure.

In Exercises 27–30, integrate f over the given curve.

27. $f(x, y) = x^3/y$, $C: y = x^2/2$, $0 \leq x \leq 2$

28. $f(x, y) = (x + y^2)/\sqrt{1 + x^2}$, $C: y = x^2/2$ from $(1, 1/2)$ to $(0, 0)$

29. $f(x, y) = x + y$, $C: x^2 + y^2 = 4$ in the first quadrant from $(2, 0)$ to $(0, 2)$

30. $f(x, y) = x^2 - y$, $C: x^2 + y^2 = 4$ in the first quadrant from $(0, 2)$ to $(\sqrt{2}, \sqrt{2})$

31. Find the area of one side of the “winding wall” standing perpendicularly on the curve $y = x^2$, $0 \leq x \leq 2$, and beneath the curve on the surface $f(x, y) = x + \sqrt{y}$.

32. Find the area of one side of the “wall” standing perpendicularly on the curve $2x + 3y = 6$, $0 \leq x \leq 6$, and beneath the curve on the surface $f(x, y) = 4 + 3x + 2y$.

Masses and Moments

33. **Mass of a wire** Find the mass of a wire that lies along the curve $\mathbf{r}(t) = (t^2 - 1)\mathbf{j} + 2t\mathbf{k}$, $0 \leq t \leq 1$, if the density is $\delta = (3/2)t$.

34. **Center of mass of a curved wire** A wire of density $\delta(x, y, z) = 15\sqrt{y + 2}$ lies along the curve $\mathbf{r}(t) = (t^2 - 1)\mathbf{j} + 2t\mathbf{k}$, $-1 \leq t \leq 1$. Find its center of mass. Then sketch the curve and center of mass together.

35. **Mass of wire with variable density** Find the mass of a thin wire lying along the curve $\mathbf{r}(t) = \sqrt{2}t\mathbf{i} + \sqrt{2}t\mathbf{j} + (4 - t^2)\mathbf{k}$, $0 \leq t \leq 1$, if the density is (a) $\delta = 3t$ and (b) $\delta = 1$.

36. **Center of mass of wire with variable density** Find the center of mass of a thin wire lying along the curve $\mathbf{r}(t) = t\mathbf{i} + 2t\mathbf{j} + (2/3)t^{3/2}\mathbf{k}$, $0 \leq t \leq 2$, if the density is $\delta = 3\sqrt{5 + t}$.

37. **Moment of inertia of wire hoop** A circular wire hoop of constant density δ lies along the circle $x^2 + y^2 = a^2$ in the xy -plane. Find the hoop’s moment of inertia about the z -axis.

38. **Inertia of a slender rod** A slender rod of constant density lies along the line segment $\mathbf{r}(t) = t\mathbf{j} + (2 - 2t)\mathbf{k}$, $0 \leq t \leq 1$, in the yz -plane. Find the moments of inertia of the rod about the three coordinate axes.

39. **Two springs of constant density** A spring of constant density δ lies along the helix

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq 2\pi.$$

a. Find I_z .

b. Suppose that you have another spring of constant density δ that is twice as long as the spring in part (a) and lies along the helix for $0 \leq t \leq 4\pi$. Do you expect I_z for the longer spring to be the same as that for the shorter one, or should it be different? Check your prediction by calculating I_z for the longer spring.

40. **Wire of constant density** A wire of constant density $\delta = 1$ lies along the curve

$$\mathbf{r}(t) = (t \cos t)\mathbf{i} + (t \sin t)\mathbf{j} + (2\sqrt{2}/3)t^{3/2}\mathbf{k}, \quad 0 \leq t \leq 1.$$

Find \bar{z} and I_z .

41. **The arch in Example 4** Find I_x for the arch in Example 4.

- 42. Center of mass and moments of inertia for wire with variable density** Find the center of mass and the moments of inertia about the coordinate axes of a thin wire lying along the curve

$$\mathbf{r}(t) = t\mathbf{i} + \frac{2\sqrt{2}}{3}t^{3/2}\mathbf{j} + \frac{t^2}{2}\mathbf{k}, \quad 0 \leq t \leq 2,$$

if the density is $\delta = 1/(t + 1)$.

COMPUTER EXPLORATIONS

In Exercises 43–46, use a CAS to perform the following steps to evaluate the line integrals.

- Find $ds = |\mathbf{v}(t)| dt$ for the path $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$.
- Express the integrand $f(g(t), h(t), k(t))|\mathbf{v}(t)|$ as a function of the parameter t .
- Evaluate $\int_C f ds$ using Equation (2) in the text.

43. $f(x, y, z) = \sqrt{1 + 30x^2 + 10y}$; $\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + 3t^2\mathbf{k}$, $0 \leq t \leq 2$

44. $f(x, y, z) = \sqrt{1 + x^3 + 5y^3}$; $\mathbf{r}(t) = t\mathbf{i} + \frac{1}{3}t^2\mathbf{j} + \sqrt{t}\mathbf{k}$, $0 \leq t \leq 2$

45. $f(x, y, z) = x\sqrt{y} - 3z^2$; $\mathbf{r}(t) = (\cos 2t)\mathbf{i} + (\sin 2t)\mathbf{j} + 5t\mathbf{k}$, $0 \leq t \leq 2\pi$

46. $f(x, y, z) = \left(1 + \frac{9}{4}z^{1/3}\right)^{1/4}$;
 $\mathbf{r}(t) = (\cos 2t)\mathbf{i} + (\sin 2t)\mathbf{j} + t^{5/2}\mathbf{k}$, $0 \leq t \leq 2\pi$

15.2 Vector Fields and Line Integrals: Work, Circulation, and Flux

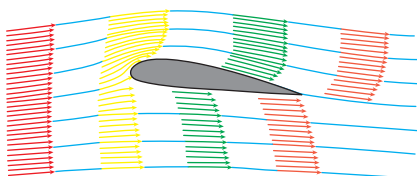

FIGURE 15.7 Velocity vectors of a flow around an airfoil.

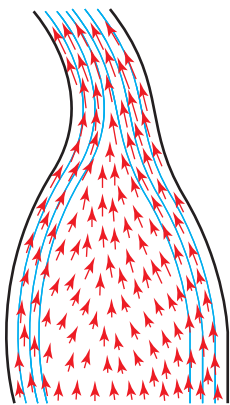

FIGURE 15.8 Streamlines in a contracting channel. The water speeds up as the channel narrows, and the velocity vectors increase in length.

Gravitational and electric forces have both a direction and a magnitude. They are represented by a vector at each point in their domain, producing a *vector field*. In this section we show how to compute the work done in moving an object through such a field by using a line integral involving the vector field. We also discuss velocity fields, such as the vector field representing the velocity of a flowing fluid in its domain. A line integral can be used to find the rate at which the fluid flows along or across a curve within the domain.

Vector Fields

Suppose a region in the plane or in space is occupied by a moving fluid, such as air or water. The fluid is made up of a large number of particles, and at any instant of time, a particle has a velocity \mathbf{v} . At different points of the region at a given (same) time, these velocities can vary. We can think of a velocity vector being attached to each point of the fluid, representing the velocity of a particle at that point. Such a fluid flow is an example of a *vector field*. Figure 15.7 shows a velocity vector field obtained from air flowing around an airfoil in a wind tunnel. Figure 15.8 shows a vector field of velocity vectors along the streamlines of water moving through a contracting channel. Vector fields are also associated with forces such as gravitational attraction (Figure 15.9) and with magnetic fields and electric fields. There are purely mathematical fields as well.

Generally, a **vector field** is a function that assigns a vector to each point in its domain. A vector field on a three-dimensional domain in space might have a formula like

$$\mathbf{F}(x, y, z) = M(x, y, z)\mathbf{i} + N(x, y, z)\mathbf{j} + P(x, y, z)\mathbf{k}.$$

The vector field is **continuous** if the **component functions** M , N , and P are continuous; it is **differentiable** if each of the component functions is differentiable. The formula for a field of two-dimensional vectors could look like

$$\mathbf{F}(x, y) = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}.$$

We encountered another type of vector field in Chapter 12. The tangent vectors \mathbf{T} and normal vectors \mathbf{N} for a curve in space both form vector fields along the curve. Along a curve $\mathbf{r}(t)$ they might have a component formula similar to the velocity field expression

$$\mathbf{v}(t) = f(t)\mathbf{i} + g(t)\mathbf{j} + h(t)\mathbf{k}.$$

If we attach the gradient vector ∇f of a scalar function $f(x, y, z)$ to each point of a level surface of the function, we obtain a three-dimensional field on the surface. If we attach the velocity vector to each point of a flowing fluid, we have a three-dimensional field

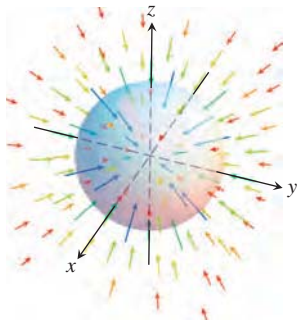

FIGURE 15.9 Vectors in a gravitational field point toward the center of mass that gives the source of the field.

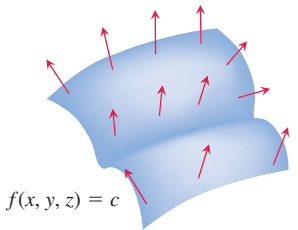

FIGURE 15.11 The field of gradient vectors ∇f on a level surface $f(x, y, z) = c$. The function f is constant on the surface, and each vector points in the direction where f is increasing fastest.

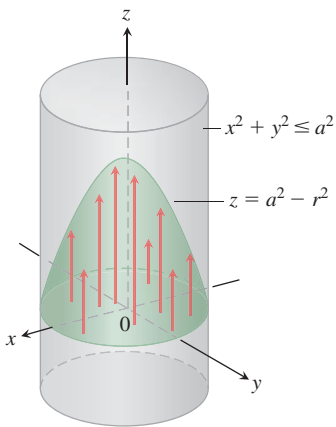

FIGURE 15.14 The flow of fluid in a long cylindrical pipe. The vectors $\mathbf{v} = (a^2 - r^2)\mathbf{k}$ inside the cylinder that have their bases in the xy -plane have their tips on the paraboloid $z = a^2 - r^2$.

defined on a region in space. These and other fields are illustrated in Figures 15.7–15.16. To sketch the fields, we picked a representative selection of domain points and drew the vectors attached to them. The arrows are drawn with their tails, not their heads, attached to the points where the vector functions are evaluated.

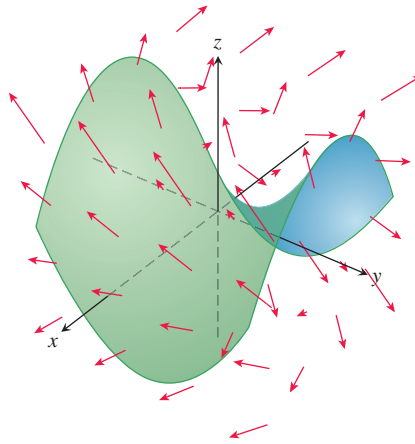

FIGURE 15.10 A surface might represent a filter (or a net or a parachute) in a vector field representing water or wind flow velocity vectors. The arrows show the direction of fluid flow, and their lengths indicate speed.

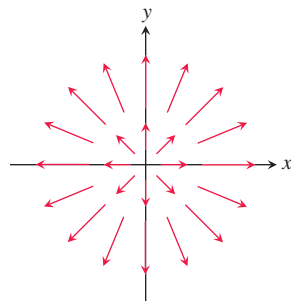

FIGURE 15.12 The radial field $\mathbf{F} = x\mathbf{i} + y\mathbf{j}$ formed by the position vectors of points in the plane. Notice the convention that an arrow is drawn with its tail, not its head, at the point where \mathbf{F} is evaluated.

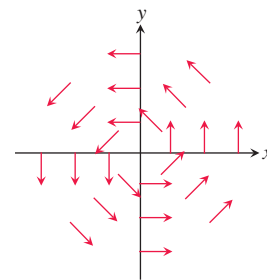

FIGURE 15.13 A “spin” field of rotating unit vectors

$$\mathbf{F} = (-y\mathbf{i} + x\mathbf{j})/(x^2 + y^2)^{1/2}$$
in the plane. The field is not defined at the origin.

Gradient Fields

The gradient vector of a differentiable scalar-valued function at a point gives the direction of greatest increase of the function. An important type of vector field is formed by all the gradient vectors of the function (see Section 13.5). We define the **gradient field** of a differentiable function $f(x, y, z)$ to be the field of gradient vectors

$$\nabla f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}.$$

At each point (x, y, z) , the gradient field gives a vector pointing in the direction of greatest increase of f , with magnitude being the value of the directional derivative in that direction. The gradient field might represent a force field, or a velocity field that gives the motion of a fluid, or the flow of heat through a medium, depending on the application being considered.

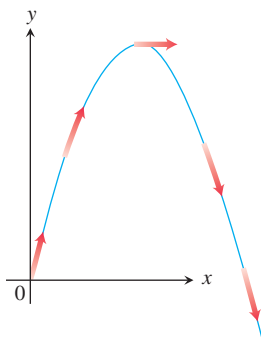

FIGURE 15.15 The velocity vectors $\mathbf{v}(t)$ of a projectile's motion make a vector field along the trajectory.

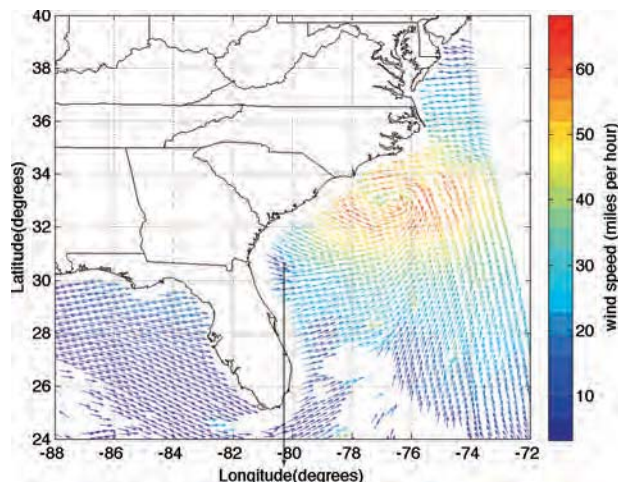

FIGURE 15.16 Data from NASA's QuikSCAT satellite were used to create this representation of wind speed and wind direction in Hurricane Irene approximately six hours before it made landfall in North Carolina on August 27, 2011. The arrows show wind direction, and speed is indicated by color (rather than length). The maximum wind speeds (over 130 km/hour) occurred over a region too small to see in this illustration. (Source: JPL-Caltech/ISRO/NASA)

In many physical applications, f represents a potential energy, and the gradient vector field indicates the corresponding force. In such situations, f is often taken to be negative, so that the force gives the direction of decreasing potential energy.

EXAMPLE 1 Suppose that a material is heated, that the resulting temperature T at each point (x, y, z) in a region of space is given by

$$T = 100 - x^2 - y^2 - z^2,$$

and that $\mathbf{F}(x, y, z)$ is defined to be the gradient of T . Find the vector field \mathbf{F} .

Solution The gradient field \mathbf{F} is the field $\mathbf{F} = \nabla T = -2x\mathbf{i} - 2y\mathbf{j} - 2z\mathbf{k}$. At each point in the region, the vector field \mathbf{F} gives the direction for which the increase in temperature is greatest. The vectors point toward the origin, where the temperature is greatest. See Figure 15.17. ■

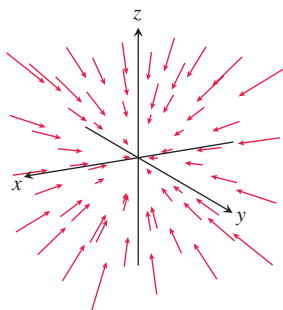

FIGURE 15.17 The vectors in a temperature gradient field point in the direction of greatest increase in temperature. In this case they are pointing toward the origin.

Line Integrals of Vector Fields

In Section 15.1 we defined the line integral of a scalar function $f(x, y, z)$ over a path C . We turn our attention now to the idea of a line integral of a vector field \mathbf{F} along the curve C . Such line integrals have important applications in the study of fluid flows, work and energy, and electrical or gravitational fields.

Assume that the vector field $\mathbf{F} = M(x, y, z)\mathbf{i} + N(x, y, z)\mathbf{j} + P(x, y, z)\mathbf{k}$ has continuous components, and that the curve C has a smooth parametrization $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$, $a \leq t \leq b$. As discussed in Section 15.1, the parametrization $\mathbf{r}(t)$ defines a direction (or orientation) along C that we call the **forward direction**. At each point along the path C , the tangent vector $\mathbf{T} = d\mathbf{r}/ds = \mathbf{v}/|\mathbf{v}|$ is a unit vector tangent to the path and pointing in this forward direction. (The vector $\mathbf{v} = d\mathbf{r}/dt$ is the velocity vector tangent to C at the point, as discussed in Sections 12.1 and 12.3.) The line integral of the vector field is the line integral of the scalar tangential component of \mathbf{F} along C . This tangential component is given by the dot product

$$\mathbf{F} \cdot \mathbf{T} = \mathbf{F} \cdot \frac{d\mathbf{r}}{ds},$$

so we are led to the following definition.

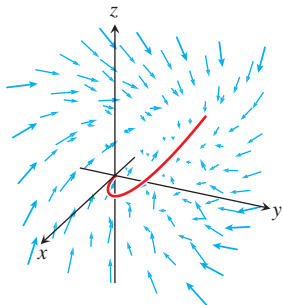

FIGURE 15.18 A curve (in red) winds through a vector field as in Example 2. The line integral is determined by the vectors that lie along the curve.

DEFINITION Let \mathbf{F} be a vector field with continuous components defined along a smooth curve C parametrized by $\mathbf{r}(t)$, $a \leq t \leq b$. Then the **line integral of \mathbf{F} along C** is

$$\int_C \mathbf{F} \cdot \mathbf{T} \, ds = \int_C \left(\mathbf{F} \cdot \frac{d\mathbf{r}}{ds} \right) ds = \int_C \mathbf{F} \cdot d\mathbf{r}. \quad (1)$$

We evaluate line integrals of vector fields in a way similar to the way we evaluate line integrals of scalar functions (Section 15.1). The vector field may also be defined on points not meeting the curve, but only the vectors along the curve play a role in the line integral. See Figure 15.18.

Evaluating the Line Integral of $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ Along $C: \mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$

1. Express the vector field \mathbf{F} along the parametrized curve C as $\mathbf{F}(\mathbf{r}(t))$ by substituting the components $x = g(t)$, $y = h(t)$, $z = k(t)$ of \mathbf{r} into the scalar components $M(x, y, z)$, $N(x, y, z)$, $P(x, y, z)$ of \mathbf{F} .
2. Find the derivative (velocity) vector $d\mathbf{r}/dt$.
3. Evaluate the line integral with respect to the parameter t , $a \leq t \leq b$, to obtain

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} dt. \quad (2)$$

EXAMPLE 2 Evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$, where $\mathbf{F}(x, y, z) = z\mathbf{i} + xy\mathbf{j} - y^2\mathbf{k}$ along the curve C given by $\mathbf{r}(t) = t^2\mathbf{i} + t\mathbf{j} + \sqrt{t}\mathbf{k}$, $0 \leq t \leq 1$.

Solution We have

$$\mathbf{F}(\mathbf{r}(t)) = \sqrt{t}\mathbf{i} + t^3\mathbf{j} - t^2\mathbf{k} \quad z = \sqrt{t}, \quad xy = t^3, \quad -y^2 = -t^2$$

and

$$\frac{d\mathbf{r}}{dt} = 2t\mathbf{i} + \mathbf{j} + \frac{1}{2\sqrt{t}}\mathbf{k}.$$

Thus,

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^1 \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} dt && \text{Eq. (2)} \\ &= \int_0^1 \left(2t^{3/2} + t^3 - \frac{1}{2}t^{3/2} \right) dt \\ &= \left[\left(\frac{3}{2} \right) \left(\frac{2}{5}t^{5/2} \right) + \frac{1}{4}t^4 \right]_0^1 = \frac{17}{20}. \end{aligned}$$

Line Integrals with Respect to dx , dy , or dz

When analyzing forces or flows, it is often useful to consider each component direction separately. For example, when analyzing the effect of a gravitational force, we might want to consider motion and forces in the vertical direction, while ignoring horizontal motions. Or we might be interested only in the force exerted horizontally by water pushing against

the face of a dam or in wind affecting the course of a plane. In such situations we want to evaluate a line integral of a scalar function with respect to only one of the coordinates, such as $\int_C M dx$. This type of integral is not the same as the arc length line integral $\int_C M ds$ we defined in Section 15.1, since it picks out displacement in the direction of only one coordinate. To define the integral $\int_C M dx$ for the scalar function $M(x, y, z)$, we specify a vector field $\mathbf{F} = M(x, y, z)\mathbf{i}$ having a component only in the x -direction, and none in the y - or the z -direction. Then, over the curve C parametrized by $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$ for $a \leq t \leq b$, we have $x = g(t)$, $dx = g'(t) dt$, and

$$\begin{aligned}\mathbf{F} \cdot d\mathbf{r} &= \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt = M(x, y, z)\mathbf{i} \cdot (g'(t)\mathbf{i} + h'(t)\mathbf{j} + k'(t)\mathbf{k}) dt \\ &= M(x, y, z)g'(t) dt = M(x, y, z) dx.\end{aligned}$$

As in the definition of the line integral of \mathbf{F} along C , we define

$$\int_C M(x, y, z) dx = \int_C \mathbf{F} \cdot d\mathbf{r}, \quad \text{where } \mathbf{F} = M(x, y, z)\mathbf{i}.$$

In the same way, by defining $\mathbf{F} = N(x, y, z)\mathbf{j}$ with a component only in the y -direction, or $\mathbf{F} = P(x, y, z)\mathbf{k}$ with a component only in the z -direction, we obtain the line integrals $\int_C N dy$ and $\int_C P dz$. Expressing everything in terms of the parameter t along the curve C , we have the following formulas for these three integrals:

$$\int_C M(x, y, z) dx = \int_a^b M(g(t), h(t), k(t)) g'(t) dt \quad (3)$$

$$\int_C N(x, y, z) dy = \int_a^b N(g(t), h(t), k(t)) h'(t) dt \quad (4)$$

$$\int_C P(x, y, z) dz = \int_a^b P(g(t), h(t), k(t)) k'(t) dt \quad (5)$$

Line Integral Notation

The commonly occurring expression

$$\int_C M dx + N dy + P dz$$

is a short way of expressing the sum of three line integrals, one for each coordinate direction:

$$\begin{aligned}\int_C M(x, y, z) dx + \int_C N(x, y, z) dy \\ + \int_C P(x, y, z) dz.\end{aligned}$$

To evaluate these integrals, we parametrize C as $g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$ and use Equations (3), (4), and (5).

It often happens that these line integrals occur in combination, and we abbreviate the notation by writing

$$\int_C M(x, y, z) dx + \int_C N(x, y, z) dy + \int_C P(x, y, z) dz = \int_C M dx + N dy + P dz.$$

EXAMPLE 3 Evaluate the line integral $\int_C -y dx + z dy + 2x dz$, where C is the helix $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$, $0 \leq t \leq 2\pi$.

Solution We express everything in terms of the parameter t , so $x = \cos t$, $y = \sin t$, $z = t$, and $dx = -\sin t dt$, $dy = \cos t dt$, $dz = dt$. Then

$$\begin{aligned}\int_C -y dx + z dy + 2x dz &= \int_0^{2\pi} [(-\sin t)(-\sin t) + t \cos t + 2 \cos t] dt \\ &= \int_0^{2\pi} [2 \cos t + t \cos t + \sin^2 t] dt \\ &= \left[2 \sin t + (t \sin t + \cos t) + \left(\frac{t}{2} - \frac{\sin 2t}{4} \right) \right]_0^{2\pi} \\ &= [0 + (0 + 1) + (\pi - 0)] - [0 + (0 + 1) + (0 - 0)] \\ &= \pi.\end{aligned}$$

Work Done by a Force over a Curve in Space

Suppose that the vector field $\mathbf{F} = M(x, y, z)\mathbf{i} + N(x, y, z)\mathbf{j} + P(x, y, z)\mathbf{k}$ represents a force throughout a region in space (it might be the force of gravity or an electromagnetic force) and that

$$\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}, \quad a \leq t \leq b,$$

represents a smooth curve C in the region. The formula for the work done by the force in moving an object along the curve is motivated by the same kind of reasoning we used in Chapter 6 to derive the ordinary single integral for the work done by a continuous force of magnitude $F(x)$ directed along an interval of the x -axis. For the curve C in space, we define the work done by a continuous force field \mathbf{F} to move an object along C from a point A to another point B as follows.

We divide C into n subarcs $P_{k-1}P_k$ with lengths Δs_k , starting at A and ending at B . We choose any point (x_k, y_k, z_k) in the subarc $P_{k-1}P_k$ and let $\mathbf{T}(x_k, y_k, z_k)$ be the unit tangent vector at the chosen point. The work W_k done to move the object along the subarc $P_{k-1}P_k$ is approximated by the tangential component of the force $\mathbf{F}(x_k, y_k, z_k)$ times the arc length Δs_k , the distance the object moves along the subarc (see Figure 15.19). The total work done in moving the object from point A to point B is then obtained by summing the work done along each of the subarcs, so

$$W = \sum_{k=1}^n W_k \approx \sum_{k=1}^n \mathbf{F}(x_k, y_k, z_k) \cdot \mathbf{T}(x_k, y_k, z_k) \Delta s_k.$$

For any subdivision of C into n subarcs, and for any choice of the points (x_k, y_k, z_k) within each subarc, as $n \rightarrow \infty$ and $\Delta s_k \rightarrow 0$, these sums approach the line integral

$$\int_C \mathbf{F} \cdot \mathbf{T} \, ds.$$

This is the line integral of \mathbf{F} along C , which now defines the total work done.

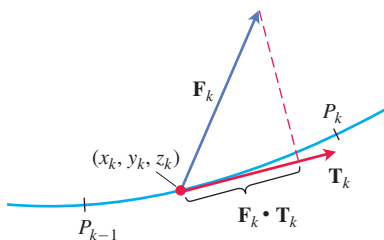

FIGURE 15.19 The work done along the subarc shown here is approximately $\mathbf{F}_k \cdot \mathbf{T}_k \Delta s_k$, where $\mathbf{F}_k = \mathbf{F}(x_k, y_k, z_k)$ and $\mathbf{T}_k = \mathbf{T}(x_k, y_k, z_k)$.

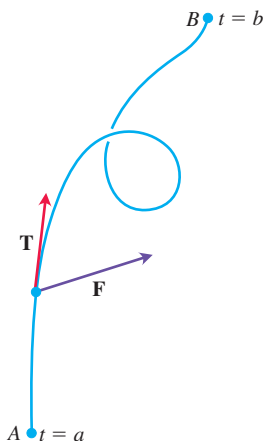

FIGURE 15.20 The work done by a force \mathbf{F} is the line integral of the scalar component $\mathbf{F} \cdot \mathbf{T}$ over the smooth curve from A to B .

DEFINITION Let C be a smooth curve parametrized by $\mathbf{r}(t)$, $a \leq t \leq b$, and let \mathbf{F} be a continuous force field over a region containing C . Then the **work** done in moving an object from the point $A = \mathbf{r}(a)$ to the point $B = \mathbf{r}(b)$ along C is

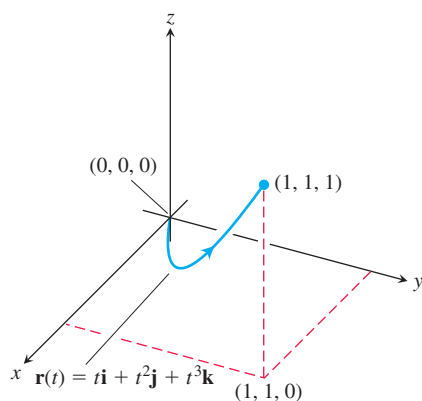

$$W = \int_C \mathbf{F} \cdot \mathbf{T} \, ds = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} \, dt. \quad (6)$$

The sign of the number we calculate with this integral depends on the direction in which the curve is traversed. If we reverse the direction of motion, then we reverse the direction of \mathbf{T} in Figure 15.20 and change the sign of $\mathbf{F} \cdot \mathbf{T}$ and its integral.

Using the notations we have presented, we can express the work integral in a variety of ways, depending upon what seems most suitable or convenient for a particular discussion. Table 15.2 shows five ways we can write the work integral in Equation (6). In the table, the field components M , N , and P are functions of the intermediate variables x , y , and z , which in turn are functions of the independent variable t along the curve C in the vector field. So along the curve, $x = g(t)$, $y = h(t)$, and $z = k(t)$ with $dx = g'(t) \, dt$, $dy = h'(t) \, dt$, and $dz = k'(t) \, dt$.

TABLE 15.2 Different ways to write the work integral for $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ over the curve $C: \mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$, $a \leq t \leq b$

$W = \int_C \mathbf{F} \cdot \mathbf{T} \, ds$	The definition
$= \int_C \mathbf{F} \cdot d\mathbf{r}$	Vector differential form
$= \int_a^b \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt$	Parametric vector evaluation
$= \int_a^b (Mg'(t) + Nh'(t) + Pk'(t)) dt$	Parametric scalar evaluation
$= \int_C M dx + N dy + P dz$	Scalar differential form

**FIGURE 15.21** The curve in Example 4.

EXAMPLE 4 Find the work done by the force field $\mathbf{F} = (y - x^2)\mathbf{i} + (z - y^2)\mathbf{j} + (x - z^2)\mathbf{k}$ in moving an object along the curve $\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + t^3\mathbf{k}$, $0 \leq t \leq 1$, from $(0, 0, 0)$ to $(1, 1, 1)$ (Figure 15.21).

Solution First we evaluate \mathbf{F} on the curve $\mathbf{r}(t)$:

$$\begin{aligned} \mathbf{F} &= (y - x^2)\mathbf{i} + (z - y^2)\mathbf{j} + (x - z^2)\mathbf{k} \\ &= \underbrace{(t^2 - t^2)}_0\mathbf{i} + (t^3 - t^4)\mathbf{j} + (t - t^6)\mathbf{k}. \end{aligned} \quad \text{Substitute } x = t, y = t^2, z = t^3.$$

Then we find $d\mathbf{r}/dt$:

$$\frac{d\mathbf{r}}{dt} = \frac{d}{dt}(t\mathbf{i} + t^2\mathbf{j} + t^3\mathbf{k}) = \mathbf{i} + 2t\mathbf{j} + 3t^2\mathbf{k}.$$

Finally, we find $\mathbf{F} \cdot d\mathbf{r}/dt$ and integrate from $t = 0$ to $t = 1$:

$$\begin{aligned} \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} &= [(t^3 - t^4)\mathbf{j} + (t - t^6)\mathbf{k}] \cdot (\mathbf{i} + 2t\mathbf{j} + 3t^2\mathbf{k}) \\ &= (t^3 - t^4)(2t) + (t - t^6)(3t^2) = 2t^4 - 2t^5 + 3t^3 - 3t^8. \end{aligned} \quad \text{Evaluate dot product.}$$

Thus

$$\begin{aligned} \text{Work} &= \int_a^b \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt = \int_0^1 (2t^4 - 2t^5 + 3t^3 - 3t^8) dt \\ &= \left[\frac{2}{5}t^5 - \frac{2}{6}t^6 + \frac{3}{4}t^4 - \frac{3}{9}t^9 \right]_0^1 = \frac{29}{60}. \end{aligned} \quad \blacksquare$$

EXAMPLE 5 Find the work done by the force field $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ in moving an object along the curve C parametrized by $\mathbf{r}(t) = \cos(\pi t)\mathbf{i} + t^2\mathbf{j} + \sin(\pi t)\mathbf{k}$, $0 \leq t \leq 1$.

Solution We begin by writing \mathbf{F} along C as a function of t :

$$\mathbf{F}(\mathbf{r}(t)) = \cos(\pi t)\mathbf{i} + t^2\mathbf{j} + \sin(\pi t)\mathbf{k}.$$

Next we compute $d\mathbf{r}/dt$:

$$\frac{d\mathbf{r}}{dt} = -\pi \sin(\pi t)\mathbf{i} + 2t\mathbf{j} + \pi \cos(\pi t)\mathbf{k}.$$

We then calculate the dot product:

$$\mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} = -\pi \sin(\pi t) \cos(\pi t) + 2t^3 + \pi \sin(\pi t) \cos(\pi t) = 2t^3.$$

The work done is the line integral

$$\int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} dt = \int_0^1 2t^3 dt = \left. \frac{t^4}{2} \right|_0^1 = \frac{1}{2}. \quad \blacksquare$$

Flow Integrals and Circulation for Velocity Fields

Suppose that \mathbf{F} represents the velocity field of a fluid flowing through a region in space (a tidal basin or the turbine chamber of a hydroelectric generator, for example). Under these circumstances, the integral of $\mathbf{F} \cdot \mathbf{T}$ along a curve in the region gives the fluid's flow along, or *circulation* around, the curve. For instance, the vector field in Figure 15.12 gives zero circulation around the unit circle in the plane. By contrast, the vector field in Figure 15.13 gives a nonzero circulation around the unit circle.

DEFINITION If $\mathbf{r}(t)$ parametrizes a smooth curve C in the domain of a continuous velocity field \mathbf{F} , then the **flow** along the curve from $A = \mathbf{r}(a)$ to $B = \mathbf{r}(b)$ is

$$\text{Flow} = \int_C \mathbf{F} \cdot \mathbf{T} ds. \quad (7)$$

The integral is called a **flow integral**. If the curve starts and ends at the same point, so that $A = B$, the flow is called the **circulation** around the curve.

The direction we travel along C matters. If we reverse the direction, then \mathbf{T} is replaced by $-\mathbf{T}$ and the sign of the integral changes. We evaluate flow integrals the same way we evaluate work integrals.

EXAMPLE 6 A fluid's velocity field is $\mathbf{F} = x\mathbf{i} + z\mathbf{j} + y\mathbf{k}$. Find the flow along the helix $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}$, $0 \leq t \leq \pi/2$.

Solution We evaluate \mathbf{F} on the curve $\mathbf{r}(t)$:

$$\mathbf{F} = x\mathbf{i} + z\mathbf{j} + y\mathbf{k} = (\cos t)\mathbf{i} + t\mathbf{j} + (\sin t)\mathbf{k} \quad \text{Substitute } x = \cos t, z = t, y = \sin t.$$

and then find $d\mathbf{r}/dt$:

$$\frac{d\mathbf{r}}{dt} = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j} + \mathbf{k}.$$

The dot product of \mathbf{F} with $d\mathbf{r}/dt$ is

$$\begin{aligned} \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} &= (\cos t)(-\sin t) + (t)(\cos t) + (\sin t)(1) \\ &= -\sin t \cos t + t \cos t + \sin t. \end{aligned}$$

Finally, we integrate $\mathbf{F} \cdot (d\mathbf{r}/dt)$ from $t = 0$ to $t = \frac{\pi}{2}$:

$$\begin{aligned} \text{Flow} &= \int_{t=0}^{t=\pi/2} \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt = \int_0^{\pi/2} (-\sin t \cos t + t \cos t + \sin t) dt \\ &= \left[\frac{\cos^2 t}{2} + t \sin t \right]_0^{\pi/2} = \left(0 + \frac{\pi}{2} \right) - \left(\frac{1}{2} + 0 \right) = \frac{\pi}{2} - \frac{1}{2}. \quad \blacksquare \end{aligned}$$

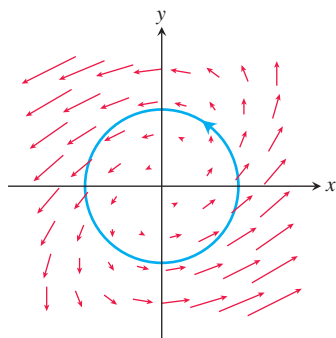

FIGURE 15.22 The vector field \mathbf{F} and curve $\mathbf{r}(t)$ in Example 7.

EXAMPLE 7 Find the circulation of the field $\mathbf{F} = (x - y)\mathbf{i} + x\mathbf{j}$ around the circle $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$ (Figure 15.22).

Solution On the circle, $\mathbf{F} = (x - y)\mathbf{i} + x\mathbf{j} = (\cos t - \sin t)\mathbf{i} + (\cos t)\mathbf{j}$, and

$$\frac{d\mathbf{r}}{dt} = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j}.$$

Then

$$\mathbf{F} \cdot \frac{d\mathbf{r}}{dt} = -\sin t \cos t + \underbrace{\sin^2 t + \cos^2 t}_1$$

gives

$$\begin{aligned} \text{Circulation} &= \int_0^{2\pi} \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt = \int_0^{2\pi} (1 - \sin t \cos t) dt \\ &= \left[t - \frac{\sin^2 t}{2} \right]_0^{2\pi} = 2\pi. \end{aligned}$$

As Figure 15.22 suggests, a fluid with this velocity field is circulating *counterclockwise* around the circle. The circle is also traversed counterclockwise as t increases from 0 to 2π , so the circulation is positive. ■

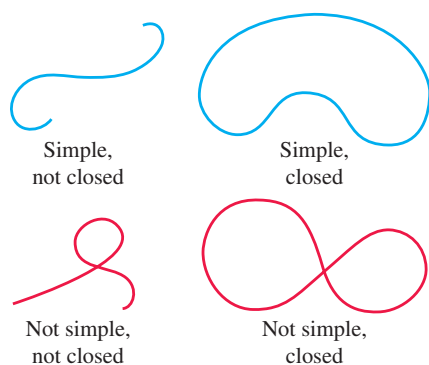

FIGURE 15.23 Distinguishing between curves that are simple and curves that are closed. Closed curves are also called loops.

Flux Across a Simple Closed Plane Curve

A curve in the xy -plane is **simple** if it does not cross itself (Figure 15.23). When a curve starts and ends at the same point, it is a **closed curve** or **loop**. To find the rate at which a fluid is entering or leaving a region enclosed by a smooth simple closed curve C in the xy -plane, we calculate the line integral over C of $\mathbf{F} \cdot \mathbf{n}$, the scalar component of the fluid's velocity field in the direction of the curve's outward-pointing normal vector. We use only the normal component of \mathbf{F} , while ignoring the tangential component, because the normal component leads to the flow across C . The value of this integral is the *flux* of \mathbf{F} across C . *Flux* is Latin for flow, but many flux calculations involve no motion at all. When \mathbf{F} is an electric or magnetic field, for instance, the integral of $\mathbf{F} \cdot \mathbf{n}$ is still called the flux of the field across C .

DEFINITION If C is a smooth simple closed curve in the domain of a continuous vector field $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ in the plane, and if \mathbf{n} is the outward-pointing unit normal vector on C , the **flux** of \mathbf{F} across C is

$$\text{Flux of } \mathbf{F} \text{ across } C = \int_C \mathbf{F} \cdot \mathbf{n} ds. \quad (8)$$

Notice the difference between flux and circulation. The flux of \mathbf{F} across C is the line integral with respect to arc length of $\mathbf{F} \cdot \mathbf{n}$, the scalar component of \mathbf{F} in the direction of the outward normal. The circulation of \mathbf{F} around C is the line integral with respect to arc length of $\mathbf{F} \cdot \mathbf{T}$, the scalar component of \mathbf{F} in the direction of the unit tangent vector. Flux is the integral of the normal component of \mathbf{F} ; circulation is the integral of the tangential component of \mathbf{F} . In Section 15.6 we will define flux across a surface.

To evaluate the integral for flux in Equation (8), we begin with a smooth parametrization

$$x = g(t), \quad y = h(t), \quad a \leq t \leq b,$$

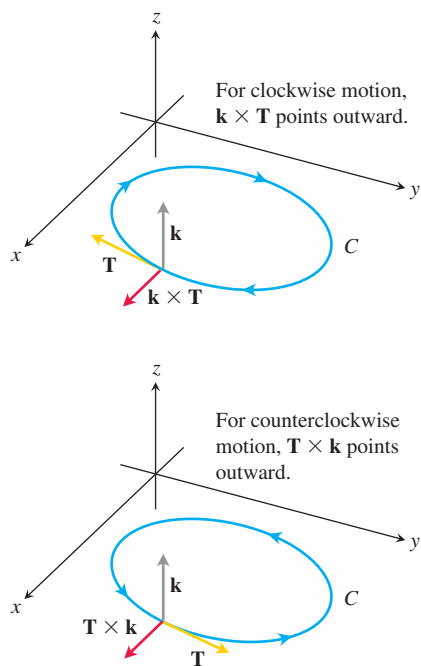

FIGURE 15.24 To find an outward unit normal vector for a smooth simple curve C in the xy -plane that is traversed counterclockwise as t increases, we take $\mathbf{n} = \mathbf{T} \times \mathbf{k}$. For clockwise motion, we take $\mathbf{n} = \mathbf{k} \times \mathbf{T}$.

that traces the curve C exactly once as t increases from a to b . We can find the outward unit normal vector \mathbf{n} by crossing the curve's unit tangent vector \mathbf{T} with the vector \mathbf{k} . But which order do we choose, $\mathbf{T} \times \mathbf{k}$ or $\mathbf{k} \times \mathbf{T}$? Which one points outward? It depends on which way C is traversed as t increases. If the motion is clockwise, $\mathbf{k} \times \mathbf{T}$ points outward; if the motion is counterclockwise, $\mathbf{T} \times \mathbf{k}$ points outward (Figure 15.24). The usual choice is $\mathbf{n} = \mathbf{T} \times \mathbf{k}$, the choice that assumes counterclockwise motion. Thus, even though the value of the integral in Equation (8) does not depend on which way C is traversed, the formulas we are about to derive for computing \mathbf{n} and evaluating the integral assume counterclockwise motion.

In terms of components,

$$\mathbf{n} = \mathbf{T} \times \mathbf{k} = \left(\frac{dx}{ds} \mathbf{i} + \frac{dy}{ds} \mathbf{j} \right) \times \mathbf{k} = \frac{dy}{ds} \mathbf{i} - \frac{dx}{ds} \mathbf{j} \quad \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{dx}{ds} & \frac{dy}{ds} & 0 \\ 0 & 0 & 1 \end{vmatrix}$$

If $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$, then

$$\mathbf{F} \cdot \mathbf{n} = M(x, y) \frac{dy}{ds} - N(x, y) \frac{dx}{ds}.$$

Hence,

$$\int_C \mathbf{F} \cdot \mathbf{n} \, ds = \int_C \left(M \frac{dy}{ds} - N \frac{dx}{ds} \right) ds = \oint_C M \, dy - N \, dx.$$

We put a directed circle \circlearrowleft on the last integral as a reminder that the integration around the closed curve C is to be in the counterclockwise direction. To evaluate this integral, we express M , dy , N , and dx in terms of the parameter t and integrate from $t = a$ to $t = b$. We do not need to know \mathbf{n} or ds explicitly to find the flux.

Calculating Flux Across a Smooth Closed Plane Curve

$$(\text{Flux of } \mathbf{F} = M\mathbf{i} + N\mathbf{j} \text{ across } C) = \oint_C M \, dy - N \, dx \quad (9)$$

The integral can be evaluated from any smooth parametrization $x = g(t)$, $y = h(t)$, $a \leq t \leq b$, that traces C counterclockwise exactly once.

EXAMPLE 8 Find the flux of $\mathbf{F} = (x - y)\mathbf{i} + x\mathbf{j}$ across the circle $x^2 + y^2 = 1$ in the xy -plane. (The vector field and curve were shown in Figure 15.22.)

Solution The parametrization $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$, traces the circle counterclockwise exactly once. We can therefore use this parametrization in Equation (9). With

$$\begin{aligned} M &= x - y = \cos t - \sin t, & dy &= d(\sin t) = \cos t \, dt, \\ N &= x = \cos t, & dx &= d(\cos t) = -\sin t \, dt, \end{aligned}$$

we find

$$\begin{aligned} \text{Flux} &= \oint_C M \, dy - N \, dx = \int_0^{2\pi} (\cos^2 t - \sin t \cos t + \cos t \sin t) \, dt && \text{Eq. (9)} \\ &= \int_0^{2\pi} \cos^2 t \, dt = \int_0^{2\pi} \frac{1 + \cos 2t}{2} \, dt = \left[\frac{t}{2} + \frac{\sin 2t}{4} \right]_0^{2\pi} = \pi. \end{aligned}$$

The flux of \mathbf{F} across the circle is π . Since the answer is positive, the net flow across the curve is outward. A net inward flow would have given a negative flux. ■

EXERCISES 15.2

Vector Fields

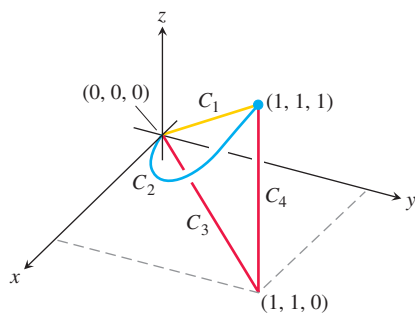

Find the gradient fields of the functions in Exercises 1–4.

- $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2}$
- $f(x, y, z) = \ln\sqrt{x^2 + y^2 + z^2}$
- $g(x, y, z) = e^z - \ln(x^2 + y^2)$
- $g(x, y, z) = xy + yz + xz$
- Give a formula $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ for the vector field in the plane that has the property that \mathbf{F} points toward the origin with magnitude inversely proportional to the square of the distance from (x, y) to the origin. (The field is not defined at $(0, 0)$.)
- Give a formula $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ for the vector field in the plane that has the properties that $\mathbf{F} = \mathbf{0}$ at $(0, 0)$ and that at any other point (a, b) , \mathbf{F} is tangent to the circle $x^2 + y^2 = a^2 + b^2$ and points in the clockwise direction with magnitude $|\mathbf{F}| = \sqrt{a^2 + b^2}$.

Line Integrals of Vector Fields

In Exercises 7–12, find the line integrals of \mathbf{F} from $(0, 0, 0)$ to $(1, 1, 1)$ over each of the following paths in the accompanying figure.

- The straight-line path $C_1: \mathbf{r}(t) = t\mathbf{i} + t\mathbf{j} + t\mathbf{k}, 0 \leq t \leq 1$
 - The curved path $C_2: \mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + t^4\mathbf{k}, 0 \leq t \leq 1$
 - The path $C_3 \cup C_4$ consisting of the line segment from $(0, 0, 0)$ to $(1, 1, 0)$ followed by the segment from $(1, 1, 0)$ to $(1, 1, 1)$
- $\mathbf{F} = 3y\mathbf{i} + 2x\mathbf{j} + 4z\mathbf{k}$ 8. $\mathbf{F} = [1/(x^2 + 1)]\mathbf{j}$
 - $\mathbf{F} = \sqrt{z}\mathbf{i} - 2x\mathbf{j} + \sqrt{y}\mathbf{k}$ 10. $\mathbf{F} = xy\mathbf{i} + yz\mathbf{j} + xz\mathbf{k}$
 - $\mathbf{F} = (3x^2 - 3x)\mathbf{i} + 3z\mathbf{j} + \mathbf{k}$
 - $\mathbf{F} = (y + z)\mathbf{i} + (z + x)\mathbf{j} + (x + y)\mathbf{k}$

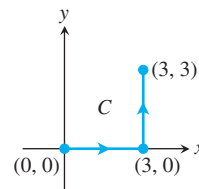

Line Integrals with Respect to x , y , and z

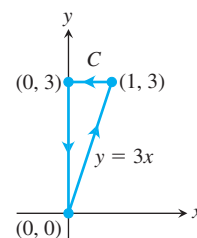

In Exercises 13–16, find the line integrals along the given path C .

- $\int_C (x - y) dx$, where $C: x = t, y = 2t + 1$, for $0 \leq t \leq 3$
- $\int_C \frac{x}{y} dy$, where $C: x = t, y = t^2$, for $1 \leq t \leq 2$

- $\int_C (x^2 + y^2) dy$, where C is given in the accompanying figure

- $\int_C \sqrt{x + y} dx$, where C is given in the accompanying figure

- Along the curve $\mathbf{r}(t) = t\mathbf{i} - \mathbf{j} + t^2\mathbf{k}, 0 \leq t \leq 1$, evaluate each of the following integrals.

- $\int_C (x + y - z) dx$
- $\int_C (x + y - z) dy$
- $\int_C (x + y - z) dz$

- Along the curve $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} - (\cos t)\mathbf{k}, 0 \leq t \leq \pi$, evaluate each of the following integrals.

- $\int_C xz dx$
- $\int_C xz dy$
- $\int_C xyz dz$

Work

In Exercises 19–22, find the work done by \mathbf{F} over the curve in the direction of increasing t .

- $\mathbf{F} = xy\mathbf{i} + y\mathbf{j} - yz\mathbf{k}$
 $\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + t\mathbf{k}, 0 \leq t \leq 1$
- $\mathbf{F} = 2y\mathbf{i} + 3x\mathbf{j} + (x + y)\mathbf{k}$
 $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (t/6)\mathbf{k}, 0 \leq t \leq 2\pi$
- $\mathbf{F} = z\mathbf{i} + x\mathbf{j} + y\mathbf{k}$
 $\mathbf{r}(t) = (\sin t)\mathbf{i} + (\cos t)\mathbf{j} + t\mathbf{k}, 0 \leq t \leq 2\pi$
- $\mathbf{F} = 6z\mathbf{i} + y^2\mathbf{j} + 12x\mathbf{k}$
 $\mathbf{r}(t) = (\sin t)\mathbf{i} + (\cos t)\mathbf{j} + (t/6)\mathbf{k}, 0 \leq t \leq 2\pi$

Line Integrals in the Plane

23. Evaluate $\int_C xy \, dx + (x + y) \, dy$ along the curve $y = x^2$ from $(-1, 1)$ to $(2, 4)$.
24. Evaluate $\int_C (x - y) \, dx + (x + y) \, dy$ counterclockwise around the triangle with vertices $(0, 0)$, $(1, 0)$, and $(0, 1)$.
25. Evaluate $\int_C \mathbf{F} \cdot \mathbf{T} \, ds$ for the vector field $\mathbf{F} = x^2\mathbf{i} - y\mathbf{j}$ along the curve $x = y^2$ from $(4, 2)$ to $(1, -1)$.
26. Evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$ for the vector field $\mathbf{F} = y\mathbf{i} - x\mathbf{j}$ counterclockwise along the unit circle $x^2 + y^2 = 1$ from $(1, 0)$ to $(0, 1)$.

Work, Circulation, and Flux in the Plane

27. **Work** Find the work done by the force $\mathbf{F} = xy\mathbf{i} + (y - x)\mathbf{j}$ over the straight line from $(1, 1)$ to $(2, 3)$.
28. **Work** Find the work done by the gradient of $f(x, y) = (x + y)^2$ counterclockwise around the circle $x^2 + y^2 = 4$ from $(2, 0)$ to itself.
29. **Circulation and flux** Find the circulation and flux of the fields

$$\mathbf{F}_1 = x\mathbf{i} + y\mathbf{j} \quad \text{and} \quad \mathbf{F}_2 = -y\mathbf{i} + x\mathbf{j}$$

around and across each of the following curves.

- a. The circle $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$
- b. The ellipse $\mathbf{r}(t) = (\cos t)\mathbf{i} + (4 \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$
30. **Flux across a circle** Find the flux of the fields

$$\mathbf{F}_1 = 2x\mathbf{i} - 3y\mathbf{j} \quad \text{and} \quad \mathbf{F}_2 = 2x\mathbf{i} + (x - y)\mathbf{j}$$

across the circle

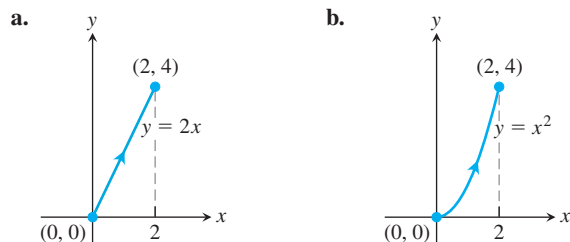

$$\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}, \quad 0 \leq t \leq 2\pi.$$

In Exercises 31–34, find the circulation and flux of the field \mathbf{F} around and across the closed semicircular path that consists of the semicircular arch $\mathbf{r}_1(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}$, $0 \leq t \leq \pi$, followed by the line segment $\mathbf{r}_2(t) = t\mathbf{i}$, $-a \leq t \leq a$.

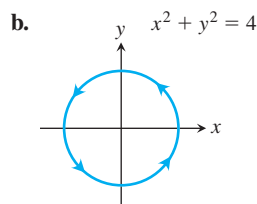

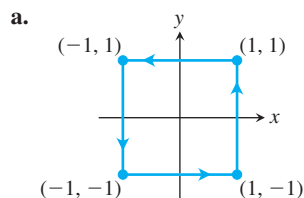

31. $\mathbf{F} = x\mathbf{i} + y\mathbf{j}$ 32. $\mathbf{F} = x^2\mathbf{i} + y^2\mathbf{j}$
33. $\mathbf{F} = -y\mathbf{i} + x\mathbf{j}$ 34. $\mathbf{F} = -y^2\mathbf{i} + x^2\mathbf{j}$
35. **Flow integrals** Find the flow of the velocity field $\mathbf{F} = (x + y)\mathbf{i} - (x^2 + y^2)\mathbf{j}$ along each of the following paths from $(1, 0)$ to $(-1, 0)$ in the xy -plane.
- a. The upper half of the circle $x^2 + y^2 = 1$
- b. The line segment from $(1, 0)$ to $(-1, 0)$
- c. The line segment from $(1, 0)$ to $(0, -1)$ followed by the line segment from $(0, -1)$ to $(-1, 0)$
36. **Flux across a triangle** Find the flux of the field \mathbf{F} in Exercise 35 outward across the triangle with vertices $(1, 0)$, $(0, 1)$, $(-1, 0)$.
37. The flow of a gas with a density of $\delta = 0.001 \text{ kg/m}^2$ over the closed curve $\mathbf{r}(t) = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j}$, $0 \leq t \leq 2\pi$, is given

by the vector field $\mathbf{F} = \delta \mathbf{v}$, where $\mathbf{v} = x\mathbf{i} + y^2\mathbf{j}$ is a velocity field measured in meters per second. Find the flux of \mathbf{F} across the curve $\mathbf{r}(t)$.

38. The flow of a gas with a density of $\delta = 0.3 \text{ kg/m}^2$ over the closed curve $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$, is given by the vector field $\mathbf{F} = \delta \mathbf{v}$, where $\mathbf{v} = x^2\mathbf{i} - y\mathbf{j}$ is a velocity field measured in meters per second. Find the flux of \mathbf{F} across the curve $\mathbf{r}(t)$.
39. Find the flow of the velocity field $\mathbf{F} = y^2\mathbf{i} + 2xy\mathbf{j}$ along each of the following paths from $(0, 0)$ to $(2, 4)$.

- c. Use any path from $(0, 0)$ to $(2, 4)$ different from parts (a) and (b).
40. Find the circulation of the field $\mathbf{F} = y\mathbf{i} + (x + 2y)\mathbf{j}$ around each of the following closed paths.

- c. Use any closed path different from parts (a) and (b).
41. Find the work done by the force $\mathbf{F} = y^2\mathbf{i} + x^3\mathbf{j}$, where force is measured in newtons, in moving an object over the curve $\mathbf{r}(t) = 2t\mathbf{i} + t^2\mathbf{j}$, $0 \leq t \leq 2$, where distance is measured in meters.
42. Find the work done by the force $\mathbf{F} = e^y\mathbf{i} + (\ln x)\mathbf{j} + 3z\mathbf{k}$, where force is measured in newtons, in moving an object over the curve $\mathbf{r}(t) = e^t\mathbf{i} + (\ln t)\mathbf{j} + t^2\mathbf{k}$, $1 \leq t \leq e$, where distance is measured in meters.
43. Find the flow of the velocity field $\mathbf{F} = \frac{x}{y+1}\mathbf{i} + \frac{y}{x+1}\mathbf{j}$, where velocity is measured in meters per second, over the curve $\mathbf{r}(t) = t^2\mathbf{i} + t\mathbf{j}$, $0 \leq t \leq 1$.

44. Find the flow of the velocity field $\mathbf{F} = (y + z)\mathbf{i} + x\mathbf{j} - y\mathbf{k}$, where velocity is measured in meters per second, over the curve $\mathbf{r}(t) = e^t\mathbf{i} - e^{2t}\mathbf{j} + e^{-t}\mathbf{k}$, $0 \leq t \leq \ln 2$.
45. Salt water with a density of $\delta = 0.25 \text{ g/cm}^2$ flows over the curve $\mathbf{r}(t) = \sqrt{t}\mathbf{i} + t\mathbf{j}$, $0 \leq t \leq 4$, according to the vector field $\mathbf{F} = \delta\mathbf{v}$, where $\mathbf{v} = xy\mathbf{i} + (y - x)\mathbf{j}$ is a velocity field measured in centimeters per second. Find the flow of \mathbf{F} over the curve $\mathbf{r}(t)$.
46. Propyl alcohol with a density of $\delta = 0.2 \text{ g/cm}^2$ flows over the closed curve $\mathbf{r}(t) = (\sin t)\mathbf{i} - (\cos t)\mathbf{j}$, $0 \leq t \leq 2\pi$, according to the vector field $\mathbf{F} = \delta\mathbf{v}$, where $\mathbf{v} = (x - y)\mathbf{i} + x^2\mathbf{j}$ is a velocity field measured in centimeters per second. Find the circulation of \mathbf{F} around the curve $\mathbf{r}(t)$.

Vector Fields in the Plane

47. **Spin field** Draw the spin field

$$\mathbf{F} = -\frac{y}{\sqrt{x^2 + y^2}}\mathbf{i} + \frac{x}{\sqrt{x^2 + y^2}}\mathbf{j}$$

(see Figure 15.13) along with its horizontal and vertical components at a representative assortment of points on the circle $x^2 + y^2 = 4$.

48. **Radial field** Draw the radial field

$$\mathbf{F} = x\mathbf{i} + y\mathbf{j}$$

(see Figure 15.12) along with its horizontal and vertical components at a representative assortment of points on the circle $x^2 + y^2 = 1$.

49. **A field of tangent vectors**

a. Find a field $\mathbf{G} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ in the xy -plane with the property that at any point $(a, b) \neq (0, 0)$, \mathbf{G} is a vector of magnitude $\sqrt{a^2 + b^2}$ tangent to the circle $x^2 + y^2 = a^2 + b^2$ and pointing in the counterclockwise direction. (The field is undefined at $(0, 0)$.)

b. How is \mathbf{G} related to the spin field \mathbf{F} in Figure 15.13?

50. **A field of tangent vectors**

a. Find a field $\mathbf{G} = P(x, y)\mathbf{i} + Q(x, y)\mathbf{j}$ in the xy -plane with the property that at any point $(a, b) \neq (0, 0)$, \mathbf{G} is a unit vector tangent to the circle $x^2 + y^2 = a^2 + b^2$ and pointing in the clockwise direction.

b. How is \mathbf{G} related to the spin field \mathbf{F} in Figure 15.13?

51. **Unit vectors pointing toward the origin** Find a field $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ in the xy -plane with the property that at each point $(x, y) \neq (0, 0)$, \mathbf{F} is a unit vector pointing toward the origin. (The field is undefined at $(0, 0)$.)

52. **Two “central” fields** Find a field $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ in the xy -plane with the property that at each point $(x, y) \neq (0, 0)$, \mathbf{F} points toward the origin and $|\mathbf{F}|$ is (a) the distance from (x, y) to the origin, (b) inversely proportional to the distance from (x, y) to the origin. (The field is undefined at $(0, 0)$.)

53. **Work and area** Suppose that $f(t)$ is differentiable and positive for $a \leq t \leq b$. Let C be the path $\mathbf{r}(t) = t\mathbf{i} + f(t)\mathbf{j}$, $a \leq t \leq b$, and $\mathbf{F} = y\mathbf{i}$. Is there any relation between the value of the work integral

$$\int_C \mathbf{F} \cdot d\mathbf{r}$$

and the area of the region bounded by the t -axis, the graph of f , and the lines $t = a$ and $t = b$? Give reasons for your answer.

54. **Work done by a radial force with constant magnitude** A particle moves along the smooth curve $y = f(x)$ from $(a, f(a))$ to $(b, f(b))$. The force moving the particle has constant magnitude k and always points away from the origin. Show that the work done by the force is

$$\int_C \mathbf{F} \cdot \mathbf{T} ds = k \left[(b^2 + (f(b))^2)^{1/2} - (a^2 + (f(a))^2)^{1/2} \right].$$

Flow Integrals in Space

In Exercises 55–58, \mathbf{F} is the velocity field of a fluid flowing through a region in space. Find the flow along the given curve in the direction of increasing t .

55. $\mathbf{F} = -4xy\mathbf{i} + 8y\mathbf{j} + 2\mathbf{k}$

$$\mathbf{r}(t) = t\mathbf{i} + t^2\mathbf{j} + \mathbf{k}, \quad 0 \leq t \leq 2$$

56. $\mathbf{F} = x^2\mathbf{i} + yz\mathbf{j} + y^2\mathbf{k}$

$$\mathbf{r}(t) = 3t\mathbf{j} + 4t\mathbf{k}, \quad 0 \leq t \leq 1$$

57. $\mathbf{F} = (x - z)\mathbf{i} + x\mathbf{k}$

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{k}, \quad 0 \leq t \leq \pi$$

58. $\mathbf{F} = -y\mathbf{i} + x\mathbf{j} + 2\mathbf{k}$

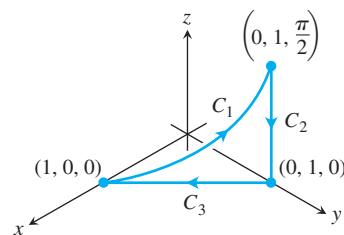

$$\mathbf{r}(t) = (-2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{j} + 2t\mathbf{k}, \quad 0 \leq t \leq 2\pi$$

59. **Circulation** Find the circulation of $\mathbf{F} = 2x\mathbf{i} + 2z\mathbf{j} + 2y\mathbf{k}$ around the closed path consisting of the following three curves traversed in the direction of increasing t .

$$C_1: \mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + t\mathbf{k}, \quad 0 \leq t \leq \pi/2$$

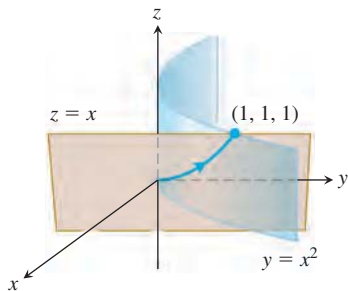

$$C_2: \mathbf{r}(t) = \mathbf{j} + (\pi/2)(1 - t)\mathbf{k}, \quad 0 \leq t \leq 1$$

$$C_3: \mathbf{r}(t) = t\mathbf{i} + (1 - t)\mathbf{j}, \quad 0 \leq t \leq 1$$

60. **Zero circulation** Let C be the ellipse in which the plane $2x + 3y - z = 0$ meets the cylinder $x^2 + y^2 = 12$. Show, without evaluating either line integral directly, that the circulation of the field $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ around C in either direction is zero.

- 61. Flow along a curve** The field $\mathbf{F} = xy\mathbf{i} + y\mathbf{j} - yz\mathbf{k}$ is the velocity field of a flow in space. Find the flow from $(0, 0, 0)$ to $(1, 1, 1)$ along the curve of intersection of the cylinder $y = x^2$ and the plane $z = x$. (Hint: Use $t = x$ as the parameter.)

- 62. Flow of a gradient field** Find the flow of the field $\mathbf{F} = \nabla(xy^2z^3)$:
- Once around the curve C in Exercise 58, clockwise as viewed from above;
 - Along the line segment from $(1, 1, 1)$ to $(2, 1, -1)$.

COMPUTER EXPLORATIONS

In Exercises 63–68, use a CAS to perform the following steps for finding the work done by force \mathbf{F} over the given path:

- Find $d\mathbf{r}$ for the path $\mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$.

- Evaluate the force \mathbf{F} along the path.

- Evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$.

63. $\mathbf{F} = xy^6\mathbf{i} + 3x(xy^5 + 2)\mathbf{j}$; $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$

64. $\mathbf{F} = \frac{3}{1+x^2}\mathbf{i} + \frac{2}{1+y^2}\mathbf{j}$; $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq \pi$

65. $\mathbf{F} = (y + yz \cos xyz)\mathbf{i} + (x^2 + xz \cos xyz)\mathbf{j} + (z + xy \cos xyz)\mathbf{k}$; $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (3 \sin t)\mathbf{j} + \mathbf{k}$, $0 \leq t \leq 2\pi$

66. $\mathbf{F} = 2xy\mathbf{i} - y^2\mathbf{j} + ze^x\mathbf{k}$; $\mathbf{r}(t) = -t\mathbf{i} + \sqrt{t}\mathbf{j} + 3t\mathbf{k}$, $1 \leq t \leq 4$

67. $\mathbf{F} = (2y + \sin x)\mathbf{i} + (z^2 + (1/3)\cos y)\mathbf{j} + x^4\mathbf{k}$; $\mathbf{r}(t) = (\sin t)\mathbf{i} + (\cos t)\mathbf{j} + (\sin 2t)\mathbf{k}$, $-\pi/2 \leq t \leq \pi/2$

68. $\mathbf{F} = (x^2y)\mathbf{i} + \frac{1}{3}x^3\mathbf{j} + xy\mathbf{k}$; $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (2 \sin^2 t - 1)\mathbf{k}$, $0 \leq t \leq 2\pi$

15.3 Path Independence, Conservative Fields, and Potential Functions

A **gravitational field** \mathbf{G} is a vector field that represents the effect of gravity at a point in space due to the presence of a massive object. The gravitational force on a body of mass m placed in the field is given by $\mathbf{F} = m\mathbf{G}$. Similarly, an **electric field** \mathbf{E} is a vector field in space that represents the effect of electric forces on a charged particle placed within it. The force on a body of charge q placed in the field is given by $\mathbf{F} = q\mathbf{E}$. In gravitational and electric fields, the amount of work it takes to move a mass or charge from one point to another depends on the initial and final positions of the object—not on which path is taken between these positions. In this section we study vector fields with this independence-of-path property and the calculation of work integrals associated with them.

Path Independence

If A and B are two points in an open region D in space, the line integral of \mathbf{F} along C from A to B for a field \mathbf{F} defined on D usually depends on the path C taken, as we saw in Section 15.1. For some special fields, however, the integral's value is the same for all paths from A to B .

DEFINITIONS Let \mathbf{F} be a vector field defined on an open region D in space, and suppose that for any two points A and B in D , the line integral $\int_C \mathbf{F} \cdot d\mathbf{r}$ along a path C from A to B in D is the same over all paths from A to B . Then the integral $\int_C \mathbf{F} \cdot d\mathbf{r}$ is **path independent in D** and the field \mathbf{F} is **conservative on D** .

The word *conservative* comes from physics, where it refers to fields in which the principle of conservation of energy holds. When a line integral is independent of the path C from point A to point B , we sometimes represent the integral by the symbol \int_A^B rather than the usual line integral symbol \int_C . This substitution helps us remember the path-independence

property by indicating that the integral depends only on the initial and final points, not on the path connecting them.

Under reasonable differentiability conditions that we will specify, we will show that a field \mathbf{F} is conservative if and only if it is the gradient field of a scalar function f —that is, if and only if $\mathbf{F} = \nabla f$ for some f . The function f then has a special name.

DEFINITION If \mathbf{F} is a vector field defined on D and $\mathbf{F} = \nabla f$ for some scalar function f on D , then f is called a **potential function for \mathbf{F}** .

A gravitational potential is a scalar function whose gradient field is a gravitational field, an electric potential is a scalar function whose gradient field is an electric field, and so on. As we will see, once we have found a potential function f for a field \mathbf{F} , we can evaluate all the line integrals in the domain of \mathbf{F} over any path between A and B by

$$\int_A^B \mathbf{F} \cdot d\mathbf{r} = \int_A^B \nabla f \cdot d\mathbf{r} = f(B) - f(A). \quad (1)$$

If you think of ∇f for functions of several variables as analogous to the derivative f' for functions of a single variable, then you see that Equation (1) is the vector calculus rendition of the Fundamental Theorem of Calculus formula

$$\int_a^b f'(x) dx = f(b) - f(a).$$

Conservative fields have other important properties. For example, saying that \mathbf{F} is conservative on D is equivalent to saying that the integral of \mathbf{F} around every closed path in D is zero. Certain conditions on the curves, fields, and domains must be satisfied for Equation (1) to be valid. We discuss these conditions next.

Assumptions on Curves, Vector Fields, and Domains

In order for the computations and results we derive below to be valid, we must assume certain properties for the curves, surfaces, domains, and vector fields we consider. We give these assumptions in the statements of theorems, and they also apply to the examples and exercises unless otherwise stated.

The curves we consider are **piecewise smooth**. Such curves are made up of finitely many smooth pieces connected end to end, as discussed in Section 12.1. For such curves we can compute lengths and, except at finitely many points where the smooth pieces connect, tangent vectors. We consider vector fields \mathbf{F} whose components have continuous first partial derivatives.

The domains D we consider are **connected**. For an open region, this means that any two points in D can be joined by a smooth curve that lies in the region. Some results require D to be **simply connected**, which means that every loop in D can be contracted to a point in D without ever leaving D . The plane with a disk removed is a two-dimensional region that is *not* simply connected; a loop in the plane that goes around the disk cannot be contracted to a point without going into the “hole” left by the removed disk (see Figure 15.25c). Similarly, if we remove a line from space, the remaining region D is *not* simply connected. A curve encircling the line cannot be shrunk to a point while remaining inside D .

Connectivity and simple connectivity are not the same, and neither property implies the other. Think of connected regions as being in “one piece” and of simply connected regions as not having any “loop-catching holes.” All of space itself is both connected and simply connected. Figure 15.25 illustrates some of these properties.

Caution Some of the results in this chapter can fail to hold if applied to situations where the conditions we’ve imposed are not met. In particular, the component test for conservative fields, given later in this section, is not valid on domains that are not simply connected (see Example 5). The condition will be stated when needed. ●

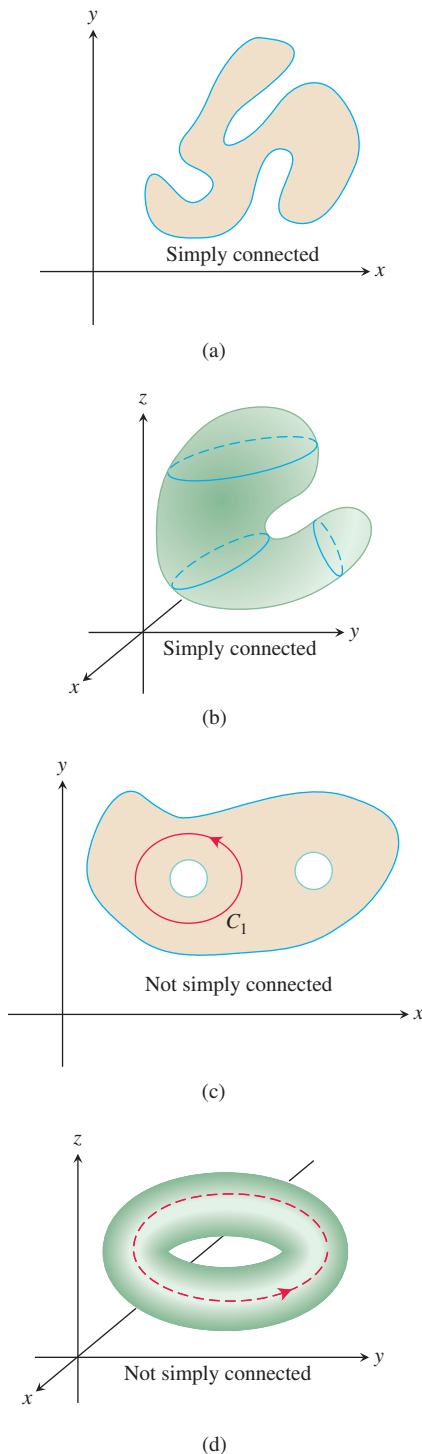

FIGURE 15.25 Four connected regions. In (a) and (b), the regions are simply connected. In (c) and (d), the regions are not simply connected because the curves C_1 and C_2 cannot be contracted to a point inside the regions containing them.

Line Integrals in Conservative Fields

A gradient field \mathbf{F} is obtained by differentiating a scalar function f . A theorem analogous to the Fundamental Theorem of Calculus gives a way to evaluate the line integrals of gradient fields.

Like the Fundamental Theorem of Calculus, Theorem 1 gives a direct way to evaluate line integrals without having to take limits of Riemann sums and without needing to compute a line integral by the procedure used in Section 15.2. Before proving Theorem 1, we give an example.

THEOREM 1—Fundamental Theorem of Line Integrals

Let C be a smooth curve joining the point A to the point B in the plane or in space and parametrized by $\mathbf{r}(t)$. Let f be a differentiable function with a continuous gradient vector $\mathbf{F} = \nabla f$ on a domain D containing C . Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = f(B) - f(A).$$

EXAMPLE 1 Suppose the force field $\mathbf{F} = \nabla f$ is the gradient of the function

$$f(x, y, z) = -\frac{1}{x^2 + y^2 + z^2}.$$

Find the work done by \mathbf{F} in moving an object along a smooth curve C joining $(1, 0, 0)$ to $(0, 0, 2)$ that does not pass through the origin.

Solution An application of Theorem 1 shows that the work done by \mathbf{F} along any smooth curve C joining the two points and not passing through the origin is

$$\int_C \mathbf{F} \cdot d\mathbf{r} = f(0, 0, 2) - f(1, 0, 0) = -\frac{1}{4} - (-1) = \frac{3}{4}. \quad \blacksquare$$

The gravitational force due to a planet, and the electric force associated with a charged particle, can both be modeled by the field \mathbf{F} given in Example 1 up to a constant that depends on the units of measurement. When used to model gravity, the function f in Example 1 represents gravitational potential energy. The sign of f is negative, and f approaches $-\infty$ near the origin. This choice ensures that the gravitational force \mathbf{F} , the gradient of f , points toward the origin, so that objects fall down rather than up.

Proof of Theorem 1 Suppose that A and B are two points in the region D and that $C: \mathbf{r}(t) = g(t)\mathbf{i} + h(t)\mathbf{j} + k(t)\mathbf{k}$, $a \leq t \leq b$, is a smooth curve in D joining A to B . In Section 13.5 we found that the derivative of a scalar function f along a path C is the dot product $\nabla f(\mathbf{r}(t)) \cdot \mathbf{r}'(t)$, so we have

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_C \nabla f \cdot d\mathbf{r} && \mathbf{F} = \nabla f \\ &= \int_{t=a}^{t=b} \nabla f(\mathbf{r}(t)) \cdot \mathbf{r}'(t) dt && \text{Eq. (2) of Section 15.2 for computing } d\mathbf{r} \\ &= \int_a^b \frac{d}{dt} f(\mathbf{r}(t)) dt && \text{Eq. (7) of Section 13.5 giving derivative along a path} \\ &= f(\mathbf{r}(b)) - f(\mathbf{r}(a)) && \text{Fundamental Theorem of Calculus} \\ &= f(B) - f(A). && \mathbf{r}(a) = A, \mathbf{r}(b) = B \quad \blacksquare \end{aligned}$$

We see from Theorem 1 that the line integral of a gradient field $\mathbf{F} = \nabla f$ is straightforward to compute once we know the function f . Many important vector fields arising in applications are indeed gradient fields. The next result, which follows from Theorem 1, shows that any conservative field is of this type.

THEOREM 2—Conservative Fields Are Gradient Fields

Let $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ be a vector field whose components are continuous throughout an open connected region D in space. Then \mathbf{F} is conservative if and only if \mathbf{F} is a gradient field ∇f for a differentiable function f .

Theorem 2 says that $\mathbf{F} = \nabla f$ if and only if, for any two points A and B in the region D , the value of the line integral $\int_C \mathbf{F} \cdot d\mathbf{r}$ is independent of the path C joining A to B in D .

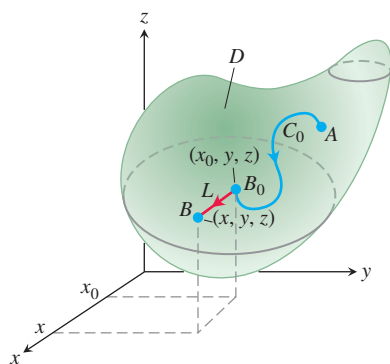

FIGURE 15.26 The function $f(x, y, z)$ in the proof of Theorem 2 is computed by a line integral $\int_{C_0} \mathbf{F} \cdot d\mathbf{r} = f(B_0)$ from A to B_0 , plus a line integral $\int_L \mathbf{F} \cdot d\mathbf{r}$ along a line segment L parallel to the x -axis and joining B_0 to B located at (x, y, z) . The value of f at A is $f(A) = 0$.

Proof of Theorem 2 If \mathbf{F} is a gradient field, then $\mathbf{F} = \nabla f$ for a differentiable function f , and Theorem 1 shows that $\int_C \mathbf{F} \cdot d\mathbf{r} = f(B) - f(A)$. The value of the line integral does not depend on C , but only on its endpoints A and B . So the line integral is path independent and \mathbf{F} satisfies the definition of a conservative field.

On the other hand, suppose that \mathbf{F} is a conservative vector field. We want to find a function f on D satisfying $\nabla f = \mathbf{F}$. First, pick a point A in D and set $f(A) = 0$. For any other point B in D define $f(B)$ to equal $\int_C \mathbf{F} \cdot d\mathbf{r}$, where C is any smooth path in D from A to B . The value of $f(B)$ does not depend on the choice of C , since \mathbf{F} is conservative. To show that $\nabla f = \mathbf{F}$, we need to demonstrate that $\partial f/\partial x = M$, $\partial f/\partial y = N$, and $\partial f/\partial z = P$.

Suppose that B has coordinates (x, y, z) . By the definition of f , the value of the function f at a nearby point B_0 located at (x_0, y, z) is $\int_{C_0} \mathbf{F} \cdot d\mathbf{r}$, where C_0 is any path from A to B_0 . We take a path $C = C_0 \cup L$ from A to B formed by first traveling along C_0 to arrive at B_0 and then traveling along the line segment L from B_0 to B (Figure 15.26). When B_0 is close to B , the segment L lies in D and, since the value $f(B)$ is independent of the path from A to B ,

$$f(x, y, z) = \int_{C_0} \mathbf{F} \cdot d\mathbf{r} + \int_L \mathbf{F} \cdot d\mathbf{r}.$$

Differentiating, we have

$$\frac{\partial}{\partial x} f(x, y, z) = \frac{\partial}{\partial x} \left(\int_{C_0} \mathbf{F} \cdot d\mathbf{r} + \int_L \mathbf{F} \cdot d\mathbf{r} \right).$$

Only the last term on the right depends on x , so

$$\frac{\partial}{\partial x} f(x, y, z) = \frac{\partial}{\partial x} \int_L \mathbf{F} \cdot d\mathbf{r}.$$

Now we parametrize L as $\mathbf{r}(t) = t\mathbf{i} + y\mathbf{j} + z\mathbf{k}$, $x_0 \leq t \leq x$. Then $d\mathbf{r}/dt = \mathbf{i}$, and since $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$, it follows that $\mathbf{F} \cdot d\mathbf{r}/dt = M$ and $\int_L \mathbf{F} \cdot d\mathbf{r} = \int_{x_0}^x M(t, y, z) dt$. Differentiating then gives

$$\frac{\partial}{\partial x} f(x, y, z) = \frac{\partial}{\partial x} \int_{x_0}^x M(t, y, z) dt = M(x, y, z)$$

by the Fundamental Theorem of Calculus. The partial derivatives $\partial f/\partial y = N$ and $\partial f/\partial z = P$ follow similarly, showing that $\mathbf{F} = \nabla f$. ■

EXAMPLE 2 Find the work done by the conservative field

$$\mathbf{F} = yz\mathbf{i} + xz\mathbf{j} + xy\mathbf{k} = \nabla f, \quad \text{where } f(x, y, z) = xyz,$$

in moving an object along any smooth curve C joining the point $A(-1, 3, 9)$ to $B(1, 6, -4)$.

Solution With $f(x, y, z) = xyz$, we have

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_A^B \nabla f \cdot d\mathbf{r} && \mathbf{F} = \nabla f \text{ and path independence} \\ &= f(B) - f(A) && \text{Theorem 1} \\ &= xyz|_{(1,6,-4)} - xyz|_{(-1,3,9)} \\ &= (1)(6)(-4) - (-1)(3)(9) \\ &= -24 + 27 = 3. \end{aligned}$$

A very useful property of line integrals in conservative fields comes into play when the path of integration is a closed curve, or loop. We often use the notation \oint_C for integration around a closed path (discussed with more detail in the next section).

THEOREM 3—Loop Property of Conservative Fields

The following statements are equivalent.

1. $\oint_C \mathbf{F} \cdot d\mathbf{r} = 0$ around every loop (that is, closed curve C) in D .
2. The field \mathbf{F} is conservative on D .

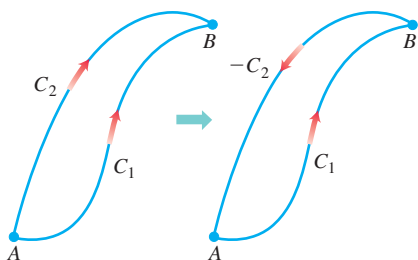

FIGURE 15.27 If we have two paths from A to B , one of them can be reversed to make a loop.

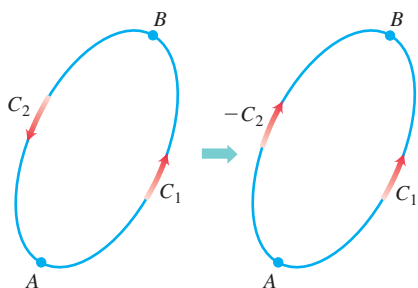

FIGURE 15.28 If A and B lie on a loop, we can reverse part of the loop to make two paths from A to B .

Proof that Part 1 \Rightarrow Part 2 We want to show that for any two points A and B in D , the integral of $\mathbf{F} \cdot d\mathbf{r}$ has the same value over any two paths C_1 and C_2 from A to B . We reverse the direction on C_2 to make a path $-C_2$ from B to A (Figure 15.27). Together, C_1 and $-C_2$ make a closed loop C , and by assumption,

$$\int_{C_1} \mathbf{F} \cdot d\mathbf{r} - \int_{C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r} + \int_{-C_2} \mathbf{F} \cdot d\mathbf{r} = \int_C \mathbf{F} \cdot d\mathbf{r} = 0.$$

Thus, the integrals over C_1 and C_2 give the same value. Note that the definition of $\mathbf{F} \cdot d\mathbf{r}$ shows that changing the direction along a curve reverses the sign of the line integral.

Proof that Part 2 \Rightarrow Part 1 We want to show that the integral of $\mathbf{F} \cdot d\mathbf{r}$ is zero over any closed loop C . We pick two points A and B on C and use them to break C into two pieces: C_1 from A to B followed by C_2 from B back to A (Figure 15.28). Then

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r} + \int_{C_2} \mathbf{F} \cdot d\mathbf{r} = \int_A^B \mathbf{F} \cdot d\mathbf{r} - \int_A^B \mathbf{F} \cdot d\mathbf{r} = 0. \quad \blacksquare$$

The following diagram summarizes the results of Theorems 2 and 3.

$$\mathbf{F} = \nabla f \text{ on } D \quad \Leftrightarrow \quad \mathbf{F} \text{ conservative on } D \quad \Leftrightarrow \quad \oint_C \mathbf{F} \cdot d\mathbf{r} = 0 \text{ over any loop in } D$$

Two questions arise:

1. How do we know whether a given vector field \mathbf{F} is conservative?
2. If \mathbf{F} is in fact conservative, how do we find a potential function f (so that $\mathbf{F} = \nabla f$)?

Finding Potentials for Conservative Fields

The test for a vector field being conservative involves the equivalence of certain first partial derivatives of the field components.

Component Test for Conservative Fields

Let $\mathbf{F} = M(x, y, z)\mathbf{i} + N(x, y, z)\mathbf{j} + P(x, y, z)\mathbf{k}$ be a field on an open simply connected domain whose component functions have continuous first partial derivatives. Then \mathbf{F} is conservative if and only if

$$\frac{\partial P}{\partial y} = \frac{\partial N}{\partial z}, \quad \frac{\partial M}{\partial z} = \frac{\partial P}{\partial x}, \quad \text{and} \quad \frac{\partial N}{\partial x} = \frac{\partial M}{\partial y}. \quad (2)$$

We can view the component test as saying that on a simply connected region, the vector

$$\left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z}\right)\mathbf{i} + \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x}\right)\mathbf{j} + \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\mathbf{k} \quad (3)$$

is zero if and only if \mathbf{F} is conservative. This interesting vector $\text{curl } \mathbf{F}$ is called the **curl** of \mathbf{F} . We study it in Sections 15.4 and 15.7.

Proof that Equations (2) hold if \mathbf{F} is conservative If \mathbf{F} is conservative, then there is a potential function f such that

$$\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k} = \nabla f = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}.$$

Hence,

$$\begin{aligned} \frac{\partial P}{\partial y} &= \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial z} \right) = \frac{\partial^2 f}{\partial y \partial z} \\ &= \frac{\partial^2 f}{\partial z \partial y} && \text{Mixed Derivative Theorem,} \\ & && \text{Section 13.3} \\ &= \frac{\partial}{\partial z} \left(\frac{\partial f}{\partial y} \right) = \frac{\partial N}{\partial z}. \end{aligned}$$

The others in Equations (2) are proved similarly. ■

The second half of the proof, that Equations (2) imply that \mathbf{F} is conservative, is a consequence of Stokes' Theorem, taken up in Section 15.7, and requires our assumption that the domain of \mathbf{F} be simply connected.

Once we know that \mathbf{F} is conservative, we often want to find a potential function for \mathbf{F} . This requires solving the equation $\nabla f = \mathbf{F}$ or

$$\frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$$

for f . We accomplish this by integrating the three equations

$$\frac{\partial f}{\partial x} = M, \quad \frac{\partial f}{\partial y} = N, \quad \frac{\partial f}{\partial z} = P,$$

as illustrated in the next example.

EXAMPLE 3 Show that $\mathbf{F} = (e^x \cos y + yz)\mathbf{i} + (xz - e^x \sin y)\mathbf{j} + (xy + z)\mathbf{k}$ is conservative over its natural domain, and find a potential function for it.

Solution The natural domain of \mathbf{F} is all of space, which is open and simply connected. We apply the test in Equations (2) to

$$M = e^x \cos y + yz, \quad N = xz - e^x \sin y, \quad P = xy + z$$

and calculate

$$\frac{\partial P}{\partial y} = x = \frac{\partial N}{\partial z}, \quad \frac{\partial M}{\partial z} = y = \frac{\partial P}{\partial x}, \quad \frac{\partial N}{\partial x} = -e^x \sin y + z = \frac{\partial M}{\partial y}.$$

The partial derivatives are continuous, so these equalities tell us that \mathbf{F} is conservative, so there is a function f with $\nabla f = \mathbf{F}$ (Theorem 2).

We find f by integrating the equations

$$\frac{\partial f}{\partial x} = e^x \cos y + yz, \quad \frac{\partial f}{\partial y} = xz - e^x \sin y, \quad \frac{\partial f}{\partial z} = xy + z. \quad (4)$$

We integrate the first equation with respect to x , holding y and z fixed, to get

$$f(x, y, z) = e^x \cos y + xyz + g(y, z).$$

We write the constant of integration as a function of y and z because its value may depend on y and z , though not on x . We then calculate $\partial f/\partial y$ from this equation and match it with the expression for $\partial f/\partial y$ in Equations (4). This gives

$$-e^x \sin y + xz + \frac{\partial g}{\partial y} = xz - e^x \sin y,$$

so $\partial g/\partial y = 0$. Therefore, g is a function of z alone, and

$$f(x, y, z) = e^x \cos y + xyz + h(z).$$

We now calculate $\partial f/\partial z$ from this equation and match it to the formula for $\partial f/\partial z$ in Equations (4). This gives

$$xy + \frac{dh}{dz} = xy + z, \quad \text{or} \quad \frac{dh}{dz} = z,$$

so

$$h(z) = \frac{z^2}{2} + C.$$

Hence,

$$f(x, y, z) = e^x \cos y + xyz + \frac{z^2}{2} + C.$$

We found infinitely many potential functions of \mathbf{F} , one for each value of C . ■

EXAMPLE 4 Show that $\mathbf{F} = (2x - 3)\mathbf{i} - z\mathbf{j} + (\cos z)\mathbf{k}$ is not conservative.

Solution We apply the Component Test in Equations (2) and find immediately that

$$\frac{\partial P}{\partial y} = \frac{\partial}{\partial y}(\cos z) = 0, \quad \frac{\partial N}{\partial z} = \frac{\partial}{\partial z}(-z) = -1.$$

The two are unequal, so \mathbf{F} is not conservative. No further testing is required. ■

EXAMPLE 5 Show that the vector field

$$\mathbf{F} = \frac{-y}{x^2 + y^2}\mathbf{i} + \frac{x}{x^2 + y^2}\mathbf{j} + 0\mathbf{k}$$

satisfies the equations in the Component Test but is not conservative over its natural domain. Explain why this is possible.

Solution We have $M = -y/(x^2 + y^2)$, $N = x/(x^2 + y^2)$, and $P = 0$. If we apply the Component Test, we find

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial N}{\partial z}, \quad \frac{\partial P}{\partial x} = 0 = \frac{\partial M}{\partial z}, \quad \text{and} \quad \frac{\partial M}{\partial y} = \frac{y^2 - x^2}{(x^2 + y^2)^2} = \frac{\partial N}{\partial x}.$$

So it may appear that the field \mathbf{F} passes the Component Test. However, the test assumes that the domain of \mathbf{F} is simply connected, which is not the case here. Since $x^2 + y^2$ cannot equal zero, the natural domain is the complement of the z -axis and contains loops that cannot be contracted to a point. One such loop is the unit circle C in the xy -plane. The circle is parametrized by $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$. This loop wraps around the z -axis and cannot be contracted to a point while staying within the complement of the z -axis.

To show that \mathbf{F} is not conservative, we compute the line integral $\oint_C \mathbf{F} \cdot d\mathbf{r}$ around the loop C . First we write the field in terms of the parameter t :

$$\mathbf{F} = \frac{-y}{x^2 + y^2}\mathbf{i} + \frac{x}{x^2 + y^2}\mathbf{j} = \frac{-\sin t}{\sin^2 t + \cos^2 t}\mathbf{i} + \frac{\cos t}{\sin^2 t + \cos^2 t}\mathbf{j} = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j}.$$

Next we find $d\mathbf{r}/dt = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j}$ and then calculate the line integral as

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \oint_C \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt = \int_0^{2\pi} (\sin^2 t + \cos^2 t) dt = 2\pi.$$

Since the line integral of \mathbf{F} around the loop C is not zero, the field \mathbf{F} is not conservative, by Theorem 3. The field \mathbf{F} is displayed in Figure 15.31d in the next section. ■

Example 5 shows that the Component Test does not apply when the domain of the field is not simply connected. However, if we change the domain in the example so that it is restricted to the ball of radius 1 centered at the point $(2, 2, 2)$, or to any similar ball-shaped region that does not contain a piece of the z -axis, then this new domain D is simply connected. Now the partial derivative Equations (2), as well as all the assumptions of the Component Test, are satisfied. In this new situation, the field \mathbf{F} in Example 5 is conservative on D . Just as we must be careful with a function when determining whether it satisfies a property throughout its domain (such as continuity, which is required for the Intermediate Value Property), so must we also be careful with a vector field in determining the properties it may or may not have over its assigned domain.

Exact Differential Forms

It is often convenient to express work and circulation integrals in the differential form

$$\int_C M dx + N dy + P dz$$

discussed in Section 15.2. Such line integrals are relatively easy to evaluate if $M dx + N dy + P dz$ is the total differential of a function f and if C is any path joining the point A to the point B , for then

$$\begin{aligned} \int_C M dx + N dy + P dz &= \int_C \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz \\ &= \int_A^B \nabla f \cdot d\mathbf{r} && \nabla f \text{ is conservative.} \\ &= f(B) - f(A). && \text{Theorem 1} \end{aligned}$$

Thus,

$$\int_A^B df = f(B) - f(A),$$

just as with differentiable functions of a single variable.

DEFINITIONS Any expression $M(x, y, z) dx + N(x, y, z) dy + P(x, y, z) dz$ is a **differential form**. A differential form is **exact** on a domain D in space if

$$M dx + N dy + P dz = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz = df$$

for some scalar function f throughout D .

Notice that if $M dx + N dy + P dz = df$ on D , then $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ is the gradient field of f on D . Conversely, if $\mathbf{F} = \nabla f$, then the form $M dx + N dy + P dz$ is exact. The test for the form being exact is therefore the same as the test for \mathbf{F} being conservative.

Component Test for Exactness of $M dx + N dy + P dz$

The differential form $M dx + N dy + P dz$ is exact on an open simply connected domain if and only if

$$\frac{\partial P}{\partial y} = \frac{\partial N}{\partial z}, \quad \frac{\partial M}{\partial z} = \frac{\partial P}{\partial x}, \quad \text{and} \quad \frac{\partial N}{\partial x} = \frac{\partial M}{\partial y}.$$

This is equivalent to saying that the field $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ is conservative.

EXAMPLE 6 Show that $y dx + x dy + 4 dz$ is exact, and evaluate the integral

$$\int_{(1,1,1)}^{(2,3,-1)} y dx + x dy + 4 dz$$

over any path from $(1, 1, 1)$ to $(2, 3, -1)$.

Solution Note that the domain of \mathbf{F} fills all of three-dimensional space, so it is simply connected. We let $M = y$, $N = x$, $P = 4$ and apply the Component Test for Exactness:

$$\frac{\partial P}{\partial y} = 0 = \frac{\partial N}{\partial z}, \quad \frac{\partial M}{\partial z} = 0 = \frac{\partial P}{\partial x}, \quad \frac{\partial N}{\partial x} = 1 = \frac{\partial M}{\partial y}.$$

These equalities tell us that $y dx + x dy + 4 dz$ is exact, so

$$y dx + x dy + 4 dz = df$$

for some function f , and the integral's value is $f(2, 3, -1) - f(1, 1, 1)$.

We find f up to a constant by integrating the equations

$$\frac{\partial f}{\partial x} = y, \quad \frac{\partial f}{\partial y} = x, \quad \frac{\partial f}{\partial z} = 4. \quad (5)$$

From the first equation we get

$$f(x, y, z) = xy + g(y, z).$$

The second equation tells us that

$$\frac{\partial f}{\partial y} = x + \frac{\partial g}{\partial y} = x, \quad \text{or} \quad \frac{\partial g}{\partial y} = 0.$$

Hence, g is a function of z alone, and

$$f(x, y, z) = xy + h(z).$$

The third of Equations (5) tells us that

$$\frac{\partial f}{\partial z} = 0 + \frac{dh}{dz} = 4, \quad \text{or} \quad h(z) = 4z + C.$$

Therefore,

$$f(x, y, z) = xy + 4z + C.$$

The value of the line integral is independent of the path taken from $(1, 1, 1)$ to $(2, 3, -1)$ and equals

$$f(2, 3, -1) - f(1, 1, 1) = 2 + C - (5 + C) = -3. \quad \blacksquare$$

EXERCISES 15.3

Testing for Conservative Fields

Which fields in Exercises 1–6 are conservative, and which are not?

- $\mathbf{F} = yz\mathbf{i} + xz\mathbf{j} + xy\mathbf{k}$
- $\mathbf{F} = (y \sin z)\mathbf{i} + (x \sin z)\mathbf{j} + (xy \cos z)\mathbf{k}$
- $\mathbf{F} = y\mathbf{i} + (x + z)\mathbf{j} - y\mathbf{k}$
- $\mathbf{F} = -y\mathbf{i} + x\mathbf{j}$
- $\mathbf{F} = (z + y)\mathbf{i} + z\mathbf{j} + (y + x)\mathbf{k}$
- $\mathbf{F} = (e^x \cos y)\mathbf{i} - (e^x \sin y)\mathbf{j} + z\mathbf{k}$

Finding Potential Functions

In Exercises 7–12, find a potential function f for the field \mathbf{F} .

- $\mathbf{F} = 2x\mathbf{i} + 3y\mathbf{j} + 4z\mathbf{k}$
- $\mathbf{F} = (y + z)\mathbf{i} + (x + z)\mathbf{j} + (x + y)\mathbf{k}$
- $\mathbf{F} = e^{y+2z}(\mathbf{i} + x\mathbf{j} + 2x\mathbf{k})$
- $\mathbf{F} = (y \sin z)\mathbf{i} + (x \sin z)\mathbf{j} + (xy \cos z)\mathbf{k}$

$$11. \mathbf{F} = (\ln x + \sec^2(x + y))\mathbf{i} + \left(\sec^2(x + y) + \frac{y}{y^2 + z^2} \right)\mathbf{j} + \frac{z}{y^2 + z^2}\mathbf{k}$$

$$12. \mathbf{F} = \frac{y}{1 + x^2y^2}\mathbf{i} + \left(\frac{x}{1 + x^2y^2} + \frac{z}{\sqrt{1 - y^2z^2}} \right)\mathbf{j} + \left(\frac{y}{\sqrt{1 - y^2z^2}} + \frac{1}{z} \right)\mathbf{k}$$

Exact Differential Forms

In Exercises 13–17, show that the differential forms in the integrals are exact. Then evaluate the integrals.

$$13. \int_{(0,0,0)}^{(2,3,-6)} 2x dx + 2y dy + 2z dz$$

$$14. \int_{(1,1,2)}^{(3,5,0)} yz dx + xz dy + xy dz$$

$$15. \int_{(0,0,0)}^{(1,2,3)} 2xy \, dx + (x^2 - z^2) \, dy - 2yz \, dz$$

$$16. \int_{(0,0,0)}^{(3,3,1)} 2x \, dx - y^2 \, dy - \frac{4}{1+z^2} \, dz$$

$$17. \int_{(1,0,0)}^{(0,1,1)} \sin y \cos x \, dx + \cos y \sin x \, dy + dz$$

Finding Potential Functions to Evaluate Line Integrals

Although they are not defined on all of space R^3 , the fields associated with Exercises 18–22 are conservative. Find a potential function for each field, and evaluate the integrals as in Example 6.

$$18. \int_{(0,2,1)}^{(1,\pi/2,2)} 2 \cos y \, dx + \left(\frac{1}{y} - 2x \sin y \right) \, dy + \frac{1}{z} \, dz$$

$$19. \int_{(1,1,1)}^{(1,2,3)} 3x^2 \, dx + \frac{z^2}{y} \, dy + 2z \ln y \, dz$$

$$20. \int_{(1,2,1)}^{(2,1,1)} (2x \ln y - yz) \, dx + \left(\frac{x^2}{y} - xz \right) \, dy - xy \, dz$$

$$21. \int_{(1,1,1)}^{(2,2,2)} \frac{1}{y} \, dx + \left(\frac{1}{z} - \frac{x}{y^2} \right) \, dy - \frac{y}{z^2} \, dz$$

$$22. \int_{(-1,-1,-1)}^{(2,2,2)} \frac{2x \, dx + 2y \, dy + 2z \, dz}{x^2 + y^2 + z^2}$$

Applications and Examples

23. **Revisiting Example 6** Evaluate the integral

$$\int_{(1,1,1)}^{(2,3,-1)} y \, dx + x \, dy + 4 \, dz$$

from Example 6 by finding parametric equations for the line segment from $(1, 1, 1)$ to $(2, 3, -1)$ and evaluating the line integral of $\mathbf{F} = y\mathbf{i} + x\mathbf{j} + 4\mathbf{k}$ along the segment. Since \mathbf{F} is conservative, the integral is independent of the path.

24. Evaluate

$$\int_C x^2 \, dx + yz \, dy + (y^2/2) \, dz$$

along the line segment C joining $(0, 0, 0)$ to $(0, 3, 4)$.

Independence of path Show that the values of the integrals in Exercises 25 and 26 do not depend on the path taken from A to B .

$$25. \int_A^B z^2 \, dx + 2y \, dy + 2xz \, dz$$

$$26. \int_A^B \frac{x \, dx + y \, dy + z \, dz}{\sqrt{x^2 + y^2 + z^2}}$$

In Exercises 27 and 28, find a potential function for \mathbf{F} .

$$27. \mathbf{F} = \frac{2x}{y} \mathbf{i} + \left(\frac{1-x^2}{y^2} \right) \mathbf{j}, \quad \{(x, y): y > 0\}$$

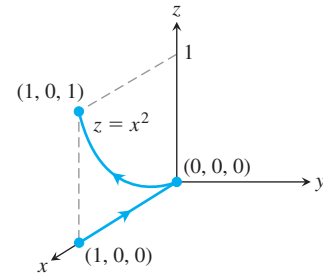

$$28. \mathbf{F} = (e^x \ln y) \mathbf{i} + \left(\frac{e^x}{y} + \sin z \right) \mathbf{j} + (y \cos z) \mathbf{k}$$

29. **Work along different paths** Find the work done by $\mathbf{F} = (x^2 + y)\mathbf{i} + (y^2 + x)\mathbf{j} + ze^z\mathbf{k}$ over the following paths from $(1, 0, 0)$ to $(1, 0, 1)$.

a. The line segment $x = 1, y = 0, 0 \leq z \leq 1$

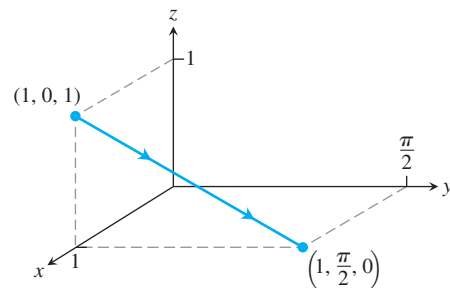

b. The helix $\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (t/2\pi)\mathbf{k}, 0 \leq t \leq 2\pi$

c. The x -axis from $(1, 0, 0)$ to $(0, 0, 0)$ followed by the parabola $z = x^2, y = 0$ from $(0, 0, 0)$ to $(1, 0, 1)$

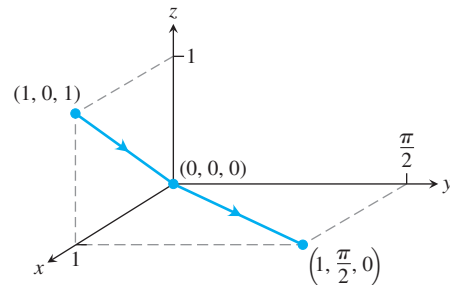

30. **Work along different paths** Find the work done by $\mathbf{F} = e^{yz}\mathbf{i} + (xz e^{yz} + z \cos y)\mathbf{j} + (xy e^{yz} + \sin y)\mathbf{k}$ over the following paths from $(1, 0, 1)$ to $(1, \pi/2, 0)$.

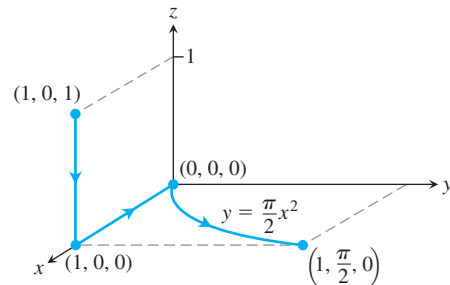

a. The line segment $x = 1, y = \pi t/2, z = 1 - t, 0 \leq t \leq 1$

b. The line segment from $(1, 0, 1)$ to the origin followed by the line segment from the origin to $(1, \pi/2, 0)$

c. The line segment from $(1, 0, 1)$ to $(1, 0, 0)$, followed by the x -axis from $(1, 0, 0)$ to the origin, followed by the parabola $y = \pi x^2/2, z = 0$ from there to $(1, \pi/2, 0)$

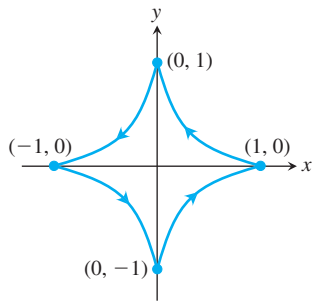

31. Evaluating a work integral two ways Let $\mathbf{F} = \nabla(x^3y^2)$ and let C be the path in the xy -plane from $(-1, 1)$ to $(1, 1)$ that consists of the line segment from $(-1, 1)$ to $(0, 0)$ followed by the line segment from $(0, 0)$ to $(1, 1)$. Evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$ in two ways.

- Find parametrizations for the segments that make up C and evaluate the integral.
- Use $f(x, y) = x^3y^2$ as a potential function for \mathbf{F} .

32. Integral along different paths Evaluate the line integral $\int_C 2x \cos y \, dx - x^2 \sin y \, dy$ along the following paths C in the xy -plane.

- The parabola $y = (x - 1)^2$ from $(1, 0)$ to $(0, 1)$
- The line segment from $(-1, \pi)$ to $(1, 0)$
- The x -axis from $(-1, 0)$ to $(1, 0)$
- The astroid $\mathbf{r}(t) = (\cos^3 t)\mathbf{i} + (\sin^3 t)\mathbf{j}$, $0 \leq t \leq 2\pi$, counterclockwise from $(1, 0)$ back to $(1, 0)$

33. a. Exact differential form How are the constants a , b , and c related if the following differential form is exact?

$$(ay^2 + 2czx) \, dx + y(bx + cz) \, dy + (ay^2 + cx^2) \, dz$$

b. Gradient field For what values of b and c will

$$\mathbf{F} = (y^2 + 2czx)\mathbf{i} + y(bx + cz)\mathbf{j} + (y^2 + cx^2)\mathbf{k}$$

be a gradient field?

34. Gradient of a line integral Suppose that $\mathbf{F} = \nabla f$ is a conservative vector field and

$$g(x, y, z) = \int_{(0,0,0)}^{(x,y,z)} \mathbf{F} \cdot d\mathbf{r}.$$

Show that $\nabla g = \mathbf{F}$.

35. Path of least work You have been asked to find the path along which a force field \mathbf{F} will perform the least work in moving a particle between two locations. A quick calculation on your part shows \mathbf{F} to be conservative. How should you respond? Give reasons for your answer.

36. A revealing experiment By experiment, you find that a force field \mathbf{F} performs only half as much work in moving an object along path C_1 from A to B as it does in moving the object along path C_2 from A to B . What can you conclude about \mathbf{F} ? Give reasons for your answer.

37. Work by a constant force Show that the work done by a constant force field $\mathbf{F} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$ in moving a particle along any path from A to B is $W = \mathbf{F} \cdot \overline{AB}$.

38. Gravitational field

a. Find a potential function for the gravitational field

$$\mathbf{F} = -GmM \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{(x^2 + y^2 + z^2)^{3/2}}$$

(G , m , and M are constants).

b. Let P_1 and P_2 be points at distances s_1 and s_2 from the origin. Show that the work done by the gravitational field in part (a) in moving a particle from P_1 to P_2 is

$$GmM \left(\frac{1}{s_2} - \frac{1}{s_1} \right).$$

15.4 Green's Theorem in the Plane

If \mathbf{F} is a conservative field, then we know $\mathbf{F} = \nabla f$ for a differentiable function f , and we can calculate the line integral of \mathbf{F} over any path C joining point A to point B as $\int_C \mathbf{F} \cdot d\mathbf{r} = f(B) - f(A)$. In this section we derive a method for computing a work or flux integral over a *closed* curve C in the plane. This method, which can be used even when the field \mathbf{F} is not conservative, comes from Green's Theorem. It enables us to convert the line integral into a double integral over the region enclosed by C .

The discussion is given in terms of velocity fields of fluid flows (a fluid is a liquid or a gas) because they are easy to visualize. However, Green's Theorem applies to any vector field, independent of any particular interpretation of the field, provided the assumptions of the theorem are satisfied. We introduce two new ideas for Green's Theorem: *circulation density* around an axis perpendicular to the plane and *divergence* (or *flux density*).

Spin Around an Axis: The \mathbf{k} -Component of Curl

Suppose that $\mathbf{F}(x, y) = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ is the velocity field of a fluid flowing in the plane and that the first partial derivatives of M and N are continuous at each point of a region R . Let (x, y) be a point in R , and let A be a small rectangle with one corner at (x, y)

that, along with its interior, lies entirely in R . The sides of the rectangle, parallel to the coordinate axes, have lengths of Δx and Δy . Assume that the components M and N do not change sign throughout a small region containing the rectangle A . The first idea we use to convey Green's Theorem quantifies the rate at which a floating paddle wheel, with axis perpendicular to the plane, spins at a point in a fluid flowing in a plane region. This idea gives some sense of how the fluid is circulating around axes located at different points and perpendicular to the plane. Physicists sometimes refer to this as the *circulation density* of a vector field \mathbf{F} at a point. To obtain it, we consider the velocity field

$$\mathbf{F}(x, y) = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$$

and the rectangle A in Figure 15.29 (where we assume both components of \mathbf{F} are positive).

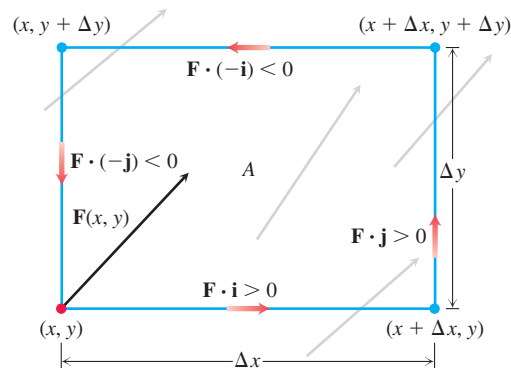

FIGURE 15.29 The rate at which a fluid flows along the bottom edge of a rectangular region A in the direction \mathbf{i} is approximately $\mathbf{F}(x, y) \cdot \mathbf{i} \Delta x$, which is positive for the vector field \mathbf{F} shown here. To approximate the rate of circulation at the point (x, y) , we calculate the (approximate) flow rates along each edge in the directions of the red arrows, sum these rates, and then divide the sum by the area of A . Taking the limit as $\Delta x \rightarrow 0$ and $\Delta y \rightarrow 0$ gives the rate of the circulation per unit area.

The circulation rate of \mathbf{F} around the boundary of A is the sum of flow rates along the sides in the tangential direction. For the bottom edge, the flow rate is approximately

$$\mathbf{F}(x, y) \cdot \mathbf{i} \Delta x = M(x, y) \Delta x.$$

This is the scalar component of the velocity $\mathbf{F}(x, y)$ in the tangent direction \mathbf{i} times the length of the segment. The flow rates may be positive or negative, depending on the components of \mathbf{F} . We approximate the net circulation rate around the rectangular boundary of A by summing the flow rates along the four edges as defined by the following dot products.

$$\text{Top:} \quad \mathbf{F}(x, y + \Delta y) \cdot (-\mathbf{i}) \Delta x = -M(x, y + \Delta y) \Delta x$$

$$\text{Bottom:} \quad \mathbf{F}(x, y) \cdot \mathbf{i} \Delta x = M(x, y) \Delta x$$

$$\text{Right:} \quad \mathbf{F}(x + \Delta x, y) \cdot \mathbf{j} \Delta y = N(x + \Delta x, y) \Delta y$$

$$\text{Left:} \quad \mathbf{F}(x, y) \cdot (-\mathbf{j}) \Delta y = -N(x, y) \Delta y$$

We sum opposite pairs to get

$$\text{Top and bottom:} \quad -(M(x, y + \Delta y) - M(x, y)) \Delta x \approx -\left(\frac{\partial M}{\partial y} \Delta y\right) \Delta x$$

$$\text{Right and left:} \quad (N(x + \Delta x, y) - N(x, y)) \Delta y \approx \left(\frac{\partial N}{\partial x} \Delta x\right) \Delta y.$$

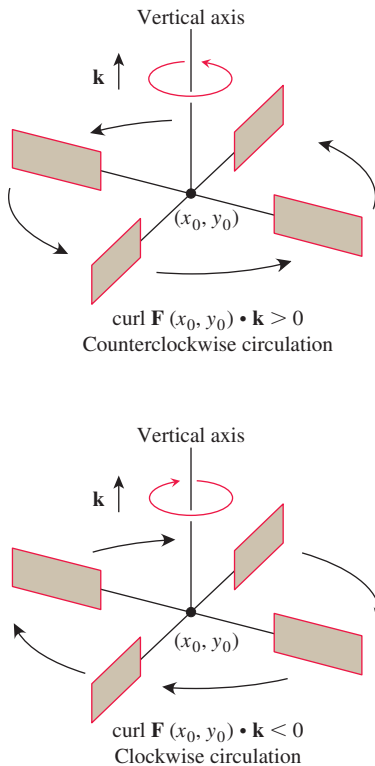

FIGURE 15.30 In the flow of an incompressible fluid over a plane region, the \mathbf{k} -component of the curl measures the rate of the fluid's rotation at a point. The \mathbf{k} -component of the curl is positive at points where the rotation is counterclockwise and negative where the rotation is clockwise.

Adding these last two equations gives the net circulation rate relative to the counterclockwise orientation,

$$\text{Circulation rate around rectangle} \approx \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \Delta x \Delta y.$$

We now divide by $\Delta x \Delta y$ to estimate the circulation rate per unit area, or *circulation density*, for the rectangle:

$$\frac{\text{Circulation around rectangle}}{\text{rectangle area}} \approx \frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}.$$

We let Δx and Δy approach zero to define the *circulation density* of \mathbf{F} at the point (x, y) .

If we see a counterclockwise rotation looking downward onto the xy -plane from the tip of the unit \mathbf{k} vector, then the circulation density is positive (Figure 15.30).

DEFINITION The **circulation density** of a vector field $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ at the point (x, y) is the scalar expression

$$\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}. \quad (1)$$

The expression in Equation (1) is the \mathbf{k} -component of the curl of \mathbf{F} , which was introduced in Equation (3) of Section 15.3:

$$\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} = (\text{curl } \mathbf{F}) \cdot \mathbf{k}.$$

If water is moving about a region in the xy -plane in a thin layer, then the \mathbf{k} -component of the curl at a point (x_0, y_0) gives a way to measure how fast and in what direction a small paddle wheel spins if it is put into the water at (x_0, y_0) with its axis perpendicular to the plane, parallel to \mathbf{k} (Figure 15.30). Looking downward onto the xy -plane, it spins counterclockwise when $(\text{curl } \mathbf{F}) \cdot \mathbf{k}$ is positive and clockwise when the \mathbf{k} -component is negative.

EXAMPLE 1 The following vector fields represent the velocity of a gas flowing in the xy -plane. Find the circulation density of each vector field and interpret its physical meaning. Figure 15.31 displays the vector fields.

(a) *Uniform expansion or compression:* $\mathbf{F}(x, y) = cx\mathbf{i} + cy\mathbf{j}$ c a constant

(b) *Uniform rotation:* $\mathbf{F}(x, y) = -cy\mathbf{i} + cx\mathbf{j}$

(c) *Shearing flow:* $\mathbf{F}(x, y) = y\mathbf{i}$

(d) *Whirlpool effect:* $\mathbf{F}(x, y) = \frac{-y}{x^2 + y^2}\mathbf{i} + \frac{x}{x^2 + y^2}\mathbf{j}$

Solution

(a) *Uniform expansion:* $(\text{curl } \mathbf{F}) \cdot \mathbf{k} = \frac{\partial}{\partial x}(cy) - \frac{\partial}{\partial y}(cx) = 0$. The gas is not circulating at very small scales.

(b) *Rotation:* $(\text{curl } \mathbf{F}) \cdot \mathbf{k} = \frac{\partial}{\partial x}(cx) - \frac{\partial}{\partial y}(-cy) = 2c$. The constant circulation density indicates rotation around every point. If $c > 0$, the rotation is counterclockwise; if $c < 0$, the rotation is clockwise.

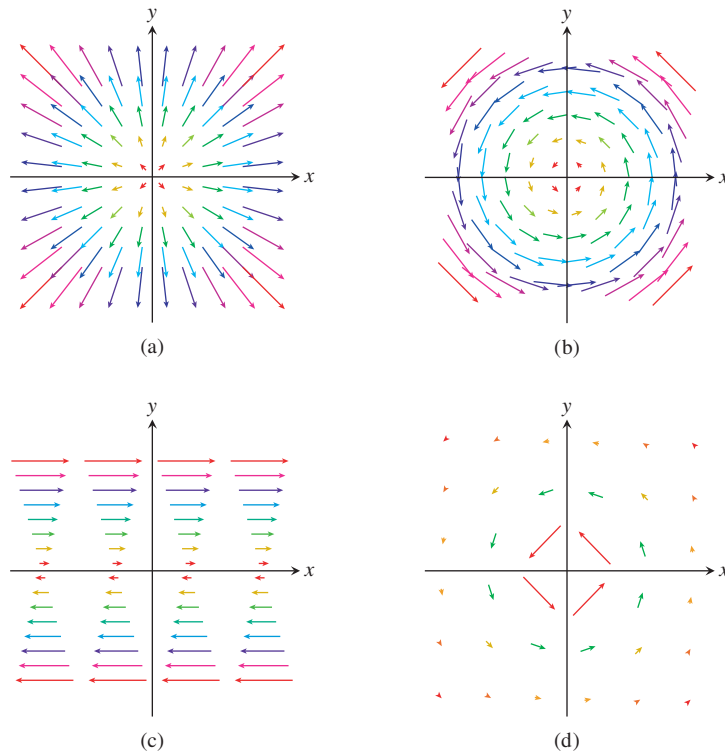

FIGURE 15.31 Velocity fields of a gas flowing in the plane (Example 1).

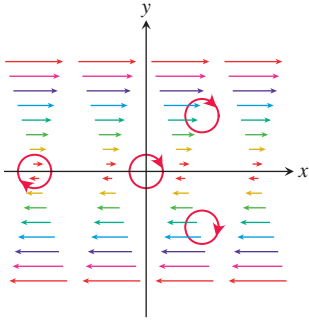

FIGURE 15.32 A shearing flow pushes the fluid clockwise around each point (Example 1c).

(c) *Shear*: $(\text{curl } \mathbf{F}) \cdot \mathbf{k} = -\frac{\partial}{\partial y}(y) = -1$. The circulation density is constant and negative, so a paddle wheel floating in water undergoing such a shearing flow spins clockwise. The rate of rotation is the same at each point. The average rotational effect of the fluid flow is to push fluid clockwise around each of the small circles shown in Figure 15.32.

(d) *Whirlpool*:

$$(\text{curl } \mathbf{F}) \cdot \mathbf{k} = \frac{\partial}{\partial x} \left(\frac{x}{x^2 + y^2} \right) - \frac{\partial}{\partial y} \left(\frac{-y}{x^2 + y^2} \right) = \frac{y^2 - x^2}{(x^2 + y^2)^2} - \frac{y^2 - x^2}{(x^2 + y^2)^2} = 0.$$

The circulation density is 0 at every point away from the origin (where the vector field is undefined and the whirlpool effect blows up), and the gas is not circulating at any point for which the vector field is defined. ■

One form of Green's Theorem tells us how circulation density can be used to calculate the line integral for flow in the xy -plane. (The flow integral was defined in Section 15.2.) A second form of the theorem tells us how we can calculate the flux integral, which gives the flow across the boundary, from *flux density*. We define this idea next and then present both versions of the theorem.

Divergence

Consider again the velocity field $\mathbf{F}(x, y) = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ in a domain containing the rectangle A , as shown in Figure 15.33. As before, we assume the field components do not change sign throughout a small region containing the rectangle A . Our interest now is to determine the rate at which the fluid leaves A by flowing across its boundary.

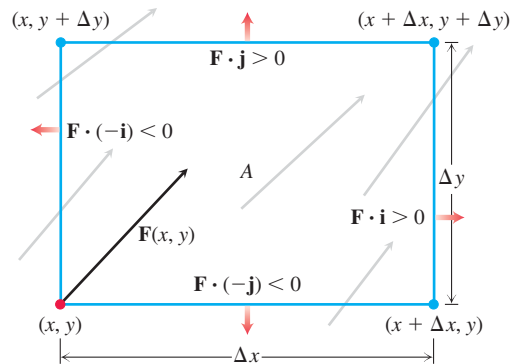

FIGURE 15.33 The rate at which the fluid leaves the rectangular region A across the bottom edge in the direction of the outward normal $-\mathbf{j}$ is approximately $\mathbf{F}(x, y) \cdot (-\mathbf{j}) \Delta x$, which is negative for the vector field \mathbf{F} shown here. To approximate the flow rate at the point (x, y) , we calculate the (approximate) flow rates across each edge in the directions of the red arrows, sum these rates, and then divide the sum by the area of A . Taking the limit as $\Delta x \rightarrow 0$ and $\Delta y \rightarrow 0$ gives the flow rate per unit area.

The rate at which fluid leaves the rectangle across the bottom edge is approximately (Figure 15.33)

$$\mathbf{F}(x, y) \cdot (-\mathbf{j}) \Delta x = -N(x, y) \Delta x.$$

This is the scalar component of the velocity at (x, y) in the direction of the outward normal times the length of the segment. If the velocity is in meters per second, for example, the flow rate will be in meters per second times meters, or square meters per second. The rates at which the fluid crosses the other three sides in the directions of their outward normals can be estimated in a similar way. The flow rates may be positive or negative, depending on the signs of the components of \mathbf{F} . We approximate the net flow rate across the rectangular boundary of A by summing the flow rates across the four edges as defined by the following dot products.

$$\begin{aligned} \text{Fluid Flow Rates: Top:} & \quad \mathbf{F}(x, y + \Delta y) \cdot \mathbf{j} \Delta x = N(x, y + \Delta y) \Delta x \\ \text{Bottom:} & \quad \mathbf{F}(x, y) \cdot (-\mathbf{j}) \Delta x = -N(x, y) \Delta x \\ \text{Right:} & \quad \mathbf{F}(x + \Delta x, y) \cdot \mathbf{i} \Delta y = M(x + \Delta x, y) \Delta y \\ \text{Left:} & \quad \mathbf{F}(x, y) \cdot (-\mathbf{i}) \Delta y = -M(x, y) \Delta y \end{aligned}$$

Summing opposite pairs gives

$$\text{Top and bottom:} \quad (N(x, y + \Delta y) - N(x, y)) \Delta x \approx \left(\frac{\partial N}{\partial y} \Delta y \right) \Delta x,$$

$$\text{Right and left:} \quad (M(x + \Delta x, y) - M(x, y)) \Delta y \approx \left(\frac{\partial M}{\partial x} \Delta x \right) \Delta y.$$

Adding these last two equations gives the net effect of the flow rates, or the

$$\text{Flux across rectangle boundary} \approx \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) \Delta x \Delta y.$$

We now divide by $\Delta x \Delta y$ to estimate the total flux per unit area, or *flux density*, for the rectangle:

$$\frac{\text{Flux across rectangle boundary}}{\text{rectangle area}} \approx \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right).$$

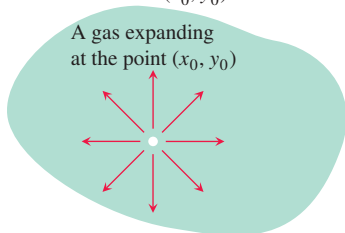

$\operatorname{div} \mathbf{F}$ is the symbol for divergence.

Finally, we let Δx and Δy approach zero to define the flux density of \mathbf{F} at the point (x, y) . The mathematical term for the flux density is the *divergence* of \mathbf{F} . The symbol for it is $\operatorname{div} \mathbf{F}$, which is pronounced “divergence of \mathbf{F} ” or “ $\operatorname{div} \mathbf{F}$.”

DEFINITION The **divergence (flux density)** of a vector field $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ at the point (x, y) is

$$\operatorname{div} \mathbf{F} = \frac{\partial M}{\partial x} + \frac{\partial N}{\partial y}. \quad (2)$$

Source: $\operatorname{div} \mathbf{F}(x_0, y_0) > 0$

Sink: $\operatorname{div} \mathbf{F}(x_0, y_0) < 0$

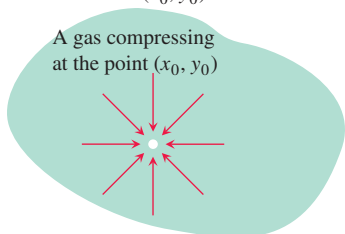

FIGURE 15.34 If a gas is expanding at a point (x_0, y_0) , the lines of flow have positive divergence; if the gas is compressing, the divergence is negative.

A gas is compressible, unlike a liquid, and the divergence of its velocity field measures to what extent it is expanding or compressing at each point. Intuitively, if a gas is expanding at the point (x_0, y_0) , the lines of flow would diverge there (hence the name), and since the gas would be flowing out of a small rectangle about (x_0, y_0) , the divergence of \mathbf{F} at (x_0, y_0) would be positive. If the gas were compressing instead of expanding, the divergence would be negative (Figure 15.34).

EXAMPLE 2 Find the divergence, and interpret what it means, for each vector field in Example 1 representing the velocity of a gas flowing in the xy -plane.

Solution

(a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(cx) + \frac{\partial}{\partial y}(cy) = 2c$: If $c > 0$, the gas is undergoing uniform expansion; if $c < 0$, it is undergoing uniform compression.

(b) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(-cy) + \frac{\partial}{\partial y}(cx) = 0$: The gas is neither expanding nor compressing.

(c) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(y) = 0$: The gas is neither expanding nor compressing.

(d) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}\left(\frac{-y}{x^2 + y^2}\right) + \frac{\partial}{\partial y}\left(\frac{x}{x^2 + y^2}\right) = \frac{2xy}{(x^2 + y^2)^2} - \frac{2xy}{(x^2 + y^2)^2} = 0$: Again, the divergence is zero at all points in the domain of the velocity field. ■

Cases (b), (c), and (d) of Figure 15.31 are plausible models for the two-dimensional flow of a liquid. In fluid dynamics, when the velocity field of a flowing fluid always has divergence equal to zero, as in those cases, the flow is said to be **incompressible**.

Two Forms for Green's Theorem

A simple closed curve C can be traversed in two possible directions. (Recall that a curve is simple if it does not cross itself.) The curve is traversed counterclockwise, and said to be *positively oriented*, if the region it encloses is always to the left when moving along the curve. If the curve is traversed clockwise, then the enclosed region is on the right when moving along the curve, and the curve is said to be *negatively oriented*. The line integral of a vector field \mathbf{F} along C reverses sign if we change the orientation. We use the notation

$$\oint_C \mathbf{F}(x, y) \cdot d\mathbf{r}$$

for the line integral when the simple closed curve C is traversed counterclockwise, with its positive orientation.

In one form, Green's Theorem says that the counterclockwise circulation of a vector field around a simple closed curve is the double integral of the \mathbf{k} -component of the curl of the field over the region enclosed by the curve. Recall the defining Equation (5) for circulation in Section 15.2.

$$\text{Circulation around } C = \oint_C \mathbf{F} \cdot \mathbf{T} \, ds$$

$$(\text{curl } \mathbf{F}) \cdot \mathbf{k} = \frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}$$

THEOREM 4—Green's Theorem (Circulation-Curl or Tangential Form)

Let C be a piecewise smooth, simple closed curve enclosing a region R in the plane. Let $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ be a vector field with M and N having continuous first partial derivatives in an open region containing R . Then the counterclockwise circulation of \mathbf{F} around C equals the double integral of $(\text{curl } \mathbf{F}) \cdot \mathbf{k}$ over R .

$$\oint_C \mathbf{F} \cdot \mathbf{T} \, ds = \oint_C M \, dx + N \, dy = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx \, dy \quad (3)$$

Counterclockwise circulation
Curl integral

A second form of Green's Theorem says that the outward flux of a vector field across a simple closed curve in the plane equals the double integral of the divergence of the field over the region enclosed by the curve. Recall the formulas for flux in Equations (8) and (9) in Section 15.2.

$$\text{Flux of } \mathbf{F} \text{ across } C = \oint_C \mathbf{F} \cdot \mathbf{n} \, ds$$

$$\text{div } \mathbf{F} = \frac{\partial M}{\partial x} + \frac{\partial N}{\partial y}$$

THEOREM 5—Green's Theorem (Flux-Divergence or Normal Form)

Let C be a piecewise smooth, simple closed curve enclosing a region R in the plane. Let $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ be a vector field with M and N having continuous first partial derivatives in an open region containing R . Then the outward flux of \mathbf{F} across C equals the double integral of $\text{div } \mathbf{F}$ over the region R enclosed by C .

$$\oint_C \mathbf{F} \cdot \mathbf{n} \, ds = \oint_C M \, dy - N \, dx = \iint_R \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) dx \, dy \quad (4)$$

Outward flux
Divergence integral

The two forms of Green's Theorem are equivalent. Applying Equation (3) to the field $\mathbf{G}_1 = -N\mathbf{i} + M\mathbf{j}$ gives Equation (4), and applying Equation (4) to $\mathbf{G}_2 = M\mathbf{i} - N\mathbf{j}$ gives Equation (3).

Both forms of Green's Theorem can be viewed as two-dimensional generalizations of the Fundamental Theorem of Calculus from Section 5.4. The counterclockwise circulation of \mathbf{F} around C , defined by the line integral on the left-hand side of Equation (3), is the integral of its rate of change (circulation density) over the region R enclosed by C , which is the double integral on the right-hand side of Equation (3). Likewise, the outward flux of \mathbf{F} across C , defined by the line integral on the left-hand side of Equation (4), is the integral of its rate of change (flux density) over the region R enclosed by C , which is the double integral on the right-hand side of Equation (4).

EXAMPLE 3 Verify both forms of Green's Theorem for the vector field

$$\mathbf{F}(x, y) = (x - y)\mathbf{i} + x\mathbf{j}$$

and the region R bounded by the unit circle

$$C: \mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j}, \quad 0 \leq t \leq 2\pi.$$

Solution First we evaluate the counterclockwise circulation of $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ around C . On the curve C we have $x = \cos t$ and $y = \sin t$. Evaluating $\mathbf{F}(\mathbf{r}(t))$ and computing the derivatives of the components of \mathbf{r} , we have

$$\begin{aligned} M &= x - y = \cos t - \sin t, & dx &= d(\cos t) = -\sin t \, dt, \\ N &= x = \cos t, & dy &= d(\sin t) = \cos t \, dt. \end{aligned}$$

Therefore,

$$\begin{aligned}\oint_C \mathbf{F} \cdot \mathbf{T} \, ds &= \oint_C M \, dx + N \, dy \\ &= \int_{t=0}^{t=2\pi} (\cos t - \sin t)(-\sin t) \, dt + (\cos t)(\cos t) \, dt \\ &= \int_0^{2\pi} (-\sin t \cos t + 1) \, dt = 2\pi.\end{aligned}$$

This gives the left side of Equation (3). Next we find the curl integral, the right side of Equation (3). Since $M = x - y$ and $N = x$, we have

$$\frac{\partial M}{\partial x} = 1, \quad \frac{\partial M}{\partial y} = -1, \quad \frac{\partial N}{\partial x} = 1, \quad \frac{\partial N}{\partial y} = 0.$$

Therefore,

$$\begin{aligned}\iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx \, dy &= \iint_R (1 - (-1)) \, dx \, dy \\ &= 2 \iint_R dx \, dy = 2(\text{area inside the unit circle}) = 2\pi.\end{aligned}$$

Thus, the right and left sides of Equation (3) both equal 2π , as asserted by the circulation-curl version of Green's Theorem.

Figure 15.35 displays the vector field and circulation around C .

Now we compute the two sides of Equation (4) in the flux-divergence form of Green's Theorem, starting with the outward flux:

$$\begin{aligned}\oint_C M \, dy - N \, dx &= \int_{t=0}^{t=2\pi} (\cos t - \sin t)(\cos t \, dt) - (\cos t)(-\sin t \, dt) \\ &= \int_0^{2\pi} \cos^2 t \, dt = \pi.\end{aligned}$$

Next we compute the divergence integral:

$$\iint_R \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) dx \, dy = \iint_R (1 + 0) \, dx \, dy = \iint_R dx \, dy = \pi.$$

Hence the right and left sides of Equation (4) both equal π , as asserted by the flux-divergence version of Green's Theorem. ■

Using Green's Theorem to Evaluate Line Integrals

If we construct a closed curve C by piecing together a number of different curves end to end, the process of evaluating a line integral over C can be lengthy because there are so many different integrals to evaluate. If C bounds a region R to which Green's Theorem applies, however, we can use Green's Theorem to change the line integral around C into one double integral over R .

EXAMPLE 4 Evaluate the line integral

$$\oint_C xy \, dy - y^2 \, dx,$$

where C is the boundary of the square $0 \leq x \leq 1$, $0 \leq y \leq 1$.

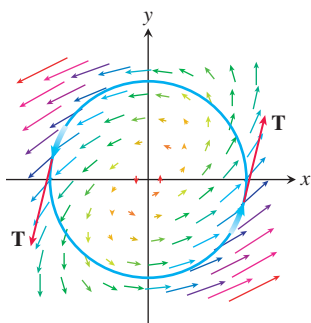

FIGURE 15.35 The vector field in Example 3 has a counterclockwise circulation of 2π around the unit circle.

Solution We can use either form of Green's Theorem to change the line integral into a double integral over the square, where C is the square's boundary and R is its interior.

1. *With the Tangential Form Equation (3):* Taking $M = -y^2$ and $N = xy$ gives the result:

$$\begin{aligned}\oint_C -y^2 dx + xy dy &= \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy = \iint_R (y - (-2y)) dx dy \\ &= \int_0^1 \int_0^1 3y dx dy = \int_0^1 [3xy]_{x=0}^{x=1} dy = \int_0^1 3y dy = \left. \frac{3}{2}y^2 \right|_0^1 = \frac{3}{2}.\end{aligned}$$

2. *With the Normal Form Equation (4):* Taking $M = xy$, $N = y^2$, gives the same result:

$$\oint_C xy dy - y^2 dx = \iint_R \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) dx dy = \iint_R (y + 2y) dx dy = \frac{3}{2}. \quad \blacksquare$$

EXAMPLE 5 Calculate the outward flux of the vector field $\mathbf{F}(x, y) = 2e^{xy}\mathbf{i} + y^3\mathbf{j}$ across the boundary of the square $-1 \leq x \leq 1$, $-1 \leq y \leq 1$.

Solution Calculating the flux with a line integral would take four integrations, one for each side of the square. With Green's Theorem, we can change the line integral to one double integral. With $M = 2e^{xy}$, $N = y^3$, C the square's boundary, and R the square's interior, we have

$$\begin{aligned}\text{Flux} &= \oint_C \mathbf{F} \cdot \mathbf{n} ds = \oint_C M dy - N dx \\ &= \iint_R \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) dx dy \quad \text{Green's Theorem, Eq. (4)} \\ &= \int_{-1}^1 \int_{-1}^1 (2ye^{xy} + 3y^2) dx dy = \int_{-1}^1 \left[2e^{xy} + 3xy^2 \right]_{x=-1}^{x=1} dy \\ &= \int_{-1}^1 (2e^y + 6y^2 - 2e^{-y}) dy = \left[2e^y + 2y^3 + 2e^{-y} \right]_{-1}^1 = 4. \quad \blacksquare\end{aligned}$$

Proof of Green's Theorem for Special Regions

Let C be a smooth simple closed curve in the xy -plane with the property that lines parallel to the axes cut it at no more than two points. Let R be the region enclosed by C and suppose that M , N , and their first partial derivatives are continuous at every point of some open region containing C and R . We want to prove the circulation-curl form of Green's Theorem,

$$\oint_C M dx + N dy = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx dy. \quad (5)$$

Figure 15.36 shows C made up of two directed parts:

$$C_1: y = f_1(x), \quad a \leq x \leq b, \quad C_2: y = f_2(x), \quad b \geq x \geq a.$$

For any x between a and b , we can integrate $\partial M/\partial y$ with respect to y from $y = f_1(x)$ to $y = f_2(x)$ and obtain

$$\int_{f_1(x)}^{f_2(x)} \frac{\partial M}{\partial y} dy = M(x, y) \Big|_{y=f_1(x)}^{y=f_2(x)} = M(x, f_2(x)) - M(x, f_1(x)).$$

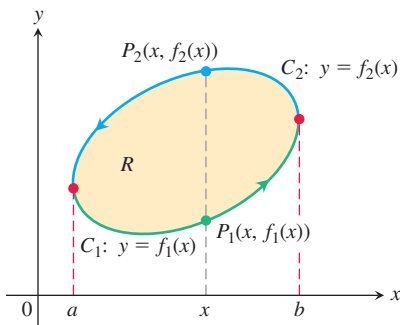

FIGURE 15.36 The boundary curve C is made up of C_1 , the graph of $y = f_1(x)$, and C_2 , the graph of $y = f_2(x)$.

We can then integrate this with respect to x from a to b :

$$\begin{aligned} \int_a^b \int_{f_1(x)}^{f_2(x)} \frac{\partial M}{\partial y} dy dx &= \int_a^b [M(x, f_2(x)) - M(x, f_1(x))] dx \\ &= -\int_b^a M(x, f_2(x)) dx - \int_a^b M(x, f_1(x)) dx \\ &= -\int_{C_2} M dx - \int_{C_1} M dx \\ &= -\oint_C M dx. \end{aligned}$$

Therefore, reversing the order of the equations, we have

$$\oint_C M dx = \iint_R \left(-\frac{\partial M}{\partial y} \right) dx dy. \quad (6)$$

Equation (6) is half the result we need for Equation (5). We derive the other half by integrating $\partial N/\partial x$ first with respect to x and then with respect to y , as suggested by Figure 15.37. This shows the curve C of Figure 15.36 decomposed into the two directed parts $C'_1: x = g_1(y)$, $d \geq y \geq c$ and $C'_2: x = g_2(y)$, $c \leq y \leq d$. The result of this double integration is

$$\oint_C N dy = \iint_R \frac{\partial N}{\partial x} dx dy. \quad (7)$$

Summing Equations (6) and (7) gives Equation (5). This concludes the proof. ■

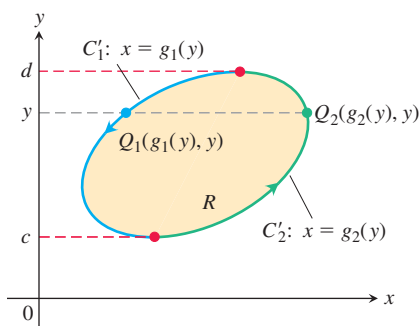

FIGURE 15.37 The boundary curve C is made up of C'_1 , the graph of $x = g_1(y)$, and C'_2 , the graph of $x = g_2(y)$.

Green's Theorem also holds for more general regions, such as those shown in Figure 15.38. Notice that the region in Figure 15.38c is not simply connected. The curves C_1 and C_h on its boundary are oriented so that the region R is always on the left-hand side as the curves are traversed in the directions shown, and cancellation occurs over common boundary arcs traversed in opposite directions. With this convention, Green's Theorem is valid for regions that are not simply connected. The proof proceeds by summing the contributions to the integral of a collection of special regions, which overlap along their boundaries. Cancellation occurs along arcs that are traversed twice, once in each direction, as in Figure 15.38c. We do not give the full proof here.

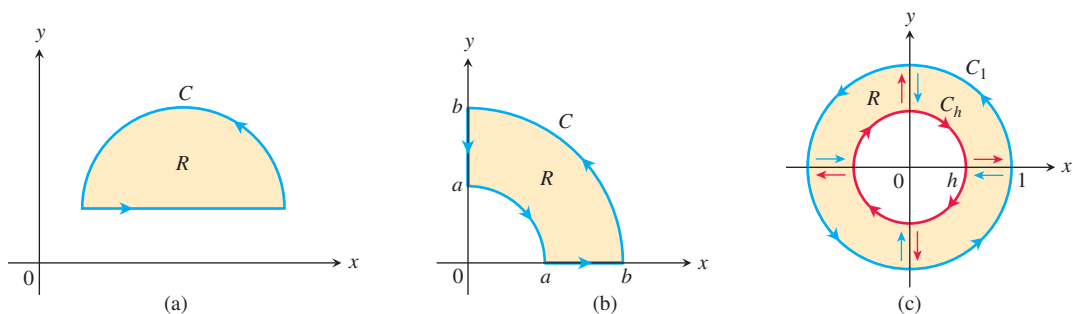

FIGURE 15.38 Other regions to which Green's Theorem applies. In (c) the axes convert the region into four simply connected regions, and we sum the line integrals along the oriented boundaries.

EXERCISES 15.4

Computing the k-Component of Curl(\mathbf{F})

In Exercises 1–6, find the k -component of $\text{curl}(\mathbf{F})$ for the following vector fields on the plane.

- $\mathbf{F} = (x + y)\mathbf{i} + (2xy)\mathbf{j}$
- $\mathbf{F} = (x^2 - y)\mathbf{i} + (y^2)\mathbf{j}$
- $\mathbf{F} = (xe^y)\mathbf{i} + (ye^x)\mathbf{j}$
- $\mathbf{F} = (x^2y)\mathbf{i} + (xy^2)\mathbf{j}$
- $\mathbf{F} = (y \sin x)\mathbf{i} + (x \sin y)\mathbf{j}$
- $\mathbf{F} = (x/y)\mathbf{i} - (y/x)\mathbf{j}$

Verifying Green's Theorem

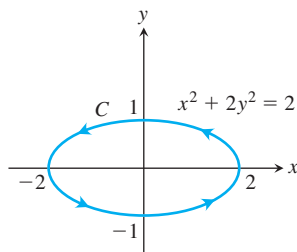

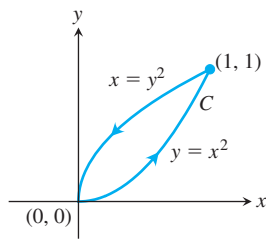

In Exercises 7–10, verify the conclusion of Green's Theorem by evaluating both sides of Equations (3) and (4) for the field $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$. Take the domains of integration in each case to be the disk $R: x^2 + y^2 \leq a^2$ and its bounding circle $C: \mathbf{r} = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$.

- $\mathbf{F} = -y\mathbf{i} + x\mathbf{j}$
- $\mathbf{F} = y\mathbf{i}$
- $\mathbf{F} = 2x\mathbf{i} - 3y\mathbf{j}$
- $\mathbf{F} = -x^2y\mathbf{i} + xy^2\mathbf{j}$

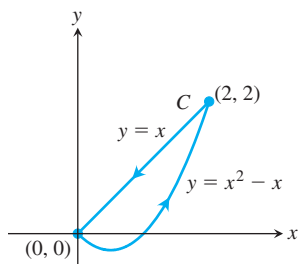

Circulation and Flux

In Exercises 11–20, use Green's Theorem to find the counterclockwise circulation and outward flux for the field \mathbf{F} and the curve C .

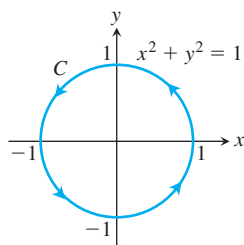

- $\mathbf{F} = (x - y)\mathbf{i} + (y - x)\mathbf{j}$
 C : The square bounded by $x = 0$, $x = 1$, $y = 0$, and $y = 1$
- $\mathbf{F} = (x^2 + 4y)\mathbf{i} + (x + y^2)\mathbf{j}$
 C : The square bounded by $x = 0$, $x = 1$, $y = 0$, and $y = 1$
- $\mathbf{F} = (y^2 - x^2)\mathbf{i} + (x^2 + y^2)\mathbf{j}$
 C : The triangle bounded by $y = 0$, $x = 3$, and $y = x$
- $\mathbf{F} = (x + y)\mathbf{i} - (x^2 + y^2)\mathbf{j}$
 C : The triangle bounded by $y = 0$, $x = 1$, and $y = x$
- $\mathbf{F} = (xy + y^2)\mathbf{i} + (x - y)\mathbf{j}$
- $\mathbf{F} = (x + 3y)\mathbf{i} + (2x - y)\mathbf{j}$

$$17. \mathbf{F} = x^3y^2\mathbf{i} + \frac{1}{2}x^4y\mathbf{j}$$

$$18. \mathbf{F} = \frac{x}{1+y^2}\mathbf{i} + (\tan^{-1}y)\mathbf{j}$$

$$19. \mathbf{F} = (x + e^x \sin y)\mathbf{i} + (x + e^x \cos y)\mathbf{j}$$

C : The right-hand loop of the lemniscate $r^2 = \cos 2\theta$

$$20. \mathbf{F} = \left(\tan^{-1}\frac{y}{x}\right)\mathbf{i} + \ln(x^2 + y^2)\mathbf{j}$$

C : The boundary of the region defined by the polar coordinate inequalities $1 \leq r \leq 2$, $0 \leq \theta \leq \pi$

- Find the counterclockwise circulation and outward flux of the field $\mathbf{F} = xy\mathbf{i} + y^2\mathbf{j}$ around and over the boundary of the region enclosed by the curve $y = x^2$ and the line $y = x$.
- Find the counterclockwise circulation and the outward flux of the field $\mathbf{F} = (-\sin y)\mathbf{i} + (x \cos y)\mathbf{j}$ around and over the boundary of the square $0 \leq x \leq \pi/2$, $0 \leq y \leq \pi/2$.
- Find the outward flux of the field

$$\mathbf{F} = \left(3xy - \frac{x}{1+y^2}\right)\mathbf{i} + (e^x + \tan^{-1}y)\mathbf{j}$$

across the cardioid $r = a(1 + \cos \theta)$, $a > 0$.

- Find the counterclockwise circulation of $\mathbf{F} = (y + e^x \ln y)\mathbf{i} + (e^x/y)\mathbf{j}$ around the boundary of the region that is bounded above by the curve $y = 3 - x^2$ and below by the curve $y = x^4 + 1$.

Work

In Exercises 25 and 26, find the work done by \mathbf{F} in moving a particle once counterclockwise around the given curve.

$$25. \mathbf{F} = 2xy^3\mathbf{i} + 4x^2y^2\mathbf{j}$$

C : The boundary of the "triangular" region in the first quadrant enclosed by the x -axis, the line $x = 1$, and the curve $y = x^3$

$$26. \mathbf{F} = (4x - 2y)\mathbf{i} + (2x - 4y)\mathbf{j}$$

C : The circle $(x - 2)^2 + (y - 2)^2 = 4$

Using Green's Theorem

Apply Green's Theorem to evaluate the integrals in Exercises 27–30.

$$27. \oint_C (y^2 dx + x^2 dy)$$

C : The boundary of the triangle enclosed by the lines $x = 0$, $x + y = 1$, and $y = 0$

$$28. \oint_C (3y dx + 2x dy)$$

C : The boundary of $0 \leq x \leq \pi$, $0 \leq y \leq \sin x$

$$29. \oint_C (6y + x) dx + (y + 2x) dy$$

C : The circle $(x - 2)^2 + (y - 3)^2 = 4$

$$30. \oint_C (2x + y^2) dx + (2xy + 3y) dy$$

C : Any simple closed curve in the plane for which Green's Theorem holds

Calculating Area with Green's Theorem If a simple closed curve C in the plane and the region R it encloses satisfy the hypotheses of Green's Theorem, the area of R is given by

Green's Theorem Area Formula

$$\text{Area of } R = \frac{1}{2} \oint_C x \, dy - y \, dx$$

The reason is that, by Equation (4) run backward,

$$\begin{aligned} \text{Area of } R &= \iint_R dy \, dx = \iint_R \left(\frac{1}{2} + \frac{1}{2} \right) dy \, dx \\ &= \oint_C \frac{1}{2} x \, dy - \frac{1}{2} y \, dx. \end{aligned}$$

Use the Green's Theorem area formula given above to find the areas of the regions enclosed by the curves in Exercises 31–34.

31. The circle $\mathbf{r}(t) = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$
 32. The ellipse $\mathbf{r}(t) = (a \cos t)\mathbf{i} + (b \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$
 33. The astroid $\mathbf{r}(t) = (\cos^3 t)\mathbf{i} + (\sin^3 t)\mathbf{j}$, $0 \leq t \leq 2\pi$
 34. One arch of the cycloid $x = t - \sin t$, $y = 1 - \cos t$
 35. Let C be the boundary of a region on which Green's Theorem holds. Use Green's Theorem to calculate
- $\oint_C f(x) \, dx + g(y) \, dy$
 - $\oint_C ky \, dx + hx \, dy$ (k and h constants).
36. **Integral dependent only on area** Show that the value of

$$\oint_C xy^2 \, dx + (x^2y + 2x) \, dy$$

around any square depends only on the area of the square and not on its location in the plane.

37. Evaluate the integral

$$\oint_C 4x^3y \, dx + x^4 \, dy$$

for any closed path C .

38. Evaluate the integral

$$\oint_C -y^3 \, dy + x^3 \, dx$$

for any closed path C .

39. **Area as a line integral** Show that if R is a region in the plane bounded by a piecewise smooth, simple closed curve C , then

$$\text{Area of } R = \oint_C x \, dy = -\oint_C y \, dx.$$

40. **Definite integral as a line integral** Suppose that a nonnegative function $y = f(x)$ has a continuous first derivative on $[a, b]$. Let C be the boundary of the region in the xy -plane that is bounded

below by the x -axis, above by the graph of f , and on the sides by the lines $x = a$ and $x = b$. Show that

$$\int_a^b f(x) \, dx = -\oint_C y \, dx.$$

41. **Area and the centroid** Let \bar{x} be the x -coordinate of the centroid of a region R that is bounded by a piecewise smooth, simple closed curve C in the xy -plane. If A is the area of R , show that

$$\frac{1}{2} \oint_C x^2 \, dy = -\oint_C xy \, dx = \frac{1}{3} \oint_C x^2 \, dy - xy \, dx = A\bar{x}.$$

42. **Moment of inertia** Let I_y be the moment of inertia about the y -axis of the region in Exercise 41. Show that

$$\frac{1}{3} \oint_C x^3 \, dy = -\oint_C x^2y \, dx = \frac{1}{4} \oint_C x^3 \, dy - x^2y \, dx = I_y.$$

43. **Green's Theorem and Laplace's equation** Assuming that all the necessary derivatives exist and are continuous, show that if $f(x, y)$ satisfies the Laplace equation

$$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = 0,$$

then

$$\oint_C \frac{\partial f}{\partial y} \, dx - \frac{\partial f}{\partial x} \, dy = 0$$

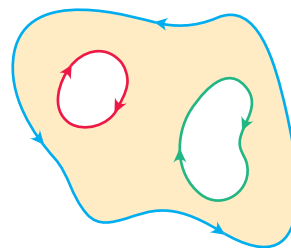

for all closed curves C to which Green's Theorem applies. (The converse is also true: If the line integral is always zero, then f satisfies the Laplace equation.)

44. **Maximizing work** Among all smooth, simple closed curves in the plane, oriented counterclockwise, find the one along which the work done by

$$\mathbf{F} = \left(\frac{1}{4}x^2y + \frac{1}{3}y^3 \right) \mathbf{i} + x\mathbf{j}$$

is greatest. (*Hint:* Where is $(\text{curl } \mathbf{F}) \cdot \mathbf{k}$ positive?)

45. **Regions with many holes** Green's Theorem holds for a region R with any finite number of holes as long as the bounding curves are smooth, simple, and closed and we integrate over each component of the boundary in the direction that keeps R on our immediate left as we proceed along the curve (see accompanying figure).

- a. Let $f(x, y) = \ln(x^2 + y^2)$ and let C be the circle $x^2 + y^2 = a^2$. Evaluate the flux integral

$$\oint_C \nabla f \cdot \mathbf{n} \, ds.$$

- b. Let K be an arbitrary smooth, simple closed curve in the plane that does not pass through $(0, 0)$. Use Green's Theorem to show that

$$\oint_K \nabla f \cdot \mathbf{n} \, ds$$

has two possible values, depending on whether $(0, 0)$ lies inside K or outside K .

- 46. Bendixson's criterion** The *streamlines* of a planar fluid flow are the smooth curves traced by the fluid's individual particles. The vectors $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ of the flow's velocity field are the tangent vectors of the streamlines. Show that if the flow takes place over a simply connected region R (no holes or missing points) and that if $M_x + N_y \neq 0$ throughout R , then none of the streamlines in R is closed. In other words, no particle of fluid ever has a closed trajectory in R . The criterion $M_x + N_y \neq 0$ is called **Bendixson's criterion** for the nonexistence of closed trajectories.
- 47.** Establish Equation (7) to finish the proof of the special case of Green's Theorem.
- 48. Curl component of conservative fields** Can anything be said about the curl component of a conservative two-dimensional vector field? Give reasons for your answer.

COMPUTER EXPLORATIONS

In Exercises 49–52, use a CAS and Green's Theorem to find the counterclockwise circulation of the field \mathbf{F} around the simple closed curve C . Perform the following CAS steps.

- Plot C in the xy -plane.
 - Determine the integrand $(\partial N/\partial x) - (\partial M/\partial y)$ for the tangential form of Green's Theorem.
 - Determine the (double integral) limits of integration from your plot in part (a), and evaluate the curl integral for the circulation.
- 49.** $\mathbf{F} = (2x - y)\mathbf{i} + (x + 3y)\mathbf{j}$, C : The ellipse $x^2 + 4y^2 = 4$
- 50.** $\mathbf{F} = (2x^3 - y^3)\mathbf{i} + (x^3 + y^3)\mathbf{j}$, C : The ellipse $\frac{x^2}{4} + \frac{y^2}{9} = 1$
- 51.** $\mathbf{F} = x^{-1}e^y\mathbf{i} + (e^y \ln x + 2x)\mathbf{j}$,
 C : The boundary of the region defined by $y = 1 + x^4$ (below) and $y = 2$ (above)
- 52.** $\mathbf{F} = xe^y\mathbf{i} + (4x^2 \ln y)\mathbf{j}$,
 C : The triangle with vertices $(0, 0)$, $(2, 0)$, and $(0, 4)$

15.5 Surfaces and Area

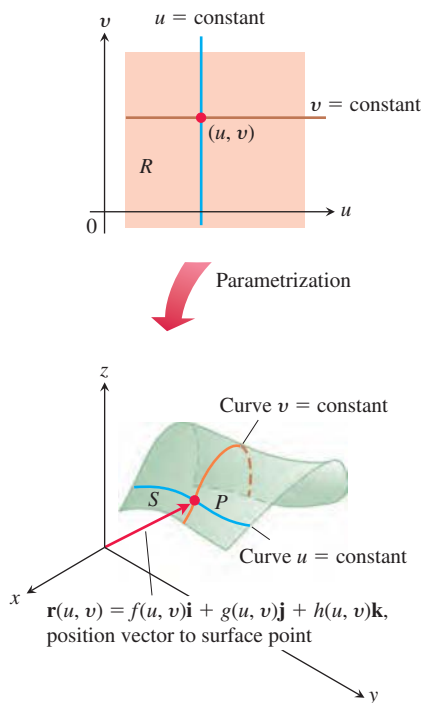

FIGURE 15.39 A parametrized surface S expressed as a vector function of two variables defined on a region R .

We have described curves in the plane in three different ways.

$$\begin{aligned} \text{Explicit form:} & \quad y = f(x) \\ \text{Implicit form:} & \quad F(x, y) = 0 \\ \text{Parametric vector form:} & \quad \mathbf{r}(t) = f(t)\mathbf{i} + g(t)\mathbf{j}, \quad a \leq t \leq b. \end{aligned}$$

We have analogous descriptions of surfaces in space.

$$\begin{aligned} \text{Explicit form:} & \quad z = f(x, y) \\ \text{Implicit form:} & \quad F(x, y, z) = 0. \end{aligned}$$

There is also a parametric form for surfaces that gives the position of a point on the surface as a vector function of two variables. We discuss this new form in this section and apply the form to obtain the area of a surface as a double integral. Double integral formulas for areas of surfaces given in implicit and explicit forms are then obtained as special cases of the more general parametric formula.

Parametrizations of Surfaces

Suppose

$$\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k} \quad (1)$$

is a continuous vector function that is defined on a region R in the uv -plane and is one-to-one on the interior of R (Figure 15.39). We call the range of \mathbf{r} the **surface** S defined or traced by \mathbf{r} . Equation (1) together with the domain R constitutes a **parametrization** of the surface. The variables u and v are the **parameters**, and R is the **parameter domain**. To simplify our discussion, we take R to be a rectangle defined by inequalities of the form $a \leq u \leq b$, $c \leq v \leq d$. The requirement that \mathbf{r} be one-to-one on the interior of R ensures that S does not cross itself. Notice that Equation (1) is the vector equivalent of *three* parametric equations:

$$x = f(u, v), \quad y = g(u, v), \quad z = h(u, v).$$

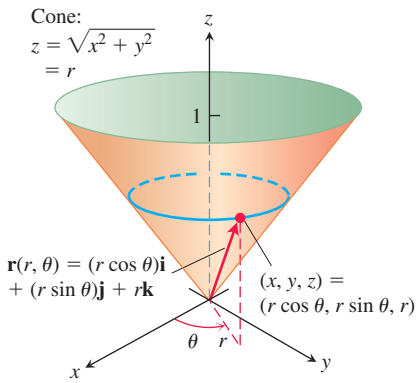

FIGURE 15.40 The cone in Example 1 can be parametrized using cylindrical coordinates.

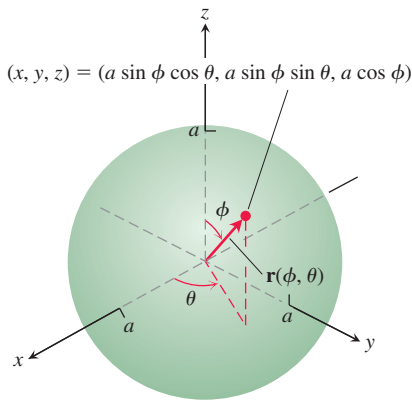

FIGURE 15.41 The sphere in Example 2 can be parametrized using spherical coordinates.

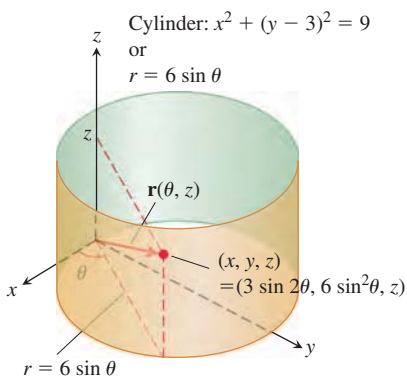

FIGURE 15.42 The cylinder in Example 3 can be parametrized using cylindrical coordinates.

EXAMPLE 1 Find a parametrization of the cone

$$z = \sqrt{x^2 + y^2}, \quad 0 \leq z \leq 1.$$

Solution Here, cylindrical coordinates provide a parametrization. A typical point (x, y, z) on the cone (Figure 15.40) has $x = r \cos \theta$, $y = r \sin \theta$, and $z = \sqrt{x^2 + y^2} = r$, with $0 \leq r \leq 1$ and $0 \leq \theta \leq 2\pi$. Taking $u = r$ and $v = \theta$ in Equation (1) gives the parametrization

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

The parametrization is one-to-one on the interior of the domain, though not on the boundary where $r = 0$ (mapped to the tip of the cone) or where $\theta = 0$ or $\theta = 2\pi$ (where the cone glues together along a seam above the x -axis). ■

EXAMPLE 2 Find a parametrization of the sphere $x^2 + y^2 + z^2 = a^2$.

Solution Spherical coordinates provide what we need. A typical point (x, y, z) on the sphere (Figure 15.41) has $x = a \sin \phi \cos \theta$, $y = a \sin \phi \sin \theta$, and $z = a \cos \phi$, $0 \leq \phi \leq \pi$, $0 \leq \theta \leq 2\pi$. Taking $u = \phi$ and $v = \theta$ in Equation (1) gives the parametrization

$$\mathbf{r}(\phi, \theta) = (a \sin \phi \cos \theta)\mathbf{i} + (a \sin \phi \sin \theta)\mathbf{j} + (a \cos \phi)\mathbf{k}, \\ 0 \leq \phi \leq \pi, \quad 0 \leq \theta \leq 2\pi.$$

Again, the parametrization is one-to-one on the interior of the domain, though not on its boundary. ■

EXAMPLE 3 Find a parametrization of the cylinder

$$x^2 + (y - 3)^2 = 9, \quad 0 \leq z \leq 5.$$

Solution In cylindrical coordinates, a point (x, y, z) has $x = r \cos \theta$, $y = r \sin \theta$, and $z = z$. For points on the cylinder $x^2 + (y - 3)^2 = 9$ (Figure 15.42), the equation is the same as the polar equation for the cylinder's base in the xy -plane:

$$x^2 + (y^2 - 6y + 9) = 9 \\ r^2 - 6r \sin \theta = 0 \quad x^2 + y^2 = r^2, y = r \sin \theta$$

or

$$r = 6 \sin \theta, \quad 0 \leq \theta \leq \pi.$$

A typical point on the cylinder therefore has

$$x = r \cos \theta = 6 \sin \theta \cos \theta = 3 \sin 2\theta \\ y = r \sin \theta = 6 \sin^2 \theta \\ z = z.$$

Taking $u = \theta$ and $v = z$ in Equation (1) gives the parametrization

$$\mathbf{r}(\theta, z) = (3 \sin 2\theta)\mathbf{i} + (6 \sin^2 \theta)\mathbf{j} + z\mathbf{k}, \quad 0 \leq \theta \leq \pi, \quad 0 \leq z \leq 5,$$

which is one-to-one on the interior of the domain. ■

Surface Area

Our goal is to find a double integral that gives the area of a curved surface S based on the parametrization

$$\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}, \quad a \leq u \leq b, \quad c \leq v \leq d.$$

We need S to be smooth for the construction we now describe. The definition of smoothness involves the partial derivatives of \mathbf{r} with respect to u and v :

$$\mathbf{r}_u = \frac{\partial \mathbf{r}}{\partial u} = \frac{\partial f}{\partial u} \mathbf{i} + \frac{\partial g}{\partial u} \mathbf{j} + \frac{\partial h}{\partial u} \mathbf{k}$$

$$\mathbf{r}_v = \frac{\partial \mathbf{r}}{\partial v} = \frac{\partial f}{\partial v} \mathbf{i} + \frac{\partial g}{\partial v} \mathbf{j} + \frac{\partial h}{\partial v} \mathbf{k}.$$

DEFINITION A parametrized surface $\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}$ is **smooth** if \mathbf{r}_u and \mathbf{r}_v are continuous and if $\mathbf{r}_u \times \mathbf{r}_v$ is never zero on the interior of the parameter domain.

The condition that $\mathbf{r}_u \times \mathbf{r}_v$ is never the zero vector in the definition of smoothness means that the two vectors \mathbf{r}_u and \mathbf{r}_v are nonzero and never lie along the same line, so they always determine a plane tangent to the surface. We relax this condition on the boundary of the domain, but this does not affect the area computations.

Now consider a small rectangle ΔA_{uv} in R with sides on the lines $u = u_0$, $u = u_0 + \Delta u$, $v = v_0$, and $v = v_0 + \Delta v$ (Figure 15.43). Each side of ΔA_{uv} maps onto a curve on the surface S , and together these four curves bound a “curved patch element” $\Delta \sigma_{uv}$. In the notation of the figure, the side $v = v_0$ maps to curve C_1 , the side $u = u_0$ maps to C_2 , and their common vertex (u_0, v_0) maps to P_0 .

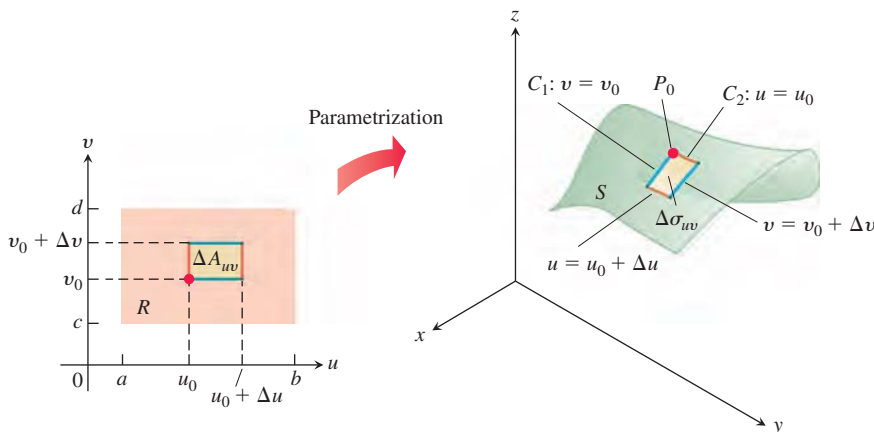

FIGURE 15.43 A rectangular area element ΔA_{uv} in the uv -plane maps onto a curved patch element $\Delta \sigma_{uv}$ on S .

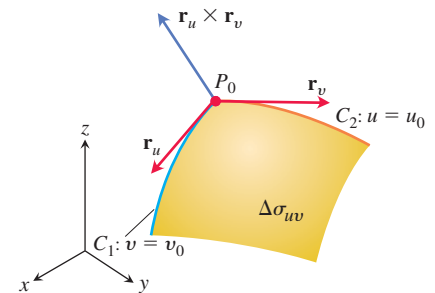

FIGURE 15.44 A magnified view of a surface patch element $\Delta \sigma_{uv}$.

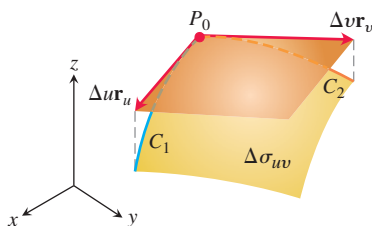

FIGURE 15.45 The area of the parallelogram determined by the vectors $\Delta u \mathbf{r}_u$ and $\Delta v \mathbf{r}_v$ approximates the area of the surface patch element $\Delta \sigma_{uv}$.

Figure 15.44 shows an enlarged view of $\Delta \sigma_{uv}$. The partial derivative vector $\mathbf{r}_u(u_0, v_0)$ is tangent to C_1 at P_0 . Likewise, $\mathbf{r}_v(u_0, v_0)$ is tangent to C_2 at P_0 . The cross product $\mathbf{r}_u \times \mathbf{r}_v$ is normal to the surface at P_0 . (Here is where we begin to use the assumption that S is smooth. We want to be sure that $\mathbf{r}_u \times \mathbf{r}_v \neq \mathbf{0}$.)

We next approximate the surface patch element $\Delta \sigma_{uv}$ by the parallelogram on the tangent plane whose sides are determined by the vectors $\Delta u \mathbf{r}_u$ and $\Delta v \mathbf{r}_v$ (Figure 15.45). The area of this parallelogram is

$$|\Delta u \mathbf{r}_u \times \Delta v \mathbf{r}_v| = |\mathbf{r}_u \times \mathbf{r}_v| \Delta u \Delta v. \quad (2)$$

A partition of the region R in the uv -plane by rectangular regions ΔA_{uv} induces a partition of the surface S into surface patch elements $\Delta \sigma_{uv}$. We approximate the area of each surface

patch element $\Delta\sigma_{uv}$ by the parallelogram area in Equation (2) and sum these areas together to obtain an approximation of the surface area of S :

$$\sum_n |\mathbf{r}_u \times \mathbf{r}_v| \Delta u \Delta v. \quad (3)$$

As Δu and Δv approach zero independently, the number of area elements n approaches ∞ and the continuity of \mathbf{r}_u and \mathbf{r}_v guarantees that the sum in Equation (3) approaches the double integral $\int_c^d \int_a^b |\mathbf{r}_u \times \mathbf{r}_v| du dv$. This double integral over the region R is used to define the area of the surface S .

DEFINITION The **area** of the smooth surface

$$\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}, \quad a \leq u \leq b, \quad c \leq v \leq d$$

is

$$A = \iint_R |\mathbf{r}_u \times \mathbf{r}_v| dA = \int_c^d \int_a^b |\mathbf{r}_u \times \mathbf{r}_v| du dv. \quad (4)$$

We can abbreviate the integral in Equation (4) by writing $d\sigma$ for $|\mathbf{r}_u \times \mathbf{r}_v| du dv$. The surface area differential $d\sigma$ is analogous to the arc length differential ds in Section 12.3.

Surface Area Differential for a Parametrized Surface

$$d\sigma = |\mathbf{r}_u \times \mathbf{r}_v| du dv \quad \iint_S d\sigma \quad (5)$$

Surface area differential, also called surface area element

Differential formula for surface area

EXAMPLE 4 Find the surface area of the cone in Example 1 (Figure 15.40).

Solution In Example 1, we found the parametrization

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

To apply Equation (4), we first find $\mathbf{r}_r \times \mathbf{r}_\theta$:

$$\begin{aligned} \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 1 \\ -r \sin \theta & r \cos \theta & 0 \end{vmatrix} \\ &= -(r \cos \theta)\mathbf{i} - (r \sin \theta)\mathbf{j} + \underbrace{(r \cos^2 \theta + r \sin^2 \theta)}_r \mathbf{k}. \end{aligned}$$

Thus, $|\mathbf{r}_r \times \mathbf{r}_\theta| = \sqrt{r^2 \cos^2 \theta + r^2 \sin^2 \theta + r^2} = \sqrt{2r^2} = \sqrt{2}r$. The area of the cone is

$$\begin{aligned} A &= \int_0^{2\pi} \int_0^1 |\mathbf{r}_r \times \mathbf{r}_\theta| dr d\theta \quad \text{Eq. (4) with } u = r, v = \theta \\ &= \int_0^{2\pi} \int_0^1 \sqrt{2}r dr d\theta = \int_0^{2\pi} \frac{\sqrt{2}}{2} d\theta = \frac{\sqrt{2}}{2}(2\pi) = \pi\sqrt{2} \text{ square units.} \quad \blacksquare \end{aligned}$$

EXAMPLE 5 Find the surface area of a sphere of radius a .

Solution We use the parametrization from Example 2:

$$\mathbf{r}(\phi, \theta) = (a \sin \phi \cos \theta)\mathbf{i} + (a \sin \phi \sin \theta)\mathbf{j} + (a \cos \phi)\mathbf{k},$$

$$0 \leq \phi \leq \pi, \quad 0 \leq \theta \leq 2\pi.$$

For $\mathbf{r}_\phi \times \mathbf{r}_\theta$, we get

$$\mathbf{r}_\phi \times \mathbf{r}_\theta = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a \cos \phi \cos \theta & a \cos \phi \sin \theta & -a \sin \phi \\ -a \sin \phi \sin \theta & a \sin \phi \cos \theta & 0 \end{vmatrix}$$

$$= (a^2 \sin^2 \phi \cos \theta)\mathbf{i} + (a^2 \sin^2 \phi \sin \theta)\mathbf{j} + (a^2 \sin \phi \cos \phi)\mathbf{k}.$$

Thus,

$$|\mathbf{r}_\phi \times \mathbf{r}_\theta| = \sqrt{a^4 \sin^4 \phi \cos^2 \theta + a^4 \sin^4 \phi \sin^2 \theta + a^4 \sin^2 \phi \cos^2 \phi}$$

$$= \sqrt{a^4 \sin^4 \phi + a^4 \sin^2 \phi \cos^2 \phi} = \sqrt{a^4 \sin^2 \phi (\sin^2 \phi + \cos^2 \phi)}$$

$$= a^2 \sqrt{\sin^2 \phi} = a^2 \sin \phi$$

because $\sin \phi \geq 0$ for $0 \leq \phi \leq \pi$. Therefore, the area of the sphere is

$$A = \int_0^{2\pi} \int_0^\pi a^2 \sin \phi \, d\phi \, d\theta$$

$$= \int_0^{2\pi} \left[-a^2 \cos \phi \right]_{\phi=0}^{\phi=\pi} d\theta = \int_0^{2\pi} 2a^2 \, d\theta = 4\pi a^2 \quad \text{square units.}$$

This gives the well-known formula for the surface area of a sphere. ■

EXAMPLE 6 Let S be the “football” surface formed by rotating the curve $x = \cos z$, $y = 0$, $-\pi/2 \leq z \leq \pi/2$ around the z -axis (see Figure 15.46). Find a parametrization for S and compute its surface area.

Solution Example 2 suggests finding a parametrization of S based on its rotation around the z -axis. If we rotate a point $(x, 0, z)$ on the curve $x = \cos z$, $y = 0$ about the z -axis, we obtain a circle at height z above the xy -plane that is centered on the z -axis and has radius $r = \cos z$ (see Figure 15.46). The point sweeps out the circle through an angle of rotation θ , $0 \leq \theta \leq 2\pi$. We let (x, y, z) be an arbitrary point on this circle, and define the parameters $u = z$ and $v = \theta$. Then we have $x = r \cos \theta = \cos u \cos v$, $y = r \sin \theta = \cos u \sin v$, and $z = u$, giving a parametrization for S as

$$\mathbf{r}(u, v) = \cos u \cos v \mathbf{i} + \cos u \sin v \mathbf{j} + u \mathbf{k}, \quad -\frac{\pi}{2} \leq u \leq \frac{\pi}{2}, \quad 0 \leq v \leq 2\pi.$$

Next we use Equation (5) to find the surface area of S . Differentiation of the parametrization gives

$$\mathbf{r}_u = -\sin u \cos v \mathbf{i} - \sin u \sin v \mathbf{j} + \mathbf{k}$$

and

$$\mathbf{r}_v = -\cos u \sin v \mathbf{i} + \cos u \cos v \mathbf{j}.$$

Computing the cross product, we have

$$\mathbf{r}_u \times \mathbf{r}_v = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -\sin u \cos v & -\sin u \sin v & 1 \\ -\cos u \sin v & \cos u \cos v & 0 \end{vmatrix}$$

$$= -\cos u \cos v \mathbf{i} - \cos u \sin v \mathbf{j} - (\sin u \cos u \cos^2 v + \cos u \sin u \sin^2 v)\mathbf{k}.$$

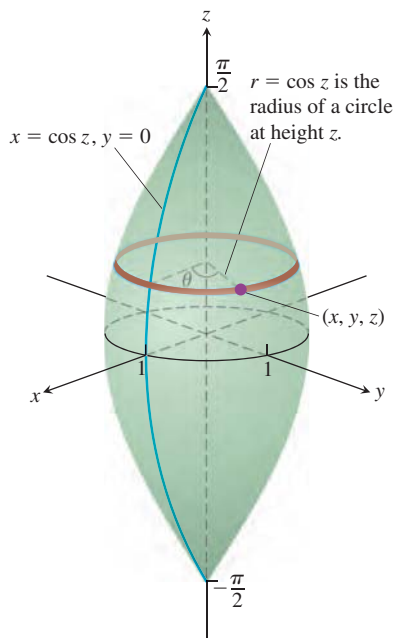

FIGURE 15.46 The “football” surface in Example 6 obtained by rotating the curve $x = \cos z$ about the z -axis.

Taking the magnitude of the cross product gives

$$\begin{aligned} |\mathbf{r}_u \times \mathbf{r}_v| &= \sqrt{\cos^2 u (\cos^2 v + \sin^2 v) + \sin^2 u \cos^2 u} \\ &= \sqrt{\cos^2 u (1 + \sin^2 u)} \\ &= \cos u \sqrt{1 + \sin^2 u}. \quad \cos u \geq 0 \text{ for } -\frac{\pi}{2} \leq u \leq \frac{\pi}{2} \end{aligned}$$

From Equation (4) the surface area is given by the integral

$$A = \int_0^{2\pi} \int_{-\pi/2}^{\pi/2} \cos u \sqrt{1 + \sin^2 u} \, du \, dv.$$

To evaluate the integral, we substitute $w = \sin u$ and $dw = \cos u \, du$, $-1 \leq w \leq 1$. Since the surface S is symmetric across the xy -plane, we need only integrate with respect to w from 0 to 1 and multiply the result by 2. In summary, we have

$$\begin{aligned} A &= 2 \int_0^{2\pi} \int_0^1 \sqrt{1 + w^2} \, dw \, dv \\ &= 2 \int_0^{2\pi} \left[\frac{w}{2} \sqrt{1 + w^2} + \frac{1}{2} \ln(w + \sqrt{1 + w^2}) \right]_{w=0}^{w=1} \, dv \quad \text{Integral Table Formula 35} \\ &= \int_0^{2\pi} 2 \left[\frac{1}{2} \sqrt{2} + \frac{1}{2} \ln(1 + \sqrt{2}) \right] \, dv \\ &= 2\pi [\sqrt{2} + \ln(1 + \sqrt{2})]. \quad \blacksquare \end{aligned}$$

Implicit Surfaces

Surfaces are often presented as level sets of a function, described by an equation such as

$$F(x, y, z) = c,$$

for some constant c . Such a level surface does not come with an explicit parametrization and is called an *implicitly defined surface*. Implicit surfaces arise, for example, as equipotential surfaces in electric or gravitational fields. Figure 15.47 shows a piece of such a surface. It may be difficult to find explicit formulas for the functions f , g , and h that describe the surface in the form $\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}$. We now show how to compute the surface area differential $d\sigma$ for implicit surfaces.

Figure 15.47 shows a piece of an implicit surface S that lies above its “shadow” region R in the plane beneath it. The surface is defined by the equation $F(x, y, z) = c$, and we choose \mathbf{p} to be a unit vector normal to the plane region R . We assume that the surface is **smooth** (F is differentiable and ∇F is nonzero and continuous on S) and that $\nabla F \cdot \mathbf{p} \neq 0$, so the surface never folds back over itself.

Assume that the normal vector \mathbf{p} is the unit vector \mathbf{k} , so the region R in Figure 15.47 lies in the xy -plane. By assumption, we then have $\nabla F \cdot \mathbf{p} = \nabla F \cdot \mathbf{k} = F_z \neq 0$ on S . The Implicit Function Theorem (see Section 13.4) implies that S is then the graph of a differentiable function $z = h(x, y)$, although the function $h(x, y)$ is not explicitly known. Define the parameters u and v by $u = x$ and $v = y$. Then $z = h(u, v)$ and

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + h(u, v)\mathbf{k} \quad (6)$$

gives a parametrization of the surface S . We use Equation (4) to find the area of S .

Calculating the partial derivatives of \mathbf{r} , we find

$$\mathbf{r}_u = \mathbf{i} + \frac{\partial h}{\partial u} \mathbf{k} \quad \text{and} \quad \mathbf{r}_v = \mathbf{j} + \frac{\partial h}{\partial v} \mathbf{k}.$$

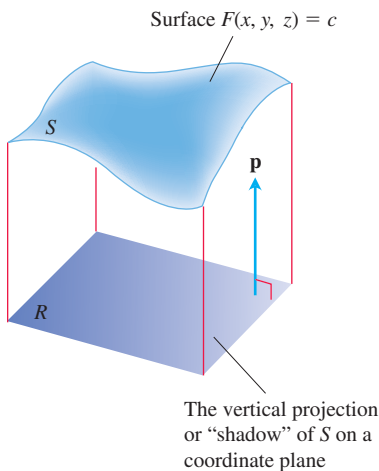

FIGURE 15.47 As we soon see, the area of a surface S in space can be calculated by evaluating a related double integral over the vertical projection or “shadow” of S on a coordinate plane. The unit vector \mathbf{p} is normal to the plane.

Applying the Chain Rule for implicit differentiation (see Equation (2) in Section 13.4) to $F(x, y, z) = c$, where $x = u$, $y = v$, and $z = h(u, v)$, we obtain the partial derivatives

$$\frac{\partial h}{\partial u} = -\frac{F_x}{F_z} \quad \text{and} \quad \frac{\partial h}{\partial v} = -\frac{F_y}{F_z}, \quad F_z \neq 0$$

Substitution of these derivatives into the derivatives of \mathbf{r} gives

$$\mathbf{r}_u = \mathbf{i} - \frac{F_x}{F_z} \mathbf{k} \quad \text{and} \quad \mathbf{r}_v = \mathbf{j} - \frac{F_y}{F_z} \mathbf{k}.$$

From a routine calculation of the cross product, we find

$$\begin{aligned} \mathbf{r}_u \times \mathbf{r}_v &= \frac{F_x}{F_z} \mathbf{i} + \frac{F_y}{F_z} \mathbf{j} + \mathbf{k} && \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -F_x/F_z \\ 0 & 1 & -F_y/F_z \end{vmatrix} && \begin{array}{l} \text{cross product of} \\ \mathbf{r}_u \\ \mathbf{r}_v \end{array} \\ &= \frac{1}{F_z} (F_x \mathbf{i} + F_y \mathbf{j} + F_z \mathbf{k}) \\ &= \frac{\nabla F}{F_z} = \frac{\nabla F}{\nabla F \cdot \mathbf{k}} \\ &= \frac{\nabla F}{\nabla F \cdot \mathbf{p}}, && \mathbf{p} = \mathbf{k} \end{aligned}$$

Therefore, the surface area differential is given by

$$d\sigma = |\mathbf{r}_u \times \mathbf{r}_v| du dv = \frac{|\nabla F|}{|\nabla F \cdot \mathbf{p}|} dx dy, \quad u = x \text{ and } v = y$$

We obtain similar calculations if instead the vector $\mathbf{p} = \mathbf{j}$ is normal to the xz -plane when $F_y \neq 0$ on S , or if $\mathbf{p} = \mathbf{i}$ is normal to the yz -plane when $F_x \neq 0$ on S . Combining these results with Equation (4) then gives the following general formula.

Formula for the Surface Area of an Implicit Surface

The area of the surface $F(x, y, z) = c$ over a closed and bounded plane region R is

$$\text{Surface area} = \iint_R \frac{|\nabla F|}{|\nabla F \cdot \mathbf{p}|} dA, \quad (7)$$

where $\mathbf{p} = \mathbf{i}, \mathbf{j}$, or \mathbf{k} is normal to R and $\nabla F \cdot \mathbf{p} \neq 0$.

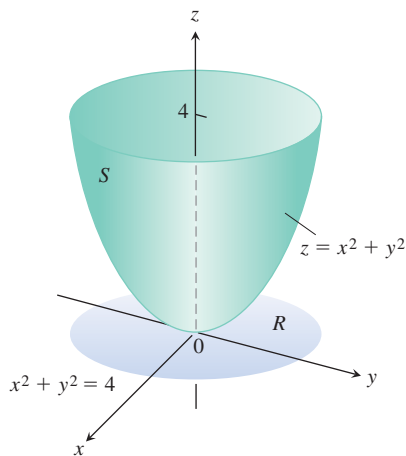

FIGURE 15.48 The area of this parabolic surface is calculated in Example 7.

Thus, the area is the double integral over R of the magnitude of ∇F divided by the magnitude of the scalar component of ∇F normal to R .

We reached Equation (7) under the assumption that $\nabla F \cdot \mathbf{p} \neq 0$ throughout R and that ∇F is continuous. Whenever the integral exists, however, we define its value to be the area of the portion of the surface $F(x, y, z) = c$ that lies over R . (Recall that the projection is assumed to be one-to-one.)

EXAMPLE 7 Find the area of the surface cut from the bottom of the paraboloid $x^2 + y^2 - z = 0$ by the plane $z = 4$.

Solution We sketch the surface S and the region R below it in the xy -plane (Figure 15.48). The surface S is part of the level surface $F(x, y, z) = x^2 + y^2 - z = 0$, and R is the disk $x^2 + y^2 \leq 4$ in the xy -plane. To get a unit vector normal to the plane of R , we can take $\mathbf{p} = \mathbf{k}$.

At any point (x, y, z) on the surface, we have

$$F(x, y, z) = x^2 + y^2 - z$$

$$\nabla F = 2x\mathbf{i} + 2y\mathbf{j} - \mathbf{k}$$

$$|\nabla F| = \sqrt{(2x)^2 + (2y)^2 + (-1)^2} = \sqrt{4x^2 + 4y^2 + 1}$$

$$|\nabla F \cdot \mathbf{p}| = |\nabla F \cdot \mathbf{k}| = |-1| = 1.$$

In the region R , $dA = dx dy$. Therefore,

$$\text{Surface area} = \iint_R \frac{|\nabla F|}{|\nabla F \cdot \mathbf{p}|} dA \quad \text{Eq. (7)}$$

$$= \iint_{x^2+y^2 \leq 4} \sqrt{4x^2 + 4y^2 + 1} dx dy$$

$$= \int_0^{2\pi} \int_0^2 \sqrt{4r^2 + 1} r dr d\theta \quad \text{Polar coordinates}$$

$$= \int_0^{2\pi} \left[\frac{1}{12} (4r^2 + 1)^{3/2} \right]_{r=0}^{r=2} d\theta$$

$$= \int_0^{2\pi} \frac{1}{12} (17^{3/2} - 1) d\theta = \frac{\pi}{6} (17\sqrt{17} - 1). \quad \blacksquare$$

Example 7 illustrates how to find the surface area for a function $z = f(x, y)$ over a region R in the xy -plane. Actually, the surface area differential can be obtained in two ways, and we show this in the next example.

EXAMPLE 8 Derive the surface area differential $d\sigma$ of the surface $z = f(x, y)$ over a region R in the xy -plane (a) parametrically using Equation (5), and (b) implicitly, as in Equation (7).

Solution

(a) We parametrize the surface by taking $x = u$, $y = v$, and $z = f(x, y)$ over R . This gives the parametrization

$$\mathbf{r}(u, v) = u\mathbf{i} + v\mathbf{j} + f(u, v)\mathbf{k}.$$

Computing the partial derivatives gives $\mathbf{r}_u = \mathbf{i} + f_u\mathbf{k}$, $\mathbf{r}_v = \mathbf{j} + f_v\mathbf{k}$ and

$$\mathbf{r}_u \times \mathbf{r}_v = -f_u\mathbf{i} - f_v\mathbf{j} + \mathbf{k} \quad \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & f_u \\ 0 & 1 & f_v \end{vmatrix}$$

Then $|\mathbf{r}_u \times \mathbf{r}_v| du dv = \sqrt{f_u^2 + f_v^2 + 1} du dv$. Substituting for u and v , then gives the surface area differential

$$d\sigma = \sqrt{f_x^2 + f_y^2 + 1} dx dy.$$

(b) We define the implicit function $F(x, y, z) = f(x, y) - z$. Since (x, y) belongs to the region R , the unit normal to the plane of R is $\mathbf{p} = \mathbf{k}$. Then $\nabla F = f_x\mathbf{i} + f_y\mathbf{j} - \mathbf{k}$ so

that $|\nabla F \cdot \mathbf{p}| = |-1| = 1$, $|\nabla F| = \sqrt{f_x^2 + f_y^2 + 1}$, and $|\nabla F|/|\nabla F \cdot \mathbf{p}| = |\nabla F|$. The surface area differential is again given by

$$d\sigma = \sqrt{f_x^2 + f_y^2 + 1} \, dx \, dy.$$

The surface area differential derived in Example 8 gives the following formula for calculating the surface area of the graph of a function defined explicitly as $z = f(x, y)$.

Formula for the Surface Area of a Graph $z = f(x, y)$

For a graph $z = f(x, y)$ over a region R in the xy -plane, the surface area formula is

$$A = \iint_R \sqrt{f_x^2 + f_y^2 + 1} \, dx \, dy. \quad (8)$$

EXERCISES 15.5

Finding Parametrizations

In Exercises 1–16, find a parametrization of the surface. (There are many correct ways to do these, so your answers may not be the same as those in the back of the text.)

- The paraboloid $z = x^2 + y^2$, $z \leq 4$
- The paraboloid $z = 9 - x^2 - y^2$, $z \geq 0$
- Cone frustum** The first-octant portion of the cone $z = \sqrt{x^2 + y^2}/2$ between the planes $z = 0$ and $z = 3$
- Cone frustum** The portion of the cone $z = 2\sqrt{x^2 + y^2}$ between the planes $z = 2$ and $z = 4$
- Spherical cap** The cap cut from the sphere $x^2 + y^2 + z^2 = 9$ by the cone $z = \sqrt{x^2 + y^2}$
- Spherical cap** The portion of the sphere $x^2 + y^2 + z^2 = 4$ in the first octant between the xy -plane and the cone $z = \sqrt{x^2 + y^2}$
- Spherical band** The portion of the sphere $x^2 + y^2 + z^2 = 3$ between the planes $z = \sqrt{3}/2$ and $z = -\sqrt{3}/2$
- Spherical cap** The upper portion cut from the sphere $x^2 + y^2 + z^2 = 8$ by the plane $z = -2$
- Parabolic cylinder between planes** The surface cut from the parabolic cylinder $z = 4 - y^2$ by the planes $x = 0$, $x = 2$, and $z = 0$
- Parabolic cylinder between planes** The surface cut from the parabolic cylinder $y = x^2$ by the planes $z = 0$, $z = 3$, and $y = 2$
- Circular cylinder band** The portion of the cylinder $y^2 + z^2 = 9$ between the planes $x = 0$ and $x = 3$
- Circular cylinder band** The portion of the cylinder $x^2 + z^2 = 4$ above the xy -plane between the planes $y = -2$ and $y = 2$
- Tilted plane inside cylinder** The portion of the plane $x + y + z = 1$
 - Inside the cylinder $x^2 + y^2 = 9$
 - Inside the cylinder $y^2 + z^2 = 9$
- Tilted plane inside cylinder** The portion of the plane $x - y + 2z = 2$

a. Inside the cylinder $x^2 + z^2 = 3$

b. Inside the cylinder $y^2 + z^2 = 2$

- Circular cylinder band** The portion of the cylinder $(x - 2)^2 + z^2 = 4$ between the planes $y = 0$ and $y = 3$
- Circular cylinder band** The portion of the cylinder $y^2 + (z - 5)^2 = 25$ between the planes $x = 0$ and $x = 10$

Surface Area of Parametrized Surfaces

In Exercises 17–26, use a parametrization to express the area of the surface as a double integral. Then evaluate the integral. (There are many correct ways to set up the integrals, so your integrals may not be the same as those in the back of the text. They should have the same values, however.)

- Tilted plane inside cylinder** The portion of the plane $y + 2z = 2$ inside the cylinder $x^2 + y^2 = 1$
- Plane inside cylinder** The portion of the plane $z = -x$ inside the cylinder $x^2 + y^2 = 4$
- Cone frustum** The portion of the cone $z = 2\sqrt{x^2 + y^2}$ between the planes $z = 2$ and $z = 6$
- Cone frustum** The portion of the cone $z = \sqrt{x^2 + y^2}/3$ between the planes $z = 1$ and $z = 4/3$
- Circular cylinder band** The portion of the cylinder $x^2 + y^2 = 1$ between the planes $z = 1$ and $z = 4$
- Circular cylinder band** The portion of the cylinder $x^2 + z^2 = 10$ between the planes $y = -1$ and $y = 1$
- Parabolic cap** The cap cut from the paraboloid $z = 2 - x^2 - y^2$ by the cone $z = \sqrt{x^2 + y^2}$
- Parabolic band** The portion of the paraboloid $z = x^2 + y^2$ between the planes $z = 1$ and $z = 4$
- Sawed-off sphere** The lower portion cut from the sphere $x^2 + y^2 + z^2 = 2$ by the cone $z = \sqrt{x^2 + y^2}$
- Spherical band** The portion of the sphere $x^2 + y^2 + z^2 = 4$ between the planes $z = -1$ and $z = \sqrt{3}$

Planes Tangent to Parametrized Surfaces

The tangent plane at a point $P_0(f(u_0, v_0), g(u_0, v_0), h(u_0, v_0))$ on a parametrized surface $\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}$ is the plane through P_0 normal to the vector $\mathbf{r}_u(u_0, v_0) \times \mathbf{r}_v(u_0, v_0)$, the cross product of the tangent vectors $\mathbf{r}_u(u_0, v_0)$ and $\mathbf{r}_v(u_0, v_0)$ at P_0 . In Exercises 27–30, find an equation for the plane tangent to the surface at P_0 . Then find a Cartesian equation for the surface, and sketch the surface and tangent plane together.

27. **Cone** The cone $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}$, $r \geq 0$, $0 \leq \theta \leq 2\pi$ at the point $P_0(\sqrt{2}, \sqrt{2}, 2)$ corresponding to $(r, \theta) = (2, \pi/4)$
28. **Hemisphere** The hemisphere surface $\mathbf{r}(\phi, \theta) = (4 \sin \phi \cos \theta)\mathbf{i} + (4 \sin \phi \sin \theta)\mathbf{j} + (4 \cos \phi)\mathbf{k}$, $0 \leq \phi \leq \pi/2$, $0 \leq \theta \leq 2\pi$, at the point $P_0(\sqrt{2}, \sqrt{2}, 2\sqrt{3})$ corresponding to $(\phi, \theta) = (\pi/6, \pi/4)$
29. **Circular cylinder** The circular cylinder $\mathbf{r}(\theta, z) = (3 \sin 2\theta)\mathbf{i} + (6 \sin^2 \theta)\mathbf{j} + z\mathbf{k}$, $0 \leq \theta \leq \pi$, at the point $P_0(3\sqrt{3}/2, 9/2, 0)$ corresponding to $(\theta, z) = (\pi/3, 0)$ (See Example 3.)
30. **Parabolic cylinder** The parabolic cylinder surface $\mathbf{r}(x, y) = x\mathbf{i} + y\mathbf{j} - x^2\mathbf{k}$, $-\infty < x < \infty$, $-\infty < y < \infty$, at the point $P_0(1, 2, -1)$ corresponding to $(x, y) = (1, 2)$

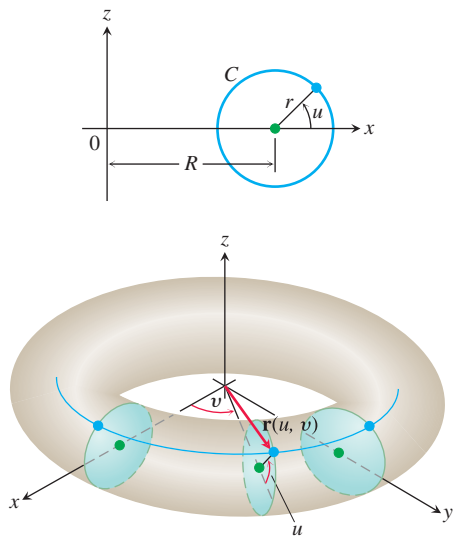

More Parametrizations of Surfaces

31. a. A *torus of revolution* (doughnut) is obtained by rotating a circle C in the xz -plane about the z -axis in space. (See the accompanying figure.) If C has radius $r > 0$ and center $(R, 0, 0)$, show that a parametrization of the torus is

$$\mathbf{r}(u, v) = ((R + r \cos u)\cos v)\mathbf{i} + ((R + r \cos u)\sin v)\mathbf{j} + (r \sin u)\mathbf{k},$$

where $0 \leq u \leq 2\pi$ and $0 \leq v \leq 2\pi$ are the angles in the figure.

- b. Show that the surface area of the torus is $A = 4\pi^2 Rr$.

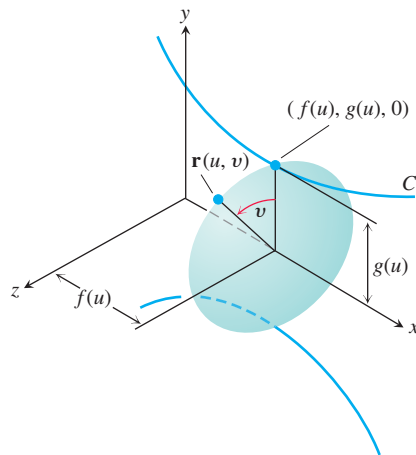

32. **Parametrization of a surface of revolution** Suppose that the parametrized curve $C: (f(u), g(u))$ is revolved about the x -axis, where $g(u) > 0$ for $a \leq u \leq b$.

- a. Show that

$$\mathbf{r}(u, v) = f(u)\mathbf{i} + (g(u)\cos v)\mathbf{j} + (g(u)\sin v)\mathbf{k}$$

is a parametrization of the resulting surface of revolution, where $0 \leq v \leq 2\pi$ is the angle from the xy -plane to the point $\mathbf{r}(u, v)$ on the surface. (See the accompanying figure.) Notice that $f(u)$ measures distance *along* the axis of revolution and $g(u)$ measures distance *from* the axis of revolution.

- b. Find a parametrization for the surface obtained by revolving the curve $x = y^2$, $y \geq 0$, about the x -axis.
33. a. **Parametrization of an ellipsoid** The parametrization $x = a \cos \theta$, $y = b \sin \theta$, $0 \leq \theta \leq 2\pi$ gives the ellipse $(x^2/a^2) + (y^2/b^2) = 1$. Using the angles θ and ϕ in spherical coordinates, show that
- $$\mathbf{r}(\theta, \phi) = (a \cos \theta \sin \phi)\mathbf{i} + (b \sin \theta \sin \phi)\mathbf{j} + (c \cos \phi)\mathbf{k}$$
- is a parametrization of the ellipsoid
- $$(x^2/a^2) + (y^2/b^2) + (z^2/c^2) = 1.$$
- b. Write an integral for the surface area of the ellipsoid, but do not evaluate the integral.
34. **Hyperboloid of one sheet**
- a. Find a parametrization for the hyperboloid of one sheet $x^2 + y^2 - z^2 = 1$ in terms of the angle θ associated with the circle $x^2 + y^2 = r^2$ and the hyperbolic parameter u associated with the hyperbolic function $r^2 - z^2 = 1$. (Hint: $\cosh^2 u - \sinh^2 u = 1$.)
- b. Generalize the result in part (a) to the hyperboloid $(x^2/a^2) + (y^2/b^2) - (z^2/c^2) = 1$.
35. (Continuation of Exercise 34.) Find a Cartesian equation for the plane tangent to the hyperboloid $x^2 + y^2 - z^2 = 25$ at the point $(x_0, y_0, 0)$, where $x_0^2 + y_0^2 = 25$.
36. **Hyperboloid of two sheets** Find a parametrization of the hyperboloid of two sheets $(z^2/c^2) - (x^2/a^2) - (y^2/b^2) = 1$.

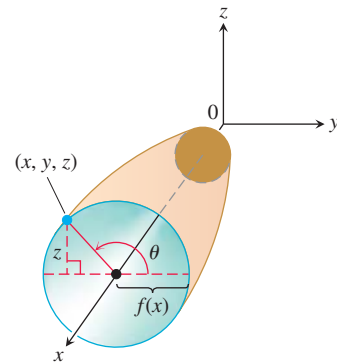

Surface Area for Implicit and Explicit Forms

37. Find the area of the surface cut from the paraboloid $x^2 + y^2 - z = 0$ by the plane $z = 2$.
38. Find the area of the band cut from the paraboloid $x^2 + y^2 - z = 0$ by the planes $z = 2$ and $z = 6$.
39. Find the area of the region cut from the plane $x + 2y + 2z = 5$ by the cylinder whose walls are $x = y^2$ and $x = 2 - y^2$.

40. Find the area of the portion of the surface $x^2 - 2z = 0$ that lies above the triangle bounded by the lines $x = \sqrt{3}$, $y = 0$, and $y = x$ in the xy -plane.
41. Find the area of the surface $x^2 - 2y - 2z = 0$ that lies above the triangle bounded by the lines $x = 2$, $y = 0$, and $y = 3x$ in the xy -plane.
42. Find the area of the cap cut from the sphere $x^2 + y^2 + z^2 = 2$ by the cone $z = \sqrt{x^2 + y^2}$.
43. Find the area of the ellipse cut from the plane $z = cx$ (c a constant) by the cylinder $x^2 + y^2 = 1$.
44. Find the area of the upper portion of the cylinder $x^2 + z^2 = 1$ that lies between the planes $x = \pm 1/2$ and $y = \pm 1/2$.
45. Find the area of the portion of the paraboloid $x = 4 - y^2 - z^2$ that lies above the ring $1 \leq y^2 + z^2 \leq 4$ in the yz -plane.
46. Find the area of the surface cut from the paraboloid $x^2 + y + z^2 = 2$ by the plane $y = 0$.
47. Find the area of the surface $x^2 - 2 \ln x + \sqrt{15}y - z = 0$ above the square $R: 1 \leq x \leq 2, 0 \leq y \leq 1$, in the xy -plane.
48. Find the area of the surface $2x^{3/2} + 2y^{3/2} - 3z = 0$ above the square $R: 0 \leq x \leq 1, 0 \leq y \leq 1$, in the xy -plane.

Find the area of the surfaces in Exercises 49–54.

49. The surface cut from the bottom of the paraboloid $z = x^2 + y^2$ by the plane $z = 3$
50. The surface cut from the “nose” of the paraboloid $x = 1 - y^2 - z^2$ by the yz -plane
51. The portion of the cone $z = \sqrt{x^2 + y^2}$ that lies over the region between the circle $x^2 + y^2 = 1$ and the ellipse $9x^2 + 4y^2 = 36$ in the xy -plane. (*Hint:* A formula from geometry states that the area inside the ellipse $x^2/a^2 + y^2/b^2 = 1$ is πab .)
52. The triangle cut from the plane $2x + 6y + 3z = 6$ by the bounding planes of the first octant. Calculate the area three ways, using different explicit forms.
53. The surface in the first octant cut from the cylinder $y = (2/3)z^{3/2}$ by the planes $x = 1$ and $y = 16/3$
54. The portion of the plane $y + z = 4$ that lies above the region cut from the first quadrant of the xz -plane by the parabola $x = 4 - z^2$
55. Use the parametrization
- $$\mathbf{r}(x, z) = x\mathbf{i} + f(x, z)\mathbf{j} + z\mathbf{k}$$
- and Equation (5) to derive a formula for $d\sigma$ associated with the explicit form $y = f(x, z)$.
56. Let S be the surface obtained by rotating the smooth curve $y = f(x)$, $a \leq x \leq b$, about the x -axis, where $f(x) \geq 0$.
- a. Show that the vector function
- $$\mathbf{r}(x, \theta) = x\mathbf{i} + f(x)\cos\theta\mathbf{j} + f(x)\sin\theta\mathbf{k}$$
- is a parametrization of S , where θ is the angle of rotation around the x -axis (see the accompanying figure).

- b. Use Equation (4) to show that the surface area of this surface of revolution is given by

$$A = \int_a^b 2\pi f(x)\sqrt{1 + [f'(x)]^2} dx.$$

15.6 Surface Integrals

To compute the mass of a surface, the flow of a liquid across a curved membrane, or the total electrical charge on a surface, we need to integrate a function over a curved surface in space. Such a *surface integral* is the two-dimensional extension of the line integral concept used to integrate over a one-dimensional curve. Like line integrals, surface integrals arise in two forms. The first occurs when we integrate a scalar function over a surface, such as integrating a mass density function defined on a surface to find its total mass. This form corresponds to line integrals of scalar functions defined in Section 15.1 and can be used to find the mass of a thin wire. The second form involves surface integrals of vector fields, analogous to the line integrals for vector fields defined in Section 15.2. An example occurs when we want to measure the net flow of a fluid across a surface submerged in the fluid (just as we previously defined the flux of \mathbf{F} across a curve). In this section we investigate these ideas and their applications.

Surface Integrals

Suppose that the function $G(x, y, z)$ gives the *mass density* (mass per unit area) at each point on a surface S . Then we can calculate the total mass of S as an integral in the following way.

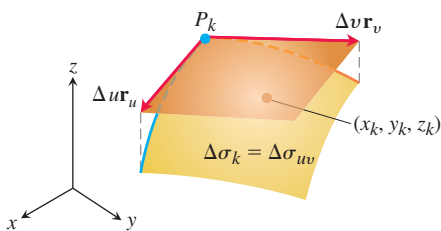

FIGURE 15.49 The area of the patch $\Delta\sigma_k$ is approximated by the area of the tangent parallelogram determined by the vectors $\Delta u \mathbf{r}_u$ and $\Delta v \mathbf{r}_v$. The point (x_k, y_k, z_k) lies on the surface patch, beneath the parallelogram shown here.

Assume, as in Section 15.5, that the surface S is defined parametrically on a region R in the uv -plane,

$$\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}, \quad (u, v) \in R.$$

In Figure 15.49, we see how a subdivision of R (considered as a rectangle for simplicity) divides the surface S into corresponding curved surface elements, or patches, of area

$$\Delta\sigma_{uv} \approx |\mathbf{r}_u \times \mathbf{r}_v| du dv.$$

As we did for the subdivisions when defining double integrals in Section 14.2, we number the surface element patches in some order with their areas given by $\Delta\sigma_1, \Delta\sigma_2, \dots, \Delta\sigma_n$. To form a Riemann sum over S , we choose a point (x_k, y_k, z_k) in the k th patch, multiply the value of the function G at that point by the area $\Delta\sigma_k$, and add together the products:

$$\sum_{k=1}^n G(x_k, y_k, z_k) \Delta\sigma_k.$$

Depending on how we pick (x_k, y_k, z_k) in the k th patch, we may get different values for this Riemann sum. Then we take the limit as the number of surface patches increases, their areas shrink to zero, and both $\Delta u \rightarrow 0$ and $\Delta v \rightarrow 0$. This limit, whenever it exists independent of all choices made, defines the **surface integral of G over the surface S** as

$$\iint_S G(x, y, z) d\sigma = \lim_{n \rightarrow \infty} \sum_{k=1}^n G(x_k, y_k, z_k) \Delta\sigma_k. \quad (1)$$

Notice the analogy with the definition of the double integral (Section 14.2) and with the line integral (Section 15.1). If S is a piecewise smooth surface, and G is continuous over S , then the surface integral defined by Equation (1) can be shown to exist.

The formula for evaluating the surface integral depends on the manner in which S is described—parametrically, implicitly, or explicitly—as discussed in Section 15.5.

Formulas for a Surface Integral of a Scalar Function

1. For a smooth surface S defined **parametrically** as

$$\mathbf{r}(u, v) = f(u, v)\mathbf{i} + g(u, v)\mathbf{j} + h(u, v)\mathbf{k}, \quad (u, v) \in R,$$

and a continuous function $G(x, y, z)$ defined on S , the surface integral of G over S is given by the double integral over R ,

$$\iint_S G(x, y, z) d\sigma = \iint_R G(f(u, v), g(u, v), h(u, v)) |\mathbf{r}_u \times \mathbf{r}_v| du dv. \quad (2)$$

2. For a surface S given **implicitly** by $F(x, y, z) = c$, where F is a continuously differentiable function, with S lying above its closed and bounded shadow region R in the coordinate plane beneath it, the surface integral of the continuous function G over S is given by the double integral over R ,

$$\iint_S G(x, y, z) d\sigma = \iint_R G(x, y, z) \frac{|\nabla F|}{|\nabla F \cdot \mathbf{p}|} dA, \quad (3)$$

where \mathbf{p} is a unit vector normal to R and $\nabla F \cdot \mathbf{p} \neq 0$.

3. For a surface S given **explicitly** as the graph of $z = f(x, y)$, where f is a continuously differentiable function over a region R in the xy -plane, the surface integral of the continuous function G over S is given by the double integral over R ,

$$\iint_S G(x, y, z) d\sigma = \iint_R G(x, y, f(x, y)) \sqrt{f_x^2 + f_y^2 + 1} dx dy. \quad (4)$$

The surface integral in Equation (1) takes on different meanings in different applications. If G has the constant value 1, the integral gives the area of S . If G gives the mass density of a thin shell of material modeled by S , the integral gives the mass of the shell. If G gives the charge density of a thin shell, the integral gives the total charge.

EXAMPLE 1 Integrate $G(x, y, z) = x^2$ over the cone $z = \sqrt{x^2 + y^2}$, $0 \leq z \leq 1$.

Solution Using Equation (2) and the calculations from Example 4 in Section 15.5, we have $|\mathbf{r}_r \times \mathbf{r}_\theta| = \sqrt{2}r$ and

$$\begin{aligned} \iint_S x^2 d\sigma &= \int_0^{2\pi} \int_0^1 (r^2 \cos^2 \theta)(\sqrt{2}r) dr d\theta & x = r \cos \theta \\ &= \sqrt{2} \int_0^{2\pi} \int_0^1 r^3 \cos^2 \theta dr d\theta \\ &= \frac{\sqrt{2}}{4} \int_0^{2\pi} \cos^2 \theta d\theta = \frac{\sqrt{2}}{4} \left[\frac{\theta}{2} + \frac{1}{4} \sin 2\theta \right]_0^{2\pi} = \frac{\pi\sqrt{2}}{4}. \end{aligned}$$

Surface integrals behave like other double integrals, the integral of the sum of two functions being the sum of their integrals and so on. The domain Additivity Property takes the form

$$\iint_S G d\sigma = \iint_{S_1} G d\sigma + \iint_{S_2} G d\sigma + \cdots + \iint_{S_n} G d\sigma.$$

When S is partitioned by smooth curves into a finite number of smooth patches with non-overlapping interiors (i.e., if S is piecewise smooth), then the integral over S is the sum of the integrals over the patches. Thus, the integral of a function over the surface of a cube is the sum of the integrals over the faces of the cube. We integrate over a “turtle shell” of welded plates by integrating over one plate at a time and adding the results.

EXAMPLE 2 Integrate $G(x, y, z) = xyz$ over the surface of the cube cut from the first octant by the planes $x = 1$, $y = 1$, and $z = 1$ (Figure 15.50).

Solution We integrate xyz over each of the six sides and add the results. Since $xyz = 0$ on the sides that lie in the coordinate planes, the integral over the surface of the cube reduces to

$$\iint_{\text{Cube surface}} xyz d\sigma = \iint_{\text{Side A}} xyz d\sigma + \iint_{\text{Side B}} xyz d\sigma + \iint_{\text{Side C}} xyz d\sigma.$$

Side A is the surface $f(x, y, z) = z = 1$ over the square region $R_{xy}: 0 \leq x \leq 1$, $0 \leq y \leq 1$, in the xy -plane. For this surface and region,

$$\mathbf{p} = \mathbf{k}, \quad \nabla f = \mathbf{k}, \quad |\nabla f| = 1, \quad |\nabla f \cdot \mathbf{p}| = |\mathbf{k} \cdot \mathbf{k}| = 1$$

$$d\sigma = \frac{|\nabla f|}{|\nabla f \cdot \mathbf{p}|} dA = \frac{1}{1} dx dy = dx dy \quad \text{Eq. (3)}$$

$$xyz = xy(1) = xy$$

and

$$\iint_{\text{Side A}} xyz d\sigma = \iint_{R_{xy}} xy dx dy = \int_0^1 \int_0^1 xy dx dy = \int_0^1 \frac{y}{2} dy = \frac{1}{4}.$$

Symmetry tells us that the integrals of xyz over sides B and C are also $1/4$. Hence,

$$\iint_{\text{Cube surface}} xyz d\sigma = \frac{1}{4} + \frac{1}{4} + \frac{1}{4} = \frac{3}{4}.$$

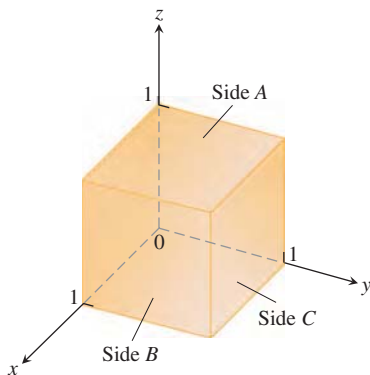

FIGURE 15.50 The cube in Example 2.

EXAMPLE 3 Integrate $G(x, y, z) = \sqrt{1 - x^2 - y^2}$ over the “football” surface S formed by rotating the curve $x = \cos z$, $y = 0$, $-\pi/2 \leq z \leq \pi/2$, around the z -axis.

Solution The surface is displayed in Figure 15.46, and in Example 6 of Section 15.5 we found the parametrization

$$x = \cos u \cos v, \quad y = \cos u \sin v, \quad z = u, \quad -\frac{\pi}{2} \leq u \leq \frac{\pi}{2} \quad \text{and} \quad 0 \leq v \leq 2\pi,$$

where v represents the angle of rotation from the xz -plane about the z -axis. Substituting this parametrization into the expression for G gives

$$\sqrt{1 - x^2 - y^2} = \sqrt{1 - (\cos^2 u)(\cos^2 v + \sin^2 v)} = \sqrt{1 - \cos^2 u} = |\sin u|.$$

The surface area differential for the parametrization was found to be (Example 6, Section 15.5)

$$d\sigma = \cos u \sqrt{1 + \sin^2 u} \, du \, dv.$$

These calculations give the surface integral

$$\begin{aligned} \iint_S \sqrt{1 - x^2 - y^2} \, d\sigma &= \int_0^{2\pi} \int_{-\pi/2}^{\pi/2} |\sin u| \cos u \sqrt{1 + \sin^2 u} \, du \, dv && \begin{array}{l} |\sin u| = \sin(-u) \\ \text{for } -\pi/2 < u < 0 \end{array} \\ &= 2 \int_0^{2\pi} \int_0^{\pi/2} \sin u \cos u \sqrt{1 + \sin^2 u} \, du \, dv \\ &= \int_0^{2\pi} \int_1^2 \sqrt{w} \, dw \, dv && \begin{array}{l} w = 1 + \sin^2 u, \\ dw = 2 \sin u \cos u \, du \\ \text{When } u = 0, w = 1. \\ \text{When } u = \pi/2, w = 2. \end{array} \\ &= 2\pi \cdot \frac{2}{3} w^{3/2} \Big|_1^2 = \frac{4\pi}{3} (2\sqrt{2} - 1). \end{aligned}$$

EXAMPLE 4 Evaluate $\iint_S \sqrt{x(1 + 2z)} \, d\sigma$ on the portion of the cylinder $z = y^2/2$ over the triangular region $R: x \geq 0, y \geq 0, x + y \leq 1$, in the xy -plane (Figure 15.51).

Solution The function G on the surface S is given by

$$G(x, y, z) = \sqrt{x(1 + 2z)} = \sqrt{x} \sqrt{1 + y^2}.$$

With $z = f(x, y) = y^2/2$, we use Equation (4) to evaluate the surface integral:

$$d\sigma = \sqrt{f_x^2 + f_y^2 + 1} \, dx \, dy = \sqrt{0 + y^2 + 1} \, dx \, dy$$

and

$$\begin{aligned} \iint_S G(x, y, z) \, d\sigma &= \iint_R (\sqrt{x} \sqrt{1 + y^2}) \sqrt{1 + y^2} \, dx \, dy \\ &= \int_0^1 \int_0^{1-x} \sqrt{x} (1 + y^2) \, dy \, dx \\ &= \int_0^1 \sqrt{x} \left[(1 - x) + \frac{1}{3}(1 - x)^3 \right] dx && \text{Integrate and evaluate.} \\ &= \int_0^1 \left(\frac{4}{3} x^{1/2} - 2x^{3/2} + x^{5/2} - \frac{1}{3} x^{7/2} \right) dx && \text{Routine algebra} \\ &= \left[\frac{8}{9} x^{3/2} - \frac{4}{5} x^{5/2} + \frac{2}{7} x^{7/2} - \frac{2}{27} x^{9/2} \right]_0^1 \\ &= \frac{8}{9} - \frac{4}{5} + \frac{2}{7} - \frac{2}{27} = \frac{284}{945} \approx 0.30. \end{aligned}$$

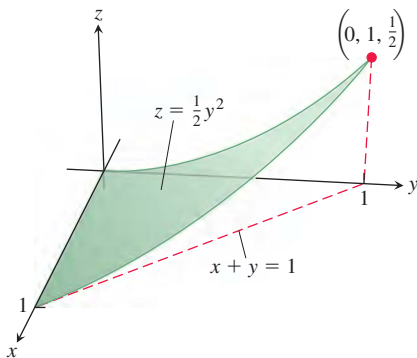

FIGURE 15.51 The surface S in Example 4.

Orientation of a Surface

A curve C with a parametrization $\mathbf{r}(t)$ has a natural orientation, or direction, that comes from the direction of increasing t . The unit tangent vector \mathbf{T} along C points in this forward direction at each point on the curve. There are two possible orientations for a curve, corresponding to whether we follow the direction of the tangent vector \mathbf{T} at each point, or the direction of $-\mathbf{T}$.

To specify an orientation on a surface in space S , we do something similar, but this time we specify a normal vector at each point on the surface. A parametrization of a surface $\mathbf{r}(u, v)$ gives a vector $\mathbf{r}_u \times \mathbf{r}_v$ that is normal to the surface, and so gives an orientation wherever the parametrization applies. A second choice of orientation is found by taking $-(\mathbf{r}_u \times \mathbf{r}_v)$, giving a vector that points to the opposite side of the surface at each point. In essence, an orientation is a way of consistently choosing one of the two sides of a surface. Not all surfaces have orientations, but a surface that does have one also has a second, opposite orientation.

Each point on the sphere in Figure 15.52 has one normal vector pointing inward, toward the center of the sphere, and another opposite normal vector pointing outward. We specify one of two possible orientations for the sphere by choosing either the inward vector at each point, or alternatively the outward vector at each point.

When we can choose a continuous field of unit normal vectors \mathbf{n} on a smooth surface S , we say that S is *orientable* (or *two-sided*). Spheres and other smooth surfaces that are the boundaries of solid regions in space are orientable since we can choose an outward-pointing unit vector \mathbf{n} at each point to specify an orientation.

A surface together with its normal field \mathbf{n} , or, equivalently, a surface with a consistent choice of sides, is called an *oriented surface*. The vector \mathbf{n} at any point gives the positive direction or positively oriented side at that point (Figure 15.52). Not all surfaces can be oriented. The Möbius band in Figure 15.53 is an example of a surface that is not orientable. No matter how you try to construct a continuous unit normal vector field (shown as the shafts of thumbtacks in the figure), starting at one point and moving the vector continuously around the surface in the manner shown will return it to the starting point, but pointing in the opposite direction. No choice of a vectors can give a continuous normal vector field on the Möbius band, so the Möbius band is not orientable.

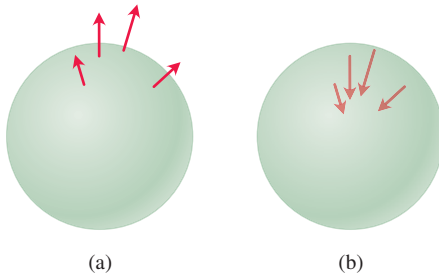

FIGURE 15.52 (a) An outward-pointing vector field and (b) an inward-pointing vector field give the two possible orientations of a sphere.

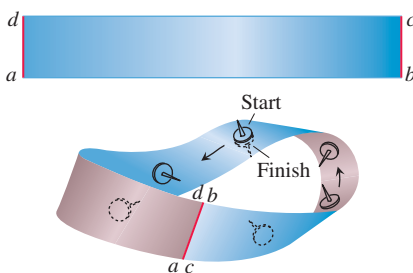

FIGURE 15.53 To make a Möbius band, take a rectangular strip of paper $abcd$, give the end bc a single twist, and paste the ends of the strip together to match a with c and b with d . The Möbius band is a nonorientable, or one-sided, surface.

Surface Integrals of Vector Fields

In Section 15.2 we defined the line integral of a vector field along a path C as $\int_C \mathbf{F} \cdot \mathbf{T} ds$, where \mathbf{T} is the unit tangent vector to the path pointing in the forward-oriented direction. We have a similar definition for surface integrals.

DEFINITION Let \mathbf{F} be a vector field in three-dimensional space with continuous components defined over a smooth surface S having a chosen field of normal unit vectors \mathbf{n} orienting S . Then the **surface integral of \mathbf{F} over S** is

$$\iint_S \mathbf{F} \cdot \mathbf{n} d\sigma. \quad (5)$$

This integral is also called the **flux** of the vector field \mathbf{F} across S .

If \mathbf{F} is the velocity field of a three-dimensional fluid flow, then the flux of \mathbf{F} across S is the net rate at which fluid is crossing S per unit time in the chosen positive direction \mathbf{n} defined by the orientation of S . Fluid flows are discussed in more detail in Section 15.7.

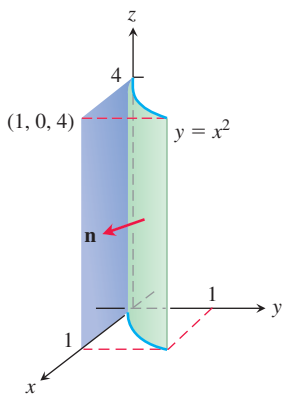

FIGURE 15.54 Finding the flux through the surface of a parabolic cylinder (Example 5).

Computing a Surface Integral for a Parametrized Surface

EXAMPLE 5 Find the flux of $\mathbf{F} = yz\mathbf{i} + x\mathbf{j} - z^2\mathbf{k}$ through the parabolic cylinder $y = x^2$, $0 \leq x \leq 1$, $0 \leq z \leq 4$, in the direction \mathbf{n} indicated in Figure 15.54.

Solution On the surface we have $x = x$, $y = x^2$, and $z = z$, so we have the parametrization $\mathbf{r}(x, z) = x\mathbf{i} + x^2\mathbf{j} + z\mathbf{k}$, $0 \leq x \leq 1$, $0 \leq z \leq 4$. The cross product of tangent vectors,

$$\mathbf{r}_x \times \mathbf{r}_z = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2x & 0 \\ 0 & 0 & 1 \end{vmatrix} = 2x\mathbf{i} - \mathbf{j}, \quad \begin{matrix} \mathbf{r}_x = \mathbf{i} + 2x\mathbf{j} \\ \mathbf{r}_z = \mathbf{k} \end{matrix}$$

can be used to find unit normal vectors to the surface,

$$\mathbf{n} = \frac{\mathbf{r}_x \times \mathbf{r}_z}{|\mathbf{r}_x \times \mathbf{r}_z|} = \frac{2x\mathbf{i} - \mathbf{j}}{\sqrt{4x^2 + 1}}.$$

We can equally well choose the unit normal vectors $-\mathbf{n}$ that point in the opposite direction. The first choice is shown in Figure 15.54.

On the surface we have $y = x^2$, so the vector field there is

$$\mathbf{F} = yz\mathbf{i} + x\mathbf{j} - z^2\mathbf{k} = x^2z\mathbf{i} + x\mathbf{j} - z^2\mathbf{k}.$$

Thus,

$$\mathbf{F} \cdot \mathbf{n} = \frac{1}{\sqrt{4x^2 + 1}}((x^2z)(2x) + (x)(-1) + (-z^2)(0)) = \frac{2x^3z - x}{\sqrt{4x^2 + 1}}.$$

The flux of \mathbf{F} outward through the surface is

$$\begin{aligned} \iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma &= \int_0^4 \int_0^1 \frac{2x^3z - x}{\sqrt{4x^2 + 1}} |\mathbf{r}_x \times \mathbf{r}_z| \, dx \, dz & d\sigma &= |\mathbf{r}_x \times \mathbf{r}_z| \, dx \, dz \\ &= \int_0^4 \int_0^1 \frac{2x^3z - x}{\sqrt{4x^2 + 1}} \sqrt{4x^2 + 1} \, dx \, dz \\ &= \int_0^4 \int_0^1 (2x^3z - x) \, dx \, dz = \int_0^4 \left[\frac{1}{2}x^4z - \frac{1}{2}x^2 \right]_{x=0}^{x=1} dz \\ &= \int_0^4 \frac{1}{2}(z - 1) \, dz = \frac{1}{4}(z - 1)^2 \Big|_0^4 \\ &= \frac{1}{4}(9) - \frac{1}{4}(1) = 2. \end{aligned}$$

There is a simple formula for the flux of \mathbf{F} across a parametrized surface $\mathbf{r}(u, v)$. Since

$$d\sigma = |\mathbf{r}_u \times \mathbf{r}_v| \, du \, dv$$

and

$$\mathbf{n} = \frac{\mathbf{r}_u \times \mathbf{r}_v}{|\mathbf{r}_u \times \mathbf{r}_v|},$$

it follows that

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iint_R \mathbf{F} \cdot \frac{\mathbf{r}_u \times \mathbf{r}_v}{|\mathbf{r}_u \times \mathbf{r}_v|} |\mathbf{r}_u \times \mathbf{r}_v| \, du \, dv = \iint_R \mathbf{F} \cdot (\mathbf{r}_u \times \mathbf{r}_v) \, du \, dv.$$

The other choice of unit normal vector, $-\mathbf{n}$, would add a negative sign to this formula. The choice of \mathbf{n} or $-\mathbf{n}$ depends on the direction in which we choose to measure the flux across the surface.

This integral for flux simplifies the computation in Example 5 by eliminating the need to compute the canceled factor $|\mathbf{r}_u \times \mathbf{r}_v|$. Since

$$\begin{aligned} \mathbf{F} \cdot (\mathbf{r}_x \times \mathbf{r}_z) &= (yz\mathbf{i} + x\mathbf{j} - z^2\mathbf{k}) \cdot (x^2z\mathbf{i} + x\mathbf{j} - z^2\mathbf{k}) \cdot (2x\mathbf{i} - \mathbf{j}) \\ &= (x^2z)(2x) + (x)(-1) = 2x^3z - x, \end{aligned}$$

Flux Across a Parametrized Surface

$$\text{Flux} = \pm \iint_R \mathbf{F} \cdot (\mathbf{r}_u \times \mathbf{r}_v) \, du \, dv$$

we obtain directly

$$\text{Flux} = \iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \int_0^4 \int_0^1 (2x^3z - x) \, dx \, dz = 2$$

in Example 5.

Computing a Surface Integral for a Level Surface

If S is part of a level surface $g(x, y, z) = c$, then \mathbf{n} may be taken to be one of the two fields

$$\mathbf{n} = \pm \frac{\nabla g}{|\nabla g|}, \quad (6)$$

depending on which one gives the preferred direction. The corresponding flux is

$$\begin{aligned} \text{Flux} &= \iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma \\ &= \iint_R \left(\mathbf{F} \cdot \frac{\pm \nabla g}{|\nabla g|} \right) \frac{|\nabla g|}{|\nabla g \cdot \mathbf{p}|} \, dA \quad \text{Eqs. (6) and (3)} \\ &= \iint_R \mathbf{F} \cdot \frac{\pm \nabla g}{|\nabla g \cdot \mathbf{p}|} \, dA. \end{aligned} \quad (7)$$

EXAMPLE 6 Find the flux of $\mathbf{F} = yz\mathbf{j} + z^2\mathbf{k}$ through the surface S cut from the cylinder $y^2 + z^2 = 1$, $z \geq 0$, by the planes $x = 0$ and $x = 1$, in the direction away from the x -axis.

Solution The normal field on S (Figure 15.55) in the specified direction may be calculated from the gradient of $g(x, y, z) = y^2 + z^2$ to be

$$\mathbf{n} = + \frac{\nabla g}{|\nabla g|} = \frac{2y\mathbf{j} + 2z\mathbf{k}}{\sqrt{4y^2 + 4z^2}} = \frac{2y\mathbf{j} + 2z\mathbf{k}}{2\sqrt{1}} = y\mathbf{j} + z\mathbf{k}.$$

With $\mathbf{p} = \mathbf{k}$, we also have

$$d\sigma = \frac{|\nabla g|}{|\nabla g \cdot \mathbf{k}|} \, dA = \frac{2}{|2z|} \, dA = \frac{1}{z} \, dA. \quad \text{Eq. (3)}$$

We can drop the absolute value bars because $z \geq 0$ on S .

The value of $\mathbf{F} \cdot \mathbf{n}$ on the surface is

$$\begin{aligned} \mathbf{F} \cdot \mathbf{n} &= (yz\mathbf{j} + z^2\mathbf{k}) \cdot (y\mathbf{j} + z\mathbf{k}) \\ &= y^2z + z^3 = z(y^2 + z^2) \\ &= z. \end{aligned} \quad y^2 + z^2 = 1 \text{ on } S.$$

The surface projects onto the shadow region R_{xy} , which is the rectangle in the xy -plane shown in Figure 15.55. Therefore, the flux of \mathbf{F} through S in the direction away from the x -axis is

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iint_{R_{xy}} (z) \left(\frac{1}{z} \, dA \right) = \iint_{R_{xy}} dA = \text{area}(R_{xy}) = 2. \quad \blacksquare$$

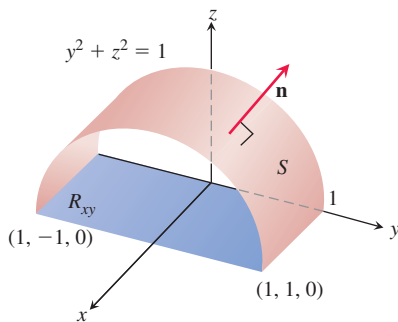

FIGURE 15.55 Calculating the flux of a vector field through the surface S . The area of the shadow region R_{xy} is 2 (Example 6).

Moments and Masses of Thin Shells

Thin shells of material like bowls, metal drums, and domes are modeled with surfaces. Their moments and masses are calculated with the formulas in Table 15.3. The derivations are similar to those in Section 6.6. The formulas resemble those for line integrals in Table 15.1, Section 15.1.

TABLE 15.3 Mass and moment formulas for very thin shells

Mass: $M = \iint_S \delta \, d\sigma$ $\delta = \delta(x, y, z)$ = density at (x, y, z) is mass per unit area.

First moments about the coordinate planes:

$$M_{yz} = \iint_S x \delta \, d\sigma, \quad M_{xz} = \iint_S y \delta \, d\sigma, \quad M_{xy} = \iint_S z \delta \, d\sigma$$

Coordinates of center of mass:

$$\bar{x} = M_{yz}/M, \quad \bar{y} = M_{xz}/M, \quad \bar{z} = M_{xy}/M$$

Moments of inertia about coordinate axes:

$$I_x = \iint_S (y^2 + z^2) \delta \, d\sigma, \quad I_y = \iint_S (x^2 + z^2) \delta \, d\sigma, \quad I_z = \iint_S (x^2 + y^2) \delta \, d\sigma,$$

$$I_L = \iint_S r^2 \delta \, d\sigma \quad r(x, y, z) = \text{distance from point } (x, y, z) \text{ to line } L$$

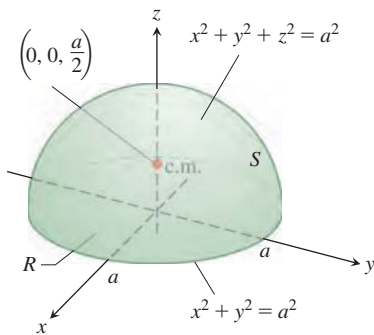

FIGURE 15.56 The center of mass of a thin hemispherical shell of constant density lies on the axis of symmetry halfway from the base to the top (Example 7).

EXAMPLE 7 Find the center of mass of a thin hemispherical shell of radius a and constant density δ .

Solution We model the shell with the hemisphere

$$f(x, y, z) = x^2 + y^2 + z^2 = a^2, \quad z \geq 0$$

(Figure 15.56). The symmetry of the surface about the z -axis tells us that $\bar{x} = \bar{y} = 0$. It remains only to find \bar{z} from the formula $\bar{z} = M_{xy}/M$.

The mass of the shell is

$$M = \iint_S \delta \, d\sigma = \delta \iint_S d\sigma = (\delta)(\text{area of } S) = 2\pi a^2 \delta. \quad \delta = \text{constant}$$

To evaluate the integral for M_{xy} , we take $\mathbf{p} = \mathbf{k}$ and calculate

$$|\nabla f| = |2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k}| = 2\sqrt{x^2 + y^2 + z^2} = 2a$$

$$|\nabla f \cdot \mathbf{p}| = |\nabla f \cdot \mathbf{k}| = |2z| = 2z$$

$$d\sigma = \frac{|\nabla f|}{|\nabla f \cdot \mathbf{p}|} dA = \frac{a}{z} dA. \quad \text{Eq. (3)}$$

Then

$$M_{xy} = \iint_S z \delta \, d\sigma = \delta \iint_R z \frac{a}{z} dA = \delta a \iint_R dA = \delta a (\pi a^2) = \delta \pi a^3$$

$$\bar{z} = \frac{M_{xy}}{M} = \frac{\pi a^3 \delta}{2\pi a^2 \delta} = \frac{a}{2}.$$

The shell's center of mass is the point $(0, 0, a/2)$. ■

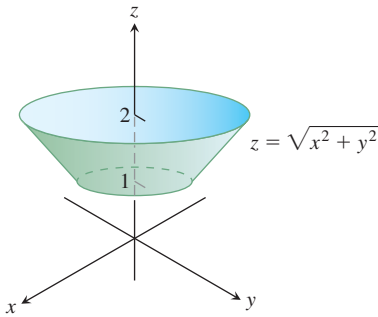

FIGURE 15.57 The cone frustum formed when the cone $z = \sqrt{x^2 + y^2}$ is cut by the planes $z = 1$ and $z = 2$ (Example 8).

EXAMPLE 8 Find the center of mass of a thin shell of density $\delta = 1/z^2$ cut from the cone $z = \sqrt{x^2 + y^2}$ by the planes $z = 1$ and $z = 2$ (Figure 15.57).

Solution Since the surface and the density function δ are symmetric about the z -axis, we have $\bar{x} = \bar{y} = 0$. We now proceed to find $\bar{z} = M_{xy}/M$. Working as in Example 4 of Section 15.5, we have

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}, \quad 1 \leq r \leq 2, \quad 0 \leq \theta \leq 2\pi,$$

and

$$|\mathbf{r}_r \times \mathbf{r}_\theta| = \sqrt{2}r.$$

Therefore,

$$\begin{aligned} M &= \iint_S \delta \, d\sigma = \int_0^{2\pi} \int_1^2 \frac{1}{r^2} \sqrt{2}r \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \left[\ln r \right]_1^2 \, d\theta = \sqrt{2} \int_0^{2\pi} \ln 2 \, d\theta \\ &= 2\pi\sqrt{2} \ln 2, \\ M_{xy} &= \iint_S \delta z \, d\sigma = \int_0^{2\pi} \int_1^2 \frac{1}{r^2} r \sqrt{2}r \, dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} \int_1^2 dr \, d\theta \\ &= \sqrt{2} \int_0^{2\pi} d\theta = 2\pi\sqrt{2}, \\ \bar{z} &= \frac{M_{xy}}{M} = \frac{2\pi\sqrt{2}}{2\pi\sqrt{2} \ln 2} = \frac{1}{\ln 2}. \end{aligned}$$

The shell's center of mass is the point $(0, 0, 1/\ln 2)$. ■

EXERCISES 15.6

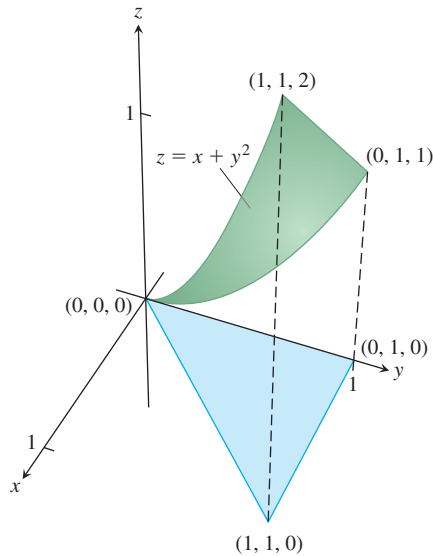

Surface Integrals of Scalar Functions

In Exercises 1–8, integrate the given function over the given surface.

- Parabolic cylinder** $G(x, y, z) = x$, over the parabolic cylinder $y = x^2$, $0 \leq x \leq 2$, $0 \leq z \leq 3$
- Circular cylinder** $G(x, y, z) = z$, over the cylindrical surface $y^2 + z^2 = 4$, $z \geq 0$, $1 \leq x \leq 4$
- Sphere** $G(x, y, z) = x^2$, over the unit sphere $x^2 + y^2 + z^2 = 1$
- Hemisphere** $G(x, y, z) = z^2$, over the hemisphere $x^2 + y^2 + z^2 = a^2$, $z \geq 0$
- Portion of plane** $F(x, y, z) = z$, over the portion of the plane $x + y + z = 4$ that lies above the square $0 \leq x \leq 1$, $0 \leq y \leq 1$, in the xy -plane
- Cone** $F(x, y, z) = z - x$, over the cone $z = \sqrt{x^2 + y^2}$, $0 \leq z \leq 1$
- Parabolic dome** $H(x, y, z) = x^2\sqrt{5 - 4z}$, over the parabolic dome $z = 1 - x^2 - y^2$, $z \geq 0$

- Spherical cap** $H(x, y, z) = yz$, over the part of the sphere $x^2 + y^2 + z^2 = 4$ that lies above the cone $z = \sqrt{x^2 + y^2}$
- Integrate $G(x, y, z) = x + y + z$ over the surface of the cube cut from the first octant by the planes $x = a$, $y = a$, $z = a$.
- Integrate $G(x, y, z) = y + z$ over the surface of the wedge in the first octant bounded by the coordinate planes and the planes $x = 2$ and $y + z = 1$.
- Integrate $G(x, y, z) = xyz$ over the surface of the rectangular solid cut from the first octant by the planes $x = a$, $y = b$, and $z = c$.
- Integrate $G(x, y, z) = xyz$ over the surface of the rectangular solid bounded by the planes $x = \pm a$, $y = \pm b$, and $z = \pm c$.
- Integrate $G(x, y, z) = x + y + z$ over the portion of the plane $2x + 2y + z = 2$ that lies in the first octant.
- Integrate $G(x, y, z) = x\sqrt{y^2 + 4}$ over the surface cut from the parabolic cylinder $y^2 + 4z = 16$ by the planes $x = 0$, $x = 1$, and $z = 0$.

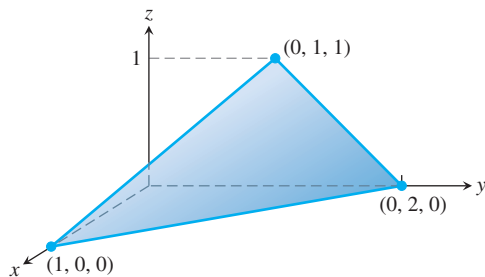

15. Integrate $G(x, y, z) = z - x$ over the portion of the graph of $z = x + y^2$ above the triangle in the xy -plane having vertices $(0, 0, 0)$, $(1, 1, 0)$, and $(0, 1, 0)$. (See accompanying figure.)

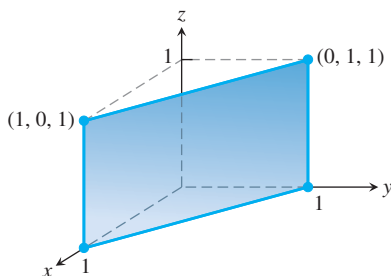

16. Integrate $G(x, y, z) = x$ over the surface given by

$$z = x^2 + y \quad \text{for } 0 \leq x \leq 1, \quad -1 \leq y \leq 1.$$

17. Integrate $G(x, y, z) = xyz$ over the triangular surface with vertices $(1, 0, 0)$, $(0, 2, 0)$, and $(0, 1, 1)$.

18. Integrate $G(x, y, z) = x - y - z$ over the portion of the plane $x + y = 1$ in the first octant between $z = 0$ and $z = 1$ (see the figure below).

Finding Flux or Surface Integrals of Vector Fields

In Exercises 19–28, use a parametrization to find the flux $\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma$ across the surface in the specified direction.

19. **Parabolic cylinder** $\mathbf{F} = z^2\mathbf{i} + x\mathbf{j} - 3z\mathbf{k}$ through the surface cut from the parabolic cylinder $z = 4 - y^2$ by the planes $x = 0$, $x = 1$, and $z = 0$ in the direction away from the x -axis
20. **Parabolic cylinder** $\mathbf{F} = x^2\mathbf{j} - xz\mathbf{k}$ through the surface cut from the parabolic cylinder $y = x^2$, $-1 \leq x \leq 1$, by the planes $z = 0$ and $z = 2$ in the direction away from the yz -plane
21. **Sphere** $\mathbf{F} = z\mathbf{k}$ across the portion of the sphere $x^2 + y^2 + z^2 = a^2$ in the first octant in the direction away from the origin
22. **Sphere** $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ across the sphere $x^2 + y^2 + z^2 = a^2$ in the direction away from the origin
23. **Plane** $\mathbf{F} = 2xy\mathbf{i} + 2yz\mathbf{j} + 2xz\mathbf{k}$ upward across the portion of the plane $x + y + z = 2a$ that lies above the square $0 \leq x \leq a$, $0 \leq y \leq a$, in the xy -plane
24. **Cylinder** $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ through the portion of the cylinder $x^2 + y^2 = 1$ cut by the planes $z = 0$ and $z = a$ in the direction away from the z -axis
25. **Cone** $\mathbf{F} = x y \mathbf{i} - z \mathbf{k}$ through the cone $z = \sqrt{x^2 + y^2}$, $0 \leq z \leq 1$, in the direction away from the z -axis
26. **Cone** $\mathbf{F} = y^2\mathbf{i} + xz\mathbf{j} - \mathbf{k}$ through the cone $z = 2\sqrt{x^2 + y^2}$, $0 \leq z \leq 2$, in the direction away from the z -axis
27. **Cone frustum** $\mathbf{F} = -x\mathbf{i} - y\mathbf{j} + z^2\mathbf{k}$ through the portion of the cone $z = \sqrt{x^2 + y^2}$ between the planes $z = 1$ and $z = 2$ in the direction away from the z -axis
28. **Paraboloid** $\mathbf{F} = 4x\mathbf{i} + 4y\mathbf{j} + 2\mathbf{k}$ through the surface cut from the bottom of the paraboloid $z = x^2 + y^2$ by the plane $z = 1$ in the direction away from the z -axis

In Exercises 29 and 30, find the surface integral of the field \mathbf{F} over the portion of the given surface in the specified direction.

29. $\mathbf{F}(x, y, z) = -\mathbf{i} + 2\mathbf{j} + 3\mathbf{k}$

S : rectangular surface $z = 0$, $0 \leq x \leq 2$, $0 \leq y \leq 3$, direction \mathbf{k}

30. $\mathbf{F}(x, y, z) = yx^2\mathbf{i} - 2\mathbf{j} + xz\mathbf{k}$

S : rectangular surface $y = 0$, $-1 \leq x \leq 2$, $2 \leq z \leq 7$, direction $-\mathbf{j}$

In Exercises 31–36, use Equation (7) to find the surface integral of the field \mathbf{F} over the portion of the sphere $x^2 + y^2 + z^2 = a^2$ in the first octant in the direction away from the origin.

31. $\mathbf{F}(x, y, z) = z\mathbf{k}$

32. $\mathbf{F}(x, y, z) = -y\mathbf{i} + x\mathbf{j}$

33. $\mathbf{F}(x, y, z) = y\mathbf{i} - x\mathbf{j} + \mathbf{k}$

34. $\mathbf{F}(x, y, z) = zx\mathbf{i} + zy\mathbf{j} + z^2\mathbf{k}$

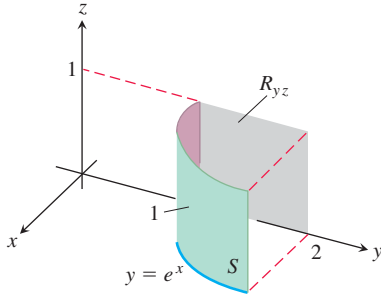

35. $\mathbf{F}(x, y, z) = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$

36. $\mathbf{F}(x, y, z) = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{\sqrt{x^2 + y^2 + z^2}}$

37. Find the flux of the field $\mathbf{F}(x, y, z) = z^2\mathbf{i} + x\mathbf{j} - 3z\mathbf{k}$ through the surface cut from the parabolic cylinder $z = 4 - y^2$ by the planes $x = 0$, $x = 1$, and $z = 0$ in the direction away from the x -axis.

38. Find the flux of the field $\mathbf{F}(x, y, z) = 4x\mathbf{i} + 4y\mathbf{j} + 2\mathbf{k}$ through the surface cut from the bottom of the paraboloid $z = x^2 + y^2$ by the plane $z = 1$ in the direction away from the z -axis.

39. Let S be the portion of the cylinder $y = e^x$ in the first octant that projects parallel to the x -axis onto the rectangle R_{yz} : $1 \leq y \leq 2$, $0 \leq z \leq 1$, in the yz -plane (see the accompanying figure). Let \mathbf{n} be the unit vector normal to S that points away from the yz -plane. Find the flux of the field $\mathbf{F}(x, y, z) = -2\mathbf{i} + 2y\mathbf{j} + z\mathbf{k}$ across S in the direction of \mathbf{n} .

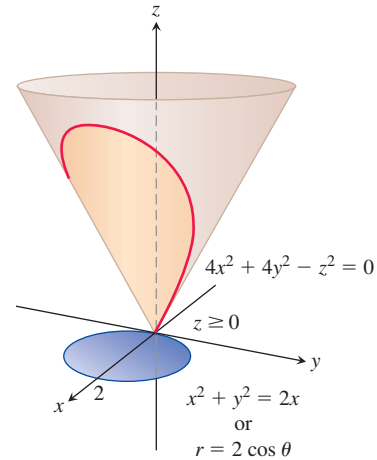

40. Let S be the portion of the cylinder $y = \ln x$ in the first octant whose projection parallel to the y -axis onto the xz -plane is the rectangle R_{xz} : $1 \leq x \leq e$, $0 \leq z \leq 1$. Let \mathbf{n} be the unit vector normal to S that points away from the xz -plane. Find the flux of $\mathbf{F} = 2y\mathbf{j} + z\mathbf{k}$ through S in the direction of \mathbf{n} .
41. Find the outward flux of the field $\mathbf{F} = 2xy\mathbf{i} + 2yz\mathbf{j} + 2xz\mathbf{k}$ across the surface of the cube cut from the first octant by the planes $x = a$, $y = a$, and $z = a$.
42. Find the outward flux of the field $\mathbf{F} = xz\mathbf{i} + yz\mathbf{j} + \mathbf{k}$ across the surface of the upper cap cut from the ball $x^2 + y^2 + z^2 \leq 25$ by the plane $z = 3$.

Moments and Masses

43. **Centroid** Find the centroid of the portion of the sphere $x^2 + y^2 + z^2 = a^2$ that lies in the first octant.
44. **Centroid** Find the centroid of the surface cut from the cylinder $y^2 + z^2 = 9$, $z \geq 0$, by the planes $x = 0$ and $x = 3$ (resembles the surface in Example 6).
45. **Thin shell of constant density** Find the center of mass and the moment of inertia about the z -axis of a thin shell of constant density δ cut from the cone $x^2 + y^2 - z^2 = 0$ by the planes $z = 1$ and $z = 2$.

46. **Conical surface of constant density** Find the moment of inertia about the z -axis of a thin shell of constant density δ cut from the cone $4x^2 + 4y^2 - z^2 = 0$, $z \geq 0$, by the circular cylinder $x^2 + y^2 = 2x$ (see the accompanying figure).

47. **Spherical shells** Find the moment of inertia about a diameter of a thin spherical shell of radius a and constant density δ . (Work with a hemispherical shell and double the result.)
48. **Conical Surface** Find the centroid of the lateral surface of a solid cone of base radius a and height h (cone surface minus the base).
49. A surface S lies on the plane $2x + 3y + 6z = 12$ directly above the rectangle in the xy -plane with vertices $(0, 0)$, $(1, 0)$, $(0, 2)$, and $(1, 2)$. If the density at a point (x, y, z) on S is given by $\delta(x, y, z) = 4xy + 6z$ mg/cm², find the total mass of S .
50. A surface S lies on the paraboloid $z = \frac{1}{2}x^2 + \frac{1}{2}y^2$ directly above the triangle in the xy -plane with vertices $(0, 0)$, $(2, 0)$, and $(2, 4)$. If the density at a point (x, y, z) on S is given by $\delta(x, y, z) = 9xy$ g/cm², find the total mass of S .

15.7 Stokes' Theorem

To calculate the counterclockwise circulation of a two-dimensional vector field $\mathbf{F} = M\mathbf{i} + N\mathbf{j}$ around a simple closed curve in the plane, Green's Theorem says we can compute the double integral over the region enclosed by the curve of the scalar quantity $(\partial N/\partial x - \partial M/\partial y)$. This expression is the \mathbf{k} -component of a *curl vector* field, and it measures the rate of rotation of \mathbf{F} at each point in the region around an axis parallel to \mathbf{k} . For a vector field in three-dimensional space, the rotation at each point is around an axis that is parallel to the curl vector at that point. When a closed curve C in space is the boundary of an oriented surface, we will see that the circulation of \mathbf{F} around C is equal to the surface integral of the curl vector field. This result extends Green's Theorem from regions in the plane to general surfaces in space having a smooth boundary curve.

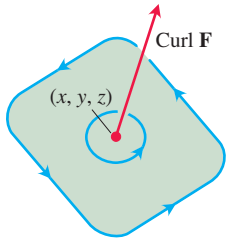

FIGURE 15.58 The circulation vector at a point (x, y, z) in a plane in a three-dimensional fluid flow. Notice its right-hand relation to the rotating particles in the fluid.

The Curl Vector Field

Suppose that \mathbf{F} is the velocity field of a fluid flowing in space. Particles near the point (x, y, z) in the fluid tend to rotate around an axis through (x, y, z) that is parallel to a certain vector we are about to identify. This vector points in the direction for which the rotation is counterclockwise when viewed looking down onto the plane of the circulation from the tip of the arrow representing the vector. This is the direction your right-hand thumb points when your fingers curl around the axis of rotation in the way consistent with the rotating motion of the particles in the fluid (see Figure 15.58). The length of the vector measures the rate of rotation. The vector, introduced in Equation (3) of Section 15.3, is called the **curl vector** for the vector field $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$, and it is given by

$$\operatorname{curl} \mathbf{F} = \left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z} \right) \mathbf{i} + \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x} \right) \mathbf{j} + \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \mathbf{k}. \quad (1)$$

This information is a consequence of Stokes' Theorem, the generalization to space of the circulation-curl form of Green's Theorem.

Notice that $(\operatorname{curl} \mathbf{F}) \cdot \mathbf{k} = (\partial N / \partial x - \partial M / \partial y)$, which is consistent with our discussion in Section 15.4 when $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$. The formula for $\operatorname{curl} \mathbf{F}$ in Equation (1) is often expressed using the symbol

$$\nabla = \mathbf{i} \frac{\partial}{\partial x} + \mathbf{j} \frac{\partial}{\partial y} + \mathbf{k} \frac{\partial}{\partial z}. \quad (2)$$

The symbol ∇ is pronounced “del,” and we can use this symbol to express the curl of \mathbf{F} with the formula

$$\begin{aligned} \nabla \times \mathbf{F} &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ M & N & P \end{vmatrix} \\ &= \left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z} \right) \mathbf{i} + \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x} \right) \mathbf{j} + \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \mathbf{k}. \end{aligned}$$

We often use this cross product notation to write the curl symbolically as “del cross \mathbf{F} .”

$$\operatorname{curl} \mathbf{F} = \nabla \times \mathbf{F} \quad (3)$$

EXAMPLE 1 Find the curl of $\mathbf{F} = (x^2 - z)\mathbf{i} + xe^z\mathbf{j} + xy\mathbf{k}$.

Solution We use Equation (3) and the determinant form for the cross product, which gives,

$$\begin{aligned} \operatorname{curl} \mathbf{F} &= \nabla \times \mathbf{F} \\ &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x^2 - z & xe^z & xy \end{vmatrix} \\ &= \left(\frac{\partial}{\partial y}(xy) - \frac{\partial}{\partial z}(xe^z) \right) \mathbf{i} - \left(\frac{\partial}{\partial x}(xy) - \frac{\partial}{\partial z}(x^2 - z) \right) \mathbf{j} \\ &\quad + \left(\frac{\partial}{\partial x}(xe^z) - \frac{\partial}{\partial y}(x^2 - z) \right) \mathbf{k} \quad \text{Curl } \mathbf{F} \text{ is a vector, not a scalar.} \\ &= (x - xe^z)\mathbf{i} - (y + 1)\mathbf{j} + (e^z - 0)\mathbf{k} \\ &= x(1 - e^z)\mathbf{i} - (y + 1)\mathbf{j} + e^z\mathbf{k}. \end{aligned}$$

∇ is the symbol “del.”

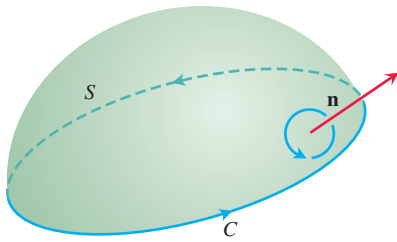

FIGURE 15.59 The orientation of the bounding curve C gives it a right-hand relation to the normal field \mathbf{n} . If the thumb of a right hand points along \mathbf{n} , the fingers curl in the direction of C .

As we will see, the operator ∇ has a number of other applications. For instance, when applied to a scalar function $f(x, y, z)$, it gives the gradient of f :

$$\nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} + \frac{\partial f}{\partial z} \mathbf{k}.$$

In this setting it is read sometimes as “del f ” and sometimes as “grad f .”

Stokes' Theorem

Stokes' Theorem generalizes Green's Theorem to three dimensions. The circulation-curl form of Green's Theorem relates the counterclockwise circulation of a vector field around a simple closed curve C in the xy -plane to a double integral over the plane region R enclosed by C . Stokes' Theorem relates the circulation of a vector field around the boundary C of an oriented surface S in space (Figure 15.59) to a surface integral over the surface S . We require that the surface be **piecewise smooth**, which means that it is a finite union of smooth surfaces joining along smooth curves.

THEOREM 6—Stokes' Theorem

Let S be a piecewise smooth oriented surface having a piecewise smooth boundary curve C . Let $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ be a vector field whose components have continuous first partial derivatives on an open region containing S . Then the circulation of \mathbf{F} around C in the direction counterclockwise with respect to the surface's unit normal vector \mathbf{n} equals the integral of the curl vector field $\nabla \times \mathbf{F}$ over S :

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma \quad (4)$$

Counterclockwise circulation
Curl integral

Notice from Equation (4) that if two different oriented surfaces S_1 and S_2 have the same boundary C , their curl integrals are equal:

$$\iint_{S_1} (\nabla \times \mathbf{F}) \cdot \mathbf{n}_1 \, d\sigma = \iint_{S_2} (\nabla \times \mathbf{F}) \cdot \mathbf{n}_2 \, d\sigma.$$

Both curl integrals equal the counterclockwise circulation integral on the left side of Equation (4) as long as the unit normal vectors \mathbf{n}_1 and \mathbf{n}_2 correctly orient the surfaces. So the curl integral is independent of the surface and depends only on circulation along the boundary curve. This independence of surface resembles the path independence for the flow integral of a conservative velocity field along a curve, where the value of the flow integral depends only on the endpoints (that is, the boundary points) of the path. In that sense, the curl field $\nabla \times \mathbf{F}$ is analogous to the gradient field ∇f of a scalar function f .

If C is a curve in the xy -plane, oriented counterclockwise, and R is the region in the xy -plane bounded by C , then $d\sigma = dx \, dy$ and

$$(\nabla \times \mathbf{F}) \cdot \mathbf{n} = (\nabla \times \mathbf{F}) \cdot \mathbf{k} = \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right).$$

Under these conditions, Stokes' equation becomes

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx \, dy,$$

which is the circulation-curl form of the equation in Green's Theorem. Conversely, by reversing these steps we can rewrite the circulation-curl form of Green's Theorem for two-dimensional fields in del notation as

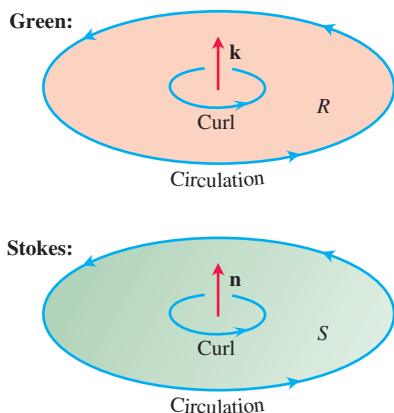

FIGURE 15.60 When applied to curves and surfaces in the plane, Stokes' Theorem gives the circulation-curl version of Green's Theorem. But Stokes' Theorem also applies more generally, to curves and surfaces not lying in the plane.

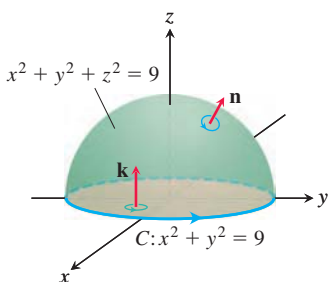

FIGURE 15.61 A hemisphere and a disk, each with boundary C (Examples 2 and 3).

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_R (\nabla \times \mathbf{F}) \cdot \mathbf{k} \, dA. \quad (5)$$

See Figure 15.60.

EXAMPLE 2 Evaluate both sides of Equation (4) for the hemisphere $S: x^2 + y^2 + z^2 = 9, z \geq 0$; its bounding circle $C: x^2 + y^2 = 9, z = 0$, traversed counterclockwise (when viewed from above); and the field $\mathbf{F} = y\mathbf{i} - x\mathbf{j}$.

Solution The hemisphere looks much like the surface in Figure 15.59 with the bounding circle C in the xy -plane (see Figure 15.61). We calculate the counterclockwise circulation around C (as viewed from above) using the parametrization $\mathbf{r}(\theta) = (3 \cos \theta)\mathbf{i} + (3 \sin \theta)\mathbf{j}$, $0 \leq \theta \leq 2\pi$:

$$d\mathbf{r} = (-3 \sin \theta \, d\theta)\mathbf{i} + (3 \cos \theta \, d\theta)\mathbf{j}$$

$$\mathbf{F} = y\mathbf{i} - x\mathbf{j} = (3 \sin \theta)\mathbf{i} - (3 \cos \theta)\mathbf{j}$$

$$\mathbf{F} \cdot d\mathbf{r} = -9 \sin^2 \theta \, d\theta - 9 \cos^2 \theta \, d\theta = -9 \, d\theta$$

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} -9 \, d\theta = -18\pi.$$

When evaluating the right side of Equation (4), we choose the orientation of the unit normal vector so that it points away from the origin, giving it a right-hand relation to the prescribed orientation of the curve C (see Figure 15.61). We have

$$\nabla \times \mathbf{F} = \left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z} \right)\mathbf{i} + \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x} \right)\mathbf{j} + \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right)\mathbf{k}$$

$$= (0 - 0)\mathbf{i} + (0 - 0)\mathbf{j} + (-1 - 1)\mathbf{k} = -2\mathbf{k}$$

$$\mathbf{n} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{\sqrt{x^2 + y^2 + z^2}} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{3} \quad \text{Unit normal vector}$$

$$d\sigma = \frac{3}{z} \, dA$$

Section 15.6, Example 7,
with $a = 3$

$$(\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = (-2\mathbf{k}) \cdot \left(\frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{3} \right) d\sigma = -\frac{2z}{3} \frac{3}{z} \, dA = -2 \, dA$$

and

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = \iint_{x^2 + y^2 \leq 9} -2 \, dA = -18\pi.$$

The circulation around the circle equals the integral of the curl over the hemisphere, as it should from Stokes' Theorem. ■

The surface integral in Stokes' Theorem can be computed using any surface having boundary curve C , provided the surface is properly oriented and lies within the domain of the field \mathbf{F} . The next example illustrates this fact for the circulation around the curve C in Example 2.

EXAMPLE 3 Calculate the circulation around the bounding circle C in Example 2, using the disk of radius 3 centered at the origin in the xy -plane as the surface S (instead of the hemisphere). See Figure 15.61.

Solution As in Example 2, $\nabla \times \mathbf{F} = -2\mathbf{k}$. When the surface is the described disk in the xy -plane, we have the normal vector $\mathbf{n} = \mathbf{k}$, chosen to give a counterclockwise direction for C as required by Stokes' Theorem, so that

$$(\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = -2\mathbf{k} \cdot \mathbf{k} \, dA = -2 \, dA$$

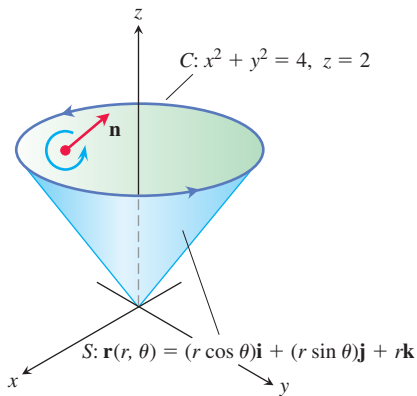

FIGURE 15.62 The curve C and cone S in Example 4.

and

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = \iint_{x^2+y^2 \leq 9} -2 \, dA = -18\pi,$$

a simpler calculation than before. ■

EXAMPLE 4 Find the circulation of the field $\mathbf{F} = (x^2 - y)\mathbf{i} + 4z\mathbf{j} + x^2\mathbf{k}$ around the curve C in which the plane $z = 2$ meets the cone $z = \sqrt{x^2 + y^2}$, counterclockwise as viewed from above (Figure 15.62).

Solution Stokes' Theorem enables us to find the circulation by integrating over the surface of the cone. Traversing C in the counterclockwise direction viewed from above corresponds to taking the *inner* normal \mathbf{n} to the cone, the normal with a positive \mathbf{k} -component.

We parametrize the cone as

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}, \quad 0 \leq r \leq 2, \quad 0 \leq \theta \leq 2\pi.$$

We then have

$$\begin{aligned} \mathbf{n} &= \frac{\mathbf{r}_r \times \mathbf{r}_\theta}{|\mathbf{r}_r \times \mathbf{r}_\theta|} = \frac{-(r \cos \theta)\mathbf{i} - (r \sin \theta)\mathbf{j} + r\mathbf{k}}{r\sqrt{2}} && \text{Section 15.5, Example 4} \\ &= \frac{1}{\sqrt{2}}(-(\cos \theta)\mathbf{i} - (\sin \theta)\mathbf{j} + \mathbf{k}) \end{aligned}$$

$$d\sigma = r\sqrt{2} \, dr \, d\theta \quad \text{Section 15.5, Example 4}$$

$$\nabla \times \mathbf{F} = -4\mathbf{i} - 2x\mathbf{j} + \mathbf{k} \quad \text{Computation of curl}$$

$$= -4\mathbf{i} - 2r \cos \theta \mathbf{j} + \mathbf{k}. \quad x = r \cos \theta$$

Accordingly,

$$\begin{aligned} (\nabla \times \mathbf{F}) \cdot \mathbf{n} &= \frac{1}{\sqrt{2}}(4 \cos \theta + 2r \cos \theta \sin \theta + 1) \\ &= \frac{1}{\sqrt{2}}(4 \cos \theta + r \sin 2\theta + 1), \end{aligned}$$

and the circulation is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma \quad \text{Stokes' Theorem, Eq. (4)} \\ &= \int_0^{2\pi} \int_0^2 \frac{1}{\sqrt{2}}(4 \cos \theta + r \sin 2\theta + 1)(r\sqrt{2} \, dr \, d\theta) = 4\pi. \quad \blacksquare \end{aligned}$$

EXAMPLE 5 The cone used in Example 4 is not the easiest surface to use for calculating the circulation around the bounding circle C lying in the plane $z = 2$. If instead we use the flat disk of radius 2 centered on the z -axis and lying in the plane $z = 2$, then the normal vector to the surface S is $\mathbf{n} = \mathbf{k}$ (chosen to give a counterclockwise direction for the curve C). Just as in the computation for Example 4, we still have $\nabla \times \mathbf{F} = -4\mathbf{i} - 2x\mathbf{j} + \mathbf{k}$. However, now we get $(\nabla \times \mathbf{F}) \cdot \mathbf{n} = 1$, so that

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = \iint_{x^2+y^2 \leq 4} 1 \, dA = 4\pi. \quad \text{The shadow is the disk of radius 2 in the } xy\text{-plane.}$$

This result agrees with the circulation value found in Example 4. ■

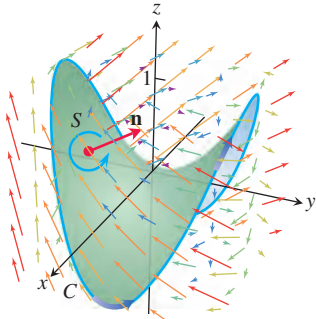

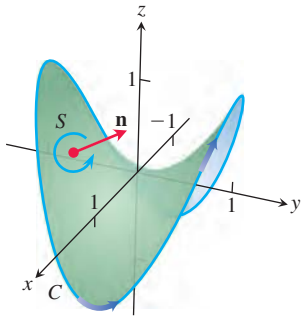

FIGURE 15.63 The surface and vector field for Example 6.

EXAMPLE 6 Find a parametrization for the surface S formed by the part of the hyperbolic paraboloid $z = y^2 - x^2$ lying inside the cylinder of radius one around the z -axis and for the boundary curve C of S . (See Figure 15.63.) Then verify Stokes' Theorem for S using the normal having positive \mathbf{k} -component and the vector field $\mathbf{F} = y\mathbf{i} - x\mathbf{j} + x^2\mathbf{k}$.

Solution As the unit circle is traversed in the xy -plane, the z -coordinate of the surface with the curve C as boundary is given by $y^2 - x^2$. We choose the orientation for the curve C to be counterclockwise when viewed from above (see Figure 15.63). A parametrization of C is given by

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + (\sin t)\mathbf{j} + (\sin^2 t - \cos^2 t)\mathbf{k}, \quad 0 \leq t \leq 2\pi$$

with

$$\frac{d\mathbf{r}}{dt} = (-\sin t)\mathbf{i} + (\cos t)\mathbf{j} + (4 \sin t \cos t)\mathbf{k}, \quad 0 \leq t \leq 2\pi.$$

Along the curve $\mathbf{r}(t)$ the formula for the vector field \mathbf{F} is

$$\mathbf{F} = (\sin t)\mathbf{i} - (\cos t)\mathbf{j} + (\cos^2 t)\mathbf{k}.$$

The counterclockwise circulation along C is the value of the line integral

$$\begin{aligned} \int_0^{2\pi} \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt &= \int_0^{2\pi} (-\sin^2 t - \cos^2 t + 4 \sin t \cos^3 t) dt \\ &= \int_0^{2\pi} (4 \sin t \cos^3 t - 1) dt \\ &= \left[-\cos^4 t - t \right]_0^{2\pi} = -2\pi. \end{aligned}$$

We now compute the same quantity by integrating $(\nabla \times \mathbf{F}) \cdot \mathbf{n}$ over the surface S . We use polar coordinates and parametrize S by noting that above the point (r, θ) in the plane, the z -coordinate of S is $y^2 - x^2 = r^2 \sin^2 \theta - r^2 \cos^2 \theta$. A parametrization of S is

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r^2(\sin^2 \theta - \cos^2 \theta)\mathbf{k}, \quad 0 \leq r \leq 1, \quad 0 \leq \theta \leq 2\pi.$$

We next compute $(\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma$. We have

$$\nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ y & -x & x^2 \end{vmatrix} = -2x\mathbf{j} - 2\mathbf{k} = -(2r \cos \theta)\mathbf{j} - 2\mathbf{k}$$

and

$$\begin{aligned} \mathbf{r}_r &= (\cos \theta)\mathbf{i} + (\sin \theta)\mathbf{j} + 2r(\sin^2 \theta - \cos^2 \theta)\mathbf{k} \\ \mathbf{r}_\theta &= (-r \sin \theta)\mathbf{i} + (r \cos \theta)\mathbf{j} + 4r^2(\sin \theta \cos \theta)\mathbf{k} \end{aligned}$$

$$\begin{aligned} \mathbf{r}_r \times \mathbf{r}_\theta &= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos \theta & \sin \theta & 2r(\sin^2 \theta - \cos^2 \theta) \\ -r \sin \theta & r \cos \theta & 4r^2(\sin \theta \cos \theta) \end{vmatrix} \\ &= 2r^2(2 \sin^2 \theta \cos \theta - \sin^2 \theta \cos \theta + \cos^3 \theta)\mathbf{i} \\ &\quad - 2r^2(2 \sin \theta \cos^2 \theta + \sin^3 \theta + \sin \theta \cos^2 \theta)\mathbf{j} + r\mathbf{k}. \end{aligned}$$

Note that the \mathbf{k} -component is always nonnegative. Therefore, we take

$$\mathbf{n} = \frac{(\mathbf{r}_r \times \mathbf{r}_\theta)}{|\mathbf{r}_r \times \mathbf{r}_\theta|}.$$

We now obtain

$$\begin{aligned}
 \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma &= \int_0^{2\pi} \int_0^1 (\nabla \times \mathbf{F}) \cdot \frac{\mathbf{r}_r \times \mathbf{r}_\theta}{|\mathbf{r}_r \times \mathbf{r}_\theta|} |\mathbf{r}_r \times \mathbf{r}_\theta| \, dr \, d\theta \\
 &= \int_0^{2\pi} \int_0^1 (\nabla \times \mathbf{F}) \cdot (\mathbf{r}_r \times \mathbf{r}_\theta) \, dr \, d\theta \\
 &= \int_0^{2\pi} \int_0^1 [4r^3(2 \sin \theta \cos^3 \theta + \sin^3 \theta \cos \theta + \sin \theta \cos^3 \theta) - 2r] \, dr \, d\theta \\
 &= \int_0^{2\pi} \left[r^4(3 \sin \theta \cos^3 \theta + \sin^3 \theta \cos \theta) - r^2 \right]_{r=0}^{r=1} d\theta \quad \text{Integrate.} \\
 &= \int_0^{2\pi} (3 \sin \theta \cos^3 \theta + \sin^3 \theta \cos \theta - 1) \, d\theta \quad \text{Evaluate.} \\
 &= \left[-\frac{3}{4} \cos^4 \theta + \frac{1}{4} \sin^4 \theta - \theta \right]_0^{2\pi} \\
 &= \left(-\frac{3}{4} + 0 - 2\pi + \frac{3}{4} - 0 + 0 \right) = -2\pi.
 \end{aligned}$$

So the surface integral of $(\nabla \times \mathbf{F}) \cdot \mathbf{n}$ over S equals the counterclockwise circulation of \mathbf{F} along C , as asserted by Stokes' Theorem. ■

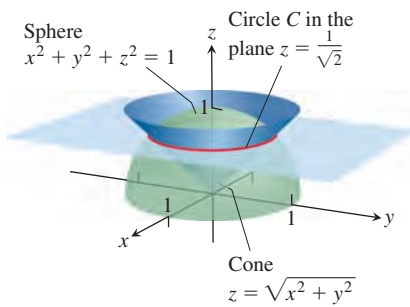

FIGURE 15.64 Circulation curve C in Example 7.

EXAMPLE 7 Calculate the circulation of the vector field

$$\mathbf{F} = (x^2 + z)\mathbf{i} + (y^2 + 2x)\mathbf{j} + (z^2 - y)\mathbf{k}$$

along the curve of intersection of the sphere $x^2 + y^2 + z^2 = 1$ with the cone $z = \sqrt{x^2 + y^2}$ traversed in the counterclockwise direction around the z -axis when viewed from above.

Solution The sphere and cone intersect when $1 = (x^2 + y^2) + z^2 = z^2 + z^2 = 2z^2$, or $z = 1/\sqrt{2}$ (see Figure 15.64). We apply Stokes' Theorem to the curve of intersection $x^2 + y^2 = 1/2$ considered as the boundary of the enclosed disk in the plane $z = 1/\sqrt{2}$. The normal vector to the surface that gives a counterclockwise orientation to the boundary curve is then $\mathbf{n} = \mathbf{k}$. We calculate the curl vector as

$$\nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ x^2 + z & y^2 + 2x & z^2 - y \end{vmatrix} = -\mathbf{i} + \mathbf{j} + 2\mathbf{k},$$

so that $(\nabla \times \mathbf{F}) \cdot \mathbf{k} = 2$. The circulation around the disk is

$$\begin{aligned}
 \oint_C \mathbf{F} \cdot d\mathbf{r} &= \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{k} \, d\sigma \\
 &= \iint_S 2 \, d\sigma = 2 \cdot \text{area of disk} = 2 \cdot \pi \left(\frac{1}{\sqrt{2}} \right)^2 = \pi. \quad \text{■}
 \end{aligned}$$

Paddle Wheel Interpretation of $\nabla \times \mathbf{F}$

Suppose that \mathbf{F} is the velocity field of a fluid moving in a region R in space containing the closed curve C . Then

$$\oint_C \mathbf{F} \cdot d\mathbf{r}$$

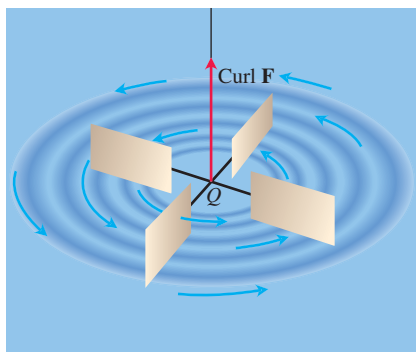

FIGURE 15.65 A small paddle wheel in a fluid spins fastest at point Q when its axle points in the direction of $\text{curl } \mathbf{F}$.

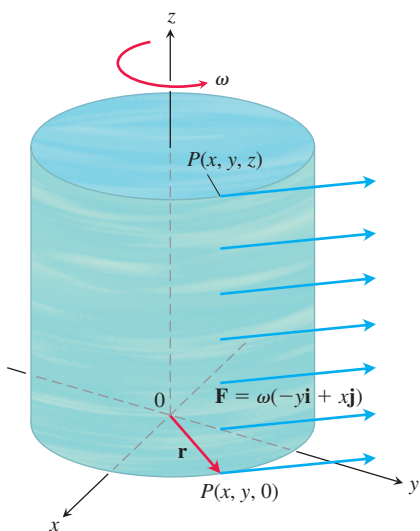

FIGURE 15.66 A steady rotational flow parallel to the xy -plane, with constant angular velocity ω in the positive (counterclockwise) direction (Example 8).

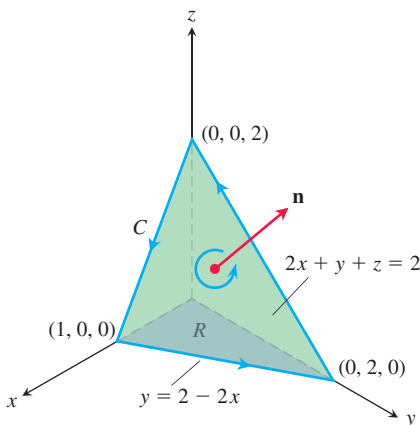

FIGURE 15.67 The planar surface in Example 9.

is the circulation of the fluid around C . By Stokes' Theorem, the circulation is equal to the flux of $\nabla \times \mathbf{F}$ through any suitably oriented surface S with boundary C :

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma.$$

Suppose we fix a point Q in the region R and a direction \mathbf{u} at Q . Take C to be a circle of radius ρ , with center at Q , whose plane is normal to \mathbf{u} . If $\nabla \times \mathbf{F}$ is continuous at Q , the average value of the \mathbf{u} -component of $\nabla \times \mathbf{F}$ over the circular disk S bounded by C approaches the \mathbf{u} -component of $\nabla \times \mathbf{F}$ at Q as the radius $\rho \rightarrow 0$:

$$((\nabla \times \mathbf{F}) \cdot \mathbf{u}) \Big|_Q = \lim_{\rho \rightarrow 0} \frac{1}{\pi\rho^2} \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{u} \, d\sigma.$$

If we apply Stokes' Theorem and replace the surface integral by a line integral over C , we get

$$((\nabla \times \mathbf{F}) \cdot \mathbf{u}) \Big|_Q = \lim_{\rho \rightarrow 0} \frac{1}{\pi\rho^2} \oint_C \mathbf{F} \cdot d\mathbf{r}. \quad (6)$$

The left-hand side of Equation (6) has its maximum value when \mathbf{u} is the direction of $\nabla \times \mathbf{F}$. When ρ is small, the limit on the right-hand side of Equation (6) is approximately

$$\frac{1}{\pi\rho^2} \oint_C \mathbf{F} \cdot d\mathbf{r},$$

which is the circulation around C divided by the area of the disk (circulation density). Suppose that a small paddle wheel of radius ρ is introduced into the fluid at Q , with its axle directed along \mathbf{u} (Figure 15.65). The circulation of the fluid around C affects the rate of spin of the paddle wheel. The wheel spins fastest when the circulation integral is maximized; therefore, it spins fastest when the axle of the paddle wheel points in the direction of $\nabla \times \mathbf{F}$.

EXAMPLE 8 A fluid of constant density rotates around the z -axis with velocity $\mathbf{F} = \omega(-y\mathbf{i} + x\mathbf{j})$, where ω is a positive constant called the *angular velocity* of the rotation (Figure 15.66). Find $\nabla \times \mathbf{F}$ and relate it to the circulation density.

Solution With $\mathbf{F} = -\omega y\mathbf{i} + \omega x\mathbf{j}$, we find the curl

$$\begin{aligned} \nabla \times \mathbf{F} &= \left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z} \right) \mathbf{i} + \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x} \right) \mathbf{j} + \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \mathbf{k} \\ &= (0 - 0)\mathbf{i} + (0 - 0)\mathbf{j} + (\omega - (-\omega))\mathbf{k} = 2\omega\mathbf{k}, \end{aligned}$$

and therefore $(\nabla \times \mathbf{F}) \cdot \mathbf{k} = 2\omega$. By Stokes' Theorem, the circulation of \mathbf{F} around a circle C of radius ρ (traversed counterclockwise when viewed from above) bounding a disk S in a plane normal to $\nabla \times \mathbf{F}$, say the xy -plane, is

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = \iint_S 2\omega\mathbf{k} \cdot \mathbf{k} \, dx \, dy = (2\omega)(\pi\rho^2).$$

Solving this last equation for 2ω , we see that

$$(\nabla \times \mathbf{F}) \cdot \mathbf{k} = 2\omega = \frac{1}{\pi\rho^2} \oint_C \mathbf{F} \cdot d\mathbf{r},$$

which is consistent with Equation (6) when $\mathbf{u} = \mathbf{k}$. ■

EXAMPLE 9 Use Stokes' Theorem to evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$, if $\mathbf{F} = xz\mathbf{i} + xy\mathbf{j} + 3xz\mathbf{k}$ and C is the boundary of the portion of the plane $2x + y + z = 2$ in the first octant, traversed counterclockwise as viewed from above (Figure 15.67).

Solution The plane is the level surface $f(x, y, z) = 2$ of the function $f(x, y, z) = 2x + y + z$. The unit normal vector

$$\mathbf{n} = \frac{\nabla f}{|\nabla f|} = \frac{(2\mathbf{i} + \mathbf{j} + \mathbf{k})}{|2\mathbf{i} + \mathbf{j} + \mathbf{k}|} = \frac{1}{\sqrt{6}}(2\mathbf{i} + \mathbf{j} + \mathbf{k})$$

is consistent with the counterclockwise motion around C . To apply Stokes' Theorem, we find

$$\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ xz & xy & 3xz \end{vmatrix} = (x - 3z)\mathbf{j} + y\mathbf{k}.$$

On the plane, z equals $2 - 2x - y$, so

$$\nabla \times \mathbf{F} = (x - 3(2 - 2x - y))\mathbf{j} + y\mathbf{k} = (7x + 3y - 6)\mathbf{j} + y\mathbf{k}$$

and

$$(\nabla \times \mathbf{F}) \cdot \mathbf{n} = \frac{1}{\sqrt{6}}(7x + 3y - 6 + y) = \frac{1}{\sqrt{6}}(7x + 4y - 6).$$

The surface area differential is

$$d\sigma = \frac{|\nabla f|}{|\nabla f \cdot \mathbf{k}|} dA = \frac{\sqrt{6}}{1} dx dy. \quad \text{Formula (7) in Section 15.5}$$

The circulation is

$$\begin{aligned} \oint_C \mathbf{F} \cdot d\mathbf{r} &= \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma && \text{Stokes' Theorem, Eq. (4)} \\ &= \int_0^1 \int_0^{2-2x} \frac{1}{\sqrt{6}}(7x + 4y - 6)\sqrt{6} dy dx \\ &= \int_0^1 \int_0^{2-2x} (7x + 4y - 6) dy dx = -1. \end{aligned}$$

EXAMPLE 10 Let the surface S be the elliptic paraboloid $z = x^2 + 4y^2$ lying beneath the plane $z = 1$ (Figure 15.68). We define the orientation of S by taking the *inner* normal vector \mathbf{n} to the surface, which is the normal having a positive \mathbf{k} -component. Find the flux of $\nabla \times \mathbf{F}$ across S in the direction \mathbf{n} for the vector field $\mathbf{F} = y\mathbf{i} - xz\mathbf{j} + xz^2\mathbf{k}$.

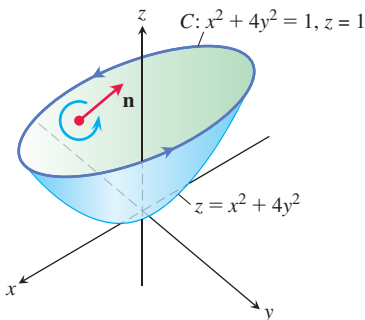

FIGURE 15.68 The portion of the elliptic paraboloid in Example 10, showing its curve of intersection C with the plane $z = 1$ and its inner normal orientation by \mathbf{n} .

Solution We use Stokes' Theorem to calculate the curl integral by finding the equivalent counterclockwise circulation of \mathbf{F} around the curve of intersection C of the paraboloid $z = x^2 + 4y^2$ and the plane $z = 1$, as shown in Figure 15.68. Note that the orientation of S is consistent with traversing C in a counterclockwise direction around the z -axis. The curve C is the ellipse $x^2 + 4y^2 = 1$ in the plane $z = 1$. We can parametrize the ellipse by $x = \cos t$, $y = \frac{1}{2} \sin t$, $z = 1$ for $0 \leq t \leq 2\pi$, so C is given by

$$\mathbf{r}(t) = (\cos t)\mathbf{i} + \frac{1}{2}(\sin t)\mathbf{j} + \mathbf{k}, \quad 0 \leq t \leq 2\pi.$$

To compute the circulation integral $\oint_C \mathbf{F} \cdot d\mathbf{r}$, we evaluate \mathbf{F} along C and find the velocity vector $d\mathbf{r}/dt$:

$$\mathbf{F}(\mathbf{r}(t)) = \frac{1}{2}(\sin t)\mathbf{i} - (\cos t)\mathbf{j} + (\cos t)\mathbf{k}$$

and

$$\frac{d\mathbf{r}}{dt} = -(\sin t)\mathbf{i} + \frac{1}{2}(\cos t)\mathbf{j}.$$

Then

$$\begin{aligned}\oint_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt} dt \\ &= \int_0^{2\pi} \left(-\frac{1}{2} \sin^2 t - \frac{1}{2} \cos^2 t \right) dt \\ &= -\frac{1}{2} \int_0^{2\pi} dt = -\pi.\end{aligned}$$

Therefore, by Stokes' Theorem the flux of the curl across S in the direction \mathbf{n} for the field \mathbf{F} is

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma = -\pi. \quad \blacksquare$$

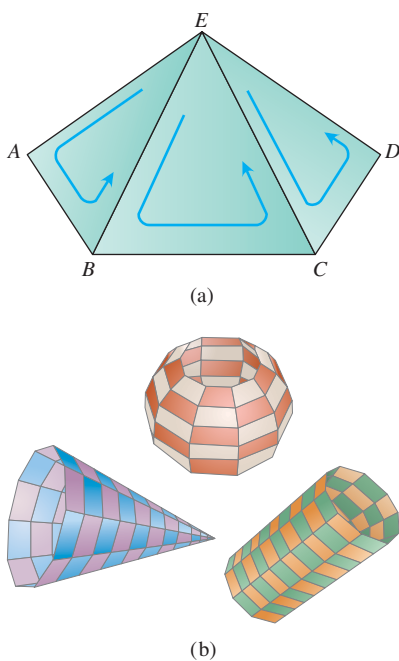

FIGURE 15.69 (a) Part of a polyhedral surface. (b) Other polyhedral surfaces.

Proof Outline of Stokes' Theorem for Polyhedral Surfaces

Let S be a polyhedral surface consisting of a finite number of plane regions or faces. (See Figure 15.69 for examples.) We apply Green's Theorem to each separate face of S . There are two types of faces:

1. Those that are surrounded on all sides by other faces.
2. Those that have one or more edges that are not adjacent to other faces.

The boundary of S consists of those edges of the type 2 faces that are not adjacent to other faces. In Figure 15.69a, the triangles EAB , BCE , and CDE represent a part of S , with $ABCD$ part of the boundary of the surface, boundary(S). Although Green's Theorem was stated for curves in the xy -plane, a generalized form applies to curves that lie in a plane in space. In the generalized form, the theorem asserts that the line integral of \mathbf{F} around the curve enclosing the plane region R normal to \mathbf{n} equals the double integral of $(\text{curl } \mathbf{F}) \cdot \mathbf{n}$ over R . Applying this generalized form to the three triangles of Figure 15.69a in turn, and adding the results, gives

$$\left(\oint_{EAB} + \oint_{BCE} + \oint_{CDE} \right) \mathbf{F} \cdot d\mathbf{r} = \left(\iint_{EAB} + \iint_{BCE} + \iint_{CDE} \right) (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma. \quad (7)$$

The three line integrals on the left-hand side of Equation (7) combine into a single line integral taken around the periphery $ABCDE$ because the integrals along interior segments cancel in pairs. For example, the integral along segment BE in triangle ABE is opposite in sign to the integral along the same segment in triangle EBC . The same holds for segment CE . Hence, Equation (7) reduces to

$$\oint_{ABCDE} \mathbf{F} \cdot d\mathbf{r} = \iint_{ABCDE} (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma.$$

When we apply Green's Theorem to all the faces and add the results, we get

$$\oint_{\text{boundary}(S)} \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma.$$

This is Stokes' Theorem for the polyhedral surface S in Figure 15.69a. More general polyhedral surfaces are shown in Figure 15.69b, and the proof can be extended to them. General smooth surfaces can be obtained as limits of polyhedral surfaces.

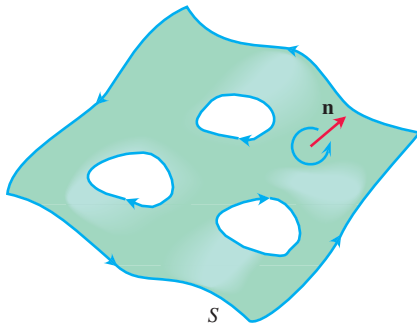

FIGURE 15.70 Stokes' Theorem also holds for oriented surfaces with holes. Consistent with the orientation of S , the outer curve is traversed counterclockwise around \mathbf{n} , and the inner curves surrounding the holes are traversed clockwise.

Stokes' Theorem for Surfaces with Holes

Stokes' Theorem holds for an oriented surface S that has one or more holes (Figure 15.70). The surface integral over S of the normal component of $\nabla \times \mathbf{F}$ equals the sum of the line integrals around all the boundary curves of the tangential component of \mathbf{F} , where the curves are to be traced in the direction induced by the orientation of S . For such surfaces the theorem is unchanged, but C is considered as a union of simple closed curves.

An Important Identity

The following identity arises frequently in mathematics and the physical sciences.

$$\text{curl grad } f = \mathbf{0} \quad \text{or} \quad \nabla \times \nabla f = \mathbf{0} \quad (8)$$

Forces arising in the study of electromagnetism and gravity are often associated with a potential function f . The identity (8) says that these forces have curl equal to zero. The identity (8) holds for any function $f(x, y, z)$ whose second partial derivatives are continuous. The proof goes like this:

$$\nabla \times \nabla f = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} & \frac{\partial f}{\partial z} \end{vmatrix} = (f_{zy} - f_{yz})\mathbf{i} - (f_{zx} - f_{xz})\mathbf{j} + (f_{yx} - f_{xy})\mathbf{k}.$$

If the second partial derivatives are continuous, the mixed second derivatives in parentheses are equal (Theorem 2, Section 13.3) and the vector is zero.

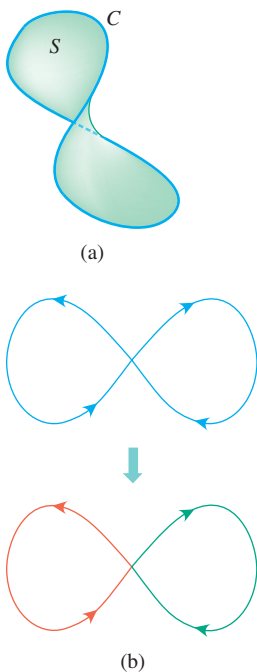

FIGURE 15.71 (a) In a simply connected open region in space, a simple closed curve C is the boundary of a smooth surface S . (b) Smooth curves that cross themselves can be divided into loops to which Stokes' Theorem applies.

Conservative Fields and Stokes' Theorem

In Section 15.3, we found that a field \mathbf{F} being conservative in an open region D in space is equivalent to the integral of \mathbf{F} around every closed loop in D being zero. This, in turn, is equivalent in *simply connected* open regions to saying that $\nabla \times \mathbf{F} = \mathbf{0}$ (which gives a test for determining whether \mathbf{F} is conservative for such regions).

THEOREM 7—Curl $\mathbf{F} = \mathbf{0}$ Related to the Closed-Loop Property

If $\nabla \times \mathbf{F} = \mathbf{0}$ at every point of a simply connected open region D in space, then on any piecewise-smooth closed path C in D ,

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = 0.$$

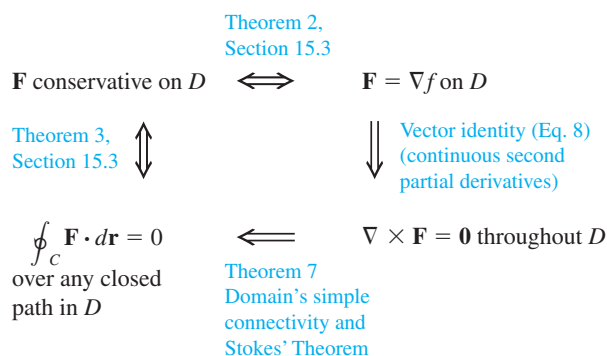

Sketch of a Proof Theorem 7 can be proved in two steps. The first step is for simple closed curves (loops that do not cross themselves), like the one in Figure 15.71a. A theorem from topology, a branch of advanced mathematics, states that every smooth simple closed

curve C in a simply connected open region D is the boundary of a smooth two-sided surface S that also lies in D . Hence, by Stokes' Theorem,

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma = 0.$$

The second step is for curves that cross themselves, like the one in Figure 15.71b. The idea is to break these into simple loops spanned by orientable surfaces, apply Stokes' Theorem one loop at a time, and add the results.

The following diagram summarizes the results for conservative fields defined on connected, simply connected open regions. For such regions, the four statements are equivalent to each other.

EXERCISES 15.7

In Exercises 1–6, find the curl of each vector field \mathbf{F} .

1. $\mathbf{F} = (x + y - z)\mathbf{i} + (2x - y + 3z)\mathbf{j} + (3x + 2y + z)\mathbf{k}$
2. $\mathbf{F} = (x^2 - y)\mathbf{i} + (y^2 - z)\mathbf{j} + (z^2 - x)\mathbf{k}$
3. $\mathbf{F} = (xy + z)\mathbf{i} + (yz + x)\mathbf{j} + (xz + y)\mathbf{k}$
4. $\mathbf{F} = ye^z\mathbf{i} + ze^x\mathbf{j} - xe^y\mathbf{k}$
5. $\mathbf{F} = x^2yz\mathbf{i} + xy^2z\mathbf{j} + xyz^2\mathbf{k}$
6. $\mathbf{F} = \frac{x}{yz}\mathbf{i} - \frac{y}{xz}\mathbf{j} + \frac{z}{xy}\mathbf{k}$

Using Stokes' Theorem to Find Line Integrals

In Exercises 7–12, use the surface integral in Stokes' Theorem to calculate the circulation of the field \mathbf{F} around the curve C in the indicated direction.

7. $\mathbf{F} = x^2\mathbf{i} + 2x\mathbf{j} + z^2\mathbf{k}$
 C : The ellipse $4x^2 + y^2 = 4$ in the xy -plane, counterclockwise when viewed from above
8. $\mathbf{F} = 2y\mathbf{i} + 3x\mathbf{j} - z^2\mathbf{k}$
 C : The circle $x^2 + y^2 = 9$ in the xy -plane, counterclockwise when viewed from above
9. $\mathbf{F} = y\mathbf{i} + xz\mathbf{j} + x^2\mathbf{k}$
 C : The boundary of the triangle cut from the plane $x + y + z = 1$ by the first octant, counterclockwise when viewed from above
10. $\mathbf{F} = (y^2 + z^2)\mathbf{i} + (x^2 + z^2)\mathbf{j} + (x^2 + y^2)\mathbf{k}$
 C : The boundary of the triangle cut from the plane $x + y + z = 1$ by the first octant, counterclockwise when viewed from above

$$11. \mathbf{F} = (y^2 + z^2)\mathbf{i} + (x^2 + y^2)\mathbf{j} + (x^2 + y^2)\mathbf{k}$$

C : The square bounded by the lines $x = \pm 1$ and $y = \pm 1$ in the xy -plane, counterclockwise when viewed from above

$$12. \mathbf{F} = x^2y^3\mathbf{i} + \mathbf{j} + z\mathbf{k}$$

C : The intersection of the cylinder $x^2 + y^2 = 4$ and the hemisphere $x^2 + y^2 + z^2 = 16$, $z \geq 0$, counterclockwise when viewed from above

Integral of the Curl Vector Field

13. Let \mathbf{n} be the unit normal in the direction away from the origin of the elliptic shell

$$S: 4x^2 + 9y^2 + 36z^2 = 36, \quad z \geq 0,$$

and let

$$\mathbf{F} = y\mathbf{i} + x^2\mathbf{j} + (x^2 + y^4)^{3/2} \sin e^{\sqrt{xyz}} \mathbf{k}.$$

Find the value of

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma.$$

(Hint: One parametrization of the ellipse at the base of the shell is $x = 3 \cos t$, $y = 2 \sin t$, $0 \leq t \leq 2\pi$.)

14. Let \mathbf{n} be the unit normal in the direction away from the origin of the parabolic shell

$$S: 4x^2 + y + z^2 = 4, \quad y \geq 0,$$

and let

$$\mathbf{F} = \left(-z + \frac{1}{2+x}\right)\mathbf{i} + (\tan^{-1}y)\mathbf{j} + \left(x + \frac{1}{4+z}\right)\mathbf{k}.$$

Find the value of

$$\iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma.$$

15. Let S be the cylinder $x^2 + y^2 = a^2$, $0 \leq z \leq h$, together with its top, $x^2 + y^2 \leq a^2$, $z = h$. Let $\mathbf{F} = -y\mathbf{i} + x\mathbf{j} + x^2\mathbf{k}$. Use Stokes' Theorem to find the flux of $\nabla \times \mathbf{F}$ through S in the direction away from the origin.

16. Evaluate

$$\iint_S (\nabla \times (y\mathbf{i})) \cdot \mathbf{n} \, d\sigma,$$

where S is the hemisphere $x^2 + y^2 + z^2 = 1$, $z \geq 0$, in the direction away from the origin.

17. Suppose $\mathbf{F} = \nabla \times \mathbf{A}$, where

$$\mathbf{A} = (y + z^2)\mathbf{i} + e^{-xyz}\mathbf{j} + \cos(xz)\mathbf{k}.$$

Determine the flux of \mathbf{F} through the hemisphere $x^2 + y^2 + z^2 = 1$, $z \geq 0$, in the direction away from the origin.

18. Repeat Exercise 17 for the flux of \mathbf{F} across the entire unit sphere.

Stokes' Theorem for Parametrized Surfaces

In Exercises 19–24, use the surface integral in Stokes' Theorem to calculate the flux of the curl of the field \mathbf{F} across the surface S .

19. $\mathbf{F} = 2z\mathbf{i} + 3x\mathbf{j} + 5y\mathbf{k}$

S : $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + (4 - r^2)\mathbf{k}$,
 $0 \leq r \leq 2$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the origin.

20. $\mathbf{F} = (y - z)\mathbf{i} + (z - x)\mathbf{j} + (x + z)\mathbf{k}$

S : $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + (9 - r^2)\mathbf{k}$,
 $0 \leq r \leq 3$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the origin.

21. $\mathbf{F} = x^2y\mathbf{i} + 2y^3z\mathbf{j} + 3z\mathbf{k}$

S : $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + r\mathbf{k}$,
 $0 \leq r \leq 1$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the z -axis.

22. $\mathbf{F} = (x - y)\mathbf{i} + (y - z)\mathbf{j} + (z - x)\mathbf{k}$

S : $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + (5 - r)\mathbf{k}$,
 $0 \leq r \leq 5$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the z -axis.

23. $\mathbf{F} = 3y\mathbf{i} + (5 - 2x)\mathbf{j} + (z^2 - 2)\mathbf{k}$

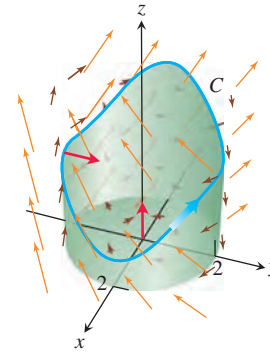

S : $\mathbf{r}(\phi, \theta) = (\sqrt{3} \sin \phi \cos \theta)\mathbf{i} + (\sqrt{3} \sin \phi \sin \theta)\mathbf{j} + (\sqrt{3} \cos \phi)\mathbf{k}$,
 $0 \leq \phi \leq \pi/2$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the origin.

24. $\mathbf{F} = y^2\mathbf{i} + z^2\mathbf{j} + x\mathbf{k}$

S : $\mathbf{r}(\phi, \theta) = (2 \sin \phi \cos \theta)\mathbf{i} + (2 \sin \phi \sin \theta)\mathbf{j} + (2 \cos \phi)\mathbf{k}$,
 $0 \leq \phi \leq \pi/2$, $0 \leq \theta \leq 2\pi$,
 in the direction away from the origin.

Theory and Examples

25. Let C be the smooth curve $\mathbf{r}(t) = (2 \cos t)\mathbf{i} + (2 \sin t)\mathbf{j} + (3 - 2 \cos^3 t)\mathbf{k}$, oriented to be traversed counterclockwise around the z -axis when viewed from above. Let S be the piecewise smooth cylindrical surface $x^2 + y^2 = 4$, below the curve for $z \geq 0$, together with the base disk in the xy -plane. Note that C lies on the cylinder S and above the xy -plane (see the accompanying figure). Verify Equation (4) in Stokes' Theorem for the vector field $\mathbf{F} = y\mathbf{i} - x\mathbf{j} + x^2\mathbf{k}$.

26. Verify Stokes' Theorem for the vector field $\mathbf{F} = 2xy\mathbf{i} + x\mathbf{j} + (y + z)\mathbf{k}$ and surface $z = 4 - x^2 - y^2$, $z \geq 0$, oriented with unit normal \mathbf{n} pointing upward.

27. **Zero circulation** Use Equation (8) and Stokes' Theorem to show that the circulations of the following fields around the boundary of any smooth orientable surface in space are zero.

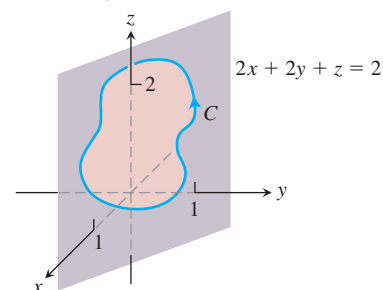

a. $\mathbf{F} = 2x\mathbf{i} + 2y\mathbf{j} + 2z\mathbf{k}$ b. $\mathbf{F} = \nabla(xy^2z^3)$
 c. $\mathbf{F} = \nabla \times (x\mathbf{i} + y\mathbf{j} + z\mathbf{k})$ d. $\mathbf{F} = \nabla f$

28. **Zero circulation** Let $f(x, y, z) = (x^2 + y^2 + z^2)^{-1/2}$. Show that the clockwise circulation of the field $\mathbf{F} = \nabla f$ around the circle $x^2 + y^2 = a^2$ in the xy -plane is zero

- a. by taking $\mathbf{r} = (a \cos t)\mathbf{i} + (a \sin t)\mathbf{j}$, $0 \leq t \leq 2\pi$, and integrating $\mathbf{F} \cdot d\mathbf{r}$ over the circle.
 b. by applying Stokes' Theorem.

29. Let C be a simple closed smooth curve in the plane $2x + 2y + z = 2$, oriented as shown here. Show that

$$\oint_C 2y \, dx + 3z \, dy - x \, dz$$

depends only on the area of the region enclosed by C and not on the position or shape of C .

30. Show that if $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$, then $\nabla \times \mathbf{F} = \mathbf{0}$.
 31. Find a vector field with twice-differentiable components whose curl is $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$, or prove that no such field exists.
 32. Does Stokes' Theorem say anything special about circulation in a field whose curl is zero? Give reasons for your answer.

33. Let R be a region in the xy -plane that is bounded by a piecewise smooth simple closed curve C , and suppose that the density is $\delta = 1$ and the moments of inertia of R about the x - and y -axes are known to be I_x and I_y . Evaluate the integral

$$\oint_C \nabla(r^4) \cdot \mathbf{n} \, ds,$$

where $r = \sqrt{x^2 + y^2}$, in terms of I_x and I_y .

34. **Zero curl, yet the field is not conservative** Show that the curl of

$$\mathbf{F} = \frac{-y}{x^2 + y^2} \mathbf{i} + \frac{x}{x^2 + y^2} \mathbf{j} + z \mathbf{k}$$

is zero but that

$$\oint_C \mathbf{F} \cdot d\mathbf{r}$$

is not zero if C is the circle $x^2 + y^2 = 1$ in the xy -plane. (Theorem 7 does not apply here because the domain of \mathbf{F} is not simply connected. The field \mathbf{F} is not defined along the z -axis, so there is no way to contract C to a point without leaving the domain of \mathbf{F} .)

15.8 The Divergence Theorem and a Unified Theory

The divergence form of Green's Theorem in the plane states that the net outward flux of a vector field across a simple closed curve can be calculated by integrating the divergence of the field over the region enclosed by the curve. The corresponding theorem in three dimensions, called the *Divergence Theorem*, states that the net outward flux of a vector field across a closed surface in space can be calculated by integrating the divergence of the field over the solid region enclosed by the surface. In this section we prove the Divergence Theorem and show how it simplifies the calculation of flux, which is the integral of the field over the closed oriented surface. We also derive Gauss's law for flux in an electric field and the continuity equation of hydrodynamics. Finally, we summarize the chapter's vector integral theorems in a single unifying principle generalizing the Fundamental Theorem of Calculus.

Divergence in Three Dimensions

The **divergence** of a vector field $\mathbf{F} = M(x, y, z)\mathbf{i} + N(x, y, z)\mathbf{j} + P(x, y, z)\mathbf{k}$ is the scalar function

$$\operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F} = \frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} + \frac{\partial P}{\partial z}. \quad (1)$$

The symbol “ $\operatorname{div} \mathbf{F}$ ” is read as “divergence of \mathbf{F} ” or “ $\operatorname{div} \mathbf{F}$.” The notation $\nabla \cdot \mathbf{F}$ is read “del dot \mathbf{F} .”

$\operatorname{Div} \mathbf{F}$ has the same physical interpretation in three dimensions as it has in two. If \mathbf{F} is the velocity field of a flowing gas, the value of $\operatorname{div} \mathbf{F}$ at a point (x, y, z) is the rate at which the gas is compressing or expanding at (x, y, z) . The gas is expanding if $\operatorname{div} \mathbf{F}$ is positive and compressing if $\operatorname{div} \mathbf{F}$ is negative. The divergence is the flux per unit volume, or *flux density*, at the point.

EXAMPLE 1 The following vector fields represent the velocity of a gas flowing in space. Find the divergence of each vector field and interpret its physical meaning. Figure 15.72 displays the vector fields.

- (a) Expansion: $\mathbf{F}(x, y, z) = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$
- (b) Compression: $\mathbf{F}(x, y, z) = -x\mathbf{i} - y\mathbf{j} - z\mathbf{k}$
- (c) Rotation about the z -axis: $\mathbf{F}(x, y, z) = -y\mathbf{i} + x\mathbf{j}$
- (d) Shearing along parallel horizontal planes: $\mathbf{F}(x, y, z) = z\mathbf{j}$

Solution

- (a) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 3$: The gas is undergoing constant uniform expansion at all points.

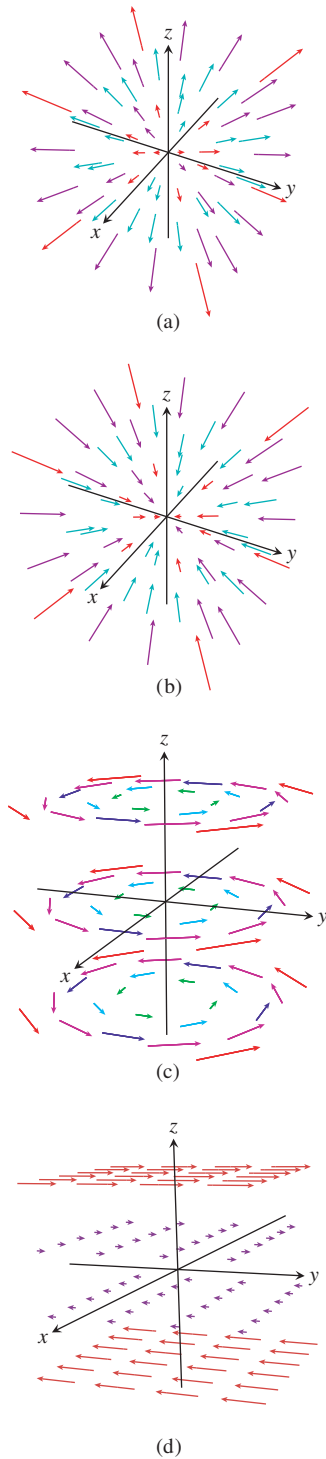

FIGURE 15.72 Velocity fields of a gas flowing in space (Example 1).

- (b) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(-x) + \frac{\partial}{\partial y}(-y) + \frac{\partial}{\partial z}(-z) = -3$: The gas is undergoing constant uniform compression at all points.
- (c) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(-y) + \frac{\partial}{\partial y}(x) = 0$: The gas is neither expanding nor compressing at any point.
- (d) $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial y}(z) = 0$: Again, the divergence is zero at all points in the domain of the velocity field, so the gas is neither expanding nor compressing at any point. ■

Divergence Theorem

The Divergence Theorem says that under suitable conditions, the outward flux of a vector field across a closed surface equals the triple integral of the divergence of the field over the three-dimensional region enclosed by the surface.

THEOREM 8—Divergence Theorem

Let \mathbf{F} be a vector field whose components have continuous first partial derivatives, and let S be a piecewise smooth oriented closed surface. The flux of \mathbf{F} across S in the direction of the surface's outward unit normal field \mathbf{n} equals the triple integral of the divergence $\nabla \cdot \mathbf{F}$ over the solid region D enclosed by the surface:

$$\underbrace{\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma}_{\text{Outward flux}} = \underbrace{\iiint_D \nabla \cdot \mathbf{F} \, dV}_{\text{Divergence integral}}. \quad (2)$$

EXAMPLE 2 Evaluate both sides of Equation (2) for the expanding vector field $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ over the sphere $x^2 + y^2 + z^2 = a^2$ (Figure 15.73).

Solution The outer unit normal to S , calculated from the gradient of $f(x, y, z) = x^2 + y^2 + z^2 - a^2$, is

$$\mathbf{n} = \frac{2(x\mathbf{i} + y\mathbf{j} + z\mathbf{k})}{\sqrt{4(x^2 + y^2 + z^2)}} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{a}. \quad x^2 + y^2 + z^2 = a^2 \text{ on } S$$

It follows that

$$\mathbf{F} \cdot \mathbf{n} \, d\sigma = \frac{x^2 + y^2 + z^2}{a} \, d\sigma = \frac{a^2}{a} \, d\sigma = a \, d\sigma.$$

Therefore, the outward flux is

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iint_S a \, d\sigma = a \iint_S d\sigma = a(4\pi a^2) = 4\pi a^3. \quad \text{Area of } S \text{ is } 4\pi a^2.$$

For the right-hand side of Equation (2), the divergence of \mathbf{F} is

$$\nabla \cdot \mathbf{F} = \frac{\partial}{\partial x}(x) + \frac{\partial}{\partial y}(y) + \frac{\partial}{\partial z}(z) = 3,$$

so we obtain the divergence integral,

$$\iiint_D \nabla \cdot \mathbf{F} \, dV = \iiint_D 3 \, dV = 3 \left(\frac{4}{3} \pi a^3 \right) = 4\pi a^3. \quad \blacksquare$$

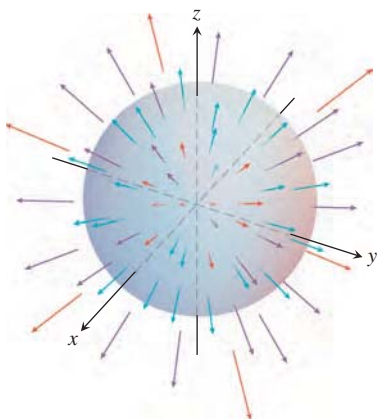

FIGURE 15.73 A uniformly expanding vector field and a sphere (Example 2).

Many vector fields of interest in applied science have zero divergence at each point. A common example is the velocity field of a circulating incompressible liquid, since it is neither expanding nor contracting. Other examples include constant vector fields $\mathbf{F} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$, and velocity fields for shearing action along a fixed plane (see Example 1d). If \mathbf{F} is a vector field whose divergence is zero at each point in the region D , then the integral on the right-hand side of Equation (2) equals 0. So if S is any closed surface for which the Divergence Theorem applies, then the outward flux of \mathbf{F} across S is zero. We state this important application of the Divergence Theorem.

COROLLARY The outward flux across a piecewise smooth oriented closed surface S is zero for any vector field \mathbf{F} having zero divergence at every point of the region enclosed by the surface.

EXAMPLE 3 Find the flux of $\mathbf{F} = xy\mathbf{i} + yz\mathbf{j} + xz\mathbf{k}$ outward through the surface of the cube cut from the first octant by the planes $x = 1$, $y = 1$, and $z = 1$.

Solution Instead of calculating the flux as a sum of six separate integrals, one for each face of the cube, we can calculate the flux by integrating the divergence

$$\nabla \cdot \mathbf{F} = \frac{\partial}{\partial x}(xy) + \frac{\partial}{\partial y}(yz) + \frac{\partial}{\partial z}(xz) = y + z + x$$

over the cube's interior:

$$\begin{aligned} \text{Flux} &= \iint_{\text{Cube surface}} \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iiint_{\text{Cube interior}} \nabla \cdot \mathbf{F} \, dV && \text{The Divergence Theorem} \\ &= \int_0^1 \int_0^1 \int_0^1 (x + y + z) \, dx \, dy \, dz = \frac{3}{2}. && \text{Routine integration} \quad \blacksquare \end{aligned}$$

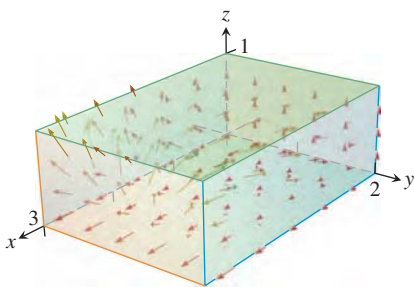

FIGURE 15.74 The integral of $\text{div } \mathbf{F}$ over this region equals the total flux across the six sides (Example 4).

EXAMPLE 4

(a) Calculate the flux of the vector field

$$\mathbf{F} = x^2\mathbf{i} + 4xyz\mathbf{j} + ze^x\mathbf{k}$$

out of the box-shaped region $D: 0 \leq x \leq 3, 0 \leq y \leq 2, 0 \leq z \leq 1$. (See Figure 15.74.)

(b) Integrate $\text{div } \mathbf{F}$ over this region and show that the result is the same value as in part (a), as asserted by the Divergence Theorem.

Solution

(a) The region D has six sides. We calculate the flux across each side in turn. Consider the top side in the plane $z = 1$, having outward normal $\mathbf{n} = \mathbf{k}$. The flux across this side is given by $\mathbf{F} \cdot \mathbf{n} = ze^x$. Since $z = 1$ on this side, the flux at a point (x, y, z) on the top is e^x . The total outward flux across this side is given by the surface integral

$$\int_0^2 \int_0^3 e^x \, dx \, dy = 2e^3 - 2. \quad \text{Routine integration}$$

The outward flux across the other sides is computed similarly, and the results are summarized in the following table.

Side	Unit normal \mathbf{n}	$\mathbf{F} \cdot \mathbf{n}$	Flux across side
$x = 0$	$-\mathbf{i}$	$-x^2 = 0$	0
$x = 3$	\mathbf{i}	$x^2 = 9$	18
$y = 0$	$-\mathbf{j}$	$-4xyz = 0$	0
$y = 2$	\mathbf{j}	$4xyz = 8xz$	18
$z = 0$	$-\mathbf{k}$	$-ze^x = 0$	0
$z = 1$	\mathbf{k}	$ze^x = e^x$	$2e^3 - 2$

The total outward flux is obtained by adding the terms for each of the six sides:

$$18 + 18 + 2e^3 - 2 = 34 + 2e^3.$$

(b) We first compute the divergence of \mathbf{F} , obtaining

$$\operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F} = 2x + 4xz + e^x.$$

The integral of the divergence of \mathbf{F} over D is

$$\begin{aligned} \iiint_D \operatorname{div} \mathbf{F} \, dV &= \int_0^1 \int_0^2 \int_0^3 (2x + 4xz + e^x) \, dx \, dy \, dz \\ &= \int_0^1 \int_0^2 (8 + 18z + e^3) \, dy \, dz \\ &= \int_0^1 (16 + 36z + 2e^3) \, dz \\ &= 34 + 2e^3. \end{aligned}$$

As asserted by the Divergence Theorem, the integral of the divergence over D equals the outward flux across the boundary surface of D . ■

Divergence and the Curl

If \mathbf{F} is a vector field on three-dimensional space, then the curl $\nabla \times \mathbf{F}$ is also a vector field on three-dimensional space. So we can calculate the divergence of $\nabla \times \mathbf{F}$ using Equation (1). The result of this calculation is always 0.

THEOREM 9 If $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ is a vector field with continuous second partial derivatives, then

$$\operatorname{div}(\operatorname{curl} \mathbf{F}) = \nabla \cdot (\nabla \times \mathbf{F}) = 0.$$

Proof From the definitions of the divergence and curl, we have

$$\begin{aligned} \operatorname{div}(\operatorname{curl} \mathbf{F}) &= \nabla \cdot (\nabla \times \mathbf{F}) \\ &= \frac{\partial}{\partial x} \left(\frac{\partial P}{\partial y} - \frac{\partial N}{\partial z} \right) + \frac{\partial}{\partial y} \left(\frac{\partial M}{\partial z} - \frac{\partial P}{\partial x} \right) + \frac{\partial}{\partial z} \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) \\ &= \frac{\partial^2 P}{\partial x \partial y} - \frac{\partial^2 N}{\partial x \partial z} + \frac{\partial^2 M}{\partial y \partial z} - \frac{\partial^2 P}{\partial y \partial x} + \frac{\partial^2 N}{\partial z \partial x} - \frac{\partial^2 M}{\partial z \partial y} \\ &= 0, \end{aligned}$$

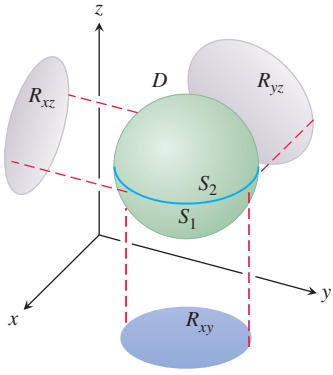

FIGURE 15.75 We prove the Divergence Theorem for the kind of three-dimensional region shown here.

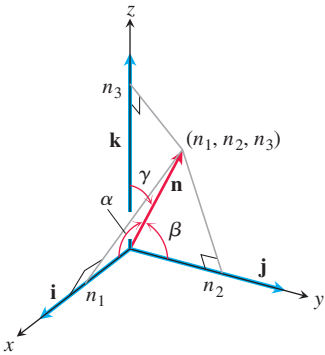

FIGURE 15.76 The components of \mathbf{n} are the cosines of the angles α , β , and γ that it makes with \mathbf{i} , \mathbf{j} , and \mathbf{k} .

because the mixed second partial derivatives cancel by the Mixed Derivative Theorem in Section 13.3. ■

Theorem 9 has some interesting applications. If a vector field $\mathbf{G} = \text{curl } \mathbf{F}$, then the field \mathbf{G} must have divergence 0. Saying this another way, if $\text{div } \mathbf{G} \neq 0$, then \mathbf{G} cannot be the curl of any vector field \mathbf{F} having continuous second partial derivatives. Moreover, if $\mathbf{G} = \text{curl } \mathbf{F}$, then the outward flux of \mathbf{G} across any closed surface S is zero by the corollary to the Divergence Theorem, provided the conditions of the theorem are satisfied. So if there is a closed surface for which the surface integral of the vector field \mathbf{G} is nonzero, we can conclude that \mathbf{G} is *not* the curl of some vector field \mathbf{F} .

Proof of the Divergence Theorem for Special Regions

To prove the Divergence Theorem, we take the components of $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ to have continuous first partial derivatives. We first assume that D is a convex region with no holes or bubbles, such as a solid ball, cube, or ellipsoid, and that S is a piecewise smooth surface. In addition, we assume that any line perpendicular to the xy -plane at an interior point of the region R_{xy} that is the projection of D on the xy -plane intersects the surface S in exactly two points, producing surfaces

$$\begin{aligned} S_1: z &= f_1(x, y), & (x, y) & \text{ in } R_{xy} \\ S_2: z &= f_2(x, y), & (x, y) & \text{ in } R_{xy}, \end{aligned}$$

with $f_1 \leq f_2$. We make similar assumptions about the projection of D onto the other coordinate planes. See Figure 15.75, which illustrates these assumptions.

The components of the unit normal vector $\mathbf{n} = n_1\mathbf{i} + n_2\mathbf{j} + n_3\mathbf{k}$ are the cosines of the angles α , β , and γ that \mathbf{n} makes with \mathbf{i} , \mathbf{j} , and \mathbf{k} (Figure 15.76). This is true because all the vectors involved are unit vectors, giving the *direction cosines*

$$\begin{aligned} n_1 &= \mathbf{n} \cdot \mathbf{i} = |\mathbf{n}||\mathbf{i}|\cos \alpha = \cos \alpha \\ n_2 &= \mathbf{n} \cdot \mathbf{j} = |\mathbf{n}||\mathbf{j}|\cos \beta = \cos \beta \\ n_3 &= \mathbf{n} \cdot \mathbf{k} = |\mathbf{n}||\mathbf{k}|\cos \gamma = \cos \gamma. \end{aligned}$$

Thus the unit normal vector is given by

$$\mathbf{n} = (\cos \alpha)\mathbf{i} + (\cos \beta)\mathbf{j} + (\cos \gamma)\mathbf{k},$$

and

$$\mathbf{F} \cdot \mathbf{n} = M \cos \alpha + N \cos \beta + P \cos \gamma.$$

In component form, the Divergence Theorem states that

$$\iint_S \underbrace{(M \cos \alpha + N \cos \beta + P \cos \gamma)}_{\mathbf{F} \cdot \mathbf{n}} d\sigma = \iiint_D \underbrace{\left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} + \frac{\partial P}{\partial z} \right)}_{\text{div } \mathbf{F}} dx dy dz.$$

We prove the theorem by establishing the following three equations:

$$\iint_S M \cos \alpha d\sigma = \iiint_D \frac{\partial M}{\partial x} dx dy dz \quad (3)$$

$$\iint_S N \cos \beta d\sigma = \iiint_D \frac{\partial N}{\partial y} dx dy dz \quad (4)$$

$$\iint_S P \cos \gamma d\sigma = \iiint_D \frac{\partial P}{\partial z} dx dy dz \quad (5)$$

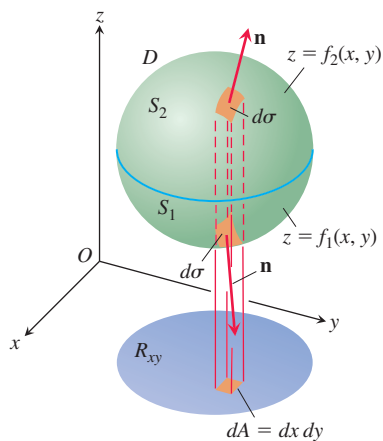

FIGURE 15.77 The region D enclosed by the surfaces S_1 and S_2 projects vertically onto R_{xy} in the xy -plane.

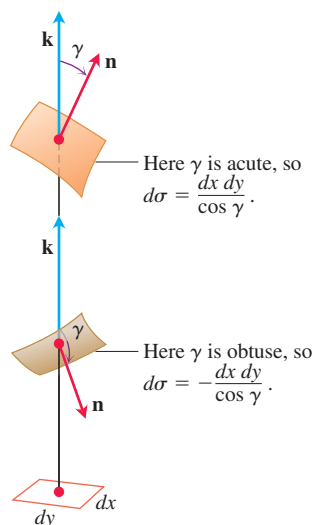

FIGURE 15.78 An enlarged view of the area patches in Figure 15.77. The relations $d\sigma = \pm dx dy / \cos \gamma$ come from Eq. (7) in Section 15.5 with $F = \mathbf{F} \cdot \mathbf{n}$.

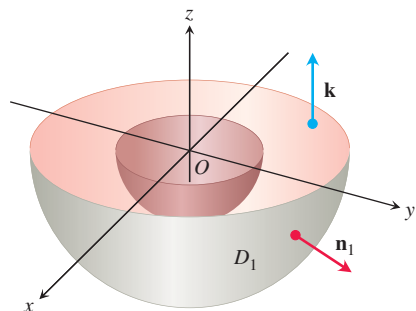

FIGURE 15.79 The lower half of the solid region between two concentric spheres.

Proof of Equation (5) We prove Equation (5) by converting the surface integral on the left to a double integral over the projection R_{xy} of D on the xy -plane (Figure 15.77). The surface S consists of an upper part S_2 whose equation is $z = f_2(x, y)$ and a lower part S_1 whose equation is $z = f_1(x, y)$. On S_2 , the outer normal \mathbf{n} has a positive \mathbf{k} -component and

$$\cos \gamma \, d\sigma = dx \, dy \quad \text{because} \quad d\sigma = \frac{dA}{|\cos \gamma|} = \frac{dx \, dy}{\cos \gamma}.$$

See Figure 15.78. On S_1 , the outer normal \mathbf{n} has a negative \mathbf{k} -component and

$$\cos \gamma \, d\sigma = -dx \, dy.$$

Therefore,

$$\begin{aligned} \iint_S P \cos \gamma \, d\sigma &= \iint_{S_2} P \cos \gamma \, d\sigma + \iint_{S_1} P \cos \gamma \, d\sigma \\ &= \iint_{R_{xy}} P(x, y, f_2(x, y)) \, dx \, dy - \iint_{R_{xy}} P(x, y, f_1(x, y)) \, dx \, dy \\ &= \iint_{R_{xy}} [P(x, y, f_2(x, y)) - P(x, y, f_1(x, y))] \, dx \, dy \\ &= \iint_{R_{xy}} \left[\int_{f_1(x, y)}^{f_2(x, y)} \frac{\partial P}{\partial z} \, dz \right] \, dx \, dy = \iiint_D \frac{\partial P}{\partial z} \, dz \, dx \, dy. \end{aligned}$$

This proves Equation (5). The proofs for Equations (3) and (4) follow the same pattern; just permute $x, y, z; M, N, P; \alpha, \beta, \gamma$, in order, and get those results from Equation (5). This proves the Divergence Theorem for these special regions. ■

Divergence Theorem for Other Regions

The Divergence Theorem can be extended to regions that can be partitioned into a finite number of simple regions of the type just discussed and to regions that can be defined as limits of simpler regions in certain ways. For an example of one step in such a splitting process, suppose that D is the region between two concentric spheres and that \mathbf{F} has continuously differentiable components throughout D and on the bounding surfaces. Split D by an equatorial plane and apply the Divergence Theorem to each half separately. The bottom half, D_1 , is shown in Figure 15.79. The surface S_1 that bounds D_1 consists of an outer hemisphere, a plane washer-shaped base, and an inner hemisphere. The Divergence Theorem says that

$$\iint_{S_1} \mathbf{F} \cdot \mathbf{n}_1 \, d\sigma = \iiint_{D_1} \nabla \cdot \mathbf{F} \, dV. \tag{6}$$

The unit normal \mathbf{n}_1 that points outward from D_1 points away from the origin along the outer surface, equals \mathbf{k} along the flat base, and points toward the origin along the inner surface. Next apply the Divergence Theorem to D_2 and its surface S_2 (Figure 15.80):

$$\iint_{S_2} \mathbf{F} \cdot \mathbf{n}_2 \, d\sigma = \iiint_{D_2} \nabla \cdot \mathbf{F} \, dV. \tag{7}$$

As we follow \mathbf{n}_2 over S_2 , pointing outward from D_2 , we see that \mathbf{n}_2 equals $-\mathbf{k}$ along the washer-shaped base in the xy -plane, points away from the origin on the outer sphere, and points toward the origin on the inner sphere. When we add Equations (6) and (7), the integrals over the flat base cancel because of the opposite signs of \mathbf{n}_1 and \mathbf{n}_2 . We thus arrive at the result

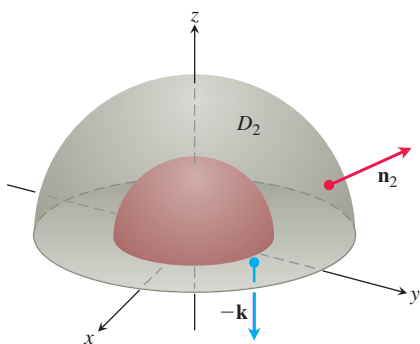

FIGURE 15.80 The upper half of the solid region between two concentric spheres.

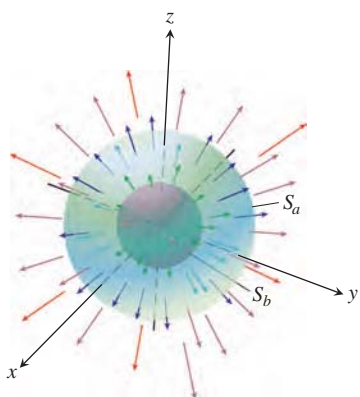

FIGURE 15.81 Two concentric spheres in an expanding vector field. The outer sphere S_a surrounds the inner sphere S_b .

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iiint_D \nabla \cdot \mathbf{F} \, dV,$$

with D the region between the spheres, S the boundary of D consisting of two spheres, and \mathbf{n} the unit normal to S directed outward from D .

EXAMPLE 5 Find the net outward flux of the field

$$\mathbf{F} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{\rho^3}, \quad \rho = \sqrt{x^2 + y^2 + z^2} \quad (8)$$

across the boundary of the region $D: 0 < b^2 \leq x^2 + y^2 + z^2 \leq a^2$ (Figure 15.81).

Solution The flux can be calculated by integrating $\nabla \cdot \mathbf{F}$ over D . Note that $\rho \neq 0$ in D . We have

$$\frac{\partial \rho}{\partial x} = \frac{1}{2}(x^2 + y^2 + z^2)^{-1/2}(2x) = \frac{x}{\rho}$$

and

$$\frac{\partial M}{\partial x} = \frac{\partial}{\partial x}(x\rho^{-3}) = \rho^{-3} - 3x\rho^{-4}\frac{\partial \rho}{\partial x} = \frac{1}{\rho^3} - \frac{3x^2}{\rho^5}.$$

Similarly,

$$\frac{\partial N}{\partial y} = \frac{1}{\rho^3} - \frac{3y^2}{\rho^5} \quad \text{and} \quad \frac{\partial P}{\partial z} = \frac{1}{\rho^3} - \frac{3z^2}{\rho^5}.$$

Hence,

$$\operatorname{div} \mathbf{F} = \frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} + \frac{\partial P}{\partial z} = \frac{3}{\rho^3} - \frac{3}{\rho^5}(x^2 + y^2 + z^2) = \frac{3}{\rho^3} - \frac{3\rho^2}{\rho^5} = 0.$$

So the net outward flux of \mathbf{F} across the boundary of D is zero by the corollary to the Divergence Theorem. There is more to learn about this vector field \mathbf{F} , though. The flux leaving D across the inner sphere S_b is the negative of the flux leaving D across the outer sphere S_a (because the sum of these fluxes is zero). Hence, the flux of \mathbf{F} across S_b in the direction away from the origin equals the flux of \mathbf{F} across S_a in the direction away from the origin. Thus, the flux of \mathbf{F} across a sphere centered at the origin is independent of the radius of the sphere. What is this flux?

To find it, we evaluate the flux integral directly for an arbitrary sphere S_a . The outward unit normal on the sphere of radius a is

$$\mathbf{n} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{\sqrt{x^2 + y^2 + z^2}} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{a}.$$

Hence, on the sphere,

$$\mathbf{F} \cdot \mathbf{n} = \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{a^3} \cdot \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{a} = \frac{x^2 + y^2 + z^2}{a^4} = \frac{a^2}{a^4} = \frac{1}{a^2}$$

and

$$\iint_{S_a} \mathbf{F} \cdot \mathbf{n} \, d\sigma = \frac{1}{a^2} \iint_{S_a} d\sigma = \frac{1}{a^2}(4\pi a^2) = 4\pi.$$

The outward flux of \mathbf{F} in Equation (8) across any sphere centered at the origin is 4π . This result does not contradict the Divergence Theorem because \mathbf{F} is not continuous at the origin. ■

Gauss's Law: One of the Four Great Laws of Electromagnetic Theory

In electromagnetic theory, the electric field created by a point charge q located at the origin is

$$\mathbf{E}(x, y, z) = \frac{1}{4\pi\epsilon_0} \frac{q}{|\mathbf{r}|^2} \left(\frac{\mathbf{r}}{|\mathbf{r}|} \right) = \frac{q}{4\pi\epsilon_0} \frac{\mathbf{r}}{|\mathbf{r}|^3} = \frac{q}{4\pi\epsilon_0} \frac{x\mathbf{i} + y\mathbf{j} + z\mathbf{k}}{\rho^3},$$

where ϵ_0 is a physical constant, \mathbf{r} is the position vector of the point (x, y, z) , and $\rho = |\mathbf{r}| = \sqrt{x^2 + y^2 + z^2}$. From Equation (8),

$$\mathbf{E} = \frac{q}{4\pi\epsilon_0} \mathbf{F}.$$

The calculations in Example 5 show that the outward flux of \mathbf{E} across any sphere centered at the origin is q/ϵ_0 , but this result is not confined to spheres. The outward flux of \mathbf{E} across any closed surface S that encloses the origin (and to which the Divergence Theorem applies) is also q/ϵ_0 . To see why, we have only to imagine a large sphere S_a centered at the origin and enclosing the surface S (see Figure 15.82). Because

$$\nabla \cdot \mathbf{E} = \nabla \cdot \frac{q}{4\pi\epsilon_0} \mathbf{F} = \frac{q}{4\pi\epsilon_0} \nabla \cdot \mathbf{F} = 0$$

when $\rho > 0$, the triple integral of $\nabla \cdot \mathbf{E}$ over the region D between S and S_a is zero. Hence, by the Divergence Theorem,

$$\iint_{\text{Boundary of } D} \mathbf{E} \cdot \mathbf{n} \, d\sigma = 0.$$

So the flux of \mathbf{E} across S in the direction away from the origin must be the same as the flux of \mathbf{E} across S_a in the direction away from the origin, which is q/ϵ_0 . This statement, called *Gauss's law*, also applies to charge distributions that are more general than the one assumed here, as shown in most physics texts. For any closed surface that encloses the origin, we have

$$\text{Gauss's law: } \iint_S \mathbf{E} \cdot \mathbf{n} \, d\sigma = \frac{q}{\epsilon_0}.$$

Continuity Equation of Hydrodynamics

Let D be a region in space bounded by a closed oriented surface S . If $\mathbf{v}(x, y, z)$ is the velocity field of a fluid flowing smoothly through D , $\delta = \delta(t, x, y, z)$ is the fluid's density at (x, y, z) at time t , and $\mathbf{F} = \delta\mathbf{v}$, then the **continuity equation** of hydrodynamics states that

$$\nabla \cdot \mathbf{F} + \frac{\partial \delta}{\partial t} = 0.$$

If the functions involved have continuous first partial derivatives, the equation evolves naturally from the Divergence Theorem, as we now demonstrate.

First, the integral

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma$$

is the rate at which mass leaves D across S (leaves because \mathbf{n} is the outer normal). To see why, consider a patch of area $\Delta\sigma$ on the surface (Figure 15.83). In a short time interval Δt , the volume ΔV of fluid that flows across the patch is approximately equal to the volume of a cylinder with base area $\Delta\sigma$ and height $(\mathbf{v} \Delta t) \cdot \mathbf{n}$, where \mathbf{v} is a velocity vector rooted at a point of the patch:

$$\Delta V \approx \mathbf{v} \cdot \mathbf{n} \, \Delta\sigma \, \Delta t.$$

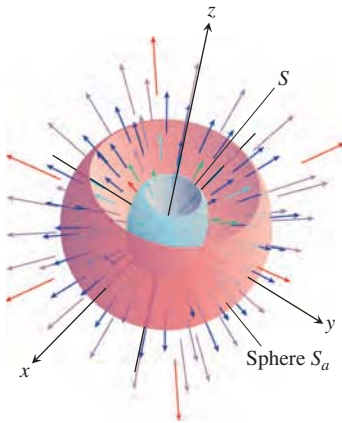

FIGURE 15.82 A sphere S_a surrounding another surface S . The tops of the surfaces are removed for visualization.

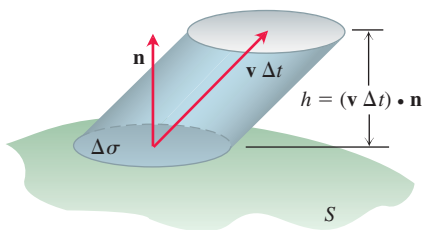

FIGURE 15.83 The fluid that flows upward through the patch $\Delta\sigma$ in a short time Δt fills a "cylinder" whose volume is approximately base \times height $= \mathbf{v} \cdot \mathbf{n} \, \Delta\sigma \, \Delta t$.

The mass of this volume of fluid is about

$$\Delta m \approx \delta \mathbf{v} \cdot \mathbf{n} \Delta \sigma \Delta t,$$

so the rate at which mass is flowing out of D across the patch is about

$$\frac{\Delta m}{\Delta t} \approx \delta \mathbf{v} \cdot \mathbf{n} \Delta \sigma.$$

This leads to the approximation

$$\sum \frac{\Delta m}{\Delta t} \approx \sum \delta \mathbf{v} \cdot \mathbf{n} \Delta \sigma$$

as an estimate of the average rate at which mass flows across S . Finally, letting $\Delta \sigma \rightarrow 0$ and $\Delta t \rightarrow 0$ gives the instantaneous rate at which mass leaves D across S as

$$\frac{dm}{dt} = \iint_S \delta \mathbf{v} \cdot \mathbf{n} d\sigma,$$

which for our particular flow is

$$\frac{dm}{dt} = \iint_S \mathbf{F} \cdot \mathbf{n} d\sigma.$$

Now let B be a solid sphere centered at a point Q in the flow. The average value of $\nabla \cdot \mathbf{F}$ over B is

$$\frac{1}{\text{volume of } B} \iiint_B \nabla \cdot \mathbf{F} dV.$$

It is a consequence of the continuity of the divergence that $\nabla \cdot \mathbf{F}$ actually takes on this value at some point P in B . Thus, by the Divergence Theorem Equation (2),

$$\begin{aligned} (\nabla \cdot \mathbf{F})(P) &= \frac{1}{\text{volume of } B} \iiint_B \nabla \cdot \mathbf{F} dV = \frac{\iint_S \mathbf{F} \cdot \mathbf{n} d\sigma}{\text{volume of } B} \\ &= \frac{\text{rate at which mass leaves } B \text{ across its surface } S}{\text{volume of } B}. \end{aligned} \quad (9)$$

The last term of the equation describes decrease in mass per unit volume.

Now let the radius of B approach zero while the center Q stays fixed. The left side of Equation (9) converges to $(\nabla \cdot \mathbf{F})_Q$, and the right side converges to $(-\partial\delta/\partial t)_Q$, since $\delta = m/V$. The equality of these two limits is the continuity equation

$$\nabla \cdot \mathbf{F} = -\frac{\partial\delta}{\partial t}.$$

The continuity equation “explains” $\nabla \cdot \mathbf{F}$: The divergence of \mathbf{F} at a point is the rate at which the density of the fluid is decreasing there. The Divergence Theorem

$$\iint_S \mathbf{F} \cdot \mathbf{n} d\sigma = \iiint_D \nabla \cdot \mathbf{F} dV$$

now says that the net decrease in density of the fluid in region D (divergence integral) is accounted for by the mass transported across the surface S (outward flux integral). So, the theorem is a statement about conservation of mass (Exercise 35).

Unifying the Integral Theorems

If we think of a two-dimensional field $\mathbf{F} = M(x, y)\mathbf{i} + N(x, y)\mathbf{j}$ as a three-dimensional field whose \mathbf{k} -component is zero, then $\nabla \cdot \mathbf{F} = (\partial M/\partial x) + (\partial N/\partial y)$, and the normal form of Green's Theorem can be written as

$$\oint_C \mathbf{F} \cdot \mathbf{n} \, ds = \iint_R \left(\frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} \right) dx \, dy = \iint_R \nabla \cdot \mathbf{F} \, dA.$$

Similarly, $(\nabla \times \mathbf{F}) \cdot \mathbf{k} = (\partial N/\partial x) - (\partial M/\partial y)$, so the tangential form of Green's Theorem can be written as

$$\oint_C \mathbf{F} \cdot \mathbf{T} \, ds = \iint_R \left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y} \right) dx \, dy = \iint_R (\nabla \times \mathbf{F}) \cdot \mathbf{k} \, dA.$$

With the equations of Green's Theorem expressed in del notation, we can see their relationships to the equations in Stokes' Theorem and the Divergence Theorem, all summarized here.

Green's Theorem and Its Generalization to Three Dimensions

Tangential form of Green's Theorem: $\oint_C \mathbf{F} \cdot \mathbf{T} \, ds = \iint_R (\nabla \times \mathbf{F}) \cdot \mathbf{k} \, dA$

Stokes' Theorem: $\oint_C \mathbf{F} \cdot \mathbf{T} \, ds = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, d\sigma$

Normal form of Green's Theorem: $\oint_C \mathbf{F} \cdot \mathbf{n} \, ds = \iint_R \nabla \cdot \mathbf{F} \, dA$

Divergence Theorem: $\iint_S \mathbf{F} \cdot \mathbf{n} \, d\sigma = \iiint_D \nabla \cdot \mathbf{F} \, dV$

Notice how Stokes' Theorem generalizes the tangential (curl) form of Green's Theorem from a flat surface in the plane to a surface in three-dimensional space. In each case, the surface integral of curl \mathbf{F} over the interior of the oriented surface equals the circulation of \mathbf{F} around the boundary.

Likewise, the Divergence Theorem generalizes the normal (flux) form of Green's Theorem from a two-dimensional region in the plane to a three-dimensional region in space. In each case, the integral of $\nabla \cdot \mathbf{F}$ over the interior of the region equals the total flux of the field across the boundary enclosing the region.

All these results can be thought of as forms of a *single fundamental theorem*. The Fundamental Theorem of Calculus in Section 5.4 says that if $f(x)$ is differentiable on (a, b) and continuous on $[a, b]$, then

$$\int_a^b \frac{df}{dx} dx = f(b) - f(a).$$

If we let $\mathbf{F} = f(x)\mathbf{i}$ throughout $[a, b]$, then $df/dx = \nabla \cdot \mathbf{F}$. If we define the unit vector field \mathbf{n} normal to the boundary of $[a, b]$ to be \mathbf{i} at b and $-\mathbf{i}$ at a (Figure 15.84), then

$$\begin{aligned} f(b) - f(a) &= f(b)\mathbf{i} \cdot (\mathbf{i}) + f(a)\mathbf{i} \cdot (-\mathbf{i}) \\ &= \mathbf{F}(b) \cdot \mathbf{n} + \mathbf{F}(a) \cdot \mathbf{n} \\ &= \text{total outward flux of } \mathbf{F} \text{ across the boundary of } [a, b]. \end{aligned}$$

FIGURE 15.84 The outward unit normals at the boundary of $[a, b]$ in one-dimensional space.

The Fundamental Theorem now says that

$$\mathbf{F}(b) \cdot \mathbf{n} + \mathbf{F}(a) \cdot \mathbf{n} = \int_{[a,b]} \nabla \cdot \mathbf{F} \, dx.$$

The Fundamental Theorem of Calculus, the normal form of Green's Theorem, and the Divergence Theorem all say that the integral of the differential operator $\nabla \cdot$ operating on a field \mathbf{F} over a region equals the sum of the normal field components over the boundary enclosing the region. (Here we are interpreting the line integral in Green's Theorem and the surface integral in the Divergence Theorem as "sums" over the boundary.)

Stokes' Theorem and the tangential form of Green's Theorem say that, when things are properly oriented, the surface integral of the differential operator $\nabla \times$ operating on a field equals the sum of the tangential field components over the boundary of the surface.

The beauty of these interpretations is the observance of a single unifying principle, which we can state as follows.

A Unifying Fundamental Theorem of Vector Integral Calculus

The integral of a differential operator acting on a field over a region equals the sum of the field components appropriate to the operator over the boundary of the region.

EXERCISES 15.8

Calculating Divergence

In Exercises 1–8, find the divergence of the field.

- $\mathbf{F} = (x - y + z)\mathbf{i} + (2x + y - z)\mathbf{j} + (3x + 2y - 2z)\mathbf{k}$
- $\mathbf{F} = (x \ln y)\mathbf{i} + (y \ln z)\mathbf{j} + (z \ln x)\mathbf{k}$
- $\mathbf{F} = ye^{xyz}\mathbf{i} + ze^{xyz}\mathbf{j} + xe^{xyz}\mathbf{k}$
- $\mathbf{F} = \sin(xy)\mathbf{i} + \cos(yz)\mathbf{j} + \tan(xz)\mathbf{k}$
- The spin field in Figure 15.13
- The radial field in Figure 15.12
- The gravitational field in Figure 15.9 and Exercise 38a in Section 15.3
- The velocity field $\mathbf{v}(x, y, z) = (a^2 - x^2 - y^2)\mathbf{k}$ in Figure 15.14

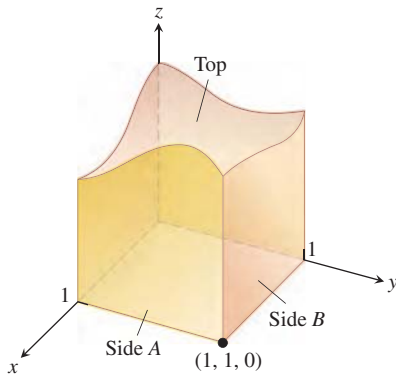

Calculating Flux Using the Divergence Theorem

In Exercises 9–20, use the Divergence Theorem to find the outward flux of \mathbf{F} across the boundary of the region D .

- Cube** $\mathbf{F} = (y - x)\mathbf{i} + (z - y)\mathbf{j} + (y - x)\mathbf{k}$
D: The cube bounded by the planes $x = \pm 1$, $y = \pm 1$, and $z = \pm 1$
- Cube** *D*: The cube cut from the first octant by the planes $x = 1$, $y = 1$, and $z = 1$
- Cylindrical can** *D*: The region cut from the solid cylinder $x^2 + y^2 \leq 4$ by the planes $z = 0$ and $z = 1$
- Cylinder and paraboloid** $\mathbf{F} = y\mathbf{i} + xy\mathbf{j} - z\mathbf{k}$
D: The region inside the solid cylinder $x^2 + y^2 \leq 4$ between the plane $z = 0$ and the paraboloid $z = x^2 + y^2$
- Ball** $\mathbf{F} = x^2\mathbf{i} + xz\mathbf{j} + 3z\mathbf{k}$
D: The ball $x^2 + y^2 + z^2 \leq 4$
- Portion of ball** $\mathbf{F} = x^2\mathbf{i} - 2xy\mathbf{j} + 3xz\mathbf{k}$
D: The region cut from the first octant by the ball $x^2 + y^2 + z^2 = 4$
- Cylindrical can** $\mathbf{F} = (6x^2 + 2xy)\mathbf{i} + (2y + x^2z)\mathbf{j} + 4x^2y^3\mathbf{k}$
D: The region cut from the first octant by the cylinder $x^2 + y^2 = 4$ and the plane $z = 3$
- Wedge** $\mathbf{F} = 2xz\mathbf{i} - xy\mathbf{j} - z^2\mathbf{k}$
D: The wedge cut from the first octant by the plane $y + z = 4$ and the elliptic cylinder $4x^2 + y^2 = 16$
- Ball** $\mathbf{F} = x^3\mathbf{i} + y^3\mathbf{j} + z^3\mathbf{k}$
D: The ball $x^2 + y^2 + z^2 \leq a^2$
- Thick sphere** $\mathbf{F} = \sqrt{x^2 + y^2 + z^2}(\mathbf{i} + \mathbf{j} + \mathbf{k})$
D: The region $1 \leq x^2 + y^2 + z^2 \leq 2$
- Thick sphere** $\mathbf{F} = (x\mathbf{i} + y\mathbf{j} + z\mathbf{k})/\sqrt{x^2 + y^2 + z^2}$
D: The region $1 \leq x^2 + y^2 + z^2 \leq 4$
- Thick sphere** $\mathbf{F} = (5x^3 + 12xy^2)\mathbf{i} + (y^3 + e^y \sin z)\mathbf{j} + (5z^3 + e^y \cos z)\mathbf{k}$
D: The solid region between the spheres $x^2 + y^2 + z^2 = 1$ and $x^2 + y^2 + z^2 = 2$
- Thick cylinder** $\mathbf{F} = \ln(x^2 + y^2)\mathbf{i} - \left(\frac{2z}{x} \arctan \frac{y}{x}\right)\mathbf{j} + z\sqrt{x^2 + y^2}\mathbf{k}$
D: The thick-walled cylinder $1 \leq x^2 + y^2 \leq 2$, $-1 \leq z \leq 2$

Theory and Examples

21. a. Show that the outward flux of the position vector field $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ through a smooth closed surface S is three times the volume of the region enclosed by the surface.
- b. Let \mathbf{n} be the outward unit normal vector field on S . Show that it is not possible for \mathbf{F} to be orthogonal to \mathbf{n} at every point of S .
22. The base of the closed cubelike surface shown here is the unit square in the xy -plane. The four sides lie in the planes $x = 0$, $x = 1$, $y = 0$, and $y = 1$. The top is an arbitrary smooth surface whose identity is unknown. Let $\mathbf{F} = x\mathbf{i} - 2y\mathbf{j} + (z + 3)\mathbf{k}$, and suppose the outward flux of \mathbf{F} through Side A is 1 and through Side B is -3 . Can you conclude anything about the outward flux through the top? Give reasons for your answer.

23. Let $\mathbf{F} = (y \cos 2x)\mathbf{i} + (y^2 \sin 2x)\mathbf{j} + (x^2y + z)\mathbf{k}$. Is there a vector field \mathbf{A} such that $\mathbf{F} = \nabla \times \mathbf{A}$? Explain your answer.
24. **Outward flux of a gradient field** Let S be the surface of the portion of the ball $x^2 + y^2 + z^2 \leq a^2$ that lies in the first octant, and let $f(x, y, z) = \ln \sqrt{x^2 + y^2 + z^2}$. Calculate

$$\iint_S \nabla f \cdot \mathbf{n} \, d\sigma.$$

($\nabla f \cdot \mathbf{n}$ is the derivative of f in the direction of outward normal \mathbf{n} .)

25. Let \mathbf{F} be a field whose components have continuous first partial derivatives throughout a portion of space containing a region D bounded by a smooth closed surface S . If $|\mathbf{F}| \leq 1$, can any bound be placed on the size of

$$\iiint_D \nabla \cdot \mathbf{F} \, dV?$$

Give reasons for your answer.

26. **Maximum flux** Among all rectangular boxes defined by the inequalities $0 \leq x \leq a$, $0 \leq y \leq b$, $0 \leq z \leq 1$, find the one for which the total flux of $\mathbf{F} = (-x^2 - 4xy)\mathbf{i} - 6yz\mathbf{j} + 12z\mathbf{k}$ outward through the six sides is greatest. What is the greatest flux?
27. Calculate the net outward flux of the vector field

$$\mathbf{F} = xy\mathbf{i} + (\sin xz + y^2)\mathbf{j} + (e^{yz} + x)\mathbf{k}$$

over the surface S surrounding the region D bounded by the planes $y = 0$, $z = 0$, $z = 2 - y$ and the parabolic cylinder $z = 1 - x^2$.

28. Compute the net outward flux of the vector field $\mathbf{F} = (x\mathbf{i} + y\mathbf{j} + z\mathbf{k})/(x^2 + y^2 + z^2)^{3/2}$ across the ellipsoid $9x^2 + 4y^2 + 6z^2 = 36$.
29. Let \mathbf{F} be a differentiable vector field, and let $g(x, y, z)$ be a differentiable scalar function. Verify the following identities.
- a. $\nabla \cdot (g\mathbf{F}) = g\nabla \cdot \mathbf{F} + \nabla g \cdot \mathbf{F}$
- b. $\nabla \times (g\mathbf{F}) = g\nabla \times \mathbf{F} + \nabla g \times \mathbf{F}$
30. Let \mathbf{F}_1 and \mathbf{F}_2 be differentiable vector fields, and let a and b be arbitrary real constants. Verify the following identities.
- a. $\nabla \cdot (a\mathbf{F}_1 + b\mathbf{F}_2) = a\nabla \cdot \mathbf{F}_1 + b\nabla \cdot \mathbf{F}_2$
- b. $\nabla \times (a\mathbf{F}_1 + b\mathbf{F}_2) = a\nabla \times \mathbf{F}_1 + b\nabla \times \mathbf{F}_2$
- c. $\nabla \cdot (\mathbf{F}_1 \times \mathbf{F}_2) = \mathbf{F}_2 \cdot \nabla \times \mathbf{F}_1 - \mathbf{F}_1 \cdot \nabla \times \mathbf{F}_2$
31. If $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ is a differentiable vector field, we define the notation $\mathbf{F} \cdot \nabla$ to mean

$$M \frac{\partial}{\partial x} + N \frac{\partial}{\partial y} + P \frac{\partial}{\partial z}.$$

For differentiable vector fields \mathbf{F}_1 and \mathbf{F}_2 , verify the following identities.

- a. $\nabla \times (\mathbf{F}_1 \times \mathbf{F}_2) = (\mathbf{F}_2 \cdot \nabla)\mathbf{F}_1 - (\mathbf{F}_1 \cdot \nabla)\mathbf{F}_2 + (\nabla \cdot \mathbf{F}_2)\mathbf{F}_1 - (\nabla \cdot \mathbf{F}_1)\mathbf{F}_2$
- b. $\nabla(\mathbf{F}_1 \cdot \mathbf{F}_2) = (\mathbf{F}_1 \cdot \nabla)\mathbf{F}_2 + (\mathbf{F}_2 \cdot \nabla)\mathbf{F}_1 + \mathbf{F}_1 \times (\nabla \times \mathbf{F}_2) + \mathbf{F}_2 \times (\nabla \times \mathbf{F}_1)$
32. **Harmonic functions** A function $f(x, y, z)$ is said to be *harmonic* in a region D in space if it satisfies the Laplace equation

$$\nabla^2 f = \nabla \cdot \nabla f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = 0$$

throughout D .

- a. Suppose that f is harmonic throughout a bounded region D enclosed by a smooth surface S and that \mathbf{n} is the chosen unit normal vector on S . Show that the integral over S of $\nabla f \cdot \mathbf{n}$, the derivative of f in the direction of \mathbf{n} , is zero.
- b. Show that if f is harmonic on D , then

$$\iint_S f \nabla f \cdot \mathbf{n} \, d\sigma = \iiint_D |\nabla f|^2 \, dV.$$

33. **Green's first formula** Suppose that f and g are scalar functions with continuous first- and second-order partial derivatives throughout a region D that is bounded by a closed piecewise smooth surface S . Show that

$$\iint_S f \nabla g \cdot \mathbf{n} \, d\sigma = \iiint_D (f \nabla^2 g + \nabla f \cdot \nabla g) \, dV. \quad (10)$$

Equation (10) is **Green's first formula**. (Hint: Apply the Divergence Theorem to the field $\mathbf{F} = f \nabla g$.)

34. **Green's second formula** (Continuation of Exercise 33.) Interchange f and g in Equation (10) to obtain a similar formula. Then subtract this formula from Equation (10) to show that

$$\iint_S (f \nabla g - g \nabla f) \cdot \mathbf{n} \, d\sigma = \iiint_D (f \nabla^2 g - g \nabla^2 f) \, dV. \quad (11)$$

This equation is **Green's second formula**.

- 35. Conservation of mass** Let $\mathbf{v}(t, x, y, z)$ be a continuously differentiable vector field over the region D in space, and let $p(t, x, y, z)$ be a continuously differentiable scalar function. The variable t represents the time domain. The Law of Conservation of Mass asserts that

$$\frac{d}{dt} \iiint_D p(t, x, y, z) dV = - \iint_S p \mathbf{v} \cdot \mathbf{n} d\sigma,$$

where S is the surface enclosing D .

- Give a physical interpretation of the conservation of mass law if \mathbf{v} is a velocity flow field and p represents the density of the fluid at point (x, y, z) at time t .
- Use the Divergence Theorem and Leibniz's Rule,

$$\frac{d}{dt} \iiint_D p(t, x, y, z) dV = \iiint_D \frac{\partial p}{\partial t} dV,$$

to show that the Law of Conservation of Mass is equivalent to the continuity equation,

$$\nabla \cdot p \mathbf{v} + \frac{\partial p}{\partial t} = 0.$$

(In the first term $\nabla \cdot p \mathbf{v}$, the variable t is held fixed, and in the second term $\partial p / \partial t$, it is assumed that the point (x, y, z) in D is held fixed.)

- 36. The heat diffusion equation** Let $T(t, x, y, z)$ be a function with continuous second derivatives giving the temperature at time t at the point (x, y, z) of a solid occupying a region D in space. If the solid's heat capacity and mass density are denoted by the constants c and ρ , respectively, the quantity $c\rho T$ is called the solid's **heat energy per unit volume**.

Let $-k\nabla T$ denote the **energy flux vector**. (Here the constant k is called the **conductivity**.) Assuming the Law of Conservation of Mass with $-k\nabla T = \mathbf{v}$ and $c\rho T = p$ in Exercise 35, derive the diffusion (heat) equation

$$\frac{\partial T}{\partial t} = K \nabla^2 T,$$

where $K = k/(c\rho) > 0$ is the *diffusivity* constant. (Notice that if $T(t, x)$ represents the temperature at time t at position x in a uniform conducting rod with perfectly insulated sides, then $\nabla^2 T = \partial^2 T / \partial x^2$ and the diffusion equation reduces to the one-dimensional heat equation in Chapter 13's Additional Exercises.)

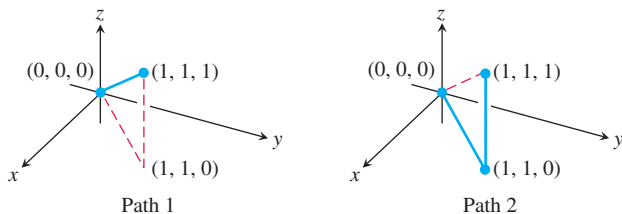

CHAPTER 15 Questions to Guide Your Review

- What are line integrals of scalar functions? How are they evaluated? Give examples.
- How can you use line integrals to find the centers of mass of springs or wires? Explain.
- What is a vector field? What is the line integral of a vector field? What is a gradient field? Give examples.
- What is the flow of a vector field along a curve? What is the work done by a vector field moving an object along a curve? How do you calculate the work done? Give examples.
- What is the Fundamental Theorem of line integrals? Explain how it is related to the Fundamental Theorem of Calculus.
- Specify three properties that are special about conservative fields. How can you tell when a field is conservative?
- What is special about path independent fields?
- What is a potential function? Show by example how to find a potential function for a conservative field.
- What is a differential form? What does it mean for such a form to be exact? How do you test for exactness? Give examples.
- What is Green's Theorem? Discuss how the two forms of Green's Theorem extend the Net Change Theorem in Chapter 5.
- How do you calculate the area of a parametrized surface in space? Of an implicitly defined surface $F(x, y, z) = 0$? Of the surface that is the graph of $z = f(x, y)$? Give examples.
- How do you integrate a scalar function over a parametrized surface? Over surfaces that are defined implicitly or in explicit form? Give examples.
- What is an oriented surface? What is the surface integral of a vector field in three-dimensional space over an oriented surface? How is it related to the net outward flux of the field? Give examples.
- What is the curl of a vector field? How can you interpret it?
- What is Stokes' Theorem? Explain how it generalizes Green's Theorem to three dimensions.
- What is the divergence of a vector field? How can you interpret it?
- What is the Divergence Theorem? Explain how it generalizes Green's Theorem to three dimensions.
- How are Green's Theorem, Stokes' Theorem, and the Divergence Theorem related to the Fundamental Theorem of Calculus for ordinary single integrals?

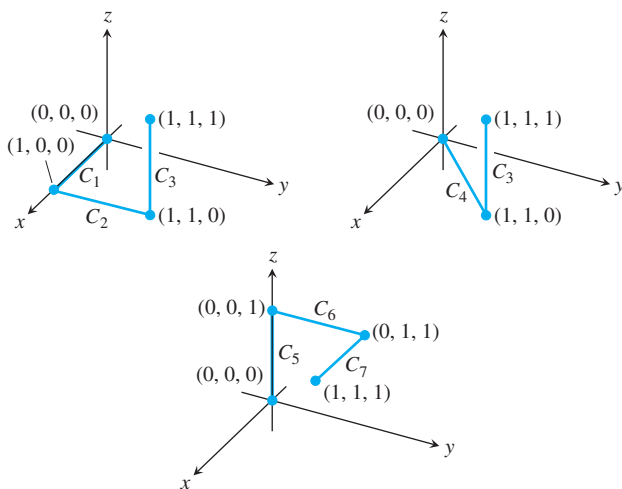

CHAPTER 15 Practice Exercises

Evaluating Line Integrals

1. The accompanying figure shows two polygonal paths in space joining the origin to the point $(1, 1, 1)$. Integrate $f(x, y, z) = 2x - 3y^2 - 2z + 3$ over each path.

2. The accompanying figure shows three polygonal paths joining the origin to the point $(1, 1, 1)$. Integrate $f(x, y, z) = x^2 + y - z$ over each path.

3. Integrate $f(x, y, z) = \sqrt{x^2 + z^2}$ over the circle
 $\mathbf{r}(t) = (a \cos t)\mathbf{j} + (a \sin t)\mathbf{k}, \quad 0 \leq t \leq 2\pi.$

4. Integrate $f(x, y, z) = \sqrt{x^2 + y^2}$ over the involute curve
 $\mathbf{r}(t) = (\cos t + t \sin t)\mathbf{i} + (\sin t - t \cos t)\mathbf{j}, \quad 0 \leq t \leq \sqrt{3}.$

Evaluate the integrals in Exercises 5 and 6.

5. $\int_{(-1,1)}^{(4,-3,0)} \frac{dx + dy + dz}{\sqrt{x + y + z}}$ 6. $\int_{(1,1,1)}^{(10,3,3)} dx - \sqrt{\frac{z}{y}} dy - \sqrt{\frac{y}{z}} dz$

7. Integrate $\mathbf{F} = -(y \sin z)\mathbf{i} + (x \sin z)\mathbf{j} + (xy \cos z)\mathbf{k}$ around the circle cut from the sphere $x^2 + y^2 + z^2 = 5$ by the plane $z = -1$, clockwise as viewed from above.

8. Integrate $\mathbf{F} = 3x^2y\mathbf{i} + (x^3 + 1)\mathbf{j} + 9z^2\mathbf{k}$ around the circle cut from the sphere $x^2 + y^2 + z^2 = 9$ by the plane $x = 2$.

Evaluate the integrals in Exercises 9 and 10.

9. $\int_C 8x \sin y \, dx - 8y \cos x \, dy$

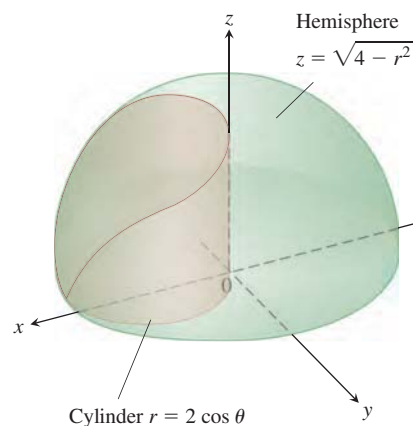

C is the square cut from the first quadrant by the lines $x = \pi/2$ and $y = \pi/2$.

10. $\int_C y^2 \, dx + x^2 \, dy$

C is the circle $x^2 + y^2 = 4$.

Finding and Evaluating Surface Integrals

11. **Area of an elliptic region** Find the area of the elliptic region cut from the plane $x + y + z = 1$ by the cylinder $x^2 + y^2 = 1$.
12. **Area of a parabolic cap** Find the area of the cap cut from the paraboloid $y^2 + z^2 = 3x$ by the plane $x = 1$.
13. **Area of a spherical cap** Find the area of the cap cut from the top of the sphere $x^2 + y^2 + z^2 = 1$ by the plane $z = \sqrt{2}/2$.
14. **a. Hemisphere cut by cylinder** Find the area of the surface cut from the hemisphere $x^2 + y^2 + z^2 = 4, z \geq 0$, by the cylinder $x^2 + y^2 = 2x$.
- b.** Find the area of the portion of the cylinder that lies inside the hemisphere. (*Hint:* Project onto the xz -plane. Or evaluate the integral $\int h \, ds$, where h is the altitude of the cylinder and ds is the element of arc length on the circle $x^2 + y^2 = 2x$ in the xy -plane.)

15. **Area of a triangle** Find the area of the triangle in which the plane $(x/a) + (y/b) + (z/c) = 1$ ($a, b, c > 0$) intersects the first octant. Check your answer with an appropriate vector calculation.

16. **Parabolic cylinder cut by planes** Integrate

a. $g(x, y, z) = \frac{yz}{\sqrt{4y^2 + 1}}$ **b.** $g(x, y, z) = \frac{z}{\sqrt{4y^2 + 1}}$

over the surface cut from the parabolic cylinder $y^2 - z = 1$ by the planes $x = 0, x = 3$, and $z = 0$.

17. **Circular cylinder cut by planes** Integrate $g(x, y, z) = x^4y(y^2 + z^2)$ over the portion of the cylinder $y^2 + z^2 = 25$ that lies in the first octant between the planes $x = 0$ and $x = 1$ and above the plane $z = 3$.

18. **Area of Wyoming** The state of Wyoming is bounded by the meridians $111^\circ 3'$ and $104^\circ 3'$ west longitude and by the circles 41° and 45° north latitude. Assuming that Earth is a sphere of radius $R = 6370$ km, find the area of Wyoming.

Parametrized Surfaces

Find parametrizations for the surfaces in Exercises 19–24. (There are many ways to do these, so your answers may not be the same as those in the back of the text.)

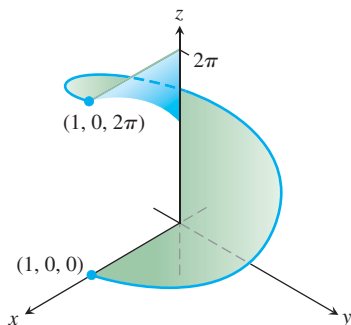

19. **Spherical band** The portion of the sphere $x^2 + y^2 + z^2 = 36$ between the planes $z = -3$ and $z = 3\sqrt{3}$

- 20. Parabolic cap** The portion of the paraboloid $z = -(x^2 + y^2)/2$ above the plane $z = -2$
- 21. Cone** The cone $z = 1 + \sqrt{x^2 + y^2}$, $z \leq 3$
- 22. Plane above square** The portion of the plane $4x + 2y + 4z = 12$ that lies above the square $0 \leq x \leq 2$, $0 \leq y \leq 2$, in the first quadrant
- 23. Portion of paraboloid** The portion of the paraboloid $y = 2(x^2 + z^2)$, $y \leq 2$, that lies above the xy -plane
- 24. Portion of hemisphere** The portion of the hemisphere $x^2 + y^2 + z^2 = 10$, $y \geq 0$, in the first octant
- 25. Surface area** Find the area of the surface

$$\mathbf{r}(u, v) = (u + v)\mathbf{i} + (u - v)\mathbf{j} + v\mathbf{k},$$

$$0 \leq u \leq 1, 0 \leq v \leq 1.$$

- 26. Surface integral** Integrate $f(x, y, z) = xy - z^2$ over the surface in Exercise 25.
- 27. Area of a helicoid** Find the surface area of the helicoid $\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + \theta\mathbf{k}$, $0 \leq \theta \leq 2\pi$, $0 \leq r \leq 1$, in the accompanying figure.

- 28. Surface integral** Evaluate the integral $\iint_S \sqrt{x^2 + y^2 + 1} \, d\sigma$, where S is the helicoid in Exercise 27.

Conservative Fields

Which of the fields in Exercises 29–32 are conservative, and which are not?

- 29.** $\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$
- 30.** $\mathbf{F} = (x\mathbf{i} + y\mathbf{j} + z\mathbf{k})/(x^2 + y^2 + z^2)^{3/2}$
- 31.** $\mathbf{F} = xe^y\mathbf{i} + ye^z\mathbf{j} + ze^x\mathbf{k}$
- 32.** $\mathbf{F} = (\mathbf{i} + z\mathbf{j} + y\mathbf{k})/(x + yz)$

Find potential functions for the fields in Exercises 33 and 34.

- 33.** $\mathbf{F} = 2\mathbf{i} + (2y + z)\mathbf{j} + (y + 1)\mathbf{k}$
- 34.** $\mathbf{F} = (z \cos xz)\mathbf{i} + e^y\mathbf{j} + (x \cos xz)\mathbf{k}$

Work and Circulation

In Exercises 35 and 36, find the work done by each field along the paths from $(0, 0, 0)$ to $(1, 1, 1)$ in Exercise 1.

- 35.** $\mathbf{F} = 2xy\mathbf{i} + \mathbf{j} + x^2\mathbf{k}$
- 36.** $\mathbf{F} = 2xy\mathbf{i} + x^2\mathbf{j} + \mathbf{k}$

- 37. Finding work in two ways** Find the work done by

$$\mathbf{F} = \frac{x\mathbf{i} + y\mathbf{j}}{(x^2 + y^2)^{3/2}}$$

over the plane curve $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j}$ from the point $(1, 0)$ to the point $(e^{2\pi}, 0)$ in two ways:

- a.** By using the parametrization of the curve to evaluate the work integral.
- b.** By evaluating a potential function for \mathbf{F} .
- 38. Flow along different paths** Find the flow of the field $\mathbf{F} = \nabla(x^2ze^y)$
- a.** once around the ellipse C in which the plane $x + y + z = 1$ intersects the cylinder $x^2 + z^2 = 25$, clockwise as viewed from the positive y -axis.
- b.** along the curved boundary of the helicoid in Exercise 27 from $(1, 0, 0)$ to $(1, 0, 2\pi)$.

In Exercises 39 and 40, use the curl integral in Stokes' Theorem to find the circulation of the field \mathbf{F} around the curve C in the indicated direction.

- 39. Circulation around an ellipse** $\mathbf{F} = y^2\mathbf{i} - y\mathbf{j} + 3z^2\mathbf{k}$

C : The ellipse in which the plane $2x + 6y - 3z = 6$ meets the cylinder $x^2 + y^2 = 1$, counterclockwise as viewed from above

- 40. Circulation around a circle** $\mathbf{F} = (x^2 + y)\mathbf{i} + (x + y)\mathbf{j} + (4y^2 - z)\mathbf{k}$

C : The circle in which the plane $z = -y$ meets the sphere $x^2 + y^2 + z^2 = 4$, counterclockwise as viewed from above

Masses and Moments

- 41. Wire with different densities** Find the mass of a thin wire lying along the curve $\mathbf{r}(t) = \sqrt{2}t\mathbf{i} + \sqrt{2}t\mathbf{j} + (4 - t^2)\mathbf{k}$, $0 \leq t \leq 1$, if the density at t is **(a)** $\delta = 3t$ and **(b)** $\delta = 1$.
- 42. Wire with variable density** Find the center of mass of a thin wire lying along the curve $\mathbf{r}(t) = t\mathbf{i} + 2t\mathbf{j} + (2/3)t^{3/2}\mathbf{k}$, $0 \leq t \leq 2$, if the density at t is $\delta = 3\sqrt{5} + t$.
- 43. Wire with variable density** Find the center of mass and the moments of inertia about the coordinate axes of a thin wire lying along the curve

$$\mathbf{r}(t) = t\mathbf{i} + \frac{2\sqrt{2}}{3}t^{3/2}\mathbf{j} + \frac{t^2}{2}\mathbf{k}, \quad 0 \leq t \leq 2,$$

if the density at t is $\delta = 1/(t + 1)$.

- 44. Center of mass of an arch** A slender metal arch lies along the semicircle $y = \sqrt{a^2 - x^2}$ in the xy -plane. The density at the point (x, y) on the arch is $\delta(x, y) = 2a - y$. Find the center of mass.
- 45. Wire with constant density** A wire of constant density $\delta = 1$ lies along the curve $\mathbf{r}(t) = (e^t \cos t)\mathbf{i} + (e^t \sin t)\mathbf{j} + e^t\mathbf{k}$, $0 \leq t \leq \ln 2$. Find \bar{x} and I_z .
- 46. Helical wire with constant density** Find the mass and center of mass of a wire of constant density δ that lies along the helix $\mathbf{r}(t) = (2 \sin t)\mathbf{i} + (2 \cos t)\mathbf{j} + 3t\mathbf{k}$, $0 \leq t \leq 2\pi$.
- 47. Inertia and center of mass of a shell** Find I_z and the center of mass of a thin shell of density $\delta(x, y, z) = z$ cut from the upper portion of the sphere $x^2 + y^2 + z^2 = 25$ by the plane $z = 3$.
- 48. Moment of inertia of a cube** Find the moment of inertia about the z -axis of the surface of the cube cut from the first octant by the planes $x = 1$, $y = 1$, and $z = 1$ if the density is $\delta = 1$.

Flux Across a Plane Curve or Surface

Use Green's Theorem to find the counterclockwise circulation and outward flux for the fields and curves in Exercises 49 and 50.

- 49. Square** $\mathbf{F} = (2xy + x)\mathbf{i} + (xy - y)\mathbf{j}$

C : The square bounded by $x = 0$, $x = 1$, $y = 0$, $y = 1$

50. **Triangle** $\mathbf{F} = (y - 6x^2)\mathbf{i} + (x + y^2)\mathbf{j}$

C : The triangle made by the lines $y = 0$, $y = x$, and $x = 1$

51. **Zero line integral** Show that

$$\oint_C \ln x \sin y \, dy - \frac{\cos y}{x} \, dx = 0$$

for any closed curve C to which Green's Theorem applies.

52. **a. Outward flux and area** Show that the outward flux of the position vector field $\mathbf{F} = x\mathbf{i} + y\mathbf{j}$ across any closed curve to which Green's Theorem applies is twice the area of the region enclosed by the curve.

b. Let \mathbf{n} be the outward unit normal vector to a closed curve to which Green's Theorem applies. Show that it is not possible for $\mathbf{F} = x\mathbf{i} + y\mathbf{j}$ to be orthogonal to \mathbf{n} at every point of C .

In Exercises 53–56, find the outward flux of \mathbf{F} across the boundary of D .

53. **Cube** $\mathbf{F} = 2xy\mathbf{i} + 2yz\mathbf{j} + 2xz\mathbf{k}$

D : The cube cut from the first octant by the planes $x = 1$, $y = 1$, and $z = 1$

54. **Spherical cap** $\mathbf{F} = xz\mathbf{i} + yz\mathbf{j} + \mathbf{k}$

D : The entire surface of the upper cap cut from the ball $x^2 + y^2 + z^2 \leq 25$ by the plane $z = 3$

55. **Spherical cap** $\mathbf{F} = -2x\mathbf{i} - 3y\mathbf{j} + z\mathbf{k}$

D : The upper region cut from the ball $x^2 + y^2 + z^2 \leq 2$ by the paraboloid $z = x^2 + y^2$

56. **Cone and cylinder** $\mathbf{F} = (6x + y)\mathbf{i} - (x + z)\mathbf{j} + 4yz\mathbf{k}$

D : The region in the first octant bounded by the cone $z = \sqrt{x^2 + y^2}$, the cylinder $x^2 + y^2 = 1$, and the coordinate planes

57. **Hemisphere, cylinder, and plane** Let S be the surface that is bounded on the left by the hemisphere $x^2 + y^2 + z^2 = a^2$, $y \leq 0$, in the middle by the cylinder $x^2 + z^2 = a^2$, $0 \leq y \leq a$, and on the right by the plane $y = a$. Find the flux of $\mathbf{F} = y\mathbf{i} + z\mathbf{j} + x\mathbf{k}$ outward across S .

58. **Cylinder and planes** Find the outward flux of the field $\mathbf{F} = 3xz^2\mathbf{i} + y\mathbf{j} - z^3\mathbf{k}$ across the surface of the solid in the first octant that is bounded by the cylinder $x^2 + 4y^2 = 16$ and the planes $y = 2z$, $x = 0$, and $z = 0$.

59. **Cylindrical can** Use the Divergence Theorem to find the flux of $\mathbf{F} = xy^2\mathbf{i} + x^2y\mathbf{j} + y\mathbf{k}$ outward through the surface of the region enclosed by the cylinder $x^2 + y^2 = 1$ and the planes $z = 1$ and $z = -1$.

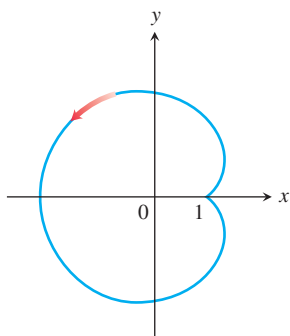

60. **Hemisphere** Find the flux of $\mathbf{F} = (3z + 1)\mathbf{k}$ upward across the hemisphere $x^2 + y^2 + z^2 = a^2$, $z \geq 0$, **(a)** with the Divergence Theorem and **(b)** by evaluating the flux integral directly.

CHAPTER 15 Additional and Advanced Exercises

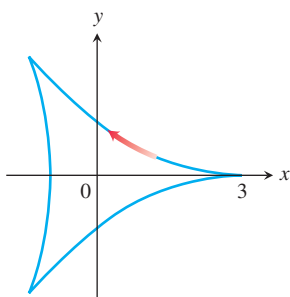

Finding Areas with Green's Theorem

Use the Green's Theorem area formula in Exercises 15.4 to find the areas of the regions enclosed by the curves in Exercises 1–4.

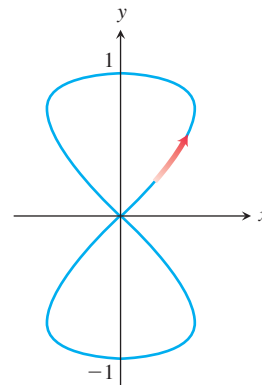

1. The limaçon $x = 2 \cos t - \cos 2t$, $y = 2 \sin t$, $0 \leq t \leq 2\pi$

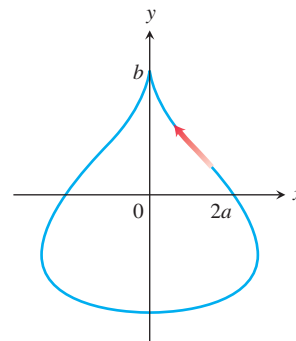

2. The deltoid $x = 2 \cos t + \cos 2t$, $y = 2 \sin t - \sin 2t$, $0 \leq t \leq 2\pi$

3. The eight curve $x = (1/2) \sin 2t$, $y = \sin t$, $0 \leq t \leq \pi$ (one loop)

4. The teardrop $x = 2a \cos t - a \sin 2t$, $y = b \sin t$, $0 \leq t \leq 2\pi$

Theory and Applications

5. a. Give an example of a vector field $\mathbf{F}(x, y, z)$ that has value $\mathbf{0}$ at only one point and such that $\text{curl } \mathbf{F}$ is nonzero everywhere. Be sure to identify the point and compute the curl.
- b. Give an example of a vector field $\mathbf{F}(x, y, z)$ that has value $\mathbf{0}$ on precisely one line and such that $\text{curl } \mathbf{F}$ is nonzero everywhere. Be sure to identify the line and compute the curl.
- c. Give an example of a vector field $\mathbf{F}(x, y, z)$ that has value $\mathbf{0}$ on a surface and such that $\text{curl } \mathbf{F}$ is nonzero everywhere. Be sure to identify the surface and compute the curl.
6. Find all points (a, b, c) on the sphere $x^2 + y^2 + z^2 = R^2$ where the vector field $\mathbf{F} = yz^2\mathbf{i} + xz^2\mathbf{j} + 2xyz\mathbf{k}$ is normal to the surface and $\mathbf{F}(a, b, c) \neq \mathbf{0}$.
7. Find the mass of a spherical shell of radius R such that at each point (x, y, z) on the surface, the mass density $\delta(x, y, z)$ is its distance to some fixed point (a, b, c) of the surface.
8. Find the mass of a helicoid

$$\mathbf{r}(r, \theta) = (r \cos \theta)\mathbf{i} + (r \sin \theta)\mathbf{j} + \theta\mathbf{k},$$

$0 \leq r \leq 1$, $0 \leq \theta \leq 2\pi$, if the density function is $\delta(x, y, z) = 2\sqrt{x^2 + y^2}$. See Practice Exercise 27 for a figure.

9. Among all rectangular regions $0 \leq x \leq a$, $0 \leq y \leq b$, find the one for which the total outward flux of $\mathbf{F} = (x^2 + 4xy)\mathbf{i} - 6y\mathbf{j}$ across the four sides is least. What is the least flux?
10. Find an equation for the plane through the origin such that the circulation of the flow field $\mathbf{F} = z\mathbf{i} + x\mathbf{j} + y\mathbf{k}$ around the circle of intersection of the plane with the sphere $x^2 + y^2 + z^2 = 4$ is a maximum.
11. A string lies along the circle $x^2 + y^2 = 4$ from $(2, 0)$ to $(0, 2)$ in the first quadrant. The density of the string is $\rho(x, y) = xy$.
- a. Partition the string into a finite number of subarcs to show that the work done by gravity to move the string straight down to the x -axis is given by

$$\text{Work} = \lim_{n \rightarrow \infty} \sum_{k=1}^n g x_k y_k^2 \Delta s_k = \int_C g xy^2 ds,$$

where g is the gravitational constant.

- b. Find the total work done by evaluating the line integral in part (a).
- c. Show that the total work done equals the work required to move the string's center of mass (\bar{x}, \bar{y}) straight down to the x -axis.
12. A thin sheet lies along the portion of the plane $x + y + z = 1$ in the first octant. The density of the sheet is $\delta(x, y, z) = xy$.
- a. Partition the sheet into a finite number of subpieces to show that the work done by gravity to move the sheet straight down to the xy -plane is given by

$$\text{Work} = \lim_{n \rightarrow \infty} \sum_{k=1}^n g x_k y_k z_k \Delta \sigma_k = \iint_S g xyz d\sigma,$$

where g is the gravitational constant.

- b. Find the total work done by evaluating the surface integral in part (a).
- c. Show that the total work done equals the work required to move the sheet's center of mass $(\bar{x}, \bar{y}, \bar{z})$ straight down to the xy -plane.

13. **Archimedes' principle** If an object such as a ball is placed in a liquid, it will either sink to the bottom, float, or sink a certain distance and remain suspended in the liquid. Suppose a fluid has constant weight density w and that the fluid's surface coincides with the plane $z = 4$. A spherical ball remains suspended in the fluid and occupies the region $x^2 + y^2 + (z - 2)^2 \leq 1$.

- a. Show that the surface integral giving the magnitude of the total force on the ball due to the fluid's pressure is

$$\text{Force} = \lim_{n \rightarrow \infty} \sum_{k=1}^n w(4 - z_k) \Delta \sigma_k = \iint_S w(4 - z) d\sigma.$$

- b. Since the ball is not moving, it is being held up by the buoyant force of the liquid. Show that the magnitude of the buoyant force on the sphere is

$$\text{Buoyant force} = \iint_S w(z - 4)\mathbf{k} \cdot \mathbf{n} d\sigma,$$

where \mathbf{n} is the outer unit normal at (x, y, z) . This illustrates Archimedes' principle that the magnitude of the buoyant force on a submerged solid equals the weight of the displaced fluid.

- c. Use the Divergence Theorem to find the magnitude of the buoyant force in part (b).

14. **Fluid force on a curved surface** A cone in the shape of the surface $z = \sqrt{x^2 + y^2}$, $0 \leq z \leq 2$, is filled with a liquid of constant weight density w . Assuming the xy -plane is "ground level," show that the total force on the portion of the cone from $z = 1$ to $z = 2$ due to liquid pressure is the surface integral

$$F = \iint_S w(2 - z) d\sigma.$$

Evaluate the integral.

15. **Faraday's law** If $\mathbf{E}(t, x, y, z)$ and $\mathbf{B}(t, x, y, z)$ represent the electric and magnetic fields at point (x, y, z) at time t , a basic principle of electromagnetic theory says that $\nabla \times \mathbf{E} = -\partial\mathbf{B}/\partial t$. In this expression $\nabla \times \mathbf{E}$ is computed with t held fixed and $\partial\mathbf{B}/\partial t$ is calculated with (x, y, z) fixed. Use Stokes' Theorem to derive Faraday's law,

$$\oint_C \mathbf{E} \cdot d\mathbf{r} = -\frac{\partial}{\partial t} \iint_S \mathbf{B} \cdot \mathbf{n} d\sigma,$$

where C represents a wire loop through which current flows counterclockwise with respect to the surface's unit normal \mathbf{n} , giving rise to the voltage

$$\oint_C \mathbf{E} \cdot d\mathbf{r}$$

around C . The surface integral on the right side of the equation is called the *magnetic flux*, and S is any oriented surface with boundary C .

15. Let

$$\mathbf{F} = -\frac{GmM}{|\mathbf{r}|^3} \mathbf{r}$$

be the gravitational force field defined for $\mathbf{r} \neq \mathbf{0}$. Use Gauss's law in Section 15.8 to show that there is no continuously differentiable vector field \mathbf{H} satisfying $\mathbf{F} = \nabla \times \mathbf{H}$.

17. If $f(x, y, z)$ and $g(x, y, z)$ are continuously differentiable scalar functions defined over the oriented surface S with boundary curve C , prove that

$$\iint_S (\nabla f \times \nabla g) \cdot \mathbf{n} \, d\sigma = \oint_C f \nabla g \cdot d\mathbf{r}.$$

18. Suppose that $\nabla \cdot \mathbf{F}_1 = \nabla \cdot \mathbf{F}_2$ and $\nabla \times \mathbf{F}_1 = \nabla \times \mathbf{F}_2$ over a region D enclosed by the oriented surface S with outward unit normal \mathbf{n} and that $\mathbf{F}_1 \cdot \mathbf{n} = \mathbf{F}_2 \cdot \mathbf{n}$ on S . Prove that $\mathbf{F}_1 = \mathbf{F}_2$ throughout D .
19. Prove or disprove that if $\nabla \cdot \mathbf{F} = 0$ and $\nabla \times \mathbf{F} = \mathbf{0}$, then $\mathbf{F} = \mathbf{0}$.
20. Let S be an oriented surface parametrized by $\mathbf{r}(u, v)$. Define the notation $d\boldsymbol{\sigma} = \mathbf{r}_u \, du \times \mathbf{r}_v \, dv$ so that $d\boldsymbol{\sigma}$ is a vector normal to the

surface. Also, the magnitude $d\sigma = |d\boldsymbol{\sigma}|$ is the element of surface area (by Equation 5 in Section 15.5). Derive the identity

$$d\sigma = (EG - F^2)^{1/2} \, du \, dv,$$

where

$$E = |\mathbf{r}_u|^2, \quad F = \mathbf{r}_u \cdot \mathbf{r}_v, \quad \text{and} \quad G = |\mathbf{r}_v|^2.$$

21. Show that the volume V of a region D in space enclosed by the oriented surface S with outward normal \mathbf{n} satisfies the identity

$$V = \frac{1}{3} \iint_S \mathbf{r} \cdot \mathbf{n} \, d\sigma,$$

where \mathbf{r} is the position vector of the point (x, y, z) in D .

First-Order Differential Equations

OVERVIEW Many real-world problems, when formulated mathematically, lead to differential equations. We encountered a number of these equations in previous chapters when studying phenomena such as the motion of an object along a straight line, the decay of a radioactive material, the growth of a population, and the cooling of a heated object placed within a medium of lower temperature.

Section 4.8 introduced differential equations of the form $dy/dx = f(x)$, where f is given and y is an unknown function of x . We learned that when f is continuous over some interval, the general solution $y(x)$ is found directly by integration, $y = \int f(x) dx$. In Section 7.2 we investigated differential equations of the form $dy/dx = f(x, y)$, where f is a function of both the independent variable x and the dependent variable y . There we learned how to find the general solution for the special case when the differential equation is separable. In this chapter we further extend our study to include other commonly occurring *first-order* differential equations. These differential equations involve only first derivatives of the unknown function $y(x)$, and they model phenomena varying from simple electrical circuits to the concentration of a chemical in a container. Differential equations involving second derivatives are examined in Chapter 17.

Chapter 17 is available online.

To access this chapter, visit the companion Website.

16.1 Solutions, Slope Fields, and Euler's Method

We begin this section by defining general differential equations involving first derivatives. We then look at slope fields, which give a geometric picture of the solutions to such equations. Many differential equations cannot be solved by obtaining an explicit formula for the solution. However, we can often find numerical approximations to solutions. We present one such method here, called *Euler's method*, which is the basis for many other numerical methods as well.

General First-Order Differential Equations and Solutions

A **first-order differential equation** is an equation

$$\frac{dy}{dx} = f(x, y) \quad (1)$$

in which $f(x, y)$ is a function of two variables defined on a region in the xy -plane. The equation is of *first order* because it involves only the first derivative dy/dx and not higher-order derivatives. In a typical situation y represents an unknown function of x , and $f(x, y)$ is a known function. Some examples of first-order differential equations are

$y' = x + y$, $y' = y/x$, and $y' = 3xy$. In all cases we should think of y as an unknown function of x whose derivative is given by $f(x, y)$. The equations

$$y' = f(x, y) \quad \text{and} \quad \frac{d}{dx}y = f(x, y)$$

are equivalent to Equation (1), and all three forms will be used interchangeably in the text.

A **solution** of Equation (1) is a differentiable function $y = y(x)$ defined on an interval I of x -values (possibly an infinite interval) such that

$$\frac{d}{dx}y(x) = f(x, y(x))$$

on that interval. That is, when $y(x)$ and its derivative $y'(x)$ are substituted into Equation (1), the resulting equation is true for all x over the interval I .

EXAMPLE 1 Show that every member of the family of functions

$$y = \frac{C}{x} + 2$$

is a solution of the first-order differential equation

$$\frac{dy}{dx} = \frac{1}{x}(2 - y)$$

on the interval $(0, \infty)$, where C is any constant.

Solution Differentiating $y = C/x + 2$ gives

$$\frac{dy}{dx} = C \frac{d}{dx}\left(\frac{1}{x}\right) + 0 = -\frac{C}{x^2}.$$

We need to show that the differential equation is satisfied when we substitute into it the expressions $(C/x) + 2$ for y , and $-C/x^2$ for dy/dx . That is, we need to verify that for all $x \in (0, \infty)$,

$$-\frac{C}{x^2} = \frac{1}{x}\left[2 - \left(\frac{C}{x} + 2\right)\right].$$

This last equation follows immediately by expanding the expression on the right-hand side:

$$\frac{1}{x}\left[2 - \left(\frac{C}{x} + 2\right)\right] = \frac{1}{x}\left(-\frac{C}{x}\right) = -\frac{C}{x^2}.$$

Therefore, for every value of C , the function $y = C/x + 2$ is a solution of the differential equation. ■

The differential equation in Example 1 has a whole family of solutions, one for each value of C . A natural question to consider is whether this family contains all the solutions to the differential equation, or whether there are others that can somehow arise. The **general solution** to a first-order differential equation is the name given to an expression that contains all possible solutions. The general solution always contains an arbitrary constant, but a solution may contain an arbitrary constant without being the general solution. Establishing when a solution is the general solution is left to a more extensive development of the theory of differential equations.

As with antiderivatives, we often need a *particular* rather than the general solution to a first-order differential equation $y' = f(x, y)$. A common way to pick out one of the collection of possible solutions is to specify the value of y at a point $x = x_0$. The **particular solution** satisfying the initial condition $y(x_0) = y_0$ is the solution $y = y(x)$ whose value is y_0 when $x = x_0$. Thus the graph of the particular solution passes through the point (x_0, y_0) in the xy -plane. A **first-order initial value problem** is a differential equation $y' = f(x, y)$ whose solution must satisfy an initial condition $y(x_0) = y_0$.

EXAMPLE 2 Show that the function

$$y = (x + 1) - \frac{1}{3}e^x$$

is a solution to the first-order initial value problem

$$\frac{dy}{dx} = y - x, \quad y(0) = \frac{2}{3}.$$

Solution The equation

$$\frac{dy}{dx} = y - x$$

is a first-order differential equation with $f(x, y) = y - x$.

On the left side of the equation:

$$\frac{dy}{dx} = \frac{d}{dx} \left(x + 1 - \frac{1}{3}e^x \right) = 1 - \frac{1}{3}e^x.$$

On the right side of the equation:

$$y - x = (x + 1) - \frac{1}{3}e^x - x = 1 - \frac{1}{3}e^x.$$

The function satisfies the initial condition because

$$y(0) = \left[(x + 1) - \frac{1}{3}e^x \right]_{x=0} = 1 - \frac{1}{3} = \frac{2}{3}.$$

The graph of the function is shown in Figure 16.1. ■

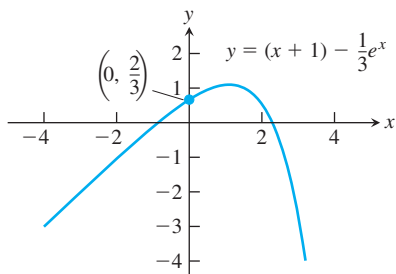

FIGURE 16.1 Graph of the solution to the initial value problem in Example 2.

Slope Fields: Viewing Solution Curves

Each time we specify an initial condition $y(x_0) = y_0$ for the solution of a differential equation $y' = f(x, y)$, the **solution curve** (graph of the solution) is required to pass through the point (x_0, y_0) and to have slope $f(x_0, y_0)$ there. We can picture these slopes graphically by drawing short line segments of slope $f(x, y)$ at selected points (x, y) in the region of the xy -plane that constitutes the domain of f . Each segment has the same slope as the solution curve through (x, y) and so is tangent to the curve there. The resulting picture is called a **slope field** (or **direction field**) and gives a visualization of the general shape of the solution curves. Figure 16.2a shows a slope field, with a particular solution sketched into it in Figure 16.2b. We see how these line segments indicate the direction the solution curve takes at each point it passes through.

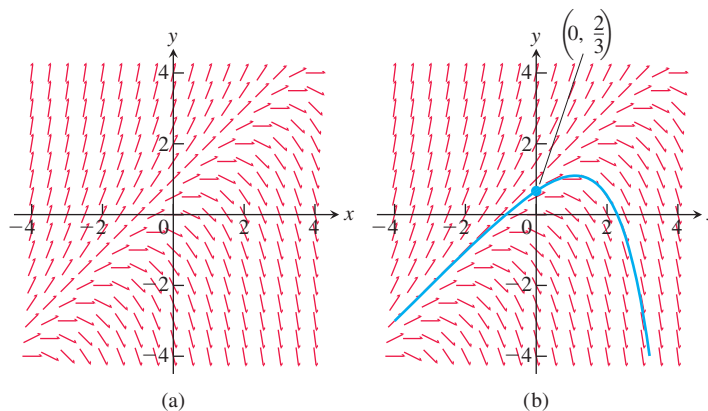

FIGURE 16.2 (a) Slope field for $\frac{dy}{dx} = y - x$. (b) The particular solution curve through the point $(0, \frac{2}{3})$ (Example 2).

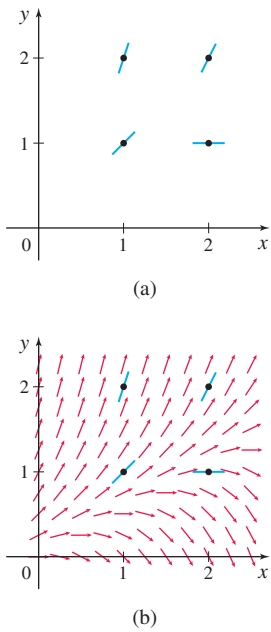

FIGURE 16.3 (a) The slope field for $y' = 2y - x$ is shown at four points. (b) The slope field at several hundred additional points in the plane.

EXAMPLE 3 For the differential equation

$$y' = 2y - x,$$

draw line segments representing the slope field at the points $(1, 2)$, $(1, 1)$, $(2, 2)$, and $(2, 1)$.

Solution At $(1, 2)$ the slope is $2(2) - (1) = 3$. Similarly, the slope at $(2, 2)$ is 2, at $(2, 1)$ is 0, and at $(1, 1)$ is 1. We indicate this on the graph by drawing short line segments of the given slope through each point, as in Figure 16.3. ■

Figure 16.4 shows three slope fields, and we see how the solution curves behave by following the tangent line segments in these fields. Slope fields are useful because they display the overall behavior of the family of solution curves for a given differential equation. For instance, the slope field in Figure 16.4b reveals that every solution $y(x)$ to the differential equation specified in the figure satisfies $\lim_{x \rightarrow \pm\infty} y(x) = 0$. We will see that knowing the overall behavior of the solution curves is often critical to understanding and predicting outcomes in a real-world system modeled by a differential equation.

Constructing a slope field with pencil and paper can be quite tedious. Our examples were generated by computer software.

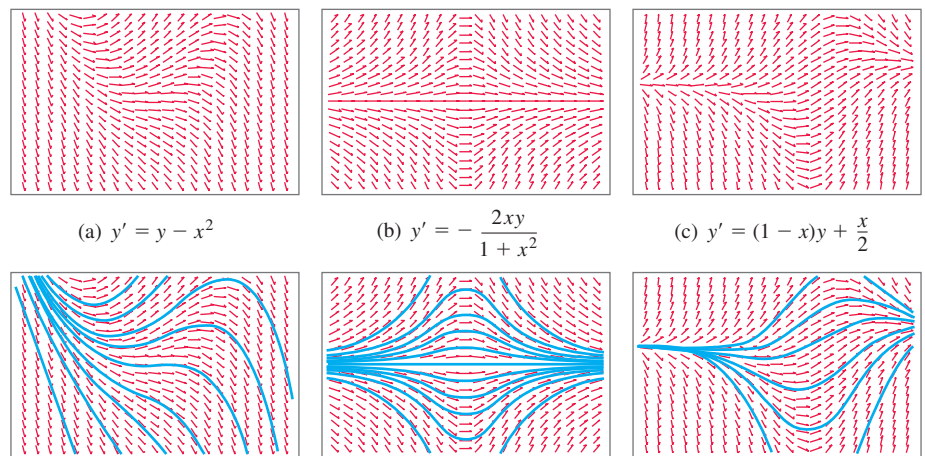

FIGURE 16.4 Slope fields (top row) and selected solution curves (bottom row). In computer renditions, slope segments are sometimes portrayed with arrows, as they are here, but they should be considered as just tangent line segments.

Euler's Method

If we do not require or cannot find an *exact* solution that gives an explicit formula for an initial value problem $y' = f(x, y)$, $y(x_0) = y_0$, we can often use a computer to generate a table of approximate numerical values of y for values of x in an appropriate interval. Such a table is called a **numerical solution** of the problem, and the process by which we generate the table is called a **numerical method**.

Given a differential equation $dy/dx = f(x, y)$ and an initial condition $y(x_0) = y_0$, we can approximate the solution $y = y(x)$ by its linearization

$$L(x) = y(x_0) + y'(x_0)(x - x_0) \quad \text{or} \quad L(x) = y_0 + f(x_0, y_0)(x - x_0).$$

The function $L(x)$ gives a good approximation to the solution $y(x)$ in a short interval about x_0 (Figure 16.5). The basis of Euler's method is to patch together a string of linearizations to approximate the curve over a longer stretch. Here is how the method works.

We know the point (x_0, y_0) lies on the solution curve. Suppose that we specify a new value for the independent variable to be $x_1 = x_0 + dx$. (Recall that $dx = \Delta x$ in the definition of differentials.) If the increment dx is small, then

$$y_1 = L(x_1) = y_0 + f(x_0, y_0) dx$$

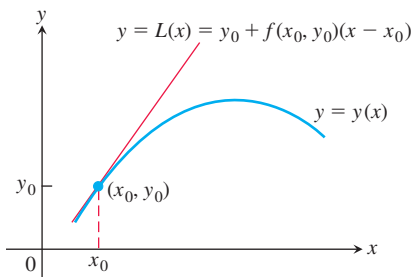

FIGURE 16.5 The linearization $L(x)$ of $y = y(x)$ at $x = x_0$.

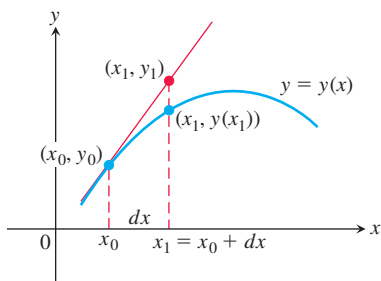

FIGURE 16.6 The first Euler step approximates $y(x_1)$ with $y_1 = L(x_1)$.

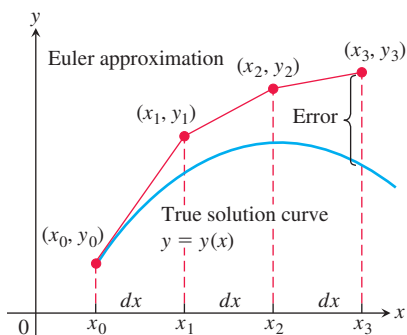

FIGURE 16.7 Three steps in the Euler approximation to the solution of the initial value problem $y' = f(x, y)$, $y(x_0) = y_0$. As we take more steps, the errors involved usually accumulate, but not in the exaggerated way shown here.

is a good approximation to the exact solution value $y = y(x_1)$. So from the point (x_0, y_0) , which lies *exactly* on the solution curve, we have obtained the point (x_1, y_1) , which lies very close to the point $(x_1, y(x_1))$ on the solution curve (Figure 16.6).

Using the point (x_1, y_1) and the slope $f(x_1, y_1)$ of the solution curve through (x_1, y_1) , we take a second step. Setting $x_2 = x_1 + dx$, we use the linearization of the solution curve through (x_1, y_1) to calculate

$$y_2 = y_1 + f(x_1, y_1) dx.$$

This gives the next approximation (x_2, y_2) to values along the solution curve $y = y(x)$ (Figure 16.7). Continuing in this fashion, we take a third step from the point (x_2, y_2) with slope $f(x_2, y_2)$ to obtain the third approximation

$$y_3 = y_2 + f(x_2, y_2) dx,$$

and so on. We are building an approximation to a solution by following the direction of the slope field of the differential equation.

The steps in Figure 16.7 are drawn large to illustrate the construction process, so the approximation looks crude. In practice, dx would be chosen small enough to make the red curve hug the blue one and give a better approximation.

EXAMPLE 4 Find the first three approximations y_1, y_2, y_3 using Euler's method for the initial value problem

$$y' = 1 + y, \quad y(0) = 1,$$

starting at $x_0 = 0$ with $dx = 0.1$.

Solution We already have the starting values $x_0 = 0$ and $y_0 = 1$. Next we determine the values of x at which the Euler approximations will take place: $x_1 = x_0 + dx = 0.1$, $x_2 = x_0 + 2 dx = 0.2$, and $x_3 = x_0 + 3 dx = 0.3$. Then we find

$$\begin{aligned} \text{First: } y_1 &= y_0 + f(x_0, y_0) dx \\ &= y_0 + (1 + y_0) dx && f(x, y) = 1 + y \\ &= 1 + (1 + 1)(0.1) = 1.2 && y_0 = 1, dx = 0.1 \end{aligned}$$

$$\begin{aligned} \text{Second: } y_2 &= y_1 + f(x_1, y_1) dx \\ &= y_1 + (1 + y_1) dx \\ &= 1.2 + (1 + 1.2)(0.1) = 1.42 && y_1 = 1.2, dx = 0.1 \end{aligned}$$

$$\begin{aligned} \text{Third: } y_3 &= y_2 + f(x_2, y_2) dx \\ &= y_2 + (1 + y_2) dx \\ &= 1.42 + (1 + 1.42)(0.1) = 1.662 && y_2 = 1.42, dx = 0.1 \end{aligned} \quad \blacksquare$$

The step-by-step process used in Example 4 can be continued with more points. Using equally spaced values for the independent variable in the table for the numerical solution, and generating n of them, set

$$\begin{aligned} x_1 &= x_0 + dx \\ x_2 &= x_1 + dx \\ &\vdots \\ x_n &= x_{n-1} + dx. \end{aligned}$$

Then calculate the approximations to the solution,

$$\begin{aligned} y_1 &= y_0 + f(x_0, y_0) dx \\ y_2 &= y_1 + f(x_1, y_1) dx \\ &\vdots \\ y_n &= y_{n-1} + f(x_{n-1}, y_{n-1}) dx. \end{aligned}$$

HISTORICAL BIOGRAPHY**Leonhard Euler**
(1707–1783)

Born in Basel, Switzerland, Leonhard Euler was the dominant mathematical figure of his century and the most prolific mathematician who ever lived. He was also an astronomer, physicist, engineer, and chemist. He was the first scientist to give the function concept prominence in his work, thereby setting a strong foundation for the development of calculus and other areas of mathematics.

To know more, visit the companion Website.

The number of steps n can be as large as we like, but errors involving the representation of numbers in software can accumulate if n is too large.

Euler's method is easy to implement on a computer or calculator. A typical software program takes as input x_0 and y_0 , the number of steps n , and the step size dx . It then calculates the approximate solution values y_1, y_2, \dots, y_n in iterative fashion, as just described.

Solving the separable equation in Example 4, we find that the exact solution to the initial value problem is $y = 2e^x - 1$. We use this information in Example 5.

EXAMPLE 5 Use Euler's method to solve

$$y' = 1 + y, \quad y(0) = 1,$$

on the interval $0 \leq x \leq 1$, starting at $x_0 = 0$ and taking (a) $dx = 0.1$ and (b) $dx = 0.05$. Compare the approximations with the values of the exact solution $y = 2e^x - 1$.

Solution

(a) We used a computer to generate the approximate values in Table 16.1. The “error” column is obtained by subtracting the unrounded Euler values from the unrounded values found using the exact solution. All entries are then rounded to four decimal places.

TABLE 16.1 Euler solution of $y' = 1 + y$, $y(0) = 1$, step size $dx = 0.1$

x	y (Euler)	y (exact)	Error
0	1	1	0
0.1	1.2	1.2103	0.0103
0.2	1.42	1.4428	0.0228
0.3	1.662	1.6997	0.0377

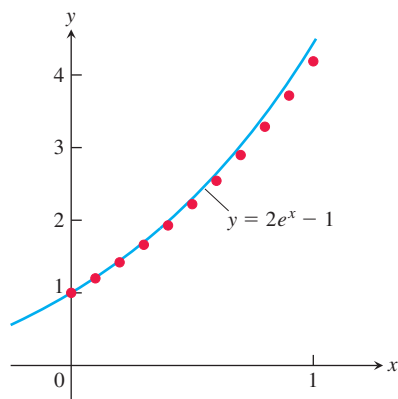

FIGURE 16.8 The graph of $y = 2e^x - 1$ superimposed on a scatter-plot of the Euler approximations shown in Table 16.1 (Example 5).

By the time we reach $x = 1$ (after 10 steps), the error is about 5.6% of the exact solution. A plot of the exact solution curve with the scatterplot of Euler solution points from Table 16.1 is shown in Figure 16.8.

(b) One way to try to reduce the error is to decrease the step size. Table 16.2 shows the results and their comparisons with the exact solutions when we decrease the step size to 0.05, doubling the number of steps to 20. As in Table 16.1, all computations are performed before rounding. This time when we reach $x = 1$, the relative error is only about 2.9%. ■

It might be tempting to reduce the step size even further in Example 5 to obtain greater accuracy. Each additional calculation, however, not only requires additional computer time but, more importantly, adds to the buildup of round-off errors due to the approximate representations of numbers inside the computer.

The analysis of error and the investigation of methods to reduce it when making numerical calculations are important. An area of mathematics called *numerical analysis* studies advanced numerical methods that are more accurate than Euler's method.

EXERCISES 16.1

Slope Fields

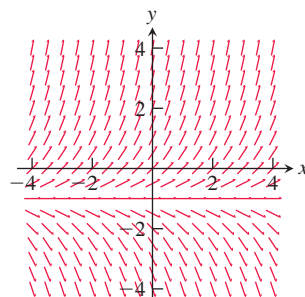

In Exercises 1–4, match the differential equations with their slope fields, graphed here.

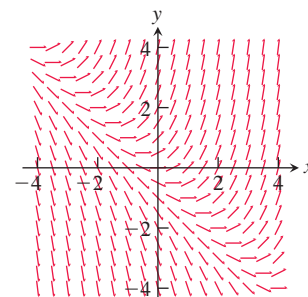

(a)

(b)

(c)

(d)

1. $y' = x + y$

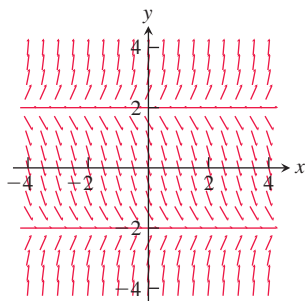

3. $y' = -\frac{x}{y}$

2. $y' = y + 1$

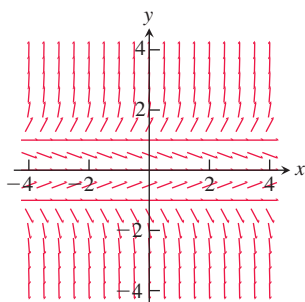

4. $y' = y^2 - x^2$

In Exercises 5 and 6, copy the slope fields, and sketch in some of the solution curves.

5. $y' = (y + 2)(y - 2)$

6. $y' = y(y + 1)(y - 1)$

Integral Equations

In Exercises 7–12, write an equivalent first-order differential equation and initial condition for y .

7. $y = -1 + \int_1^x (t - y(t)) dt$ 8. $y = \int_1^x \frac{1}{t} dt$

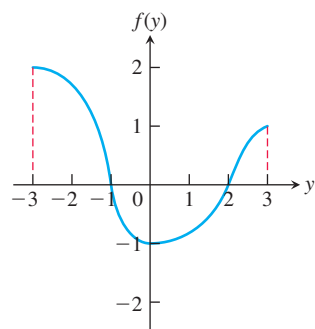

9. $y = 2 - \int_0^x (1 + y(t)) \sin t dt$

10. $y = 1 + \int_0^x y(t) dt$ 11. $y = x + 4 + \int_{-2}^x te^{y(t)} dt$

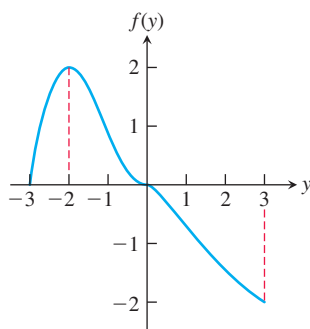

12. $y = \ln x + \int_x^e \sqrt{t^2 + (y(t))^2} dt$

In Exercises 13 and 14, consider the differential equation $y' = f(y)$ and the given graph of f . Make a rough sketch of a direction field for each differential equation.

13.

14.

Using Euler's Method

In Exercises 15–20, use Euler's method to calculate the first three approximations to the given initial value problem for the specified increment size. Calculate the exact solution and investigate the accuracy of your approximations. Round your results to four decimal places.

15. $y' = \frac{2y}{x}$, $y(1) = -1$, $dx = 0.5$

16. $y' = x(1 - y)$, $y(1) = 0$, $dx = 0.2$

17. $y' = 2xy + 2y$, $y(0) = 3$, $dx = 0.2$

18. $y' = y^2(1 + 2x)$, $y(-1) = 1$, $dx = 0.5$

T 19. $y' = 2xe^{x^2}$, $y(0) = 2$, $dx = 0.1$

T 20. $y' = ye^x$, $y(0) = 2$, $dx = 0.5$

21. Use Euler's method with $dx = 0.2$ to estimate $y(1)$ if $y' = y$ and $y(0) = 1$. What is the exact value of $y(1)$?

22. Use Euler's method with $dx = 0.2$ to estimate $y(2)$ if $y' = y/x$ and $y(1) = 2$. What is the exact value of $y(2)$?

23. Use Euler's method with $dx = 0.5$ to estimate $y(5)$ if $y' = y^2/\sqrt{x}$ and $y(1) = -1$. What is the exact value of $y(5)$?

24. Use Euler's method with $dx = 1/3$ to estimate $y(2)$ if $y' = x \sin y$ and $y(0) = 1$. What is the exact value of $y(2)$?

25. Show that the solution of the initial value problem

$$y' = x + y, \quad y(x_0) = y_0$$

is

$$y = -1 - x + (1 + x_0 + y_0) e^{x-x_0}.$$

26. What integral equation is equivalent to the initial value problem $y' = f(x)$, $y(x_0) = y_0$?

COMPUTER EXPLORATIONS

In Exercises 27–32, obtain a slope field and add to it graphs of the solution curves passing through the given points.

27. $y' = y$ with

a. (0, 1) b. (0, 2) c. (0, -1)

28. $y' = 2(y - 4)$ with

a. (0, 1) b. (0, 4) c. (0, 5)

29. $y' = y(x + y)$ with

a. (0, 1) b. (0, -2) c. (0, 1/4) d. (-1, -1)

30. $y' = y^2$ with

a. (0, 1) b. (0, 2) c. (0, -1) d. (0, 0)

31. $y' = (y - 1)(x + 2)$ with

a. (0, -1) b. (0, 1) c. (0, 3) d. (1, -1)

32. $y' = \frac{xy}{x^2 + 4}$ with

a. (0, 2) b. (0, -6) c. $(-2\sqrt{3}, -4)$

In Exercises 33 and 34, obtain a slope field, and graph the particular solution over the specified interval. Use your CAS DE solver to find the general solution of the differential equation.

33. **A logistic equation** $y' = y(2 - y)$, $y(0) = 1/2$; $0 \leq x \leq 4$, $0 \leq y \leq 3$

34. $y' = (\sin x)(\sin y)$, $y(0) = 2$; $-6 \leq x \leq 6$, $-6 \leq y \leq 6$

Exercises 35 and 36 have no explicit solution in terms of elementary functions. Use a CAS to explore graphically each of the differential equations.

35. $y' = \cos(2x - y)$, $y(0) = 2$; $0 \leq x \leq 5$, $0 \leq y \leq 5$
 36. **A Gompertz equation** $y' = y(1/2 - \ln y)$, $y(0) = 1/3$; $0 \leq x \leq 4$, $0 \leq y \leq 3$
 37. Use a CAS to find the solutions of $y' + y = f(x)$, subject to the initial condition $y(0) = 0$, if $f(x)$ is
 a. $2x$ b. $\sin 2x$ c. $3e^{x/2}$ d. $2e^{-x/2} \cos 2x$.

Graph all four solutions over the interval $-2 \leq x \leq 6$ to compare the results.

38. a. Use a CAS to plot the slope field of the differential equation

$$y' = \frac{3x^2 + 4x + 2}{2(y - 1)}$$

over the region $-3 \leq x \leq 3$ and $-3 \leq y \leq 3$.

- b. Separate the variables and use a CAS integrator to find the general solution in implicit form.
 c. Using a CAS implicit function grapher, plot solution curves for the arbitrary constant values $C = -6, -4, -2, 0, 2, 4, 6$.
 d. Find and graph the solution that satisfies the initial condition $y(0) = -1$.

In Exercises 39–42, use Euler's method with the specified step size to estimate the value of the solution at the given point x^* . Find the value of the exact solution at x^* .

39. $y' = 2xe^{x^2}$, $y(0) = 2$, $dx = 0.1$, $x^* = 1$
 40. $y' = 2y^2(x - 1)$, $y(2) = -1/2$, $dx = 0.1$, $x^* = 3$
 41. $y' = \sqrt{x}/y$, $y > 0$, $y(0) = 1$, $dx = 0.1$, $x^* = 1$
 42. $y' = 1 + y^2$, $y(0) = 0$, $dx = 0.1$, $x^* = 1$

Use a CAS to explore graphically each of the differential equations in Exercises 43–46. Perform the following steps to help with your explorations.

- a. Plot a slope field for the differential equation in the given xy -window.
 b. Find the general solution of the differential equation using your CAS DE solver.
 c. Graph the solutions for the values of the arbitrary constant $C = -2, -1, 0, 1, 2$ superimposed on your slope field plot.
 d. Find and graph the solution that satisfies the specified initial condition over the interval $[0, b]$.
 e. Find the Euler numerical approximation to the solution of the initial value problem with 4 subintervals of the x -interval, and plot the Euler approximation superimposed on the graph produced in part (d).
 f. Repeat part (e) for 8, 16, and 32 subintervals. Plot these three Euler approximations superimposed on the graph from part (e).
 g. Find the error ($y(\text{exact}) - y(\text{Euler})$) at the specified point $x = b$ for each of your four Euler approximations. Discuss the improvement in the percentage error.
43. $y' = x + y$, $y(0) = -7/10$; $-4 \leq x \leq 4$, $-4 \leq y \leq 4$; $b = 1$
 44. $y' = -x/y$, $y(0) = 2$; $-3 \leq x \leq 3$, $-3 \leq y \leq 3$; $b = 2$
 45. $y' = y(2 - y)$, $y(0) = 1/2$; $0 \leq x \leq 4$, $0 \leq y \leq 3$; $b = 3$
 46. $y' = (\sin x)(\sin y)$, $y(0) = 2$; $-6 \leq x \leq 6$, $-6 \leq y \leq 6$; $b = 3\pi/2$

16.2 First-Order Linear Equations

A first-order **linear** differential equation is one that can be written in the form

$$\frac{dy}{dx} + P(x)y = Q(x), \quad (1)$$

where P and Q are continuous functions of x . Equation (1) is the linear equation's **standard form**. Since the exponential growth/decay equation $dy/dx = ky$ (Section 7.2) can be put in the standard form

$$\frac{dy}{dx} - ky = 0,$$

we see it is a linear equation with $P(x) = -k$ and $Q(x) = 0$. Equation (1) is *linear* (in y) because y and its derivative dy/dx occur only to the first power, they are not multiplied together, nor do they appear as the argument of a function (such as $\sin y$, e^y , or $\sqrt{dy/dx}$).

EXAMPLE 1 Put the following equation in standard form:

$$x \frac{dy}{dx} = x^2 + 3y, \quad x > 0.$$

Solution

$$x \frac{dy}{dx} = x^2 + 3y$$

$$\frac{dy}{dx} = x + \frac{3}{x}y \quad \text{Divide by } x.$$

$$\frac{dy}{dx} - \frac{3}{x}y = x \quad \text{Standard form with } P(x) = -3/x \text{ and } Q(x) = x$$

Notice that $P(x)$ is $-3/x$, not $+3/x$. The standard form is $y' + P(x)y = Q(x)$, so the minus sign is part of the formula for $P(x)$. ■

Solving Linear Equations

We solve the equation

$$\frac{dy}{dx} + P(x)y = Q(x)$$

by multiplying both sides by a *positive* function $v(x)$ that transforms the left-hand side into the derivative of the product $v(x) \cdot y$. We will show how to find v in a moment, but first we want to show how, once found, it provides the solution we seek.

Here is why multiplying by $v(x)$ works:

$$\frac{dy}{dx} + P(x)y = Q(x) \quad \text{Original equation is in standard form.}$$

$$v(x) \frac{dy}{dx} + P(x)v(x)y = v(x)Q(x) \quad \text{Multiply by positive } v(x).$$

$$\frac{d}{dx}(v(x) \cdot y) = v(x)Q(x) \quad \begin{array}{l} v(x) \text{ is chosen to make} \\ v \frac{dy}{dx} + Pvy = \frac{d}{dx}(v \cdot y). \end{array}$$

$$v(x) \cdot y = \int v(x)Q(x) dx \quad \text{Integrate with respect to } x.$$

$$y = \frac{1}{v(x)} \int v(x)Q(x) dx \quad \text{Divide by } v(x). \quad (2)$$

Equation (2) expresses the solution of Equation (1) in terms of the functions $v(x)$ and $Q(x)$. We call $v(x)$ an **integrating factor** for Equation (1) because its presence makes the equation integrable.

Why doesn't the formula for $P(x)$ appear in the solution as well? It does, but indirectly, in the construction of the positive function $v(x)$. We have

$$\frac{d}{dx}(vy) = v \frac{dy}{dx} + Pvy \quad \text{Condition imposed on } v$$

$$v \frac{dy}{dx} + y \frac{dv}{dx} = v \frac{dy}{dx} + Pvy \quad \text{Derivative Product Rule}$$

$$y \frac{dv}{dx} = Pvy. \quad \text{The terms } v \frac{dy}{dx} \text{ cancel.}$$

This last equation will hold if

$$\frac{dv}{dx} = Pv$$

$$\frac{dv}{v} = P dx \quad \text{Variables separated, } v > 0$$

$$\int \frac{dv}{v} = \int P dx \quad \text{Integrate both sides.}$$

$$\begin{aligned} \ln v &= \int P \, dx && \text{Since } v > 0, \text{ we do not need absolute} \\ &&& \text{value signs in } \ln v. \\ e^{\ln v} &= e^{\int P \, dx} && \text{Exponentiate both sides to solve for } v. \\ v &= e^{\int P \, dx}. \end{aligned} \quad (3)$$

Thus a formula for the general solution to Equation (1) is given by Equation (2), where $v(x)$ is given by Equation (3). However, rather than memorizing the formula, just remember how to find the integrating factor once you have the standard form so $P(x)$ is correctly identified. Any antiderivative of P works for Equation (3).

Integrating Factors

To solve the linear equation $y' + P(x)y = Q(x)$, multiply both sides by the integrating factor $v(x) = e^{\int P(x) \, dx}$ and integrate both sides.

When you integrate the product on the left-hand side in this procedure, you always obtain the product $v(x)y$ of the integrating factor and solution function y because of the way v is defined.

EXAMPLE 2 Solve the equation

$$x \frac{dy}{dx} = x^2 + 3y, \quad x > 0.$$

Solution First we put the equation in standard form (Example 1):

$$\frac{dy}{dx} - \frac{3}{x}y = x,$$

so $P(x) = -3/x$ is identified.

The integrating factor is

$$\begin{aligned} v(x) &= e^{\int P(x) \, dx} = e^{\int (-3/x) \, dx} && \text{Constant of integration is 0,} \\ &= e^{-3 \ln |x|} && \text{so } v \text{ is as simple as possible.} \\ &= e^{-3 \ln x} && x > 0 \\ &= e^{\ln x^{-3}} = \frac{1}{x^3}. \end{aligned}$$

Next we multiply both sides of the standard form by $v(x)$ and integrate:

$$\begin{aligned} \frac{1}{x^3} \cdot \left(\frac{dy}{dx} - \frac{3}{x}y \right) &= \frac{1}{x^3} \cdot x \\ \frac{1}{x^3} \frac{dy}{dx} - \frac{3}{x^4}y &= \frac{1}{x^2} \\ \frac{d}{dx} \left(\frac{1}{x^3}y \right) &= \frac{1}{x^2} && \text{Left-hand side is } \frac{d}{dx}(v \cdot y). \\ \frac{1}{x^3}y &= \int \frac{1}{x^2} \, dx && \text{Integrate both sides.} \\ \frac{1}{x^3}y &= -\frac{1}{x} + C. \end{aligned}$$

Solving this last equation for y gives the general solution:

$$y = x^3 \left(-\frac{1}{x} + C \right) = -x^2 + Cx^3, \quad x > 0. \quad \blacksquare$$

HISTORICAL BIOGRAPHY

Adrien-Marie Legendre
(1752–1833)

Legendre, a French mathematician, taught at the École polytechnique and won a research prize from the Berlin Academy in 1782. He encountered and developed polynomials, today named for him, in his research on the gravitational attraction of ellipsoids. He devoted 40 years to this research to elliptic integrals.

To know more, visit the companion Website.

EXAMPLE 3 Find the particular solution of

$$3xy' - y = \ln x + 1, \quad x > 0,$$

that satisfying $y(1) = -2$.

Solution With $x > 0$, we write the equation in standard form:

$$y' - \frac{1}{3x}y = \frac{\ln x + 1}{3x}.$$

Then the integrating factor is given by

$$v = e^{\int -1/(3x) dx} = e^{(-1/3)\ln x} = x^{-1/3}. \quad x > 0$$

Thus

$$x^{-1/3}y = \frac{1}{3} \int (\ln x + 1)x^{-4/3} dx. \quad \text{Left-hand side is } vy.$$

Integration by parts of the right-hand side gives

$$x^{-1/3}y = -x^{-1/3}(\ln x + 1) + \int x^{-4/3} dx + C.$$

Therefore,

$$x^{-1/3}y = -x^{-1/3}(\ln x + 1) - 3x^{-1/3} + C$$

or, solving for y ,

$$y = -(\ln x + 4) + Cx^{1/3}.$$

When $x = 1$ and $y = -2$, this last equation becomes

$$-2 = -(0 + 4) + C,$$

so

$$C = 2.$$

Substitution into the equation for y gives the particular solution

$$y = 2x^{1/3} - \ln x - 4. \quad \blacksquare$$

In solving the linear equation in Example 2, we integrated both sides of the equation after multiplying each side by the integrating factor. However, we can shorten the amount of work, as in Example 3, by remembering that the left-hand side *always* integrates into the product $v(x) \cdot y$ of the integrating factor times the solution function. From Equation (2) this means that

$$v(x)y = \int v(x)Q(x) dx. \quad (4)$$

We need only integrate the product of the integrating factor $v(x)$ with $Q(x)$ on the right-hand side of Equation (1) and then equate the result with $v(x)y$ to obtain the general solution. Nevertheless, to emphasize the role of $v(x)$ in the solution process, we sometimes follow the complete procedure as illustrated in Example 2.

Observe that if the function $Q(x)$ is identically zero in the standard form given by Equation (1), the linear equation is separable and can be solved by the method of Section 7.2:

$$\frac{dy}{dx} + P(x)y = Q(x)$$

$$\frac{dy}{dx} + P(x)y = 0 \quad Q(x) = 0$$

$$\frac{dy}{y} = -P(x) dx. \quad \text{Separating the variables}$$

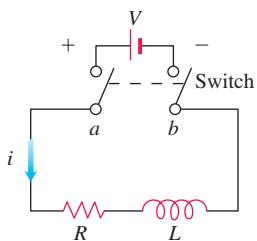

FIGURE 16.9 The RL circuit in Example 4.

RL Circuits

The diagram in Figure 16.9 represents an electrical circuit whose total resistance is a constant R ohms and whose self-inductance, shown as a coil, is L henries, also a constant. There is a switch whose terminals at a and b can be closed to connect a constant electrical source of V volts.

Ohm's Law, $V = RI$, has to be augmented for such a circuit. The correct equation accounting for both resistance and inductance is

$$L \frac{di}{dt} + Ri = V, \quad (5)$$

where i is the current in amperes and t is the time in seconds. By solving this equation, we can predict how the current will flow after the switch is closed.

EXAMPLE 4 The switch in the RL circuit in Figure 16.9 is closed at time $t = 0$. How will the current flow as a function of time?

Solution Equation (5) is a first-order linear differential equation for i as a function of t . Its standard form is

$$\frac{di}{dt} + \frac{R}{L}i = \frac{V}{L}, \quad (6)$$

and the corresponding solution, given that $i = 0$ when $t = 0$, is

$$i = \frac{V}{R} - \frac{V}{R}e^{-(R/L)t}. \quad (7)$$

(We leave the calculation of the solution to Exercise 28.) Since R and L are positive, $-(R/L)$ is negative and $e^{-(R/L)t} \rightarrow 0$ as $t \rightarrow \infty$. Thus,

$$\lim_{t \rightarrow \infty} i = \lim_{t \rightarrow \infty} \left(\frac{V}{R} - \frac{V}{R}e^{-(R/L)t} \right) = \frac{V}{R} - \frac{V}{R} \cdot 0 = \frac{V}{R}.$$

At any given time, the current is less than V/R , but as time passes, the current approaches the **steady-state value** V/R . According to the equation

$$L \frac{di}{dt} + Ri = V,$$

$I = V/R$ is the current that will flow in the circuit if either $L = 0$ (no inductance) or $di/dt = 0$ (steady current, $i = \text{constant}$) (Figure 16.10).

Equation (7) expresses the solution of Equation (6) as the sum of two terms: a steady-state solution V/R and a transient solution $-(V/R)e^{-(R/L)t}$ that tends to zero as $t \rightarrow \infty$. ■

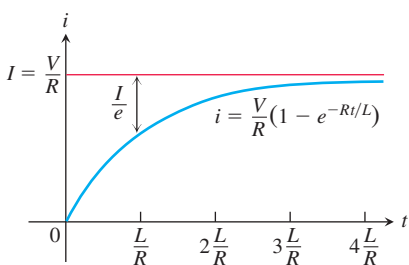

FIGURE 16.10 The growth of the current in the RL circuit in Example 4. I is the current's steady-state value. The number $t = L/R$ is the time constant of the circuit. The current gets to within 5% of its steady-state value in 3 time constants (Exercise 27).

EXERCISES 16.2

First-Order Linear Equations

Solve the differential equations in Exercises 1–14.

1. $x \frac{dy}{dx} + y = e^x, \quad x > 0$

2. $e^x \frac{dy}{dx} + 2e^x y = 1$

3. $xy' + 3y = \frac{\sin x}{x^2}, \quad x > 0$

4. $y' + (\tan x)y = \cos^2 x, \quad -\pi/2 < x < \pi/2$

5. $x \frac{dy}{dx} + 2y = 1 - \frac{1}{x}, \quad x > 0$

6. $(1+x)y' + y = \sqrt{x}$

7. $2y' = e^{x/2} + y$

8. $e^{2x}y' + 2e^{2x}y = 2x$

9. $xy' - y = 2x \ln x$

10. $x \frac{dy}{dx} = \frac{\cos x}{x} - 2y, \quad x > 0$

11. $(t-1)^3 \frac{ds}{dt} + 4(t-1)^2 s = t+1, \quad t > 1$
12. $(t+1) \frac{ds}{dt} + 2s = 3(t+1) + \frac{1}{(t+1)^2}, \quad t > -1$
13. $\sin \theta \frac{dr}{d\theta} + (\cos \theta)r = \tan \theta, \quad 0 < \theta < \pi/2$
14. $\tan \theta \frac{dr}{d\theta} + r = \sin^2 \theta, \quad 0 < \theta < \pi/2$

Solving Initial Value Problems

Solve the initial value problems in Exercises 15–20.

15. $\frac{dy}{dt} + 2y = 3, \quad y(0) = 1$
16. $t \frac{dy}{dt} + 2y = t^3, \quad t > 0, \quad y(2) = 1$
17. $\theta \frac{dy}{d\theta} + y = \sin \theta, \quad \theta > 0, \quad y(\pi/2) = 1$
18. $\theta \frac{dy}{d\theta} - 2y = \theta^3 \sec \theta \tan \theta, \quad \theta > 0, \quad y(\pi/3) = 2$
19. $(x+1) \frac{dy}{dx} - 2(x^2+x)y = \frac{e^{x^2}}{x+1}, \quad x > -1, \quad y(0) = 5$
20. $\frac{dy}{dx} + xy = x, \quad y(0) = -6$
21. Solve the exponential growth/decay initial value problem for y as a function of t by thinking of the differential equation as a first-order linear equation with $P(x) = -k$ and $Q(x) = 0$:

$$\frac{dy}{dt} = ky \quad (k \text{ constant}), \quad y(0) = y_0$$

22. Solve the following initial value problem for u as a function of t :

$$\frac{du}{dt} + \frac{k}{m}u = 0 \quad (k \text{ and } m \text{ positive constants}), \quad u(0) = u_0$$

- a. as a first-order linear equation.
b. as a separable equation.

Theory and Examples

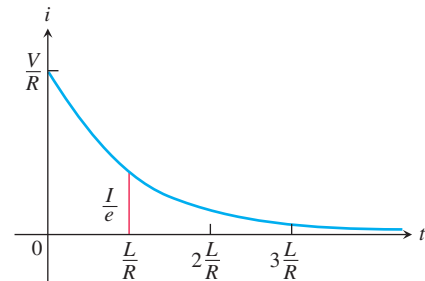

23. Is either of the following equations correct? Give reasons for your answers.
- a. $x \int \frac{1}{x} dx = x \ln|x| + C$
b. $x \int \frac{1}{x} dx = x \ln|x| + Cx$
24. Is either of the following equations correct? Give reasons for your answers.
- a. $\frac{1}{\cos x} \int \cos x dx = \tan x + C$
b. $\frac{1}{\cos x} \int \cos x dx = \tan x + \frac{C}{\cos x}$
25. **Current in a closed RL circuit** How many seconds after the switch in an RL circuit is closed will it take the current i to reach half of its steady-state value? Notice that the time depends on R and L , not on how much voltage is applied.
26. **Current in an open RL circuit** If the switch is thrown open after the current in an RL circuit has built up to its steady-state

value $I = V/R$, the decaying current (see accompanying figure) obeys the equation

$$L \frac{di}{dt} + Ri = 0,$$

which is Equation (5) with $V = 0$.

- a. Solve the equation to express i as a function of t .
b. How long after the switch is thrown will it take the current to fall to half its original value?
c. Show that the value of the current when $t = L/R$ is I/e . (The significance of this time is explained in the next exercise.)

27. **Time constants** Engineers call the number L/R the *time constant* of the RL circuit in Figure 16.10. The significance of the time constant is that the current will reach 95% of its final value within 3 time constants of the time the switch is closed (Figure 16.10). Thus, the time constant gives a built-in measure of how rapidly an individual circuit will reach equilibrium.
- a. Find the value of i in Equation (7) that corresponds to $t = 3L/R$, and show that it is about 95% of the steady-state value $I = V/R$.
b. Approximately what percentage of the steady-state current will be flowing in the circuit 2 time constants after the switch is closed (i.e., when $t = 2L/R$)?
28. **Derivation of Equation (7) in Example 4**
- a. Show that the solution of the equation

$$\frac{di}{dt} + \frac{R}{L}i = \frac{V}{L}$$

is

$$i = \frac{V}{R} + Ce^{-(R/L)t}.$$

- b. Then use the initial condition $i(0) = 0$ to determine the value of C . This will complete the derivation of Equation (7).
c. Show that $i = V/R$ is a solution of Equation (6) and that $i = Ce^{-(R/L)t}$ satisfies the equation

$$\frac{di}{dt} + \frac{R}{L}i = 0.$$

A **Bernoulli differential equation** is of the form

$$\frac{dy}{dx} + P(x)y = Q(x)y^n.$$

Observe that, if $n = 0$ or 1 , the Bernoulli equation is linear. For other values of n , the substitution $u = y^{1-n}$ transforms the Bernoulli equation into the linear equation

$$\frac{du}{dx} + (1-n)P(x)u = (1-n)Q(x).$$

HISTORICAL BIOGRAPHY**Jakob Bernoulli**
(1654–1705)

Jakob Bernoulli was born in Switzerland and received his degree in 1671 after studying philosophy and theology at the request of his father and mathematics and astronomy against the will of his father. Working on problems in optics and mechanics, Bernoulli contributed to important developments in infinitesimal geometry and calculus.

To know more, visit the companion Website.

For example, in the equation

$$\frac{dy}{dx} - y = e^{-x}y^2,$$

we have $n = 2$, so that $u = y^{1-2} = y^{-1}$ and

$$du/dx = -y^{-2}dy/dx. \text{ Then}$$

$$dy/dx = -y^2 du/dx = -u^{-2} du/dx.$$

Substitution into the original equation gives

$$-u^{-2} \frac{du}{dx} - u^{-1} = e^{-x} u^{-2},$$

or, equivalently,

$$\frac{du}{dx} + u = -e^{-x}.$$

This last equation is linear in the (unknown) dependent variable u .

Solve the Bernoulli equations in Exercises 29–32.

29. $y' - y = -y^2$

30. $y' - y = xy^2$

31. $xy' + y = y^{-2}$

32. $x^2y' + 2xy = y^3$

16.3 Applications

We now look at four applications of first-order differential equations. The first application analyzes an object moving along a straight line while subject to a force opposing its motion. The second is a model of population growth. The third application considers a curve or curves intersecting each curve in a second family of curves *orthogonally* (that is, at right angles). The final application analyzes chemical concentrations entering and leaving a container. The various models involve separable or linear first-order equations.

Motion with Resistance Proportional to Velocity

In some cases it is reasonable to assume that the resistance encountered by a moving object, such as a car coasting to a stop, is proportional to the object's velocity. The faster the object moves, the more its forward progress is resisted by the air through which it passes. Picture the object as a mass m moving along a coordinate line with position function s and velocity v at time t . From Newton's second law of motion, the resisting force opposing the motion is

$$\text{Force} = \text{mass} \times \text{acceleration} = m \frac{dv}{dt}.$$

If the resisting force is proportional to velocity, we have

$$m \frac{dv}{dt} = -kv \quad \text{or} \quad \frac{dv}{dt} = -\frac{k}{m}v \quad (k > 0).$$

This is a separable differential equation representing exponential change. The solution to the equation with initial condition $v = v_0$ at $t = 0$ is (Section 7.2)

$$v = v_0 e^{-(k/m)t}. \tag{1}$$

What can we learn from Equation (1)? For one thing, we can see that if m is something large, like the mass of a 20,000-ton ore boat in Lake Erie, it will take a long time for the velocity to approach zero (because t must be large in the exponent of the equation in order to make kt/m large enough for v to be small). We can learn even more if we integrate Equation (1) to find the position s as a function of time t .

Suppose that an object is coasting to a stop and the only force acting on it is a resistance proportional to its speed. How far will it coast? To find out, we start with Equation (1) and solve the initial value problem

$$\frac{ds}{dt} = v_0 e^{-(k/m)t}, \quad s(0) = 0.$$

Integrating with respect to t gives

$$s = -\frac{v_0 m}{k} e^{-(k/m)t} + C.$$

Substituting $s = 0$ when $t = 0$ gives

$$0 = -\frac{v_0 m}{k} + C \quad \text{and} \quad C = \frac{v_0 m}{k}.$$

The body's position at time t is therefore

$$s(t) = -\frac{v_0 m}{k} e^{-(k/m)t} + \frac{v_0 m}{k} = \frac{v_0 m}{k} (1 - e^{-(k/m)t}). \quad (2)$$

To find how far the body will coast, we find the limit of $s(t)$ as $t \rightarrow \infty$. Since $-(k/m) < 0$, we know that $e^{-(k/m)t} \rightarrow 0$ as $t \rightarrow \infty$, so that

$$\lim_{t \rightarrow \infty} s(t) = \lim_{t \rightarrow \infty} \frac{v_0 m}{k} (1 - e^{-(k/m)t}) = \frac{v_0 m}{k} (1 - 0) = \frac{v_0 m}{k}.$$

Thus,

$$\text{Distance coasted} = \frac{v_0 m}{k}. \quad (3)$$

The number $v_0 m/k$ is only an upper bound (albeit a useful one). It is true to life in one respect, at least: If m is large, the body will coast a long way.

EXAMPLE 1 For a 90-kg ice skater, the k in Equation (1) is about 5 kg/s. How long will it take the skater to coast from 3.3 m/s (11.88 km/h) to 0.3 m/s? How far will the skater coast before coming to a complete stop?

Solution We answer the first question by solving Equation (1) for t :

$$\begin{aligned} 33e^{-t/18} &= 0.3 && \text{Eq. (1) with } k = 5, \\ e^{-t/18} &= 1/11 && m = 90, v_0 = 3.3, v = 0.3 \\ -t/18 &= \ln(1/11) = -\ln 11 \\ t &= 18 \ln 11 \approx 43 \text{ s.} \end{aligned}$$

We answer the second question with Equation (3):

$$\text{Distance coasted} = \frac{v_0 m}{k} = \frac{3.3 \cdot 90}{5} = 59.4 \text{ m.} \quad \blacksquare$$

Inaccuracy of the Exponential Population Growth Model

In Section 7.2 we modeled population growth with the Law of Exponential Change:

$$\frac{dP}{dt} = kP, \quad P(0) = P_0,$$

where P is the population at time t , $k > 0$ is a constant growth rate, and P_0 is the size of the population at time $t = 0$. In Section 7.2 we found the solution $P = P_0 e^{kt}$ to this model.

To assess the model, notice that the exponential growth differential equation says that

$$\frac{dP/dt}{P} = k \quad (4)$$

is constant. This rate is called the **relative growth rate**. We can use this to predict total future world population based on historical data. Table 16.3 gives the world population at

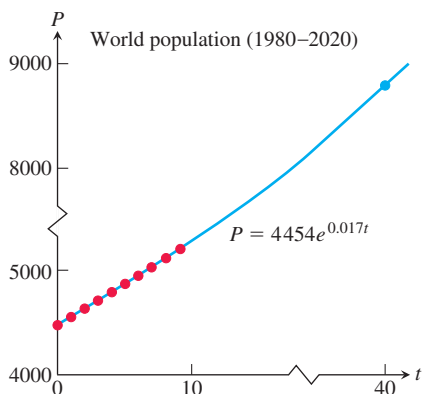

FIGURE 16.11 The value of the solution $P = 4454e^{0.017t}$ is 8792 when $t = 40$, which is nearly 13% more than the actual population in 2020.

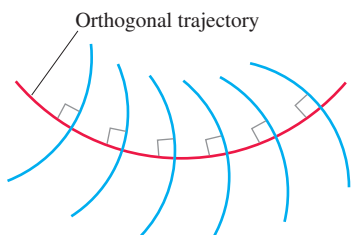

FIGURE 16.12 An orthogonal trajectory intersects the family of curves at right angles, or orthogonally.

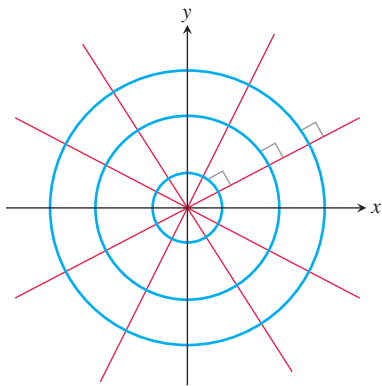

FIGURE 16.13 Every straight line through the origin is orthogonal to the family of circles centered at the origin.

TABLE 16.3 World population (midyear)

Year	Population (millions)	$\Delta P/P$
1980	4454	$76/4454 \approx 0.0171$
1981	4530	$80/4530 \approx 0.0177$
1982	4610	$80/4610 \approx 0.0174$
1983	4690	$80/4690 \approx 0.0171$
1984	4770	$81/4770 \approx 0.0170$
1985	4851	$82/4851 \approx 0.0169$
1986	4933	$85/4933 \approx 0.0172$
1987	5018	$87/5018 \approx 0.0173$
1988	5105	$85/5105 \approx 0.0167$
1989	5190	

midyear for the years 1980 to 19816. Taking $dt = 1$ and $dP \approx \Delta P$, we see from the table that the relative growth rate in Equation (4) is approximately equal to 0.017. Thus, based on the tabled data with $t = 0$ representing 1980, $t = 1$ representing 1981, and so forth, the world population could be modeled by the initial value problem

$$\frac{dP}{dt} = 0.017P, \quad P(0) = 4454.$$

The solution to this initial value problem gives the population function $P = 4454e^{0.017t}$. In year 2008 (so $t = 28$), the solution predicts the world population in midyear to be about 7169 million, or 7.2 billion (Figure 16.11), which is more than the actual population of 6707 million, an error of about 7%. The error grows as the number of years increases. For 2020 ($t = 40$) the model predicts a population of 8792 million. The reported population for 2020 is 7795 million, an overprediction error of about 13%. A more realistic model would consider environmental, economic, and other factors affecting the growth rate, which has been steadily declining. We consider one such model in Section 16.4.

Orthogonal Trajectories

An **orthogonal trajectory** of a family of curves is a curve that intersects each curve of the family at right angles, or *orthogonally* (Figure 16.12). For instance, each straight line through the origin is an orthogonal trajectory of the family of circles $x^2 + y^2 = a^2$, centered at the origin (Figure 16.13). Such mutually orthogonal systems of curves are of particular importance in physical problems related to electrical potential, where the curves in one family correspond to strength of an electric field, and those in the other family correspond to constant electric potential. They also occur in hydrodynamics and heat-flow problems.

EXAMPLE 2 Find the orthogonal trajectories of the family of curves $xy = a$, where $a \neq 0$ is an arbitrary constant.

Solution The curves $xy = a$ form a family of hyperbolas having the coordinate axes as asymptotes. First we find the slopes of each curve in this family, or their dy/dx values. Differentiating $xy = a$ implicitly gives

$$x \frac{dy}{dx} + y = 0 \quad \text{or} \quad \frac{dy}{dx} = -\frac{y}{x}.$$

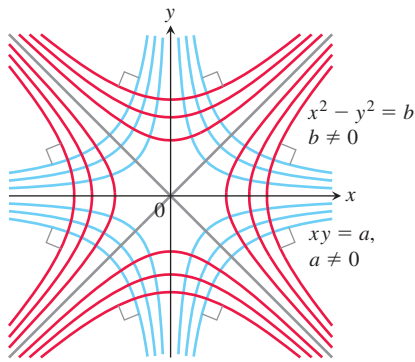

FIGURE 16.14 Each curve is orthogonal to every curve it meets in the other family (Example 2).

Thus the slope of the tangent line at any point (x, y) on one of the hyperbolas $xy = a$ is $y' = -y/x$. On an orthogonal trajectory the slope of the tangent line at this same point must be the negative reciprocal, or x/y . Therefore, the orthogonal trajectories must satisfy the differential equation

$$\frac{dy}{dx} = \frac{x}{y}.$$

This differential equation is separable, and we solve it as in Section 7.2:

$$\begin{aligned} y \, dy &= x \, dx && \text{Separate variables.} \\ \int y \, dy &= \int x \, dx && \text{Integrate both sides.} \\ \frac{1}{2}y^2 &= \frac{1}{2}x^2 + C \\ y^2 - x^2 &= b, \end{aligned} \quad (5)$$

where $b = 2C$ is an arbitrary constant. The orthogonal trajectories are the family of hyperbolas given by Equation (5) and sketched in Figure 16.14. ■

Mixture Problems

Suppose a chemical in a liquid solution (or dispersed in a gas) runs into a container holding the liquid (or the gas) with, possibly, a specified amount of the chemical dissolved as well. The mixture is kept uniform by stirring and flows out of the container at a known rate. In this process, it is often important to know the concentration of the chemical in the container at any given time. The differential equation describing the process is based on the formula

$$\begin{array}{l} \text{Rate of change} \\ \text{of amount} \\ \text{in container} \end{array} = \left(\begin{array}{l} \text{rate at which} \\ \text{chemical} \\ \text{arrives} \end{array} \right) - \left(\begin{array}{l} \text{rate at which} \\ \text{chemical} \\ \text{departs.} \end{array} \right). \quad (6)$$

If $y(t)$ is the amount of chemical in the container at time t , and $V(t)$ is the total volume of liquid in the container at time t , then the departure rate of the chemical at time t is

$$\begin{aligned} \text{Departure rate} &= \frac{y(t)}{V(t)} \cdot (\text{outflow rate}) \\ &= \left(\begin{array}{l} \text{concentration in} \\ \text{container at time } t \end{array} \right) \cdot (\text{outflow rate}). \end{aligned} \quad (7)$$

Accordingly, Equation (6) becomes

$$\frac{dy}{dt} = (\text{chemical's arrival rate}) - \frac{y(t)}{V(t)} \cdot (\text{outflow rate}). \quad (8)$$

If, say, y is measured in kilograms, V in liters, and t in minutes, the units in Equation (8) are

$$\frac{\text{kilograms}}{\text{minutes}} = \frac{\text{kilograms}}{\text{minutes}} - \frac{\text{kilograms}}{\text{liters}} \cdot \frac{\text{liters}}{\text{minutes}}.$$

EXAMPLE 3 In an oil refinery, a storage tank contains 10,000 L of gasoline that initially has 50 kg of an additive dissolved in it. In preparation for winter weather, gasoline containing 0.2 kg of additive per liter is pumped into the tank at a rate of 200 L/min.

The well-mixed solution is pumped out at a rate of 220 L/min. How much of the additive is in the tank 20 min after the pumping process begins (Figure 16.15)?

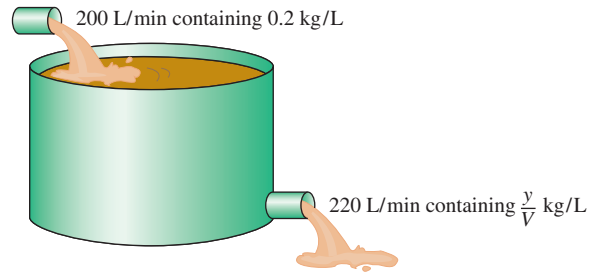

FIGURE 16.15 The storage tank in Example 3 mixes input liquid with stored liquid to produce an output liquid.

Solution Let y be the amount (in kilograms) of additive in the tank at time t . We know that $y = 50$ when $t = 0$. The number of liters of gasoline and additive in solution in the tank at any time t is

$$V(t) = 10,000 \text{ L} + \left(200 \frac{\text{L}}{\text{min}} - 220 \frac{\text{L}}{\text{min}}\right)(t \text{ min}) = (10,000 - 20t) \text{ L}.$$

Therefore,

$$\begin{aligned} \text{Rate out} &= \frac{y(t)}{V(t)} \cdot \text{outflow rate} && \text{Eq. (7)} \\ &= \left(\frac{y}{10,000 - 20t}\right) 220 && \text{Outflow rate is 220 L/min} \\ &= \frac{220y}{10,000 - 20t} \frac{\text{kg}}{\text{min}}. && \text{and } V = 10,000 - 20t. \end{aligned}$$

Also,

$$\text{Rate in} = \left(0.2 \frac{\text{kg}}{\text{L}}\right) \left(200 \frac{\text{L}}{\text{min}}\right) = 40 \frac{\text{kg}}{\text{min}}.$$

The differential equation modeling the mixture process is

$$\frac{dy}{dt} = 40 - \frac{220y}{10,000 - 20t} \quad \text{Eq. (8)}$$

in kilograms per minute.

To solve this differential equation, we first write it in standard linear form:

$$\frac{dy}{dt} + \frac{220}{10,000 - 20t} y = 40.$$

Thus, $P(t) = 220/(10,000 - 20t)$ and $Q(t) = 40$. The integrating factor is

$$\begin{aligned} v(t) &= e^{\int P dt} = e^{\int \frac{220}{10,000 - 20t} dt} \\ &= e^{-11 \ln(10,000 - 20t)} && 10,000 - 20t > 0 \\ &= (10,000 - 20t)^{-11}. \end{aligned}$$

Multiplying both sides of the standard equation by $v(t)$ and integrating both sides gives

$$\begin{aligned}(10,000 - 20t)^{-11} \cdot \left(\frac{dy}{dt} + \frac{220}{10,000 - 20t} y \right) &= 40(10,000 - 20t)^{-11} \\ (10,000 - 20t)^{-11} \frac{dy}{dt} + 220(10,000 - 20t)^{-12} y &= 40(10,000 - 20t)^{-11} \\ \frac{d}{dt} [(10,000 - 20t)^{-11} y] &= 40(10,000 - 20t)^{-11} \\ (10,000 - 20t)^{-11} y &= \int 40(10,000 - 20t)^{-11} dt \\ (10,000 - 20t)^{-11} y &= 40 \cdot \frac{(10,000 - 20t)^{-10}}{(-10)(-20)} + C.\end{aligned}$$

The general solution is

$$y = 0.2(10,000 - 20t) + C(10,000 - 20t)^{11}.$$

Because $y = 50$ when $t = 0$, we can determine the value of C :

$$\begin{aligned}50 &= 0.2(10,000 - 0) + C(10,000 - 0)^{11} \\ C &= -\frac{1950}{(10,000)^{11}}.\end{aligned}$$

The particular solution of the initial value problem is

$$y = 0.2(10,000 - 20t) - \frac{1950}{(10,000)^{11}}(10,000 - 20t)^{11}.$$

The amount of additive in the tank 20 min after the pumping begins is

$$y(20) = 0.2[10,000 - 20(20)] - \frac{1950}{(10,000)^{11}}[10,000 - 20(20)]^{11} \approx 675 \text{ kg.} \quad \blacksquare$$

EXERCISES 16.3

Motion Along a Line

- Coasting bicycle** A 66-kg cyclist on a 7-kg bicycle starts coasting on level ground at 9 m/s. The k in Equation (1) is about 3.9 kg/s.
 - About how far will the cyclist coast before reaching a complete stop?
 - How long will it take the cyclist's speed to drop to 1 m/s?
- Coasting battleship** An Iowa class battleship has mass around 51,000 metric tons (51,000,000 kg) and a k value in Equation (1) of about 59,000 kg/s. Assume that the ship loses power when it is moving at a speed of 9 m/s.
 - About how far will the ship coast before it is dead in the water?
 - About how long will it take the ship's speed to drop to 1 m/s?
- The data in Table 16.4 were collected with a motion detector and a CBL™ by Valerie Sharritts, then a mathematics teacher at St. Francis DeSales High School in Columbus, Ohio. The table shows the distance s (meters) coasted on inline skates in t s by her daughter Ashley when she was 10 years old. Find a model for Ashley's position given by the data in Table 16.4 in the form of

TABLE 16.4 Ashley Sharritts skating data

t (s)	s (m)	t (s)	s (m)	t (s)	s (m)

Orthogonal Trajectories

In Exercises 5–10, find the orthogonal trajectories of the family of curves. Sketch several members of each family.

5. $y = mx$ 6. $y = cx^2$ 7. $kx^2 + y^2 = 1$

8. $2x^2 + y^2 = c^2$ 9. $y = ce^{-x}$ 10. $y = e^{kx}$

11. Show that the curves $2x^2 + 3y^2 = 5$ and $y^2 = x^3$ are orthogonal.

12. Find the family of solutions of the given differential equation and the family of orthogonal trajectories. Sketch both families.

a. $x dx + y dy = 0$

b. $x dy - 2y dx = 0$

Mixture Problems

13. **Salt mixture** A tank initially contains 400 L of brine in which 20 kg/L of salt are dissolved. A brine containing 0.2 kg/L of salt runs into the tank at the rate of 20 L/min. The mixture is kept uniform by stirring and flows out of the tank at the rate of 16 L/min.

- At what rate (kilograms per minute) does salt enter the tank at time t ?
- What is the volume of brine in the tank at time t ?
- At what rate (kilograms per minute) does salt leave the tank at time t ?
- Write down and solve the initial value problem describing the mixing process.
- Find the concentration of salt in the tank 25 min after the process starts.

14. **Mixture problem** A 800-L tank is half full of distilled water. At time $t = 0$, a solution containing 50 grams/L of concentrate enters the tank at the rate of 20 L/min, and the well-stirred mixture is withdrawn at the rate of 12 L/min.

- At what time will the tank be full?
- At the time the tank is full, how many kilograms of concentrate will it contain?

15. **Fertilizer mixture** A tank contains 400 L of fresh water. A solution containing 0.1 kg/L of soluble lawn fertilizer runs into the tank at the rate of 4 L/min, and the mixture is pumped out of the tank at the rate of 12 L/min. Find the maximum amount of fertilizer in the tank and the time required to reach the maximum.

16. **Carbon monoxide pollution** An executive conference room of a corporation contains 120 m^3 of air initially free of carbon monoxide. Starting at time $t = 0$, cigarette smoke containing 4% carbon monoxide is blown into the room at the rate of $0.008 \text{ m}^3/\text{min}$. A ceiling fan keeps the air in the room well circulated and the air leaves the room at the same rate of $0.008 \text{ m}^3/\text{min}$. Find the time when the concentration of carbon monoxide in the room reaches 0.01%.

16.4 Graphical Solutions of Autonomous Equations

In Chapter 4 we learned that the sign of the first derivative tells where the graph of a function is increasing and where it is decreasing. The sign of the second derivative tells the concavity of the graph. We can build on our knowledge of how derivatives determine the shape of a graph to solve differential equations graphically. We will see that the ability to discern physical behavior from graphs is a powerful tool in understanding real-world systems. The starting ideas for a graphical solution are the notions of *phase line* and *equilibrium value*. We arrive at these notions by investigating, from a point of view quite different from that studied in Chapter 4, what happens when the derivative of a differentiable function is zero.

Equilibrium Values and Phase Lines

When we differentiate implicitly the equation

$$\frac{1}{5} \ln(5y - 15) = x + 1,$$

we obtain

$$\frac{1}{5} \left(\frac{5}{5y - 15} \right) \frac{dy}{dx} = 1.$$

Solving for $y' = dy/dx$, we find $y' = 5y - 15 = 5(y - 3)$. In this case the derivative y' is a function of y only (the dependent variable) and is zero when $y = 3$.

A differential equation for which dy/dx is a function of y only is called an **autonomous** differential equation. Let's investigate what happens when the derivative in an autonomous equation equals zero. We assume any derivatives are continuous.

DEFINITION If $dy/dx = g(y)$ is an autonomous differential equation, then the values of y for which $dy/dx = 0$ are called **equilibrium values** or **rest points**.

Thus, equilibrium values are those at which no change occurs in the dependent variable, so y is at *rest*. The emphasis is on the value of y where $dy/dx = 0$, not the value of x , as we studied in Chapter 4. For example, the equilibrium values for the autonomous differential equation

$$\frac{dy}{dx} = (y + 1)(y - 2)$$

are $y = -1$ and $y = 2$.

To construct a graphical solution to an autonomous differential equation, we first make a **phase line** for the equation, a plot on the y -axis that shows the equation's equilibrium values along with the intervals where dy/dx and d^2y/dx^2 are positive and negative. Then we know where the solutions are increasing and decreasing, and the concavity of the solution curves. These are the essential features we found in Section 4.4, so we can determine the shapes of the solution curves without having to find formulas for them.

EXAMPLE 1 Draw a phase line for the equation

$$\frac{dy}{dx} = (y + 1)(y - 2),$$

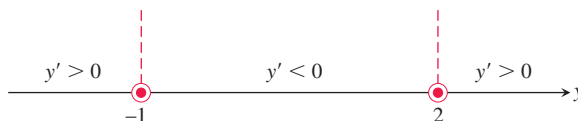

and use it to sketch solutions to the equation.

Solution

1. Draw a number line for y and mark the equilibrium values $y = -1$ and $y = 2$, where $dy/dx = 0$.

2. Identify and label the intervals where $y' > 0$ and $y' < 0$. This step resembles what we did in Section 4.3, only now we are marking the y -axis instead of the x -axis.

We can encapsulate the information about the sign of y' on the phase line itself. Since $y' > 0$ on the interval to the left of $y = -1$, a solution of the differential equation

with a y -value less than -1 will increase from there toward $y = -1$. We display this information by drawing an arrow on the interval pointing to -1 .

Similarly, $y' < 0$ between $y = -1$ and $y = 2$, so any solution with a value in this interval will decrease toward $y = -1$.

For $y > 2$, we have $y' > 0$, so a solution with a y -value greater than 2 will increase from there without bound.

In short, solution curves below the horizontal line $y = -1$ in the xy -plane rise toward $y = -1$. Solution curves between the lines $y = -1$ and $y = 2$ fall away from $y = 2$ toward $y = -1$. Solution curves above $y = 2$ rise away from $y = 2$ and keep going up.

3. Calculate y'' and mark the intervals where $y'' > 0$ and $y'' < 0$. To find y'' , we differentiate y' with respect to x , using implicit differentiation.

$$y' = (y + 1)(y - 2) = y^2 - y - 2 \quad \text{Formula for } y'$$

$$y'' = \frac{d}{dx}(y') = \frac{d}{dx}(y^2 - y - 2) \quad \text{Substitute for } y'$$

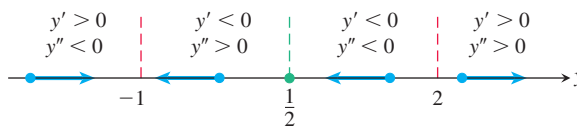

$$= 2yy' - y'$$

Differentiate implicitly
with respect to x .

$$= (2y - 1)y'$$

$$= (2y - 1)(y + 1)(y - 2).$$

From this formula, we see that y'' changes sign at $y = -1$, $y = 1/2$, and $y = 2$. We add the sign information to the phase line.

4. Sketch an assortment of solution curves in the xy -plane. The horizontal lines $y = -1$, $y = 1/2$, and $y = 2$ partition the plane into horizontal bands in which we know the signs of y' and y'' . In each band, this information tells us whether the solution curves rise or fall and how they bend as x increases (Figure 16.16).

The “equilibrium lines” $y = -1$ and $y = 2$ are also solution curves. (The constant functions $y = -1$ and $y = 2$ satisfy the differential equation.) Solution curves that cross the line $y = 1/2$ have an inflection point there. The concavity changes from concave down (above the line) to concave up (below the line).

As predicted in Step 2, solutions in the middle and lower bands approach the equilibrium value $y = -1$ as x increases. Solutions in the upper band rise steadily away from the value $y = 2$. ■

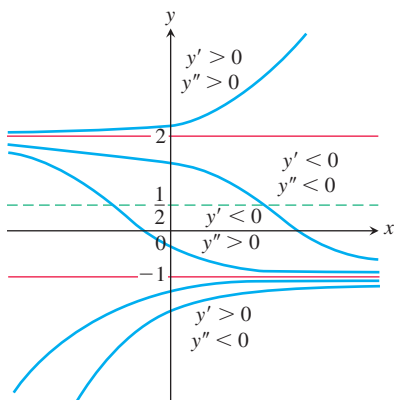

FIGURE 16.16 Graphical solutions from Example 1 include the horizontal lines $y = -1$ and $y = 2$ through the equilibrium values. No two solution curves can ever cross or touch each other.

Stable and Unstable Equilibria

Look at Figure 16.16 once more, in particular at the behavior of the solution curves near the equilibrium values. Once a solution curve has a value near $y = -1$, it tends steadily toward that value; $y = -1$ is a **stable equilibrium**. The behavior near $y = 2$ is just the opposite: All solutions except the equilibrium solution $y = 2$ itself move *away* from it as x increases. We call $y = 2$ an **unstable equilibrium**. If the solution is *at* that value, it stays, but if it is off by any amount, no matter how small, it moves away. (Sometimes an equilibrium value is unstable because a solution moves away from it only on one side of the point.)

Now that we know what to look for, we can already see this behavior on the initial phase line (the second diagram in Step 2 of Example 1). The arrows lead away from $y = 2$ and, once to the left of $y = 2$, toward $y = -1$.

We now present several applied examples for which we can sketch a family of solution curves to the differential equation models using the method in Example 1.

Newton's Law of Cooling

In Section 7.2 we solved analytically the differential equation

$$\frac{dH}{dt} = -k(H - H_s), \quad k > 0$$

modeling Newton's Law of Cooling. Here H is the temperature of an object at time t , and H_s is the constant temperature of the surrounding medium.

Suppose that the surrounding medium (say, a room in a house) has a constant Celsius temperature of 15°C . We can then express the difference in temperature as $H(t) - 15$. Assuming H is a differentiable function of time t , by Newton's Law of Cooling, there is a constant of proportionality $k > 0$ such that

$$\frac{dH}{dt} = -k(H - 15) \quad (1)$$

(minus k to give a negative derivative when $H > 15$).

Since $dH/dt = 0$ at $H = 15$, the temperature 15°C is an equilibrium value. If $H > 15$, Equation (1) tells us that $(H - 15) > 0$ and $dH/dt < 0$. If the object is hotter than the room, it will get cooler. Similarly, if $H < 15$, then $(H - 15) < 0$ and $dH/dt > 0$. An object cooler than the room will warm up. Thus, the behavior described by Equation (1) agrees with our intuition of how temperature should behave. These observations are captured in the initial phase line diagram in Figure 16.17. The value $H = 15$ is a stable equilibrium.

We determine the concavity of the solution curves by differentiating both sides of Equation (1) with respect to t :

$$\begin{aligned} \frac{d}{dt}\left(\frac{dH}{dt}\right) &= \frac{d}{dt}(-k(H - 15)) \\ \frac{d^2H}{dt^2} &= -k\frac{dH}{dt}. \end{aligned}$$

Since $-k$ is negative, we see that d^2H/dt^2 is positive when $dH/dt < 0$ and negative when $dH/dt > 0$. Figure 16.18 adds this information to the phase line.

The completed phase line shows that if the temperature of the object is above the equilibrium value of 15°C , the graph of $H(t)$ will be decreasing and concave upward. If the temperature is below 15°C (the temperature of the surrounding medium), the graph of $H(t)$ will be increasing and concave downward. We use this information to sketch typical solution curves (Figure 16.19).

From the upper solution curve in Figure 16.19, we see that as the object cools down, the rate at which it cools slows down because dH/dt approaches zero. This observation is implicit in Newton's Law of Cooling and contained in the differential equation, but the flattening of the graph as time advances gives an immediate visual representation of the phenomenon.

A Falling Body Encountering Resistance

Newton observed that the rate of change of the momentum of a moving object is equal to the net force applied to it. In mathematical terms,

$$F = \frac{d}{dt}(mv), \quad (2)$$

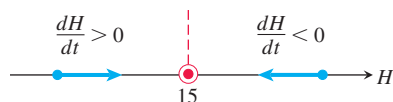

FIGURE 16.17 First step in constructing the phase line for Newton's Law of Cooling. The temperature tends toward the equilibrium (surrounding-medium) value in the long run.

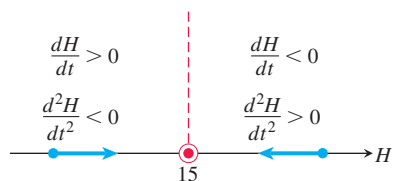

FIGURE 16.18 The complete phase line for Newton's Law of Cooling.

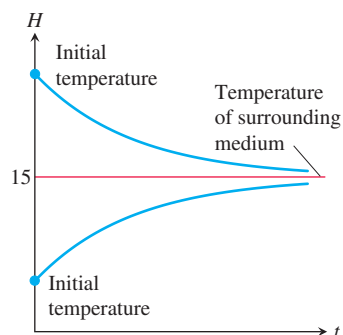

FIGURE 16.19 Temperature versus time. Regardless of initial temperature, the object's temperature $H(t)$ tends toward 15°C , the temperature of the surrounding medium.

where F is the net force acting on the object, and m and v are the object's mass and velocity. If m varies with time, as it will if the object is a rocket burning fuel, the right-hand side of Equation (2) expands to

$$m \frac{dv}{dt} + v \frac{dm}{dt}$$

using the Derivative Product Rule. In many situations, however, m is constant, $dm/dt = 0$, and Equation (2) takes the simpler form

$$F = m \frac{dv}{dt} \quad \text{or} \quad F = ma, \quad (3)$$

which is known as *Newton's second law of motion* (see Section 16.3).

In free fall, the constant acceleration due to gravity is denoted by g , and the one force propelling the body downward is

$$F_p = mg,$$

the force due to gravity. If, however, we think of a real body falling through the air—say, a penny from a great height or a parachutist from an even greater height—we know that at some point air resistance is a factor in the speed of the fall. A more realistic model of free fall would include air resistance, shown as a force F_r in the schematic diagram in Figure 16.20.

For low speeds well below the speed of sound, physical experiments have shown that F_r is approximately proportional to the body's velocity. The net force on the falling body is therefore

$$F = F_p - F_r,$$

giving

$$\begin{aligned} m \frac{dv}{dt} &= mg - kv \\ \frac{dv}{dt} &= g - \frac{k}{m}v. \end{aligned} \quad (4)$$

We can use a phase line to analyze the velocity functions that solve this differential equation.

The equilibrium point, obtained by setting the right-hand side of Equation (4) equal to zero, is

$$v = \frac{mg}{k}.$$

If the body is initially moving faster than this, dv/dt is negative and the body slows down. If the body is moving at a velocity below mg/k , then $dv/dt > 0$ and the body speeds up. These observations are captured in the initial phase line diagram in Figure 16.21.

We determine the concavity of the solution curves by differentiating both sides of Equation (4) with respect to t :

$$\frac{d^2v}{dt^2} = \frac{d}{dt} \left(g - \frac{k}{m}v \right) = -\frac{k}{m} \frac{dv}{dt}.$$

We see that $d^2v/dt^2 < 0$ when $v < mg/k$ and that $d^2v/dt^2 > 0$ when $v > mg/k$. Figure 16.22 adds this information to the phase line. Notice the similarity to the phase line for Newton's Law of Cooling (Figure 16.18). The solution curves are similar as well (Figure 16.23).

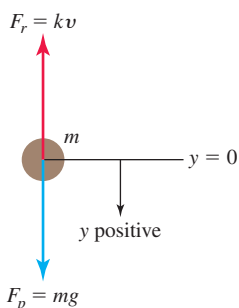

FIGURE 16.20 An object falling under the propulsion due to gravity, with a resistive force assumed to be proportional to the velocity.

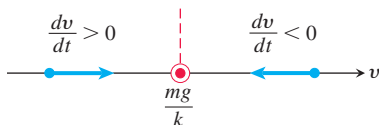

FIGURE 16.21 Initial phase line for the falling body encountering resistance.

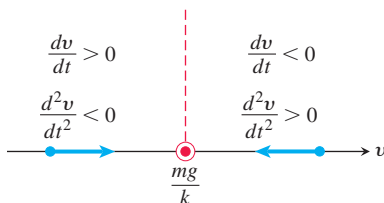

FIGURE 16.22 The completed phase line for the falling body.

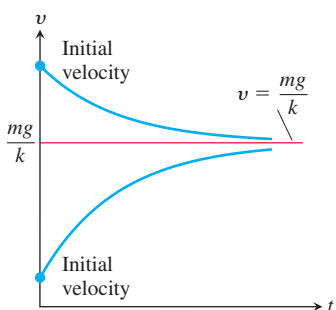

FIGURE 16.23 Typical velocity curves for a falling body encountering resistance. The value $v = mg/k$ is the terminal velocity.

Figure 16.23 shows two typical solution curves. Regardless of the initial velocity, we see the body's velocity tending toward the limiting value $v = mg/k$. This value, a stable equilibrium point, is called the body's **terminal velocity**. Skydivers can vary their terminal velocity from 153 km/h to 290 km/h by changing the amount of body area opposing the fall, which affects the value of k .

The Logistic Model for Population Growth

In Section 16.3 we examined population growth using the model of exponential change. That is, if P represents the number of individuals and we neglect departures and arrivals, then

$$\frac{dP}{dt} = kP, \quad (5)$$

where $k > 0$ is the birth rate minus the death rate per individual per unit time.

Because the natural environment has only a limited number of resources to sustain life, it is reasonable to assume that only a maximum population M can be accommodated. As the population approaches this **limiting population** or **carrying capacity**, resources become less abundant and the growth rate k decreases. A simple relationship exhibiting this behavior is

$$k = r(M - P),$$

where $r > 0$ is a constant. Notice that k decreases as P increases toward M and that k is negative if P is greater than M . Substituting $r(M - P)$ for k in Equation (5) gives the differential equation

$$\frac{dP}{dt} = r(M - P)P = rMP - rP^2. \quad (6)$$

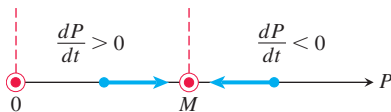

FIGURE 16.24 The initial phase line for logistic growth (Equation 6).

The model given by Equation (6) is referred to as **logistic growth**.

We can forecast the behavior of the population over time by analyzing the phase line for Equation (6). The equilibrium values are $P = M$ and $P = 0$, and we can see that $dP/dt > 0$ if $0 < P < M$ and $dP/dt < 0$ if $P > M$. These observations are recorded on the phase line in Figure 16.24.

We determine the concavity of the population curves by differentiating both sides of Equation (6) with respect to t :

$$\begin{aligned} \frac{d^2P}{dt^2} &= \frac{d}{dt}(rMP - rP^2) \\ &= rM \frac{dP}{dt} - 2rP \frac{dP}{dt} \\ &= r(M - 2P) \frac{dP}{dt}. \end{aligned} \quad (7)$$

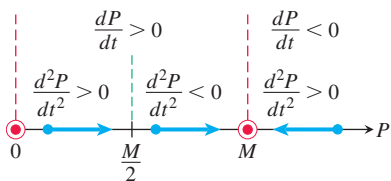

FIGURE 16.25 The completed phase line for logistic growth (Equation 6).

If $P = M/2$, then $d^2P/dt^2 = 0$. If $P < M/2$, then $(M - 2P)$ and dP/dt are positive and $d^2P/dt^2 > 0$. If $M/2 < P < M$, then $(M - 2P) < 0$, $dP/dt > 0$, and $d^2P/dt^2 < 0$. If $P > M$, then $(M - 2P)$ and dP/dt are both negative and $d^2P/dt^2 > 0$. We add this information to the phase line (Figure 16.25).

The lines $P = M/2$ and $P = M$ divide the first quadrant of the tP -plane into horizontal bands in which we know the signs of both dP/dt and d^2P/dt^2 . In each band, we know how the solution curves rise and fall, and how they bend as time passes. The equilibrium lines $P = 0$ and $P = M$ are both population curves. Population curves crossing the line

$P = M/2$ have an inflection point there, giving them a **sigmoid** shape (curved in two directions like a letter S). Figure 16.26 displays typical population curves. Notice that each population curve approaches the limiting population M as $t \rightarrow \infty$.

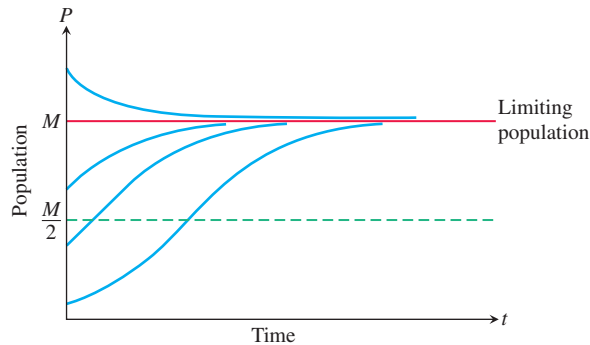

FIGURE 16.26 Population curves for logistic growth.

The Logistic Equation in Neural Networks and Machine Learning

While Figure 16.26 gives a general idea of the behavior of solutions to the Logistic Equation (6), we have not yet found explicit solutions. Exact formulas for solutions of first order differential equations cannot always be found, but they can be derived for the case of the Logistic Equation, where the solutions are called *logistic functions*. In Example 2 we find the solutions lying between $y = 0$ and $y = 1$ for the Logistic Equation in the case where $M = 1$ and r is an arbitrary positive constant.

EXAMPLE 2 Find the solutions to the Logistic Equation $\frac{dy}{dx} = ry - ry^2$ that satisfy $0 < y < 1$. Where does a solution cross the horizontal line $y = 1/2$, and what is the slope of its graph at this point?

Solution To solve the differential equation we use the method of separation of variables introduced in Section 7.2.

$$\frac{dy}{dx} = ry - ry^2 = ry(1 - y)$$

$$\frac{1}{y(1 - y)} dy = r dx$$

$$\int \frac{1}{y(1 - y)} dy = \int r dx$$

$$\int \frac{1}{y} + \frac{1}{1 - y} dy = \int r dx$$

Partial fractions

$$\ln y + C_1 - \ln(1 - y) + C_2 = rx + C_3$$

$|y| = y$ and $|1 - y| = 1 - y$, since $0 < y < 1$.

$$\ln y - \ln(1 - y) = rx + C$$

Combine constants, $C = C_3 - C_1 - C_2$.

$$\ln \frac{y}{1 - y} = rx + C$$

$$\frac{y}{1 - y} = e^{rx+C}$$

Exponentiate.

$$y = \frac{e^{rx+C}}{1 + e^{rx+C}}$$

Use algebra to solve for y .

$$y = \frac{1}{1 + e^{-rx-C}}$$

Divide through by e^{rx+C} .

This gives an explicit formula for all the solutions whose graphs lie strictly between $y = 0$ and $y = 1$.

When a solution crosses the line $y = 1/2$ we have

$$\begin{aligned}\frac{1}{1 + e^{-rx-C}} &= \frac{1}{2} \\ 1 + e^{-rx-C} &= 2 \\ e^{-rx-C} &= 1 \\ rx + C &= 0 \\ x &= -C/r.\end{aligned}$$

So the solution graph crosses at the point $(-C/r, 1/2)$. The slope is found by evaluating $dy/dx = ry - ry^2$ at this point,

$$\frac{dy}{dx}(-C/r) = ry - ry^2 = r(1/2) - r(1/2)^2 = \frac{r}{4}. \quad \blacksquare$$

Figure 16.27 shows the graph of a logistic function with $r = 3$ and $C = -6$.

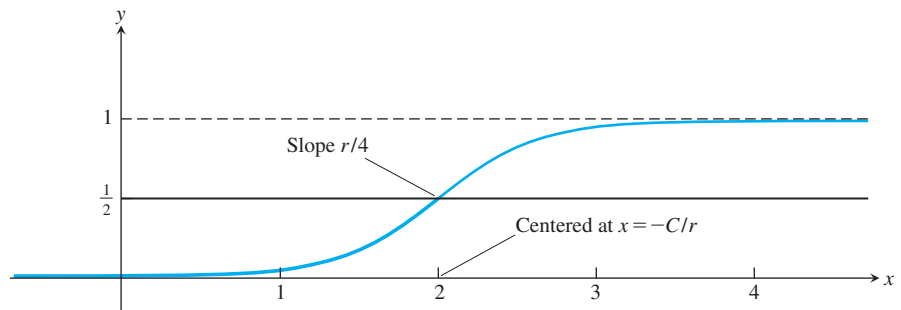

FIGURE 16.27 The constants r and C determine the steepness and horizontal displacement of a solution to the logistic equation. In this example $r = 3$ and $C = -6$.

Logistic functions have applications in many areas beyond the study of population growth. A field of Computer Science called *Machine Learning* develops methods to use a large collection of experimental data, called a training set, to construct a predictor function. The training set might consist of thousands of images of signs, for example, and the predictor function might decide whether a newly obtained image represents a Stop sign.

One highly successful approach to Machine Learning is the method of *Neural Networks*, which creates predictor functions based on a model of interacting neurons. Neural network models are built by taking repeated compositions of linear and logistic functions. Linear functions, such as $L(x) = ax + b$ can give accurate approximations of a function f nearby to a point where f is differentiable, as seen in Chapter 3. The optimal choices for the constants a and b in $L(x)$ are found by minimizing an error function that is calculated using the training set in a process called linear regression. Logistic functions have several features that make them a useful complement to linear functions in constructing predictor functions. They have values lying between 0 and 1 and are well suited to modeling probabilities. They are differentiable and specified by a small number of constants, such as the constants r and C in Example 2. These constants can be adjusted, or tuned, to minimize the error of a prediction. Logistic functions are nonlinear, and taking compositions of linear and logistic functions allows for the approximation of much more complicated functions than linear functions alone. A more complete discussion of the utility of logistic functions involves multivariable functions and their derivatives, which are introduced in Chapter 13.

EXERCISES 16.4

Phase Lines and Solution Curves

In Exercises 1–8,

- Identify the equilibrium values. Which are stable and which are unstable?
- Construct a phase line. Identify the signs of y' and y'' .
- Sketch several solution curves.

- $\frac{dy}{dx} = (y + 2)(y - 3)$
- $\frac{dy}{dx} = y^2 - 4$
- $\frac{dy}{dx} = y^3 - y$
- $\frac{dy}{dx} = y^2 - 2y$
- $y' = \sqrt{y}, \quad y > 0$
- $y' = y - \sqrt{y}, \quad y > 0$
- $y' = (y - 1)(y - 2)(y - 3)$
- $y' = y^3 - y^2$

Models of Population Growth

The autonomous differential equations in Exercises 16–12 represent models for population growth. For each exercise, use a phase line analysis to sketch solution curves for $P(t)$, selecting different starting values $P(0)$. Which equilibria are stable, and which are unstable?

- $\frac{dP}{dt} = 1 - 2P$
- $\frac{dP}{dt} = P(1 - 2P)$
- $\frac{dP}{dt} = 2P(P - 3)$
- $\frac{dP}{dt} = 3P(1 - P)\left(P - \frac{1}{2}\right)$

- Catastrophic change in logistic growth** Suppose that a healthy population of some species is growing in a limited environment and that the current population P_0 is fairly close to the carrying capacity M_0 . You might imagine a population of fish living in a freshwater lake in a wilderness area. Suddenly a catastrophe such as the Mount St. Helens volcanic eruption contaminates the lake and destroys a significant part of the food and oxygen on which the fish depend. The result is a new environment with a carrying capacity M_1 considerably less than M_0 and, in fact, less than the current population P_0 . Starting at some time before the catastrophe, sketch a “before-and-after” curve that shows how the fish population responds to the change in environment.
- Controlling a population** The fish and game department in a certain state is planning to issue hunting permits to control the deer population (one deer per permit). It is known that if the deer population falls below a certain level m , the deer will become extinct. It is also known that if the deer population rises above the carrying capacity M , the population will decrease back to M through disease and malnutrition.

- Discuss the reasonableness of the following model for the growth rate of the deer population as a function of time:

$$\frac{dP}{dt} = rP(M - P)(P - m),$$

where P is the population of the deer and r is a positive constant of proportionality. Include a phase line.

- Explain how this model differs from the logistic model $dP/dt = rP(M - P)$. Is it more or less reasonable than the logistic model?

- Show that if $P > M$ for all t , then $\lim_{t \rightarrow \infty} P(t) = M$.
- What happens if $P < m$ for all t ?
- Discuss the solutions to the differential equation. What are the equilibrium points of the model? Explain the dependence of the steady-state value of P on the initial values of P . About how many permits should be issued?

Applications and Examples

- Skydiving** If a body of mass m falling from rest under the action of gravity encounters an air resistance proportional to the square of velocity, then the body's velocity t seconds into the fall satisfies the equation

$$m \frac{dv}{dt} = mg - kv^2, \quad k > 0,$$

where k is a constant that depends on the body's aerodynamic properties and the density of the air. (We assume that the fall is too short to be affected by changes in the air's density.)

- Draw a phase line for the equation.
 - Sketch a typical velocity curve.
 - For a 45-kg skydiver ($mg = 441$) and with time in seconds and distance in meter, a typical value of k is 0.15. What is the diver's terminal velocity? Repeat for an 80-kg skydiver.
- Resistance proportional to \sqrt{v}** A body of mass m is projected vertically downward with initial velocity v_0 . Assume that the resisting force is proportional to the square root of the velocity, and find the terminal velocity from a graphical analysis.
 - Sailing** A sailboat is running along a straight course with the wind providing a constant forward force of 200 N. The only other force acting on the boat is resistance as the boat moves through the water. The resisting force is numerically equal to five times the boat's speed, and the initial velocity is 1 m/s. What is the maximum velocity in meters per second of the boat under this wind?
 - The spread of information** Sociologists recognize a phenomenon called *social diffusion*, which is the spreading of a piece of information, technological innovation, or cultural fad among a population. The members of the population can be divided into two classes: those who have the information and those who do not. In a fixed population whose size is known, it is reasonable to assume that the rate of diffusion is proportional to the number who have the information times the number yet to receive it. If X denotes the number of individuals who have the information in a population of N people, then a mathematical model for social diffusion is given by

$$\frac{dX}{dt} = kX(N - X),$$

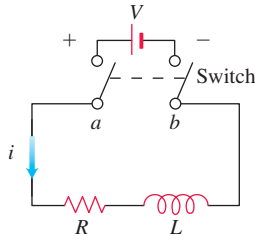

where t represents time in days and k is a positive constant.

- Discuss the reasonableness of the model.
- Construct a phase line identifying the signs of X' and X'' .
- Sketch representative solution curves.
- Predict the value of X for which the information is spreading most rapidly. How many people eventually receive the information?

19. Current in an RL circuit The accompanying diagram represents an electrical circuit whose total resistance is a constant R ohms and whose self-inductance, shown as a coil, is L henries, also a constant. There is a switch whose terminals at a and b can be closed to connect a constant electrical source of V volts. From Section 16.2, we have

$$L \frac{di}{dt} + Ri = V,$$

where i is the current in amperes and t is the time in seconds.

Use a phase line analysis to sketch the solution curve assuming that the switch in the RL circuit is closed at time $t = 0$. What happens to the current as $t \rightarrow \infty$? This value is called the *steady-state solution*.

20. A pearl in shampoo Suppose that a pearl is sinking in a thick fluid, like shampoo, subject to a frictional force opposing its fall and

proportional to its velocity. Suppose that there is also a resistive buoyant force exerted by the shampoo. According to *Archimedes' principle*, the buoyant force equals the weight of the fluid displaced by the pearl. Using m for the mass of the pearl and P for the mass of the shampoo displaced by the pearl as it descends, complete the following steps.

- Draw a schematic diagram showing the forces acting on the pearl as it sinks, as in Figure 16.20.
- Using $v(t)$ for the pearl's velocity as a function of time t , write a differential equation modeling the velocity of the pearl as a falling body.
- Construct a phase line displaying the signs of v' and v'' .
- Sketch typical solution curves.
- What is the terminal velocity of the pearl?

Logistic Functions

- Write the formula for a logistic function that has values between $y = 0$ and $y = 1$, crosses the line $y = 1/2$ at $x = 0$, and has slope 5 at this point.
- Write the formula for a logistic function that has values between $y = 0$ and $y = 1$, crosses the line $y = 1/2$ at $x = 0$, and has slope $1/5$ at this point.

16.5 Systems of Equations and Phase Planes

In some situations we are led to consider not one, but several, first-order differential equations. Such a collection is called a **system** of differential equations. In this section we present an approach to understanding systems through a graphical procedure known as a *phase-plane analysis*. We present this analysis in the context of modeling the populations of trout and bass living in a common pond.

Phase Planes

A general system of two first-order differential equations may take the form

$$\begin{aligned} \frac{dx}{dt} &= F(x, y), \\ \frac{dy}{dt} &= G(x, y). \end{aligned}$$

In this system we often think of t as representing time and take $x(t)$ and $y(t)$ to be two functions of t . Such a system of equations is called **autonomous** because dx/dt and dy/dt do not depend on the independent variable time t , but only on the dependent variables x and y . A **solution** of such a system consists of a pair of functions $x(t)$ and $y(t)$ that satisfies both of the differential equations simultaneously for every t over some time interval (finite or infinite).

We cannot look at just one of these equations in isolation to find solutions $x(t)$ or $y(t)$ since each derivative depends on both x and y . To gain insight into the solutions, we look at both dependent variables together by plotting the points $(x(t), y(t))$ in the xy -plane starting at some specified point. Therefore the solution functions define a solution curve through the specified point, called a **trajectory** of the system. The xy -plane itself, in which these trajectories reside, is referred to as the **phase plane**. Thus we consider both solutions together and study the behavior of all the solution trajectories in the phase plane. It can be

proved that two trajectories can never cross or touch each other. (Solution trajectories are examples of *parametric curves*, which will be examined in detail in Chapter 9.)

A Competitive-Hunter Model

Imagine two species of fish, say trout and bass, competing for the same limited resources (such as food and oxygen) in a certain pond. We let $x(t)$ represent the number of trout and $y(t)$ the number of bass living in the pond at time t . In reality, $x(t)$ and $y(t)$ are always integer valued, but we will approximate them with real-valued differentiable functions. This allows us to apply the methods of differential equations.

Several factors affect the rates of change of these populations. As time passes, each species breeds, so we assume its population increases proportionally to its size. Taken by itself, this would lead to exponential growth in each of the two populations. However, there is a countervailing effect from the fact that the two species are in competition. A large number of bass tends to cause a decrease in the number of trout, and vice versa. Our model takes the size of this effect to be proportional to the frequency with which the two species interact, which in turn is proportional to xy , the product of the two populations. These considerations lead to the following model for the growth of the trout and bass in the pond:

$$\frac{dx}{dt} = (a - by)x, \quad (1a)$$

$$\frac{dy}{dt} = (m - nx)y. \quad (1b)$$

Here $x(t)$ represents the trout population, $y(t)$ the bass population, and a, b, m, n are positive constants. A solution of this system then consists of a pair of functions $x(t)$ and $y(t)$ that give the population of each fish species at time t . Each equation in (1) contains both of the unknown functions x and y , so we are unable to solve them individually. Instead, we will use a graphical analysis to study the solution trajectories of this **competitive-hunter model**.

We now examine the nature of the phase plane in the trout-bass population model. We will be interested in the 1st quadrant of the xy -plane, where $x \geq 0$ and $y \geq 0$, since populations cannot be negative. First, we determine where the bass and trout populations are both constant. Noting that the $(x(t), y(t))$ values remain unchanged when $dx/dt = 0$ and $dy/dt = 0$, we see that Equations (1a and 1b) then become

$$(a - by)x = 0,$$

$$(m - nx)y = 0.$$

This pair of simultaneous equations has two solutions: $(x, y) = (0, 0)$ and $(x, y) = (m/n, a/b)$. At these (x, y) values, called **equilibrium** or **rest points**, the two populations remain at constant values over all time. The point $(0, 0)$ represents a pond containing no members of either fish species; the point $(m/n, a/b)$ corresponds to a pond with an unchanging number of each fish species.

Next, we note that if $y = a/b$, then Equation (1a) implies $dx/dt = 0$, so the trout population $x(t)$ is constant. Similarly, if $x = m/n$, then Equation (1b) implies $dy/dt = 0$, and the bass population $y(t)$ is constant. This information is recorded in Figure 16.28.

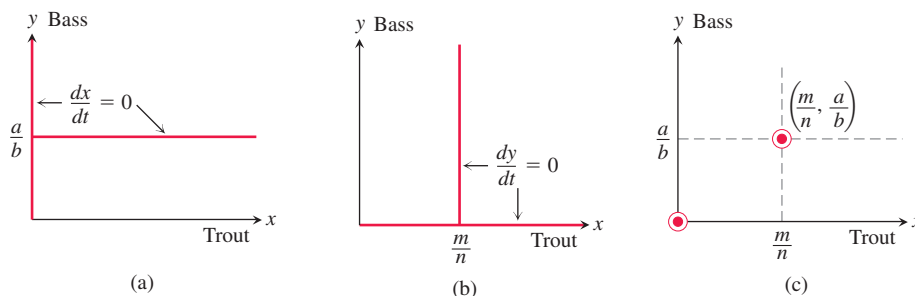

FIGURE 16.28 Rest points in the competitive-hunter model given by Equations (1a) and (1b).

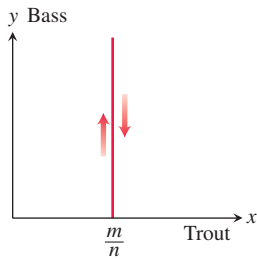

FIGURE 16.29 To the left of the line $x = m/n$ the trajectories move upward, and to the right they move downward.

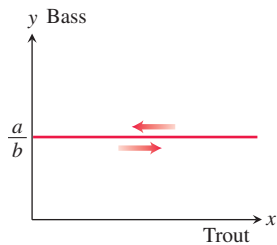

FIGURE 16.30 Above the line $y = a/b$ the trajectories move to the left, and below it they move to the right.

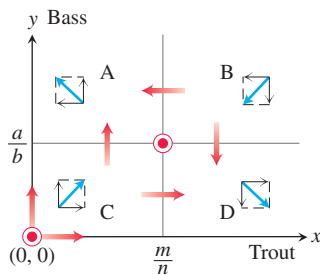

FIGURE 16.31 Composite graphical analysis of the trajectory directions in the four regions determined by $x = m/n$ and $y = a/b$.

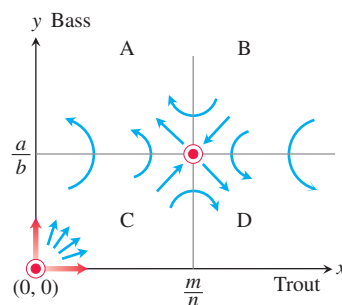

FIGURE 16.32 Motion along the trajectories near the rest points $(0, 0)$ and $(m/n, a/b)$.

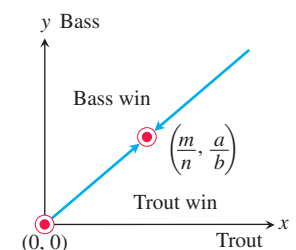

FIGURE 16.33 Qualitative results of analyzing the competitive-hunter model. There are exactly two trajectories approaching the point $(m/n, a/b)$.

Our graphical analysis leads us to conclude that, under the assumptions of the competitive-hunter model, it is unlikely that both species will reach equilibrium levels. This is because it would be almost impossible for the fish populations to move exactly along one of the two approaching trajectories for all time. Furthermore, the initial populations point (x_0, y_0) determines which of the two species is likely to survive over time, and mutual coexistence of the species is highly improbable.

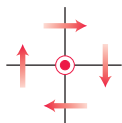

FIGURE 16.34 Trajectory direction near the rest point $(0, 0)$.

Limitations of the Phase-Plane Analysis Method

Unlike the situation for the competitive-hunter model, it is not always possible to determine the behavior of trajectories near a rest point. For example, suppose we know that the trajectories near a rest point, chosen here to be the origin $(0, 0)$, behave as in Figure 16.34. The information provided by Figure 16.34 is not sufficient to distinguish among the three possible trajectories shown in Figure 16.35. Even if we could determine that a trajectory near an equilibrium point resembles that of Figure 16.35c, we would still not know how the other trajectories behave. It could happen that a trajectory closer to the origin behaves like the motions displayed in Figure 16.35a or 16.35b. The spiraling trajectory in Figure 16.35c can never actually reach the rest point in a finite time period.

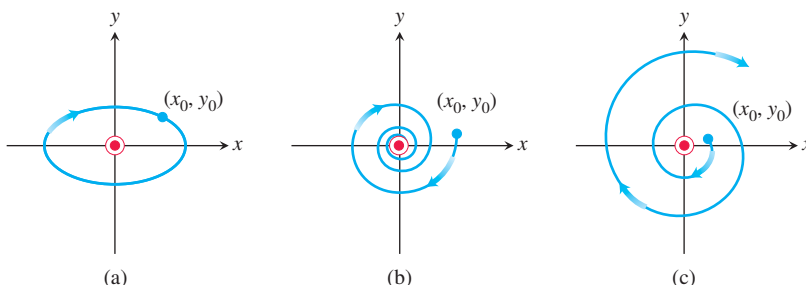

FIGURE 16.35 Three possible trajectory motions: (a) periodic motion, (b) motion toward an asymptotically stable rest point, and (c) motion near an unstable rest point.

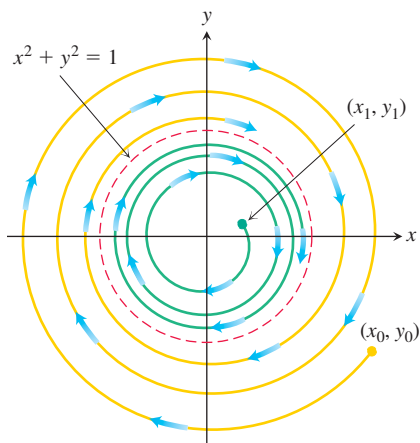

FIGURE 16.36 The solution $x^2 + y^2 = 1$ is a limit cycle.

Another Type of Behavior

The system

$$\frac{dx}{dt} = y + x - x(x^2 + y^2), \quad (2a)$$

$$\frac{dy}{dt} = -x + y - y(x^2 + y^2) \quad (2b)$$

can be shown to have only one equilibrium point at $(0, 0)$. Yet any trajectory starting on the unit circle traverses it clockwise because, when $x^2 + y^2 = 1$, we have $dy/dx = -x/y$ (see Exercise 2). If a trajectory starts inside the unit circle, it spirals outward, asymptotically approaching the circle as $t \rightarrow \infty$. If a trajectory starts outside the unit circle, it spirals inward, again asymptotically approaching the circle as $t \rightarrow \infty$. The circle $x^2 + y^2 = 1$ is called a **limit cycle** of the system (Figure 16.36). In this system, the values of x and y eventually become periodic.

EXERCISES 16.5

- List three of the important considerations that are ignored in the competitive-hunter model as presented in the text.
- For the system (2a) and (2b), show that any trajectory starting on the unit circle $x^2 + y^2 = 1$ will traverse the unit circle in a periodic solution. First introduce polar coordinates and rewrite the system as $dr/dt = r(1 - r^2)$ and $-d\theta/dt = -1$.
- Develop a model for the growth of trout and bass, assuming that in isolation trout demonstrate exponential decay [so that $a < 0$ in Equations (1a) and (1b)] and that the bass population grows logistically with a population limit M . Analyze graphically the motion in the vicinity of the rest points in your model. Is coexistence possible?

4. How might the competitive-hunter model be validated? Include a discussion of how the various constants a , b , m , and n might be estimated. How could state conservation authorities use the model to ensure the survival of both species?

5. Consider another competitive-hunter model defined by

$$\frac{dx}{dt} = a \left(1 - \frac{x}{k_1} \right) x - bxy,$$

$$\frac{dy}{dt} = m \left(1 - \frac{y}{k_2} \right) y - nxy,$$

where x and y represent trout and bass populations, respectively.

- What assumptions are implicitly being made about the growth of trout and bass in the absence of competition?
- Interpret the constants a , b , m , n , k_1 , k_2 , a/b , and m/n in terms of the physical problem.
- Perform a graphical analysis:
 - Find the possible equilibrium levels.
 - Determine whether coexistence is possible.
 - Pick several typical starting points, and sketch typical trajectories in the phase plane.
 - Interpret the outcomes predicted by your graphical analysis in terms of the constants a , b , m , n , k_1 , and k_2 .

Note: When you get to part (iii), you should realize that five cases exist. You will need to analyze all five cases.

6. **An economic model** Consider the following economic model. Let P be the price of a single item on the market. Let Q be the quantity of the item available on the market. Both P and Q are functions of time. If one considers price and quantity as two interacting species, the following model might be proposed:

$$\frac{dP}{dt} = aP \left(\frac{b}{Q} - P \right),$$

$$\frac{dQ}{dt} = cQ(fP - Q),$$

where a , b , c , and f are positive constants. Justify and discuss the adequacy of the model.

- If $a = 1$, $b = 20,000$, $c = 1$, and $f = 30$, find the equilibrium points of this system. If possible, classify each equilibrium point with respect to its stability. If a point cannot be readily classified, give some explanation.
 - Perform a graphical stability analysis to determine what will happen to the levels of P and Q as time increases.
 - Give an economic interpretation of the curves that determine the equilibrium points.
7. **Two trajectories approach equilibrium** Show that the two trajectories leading to $(m/n, a/b)$ shown in Figure 16.33 are unique by carrying out the following steps.
- From system (1a) and (1b) apply the Chain Rule to derive the following equation:

$$\frac{dy}{dx} = \frac{(m - nx)y}{(a - by)x}.$$

- Separate the variables, integrate, and exponentiate to obtain

$$y^a e^{-by} = Kx^m e^{-nx},$$

where K is a constant of integration.

- Let $f(y) = y^a/e^{by}$ and $g(x) = x^m/e^{nx}$. Show that $f(y)$ has a unique maximum of $M_y = (a/be)^a$ when $y = a/b$ as shown in Figure 16.37. Similarly, show that $g(x)$ has a unique maximum $M_x = (m/en)^m$ when $x = m/n$, also shown in Figure 16.37.

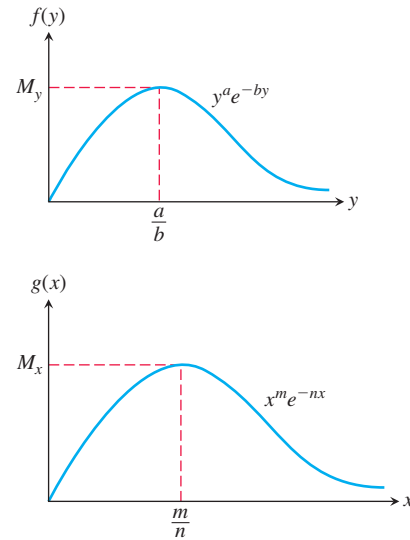

FIGURE 16.37 Graphs of the functions $f(y) = y^a/e^{by}$ and $g(x) = x^m/e^{nx}$.

- Consider what happens as (x, y) approaches $(m/n, a/b)$. Take limits in part (b) as $x \rightarrow m/n$ and $y \rightarrow a/b$ to show that either

$$\lim_{\substack{x \rightarrow m/n \\ y \rightarrow a/b}} \left[\left(\frac{y^a}{e^{by}} \right) \left(\frac{e^{nx}}{x^m} \right) \right] = K$$

or $M_y/M_x = K$. Thus any solution trajectory that approaches $(m/n, a/b)$ must satisfy

$$\frac{y^a}{e^{by}} = \left(\frac{M_y}{M_x} \right) \left(\frac{x^m}{e^{nx}} \right).$$

- Show that only one trajectory can approach $(m/n, a/b)$ from below the line $y = a/b$. Pick $y_0 < a/b$. From Figure 16.37 you can see that $f(y_0) < M_y$, which implies that

$$\frac{M_y}{M_x} \left(\frac{x^m}{e^{nx}} \right) = y_0^a / e^{by_0} < M_y.$$

This in turn implies that

$$\frac{x^m}{e^{nx}} < M_x.$$

Figure 16.37 tells you that for $g(x)$ there is a unique value $x_0 < m/n$ satisfying this last inequality. That is, for each $y < a/b$ there is a unique value of x satisfying the equation in part (d). Thus there can exist only one trajectory solution approaching $(m/n, a/b)$ from below, as shown in Figure 16.38.

- f. Use a similar argument to show that the solution trajectory leading to $(m/n, a/b)$ is unique if $y_0 > a/b$.

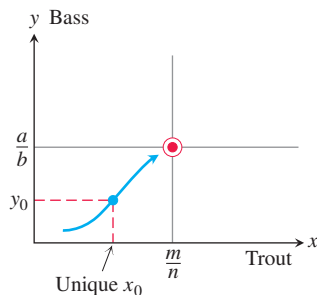

FIGURE 16.38 For any $y < a/b$, only one solution trajectory leads to the rest point $(m/n, a/b)$.

8. Show that the second-order differential equation $y'' = F(x, y, y')$ can be reduced to a system of two first-order differential equations

$$\begin{aligned} \frac{dy}{dx} &= z, \\ \frac{dz}{dx} &= F(x, y, z). \end{aligned}$$

Can something similar be done to the n th-order differential equation $y^{(n)} = F(x, y, y', y'', \dots, y^{(n-1)})$?

Lotka-Volterra Equations for a Predator-Prey Model

In 1925 Lotka and Volterra introduced the *predator-prey* equations, a system of equations that models the populations of two species, one of which preys on the other. Let $x(t)$ represent the number of rabbits living in a region at time t , and $y(t)$ the number of foxes in the same region. As time passes, the number of rabbits increases at a rate proportional to their population, and decreases at a rate proportional to the number of encounters between rabbits and foxes. The foxes, which compete for food, increase in number at a rate proportional to the number of encounters with rabbits but decrease at a rate proportional to the number of foxes. The number of encounters between rabbits and foxes is assumed to be proportional to the product of the two populations. These assumptions lead to the autonomous system

$$\begin{aligned} \frac{dx}{dt} &= (a - by)x, \\ \frac{dy}{dt} &= (-c + dx)y, \end{aligned}$$

where a, b, c, d are positive constants. The values of these constants vary according to the specific situation being modeled. We can study the nature of the population changes without setting these constants to specific values.

9. What happens to the rabbit population if there are no foxes present?
10. What happens to the fox population if there are no rabbits present?
11. Show that $(0, 0)$ and $(c/d, a/b)$ are equilibrium points. Explain the meaning of each of these points.
12. Show, by differentiating, that the function

$$C(t) = a \ln y(t) - by(t) - dx(t) + c \ln x(t)$$

is constant when $x(t)$ and $y(t)$ are positive and satisfy the predator-prey equations.

While x and y may change over time, $C(t)$ does not. Thus, C is a *conserved quantity* and its existence gives a *conservation law*. A trajectory that begins at a point (x, y) at time $t = 0$ gives a value of C that remains unchanged at future times. Each value of the constant C gives a trajectory for the autonomous system, and these trajectories close up, rather than spiraling inward or outward. The rabbit and fox populations oscillate through repeated cycles along a fixed trajectory. Figure 16.39 shows several trajectories for the predator-prey system.

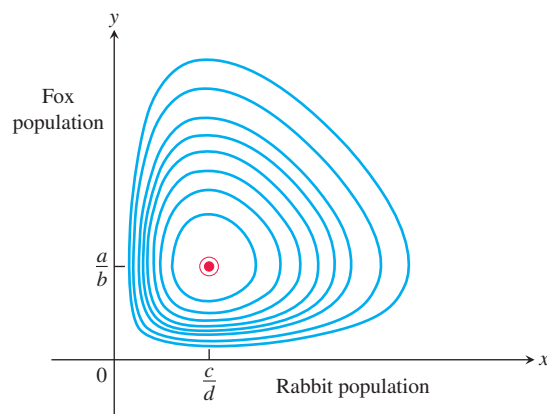

FIGURE 16.39 Some trajectories along which C is conserved.

13. Using a procedure similar to that in the text for the competitive-hunter model, show that each trajectory is traversed in a counterclockwise direction as time t increases.

Along each trajectory, both the rabbit and fox populations fluctuate between their maximum and minimum levels. The maximum and minimum levels for the rabbit population occur where the trajectory intersects the horizontal line $y = a/b$. For the fox population, they occur where the trajectory intersects the vertical line $x = c/d$. When the rabbit population is at its maximum, the fox population is below its maximum value. As the rabbit population declines from this point in time, we move counterclockwise around the trajectory, and the fox population grows until it reaches its maximum value. At this point the rabbit population has declined to $x = c/d$ and is no longer at its peak value. We see that the fox population reaches its maximum value at a later time than the rabbits. The predator population *lags behind* that of the prey in achieving its maximum values. This lag effect is shown in Figure 16.40, which graphs both $x(t)$ and $y(t)$.

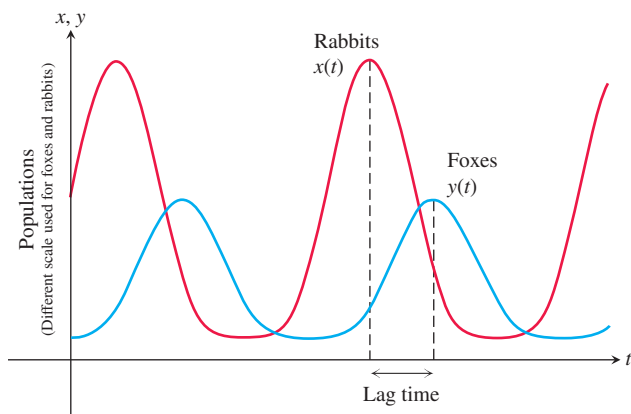

FIGURE 16.40 The fox and rabbit populations oscillate periodically, with the maximum fox population lagging the maximum rabbit population.

14. At some time during a trajectory cycle, a wolf invades the rabbit-fox territory, eats some rabbits, and then leaves. Does this mean that the fox population will from then on have a lower maximum value? Explain your answer.

CHAPTER 16 Questions to Guide Your Review

1. What is a first-order differential equation? When is a function a solution of such an equation?
2. What is a general solution? What is a particular solution?
3. What is the slope field of a differential equation $y' = f(x, y)$? What can we learn from such fields?
4. Describe Euler's method for solving the initial value problem $y' = f(x, y)$, $y(x_0) = y_0$ numerically. Give an example. Comment on the method's accuracy. Why might you want to solve an initial value problem numerically?
5. How do you solve linear first-order differential equations?
6. What is an orthogonal trajectory of a family of curves? Describe how one is found for a given family of curves.
7. What is an autonomous differential equation? What are its equilibrium values? How do they differ from critical points? What is a stable equilibrium value? Unstable?
8. How do you construct the phase line for an autonomous differential equation? How does the phase line help you produce a graph that qualitatively depicts a solution to the differential equation?
9. Why is the exponential model unrealistic for predicting long-term population growth? How does the logistic model correct for the deficiency in the exponential model for population growth? What is the logistic differential equation? What is the form of its solution? Describe the graph of the logistic solution.
10. What is an autonomous system of differential equations? What is a solution to such a system? What is a trajectory of the system?

CHAPTER 16 Practice Exercises

In Exercises 1–22, solve the differential equation.

1. $y' = xe^y\sqrt{x-2}$
2. $y' = xy e^{x^2}$
3. $\sec x \, dy + x \cos^2 y \, dx = 0$
4. $2x^2 \, dx - 3\sqrt{y} \csc x \, dy = 0$
5. $y' = \frac{e^y}{xy}$
6. $y' = xe^{x-y} \csc y$
7. $x(x-1) \, dy - y \, dx = 0$
8. $y' = (y^2 - 1)x^{-1}$
9. $2y' - y = xe^{x/2}$
10. $\frac{y'}{2} + y = e^{-x} \sin x$
11. $xy' + 2y = 1 - x^{-1}$
12. $xy' - y = 2x \ln x$
13. $(1 + e^x) \, dy + (ye^x + e^{-x}) \, dx = 0$
14. $e^{-x} \, dy + (e^{-x}y - 4x) \, dx = 0$
15. $(x + 3y^2) \, dy + y \, dx = 0$ (Hint: $d(xy) = y \, dx + x \, dy$)
16. $x \, dy + (3y - x^{-2} \cos x) \, dx = 0$, $x > 0$
17. $y' = \sin^3 x \cos^2 y$
18. $x \, dy - (x^4 - y) \, dx = 0$
19. $dy + x(2y - e^{x-x^2}) \, dx = 0$
20. $y' + 3x^2y = 7x^2$
21. $y' = xy \ln x \ln y$
22. $xy' + 2y \ln x = \ln x$

Initial Value Problems

In Exercises 23–28, solve the initial value problem.

23. $(x+1)\frac{dy}{dx} + 2y = x$, $x > -1$, $y(0) = 1$
24. $x\frac{dy}{dx} + 2y = x^2 + 1$, $x > 0$, $y(1) = 1$
25. $\frac{dy}{dx} + 3x^2y = x^2$, $y(0) = -1$
26. $x \, dy + (y - \cos x) \, dx = 0$, $y\left(\frac{\pi}{2}\right) = 0$
27. $xy' + (x-2)y = 3x^3e^{-x}$, $y(1) = 0$
28. $y \, dx + (3x - xy + 2) \, dy = 0$, $y(2) = -1$, $y < 0$

Euler's Method

In Exercises 29 and 30, use Euler's method to solve the initial value problem on the given interval starting at x_0 with $dx = 0.1$.

29. $y' = y + \cos x$, $y(0) = 0$; $0 \leq x \leq 2$; $x_0 = 0$
30. $y' = (2-y)(2x+3)$, $y(-3) = 1$; $-3 \leq x \leq -1$; $x_0 = -3$

In Exercises 31 and 32, use Euler's method with $dx = 0.05$ to estimate $y(c)$, where y is the solution to the given initial value problem.

T 31. $c = 3$; $\frac{dy}{dx} = \frac{x - 2y}{x + 1}$, $y(0) = 1$

T 32. $c = 4$; $\frac{dy}{dx} = \frac{x^2 - 2y + 1}{x}$, $y(1) = 1$

In Exercises 33 and 34, use Euler's method to solve the initial value problem graphically, starting at $x_0 = 0$ with

a. $dx = 0.1$. b. $dx = -0.1$.

T 33. $\frac{dy}{dx} = \frac{1}{e^{x+y+2}}$, $y(0) = -2$

T 34. $\frac{dy}{dx} = \frac{-x^2 + y}{e^y + x}$, $y(0) = 0$

Slope Fields

In Exercises 35–38, sketch part of the equation's slope field. Then add to your sketch the solution curve that passes through the point $P(1, -1)$. Use Euler's method with $x_0 = 1$ and $dx = 0.2$ to estimate $y(2)$. Round your answers to four decimal places. Find the exact value of $y(2)$ for comparison.

35. $y' = x$ 36. $y' = 1/x$

37. $y' = xy$ 38. $y' = 1/y$

Autonomous Differential Equations and Phase Lines

In Exercises 39 and 40:

a. Identify the equilibrium values. Which are stable and which are unstable?

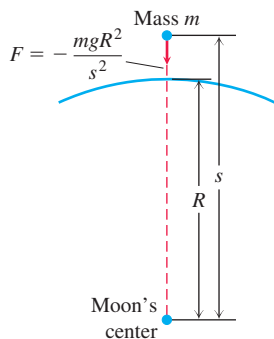

b. Construct a phase line. Identify the signs of y' and y'' .

c. Sketch a representative selection of solution curves.

39. $\frac{dy}{dx} = y^2 - 1$ 40. $\frac{dy}{dx} = y - y^2$

Applications

41. Escape velocity The gravitational attraction F exerted by an airless moon on a body of mass m at a distance s from the moon's center is given by the equation $F = -mgR^2s^{-2}$, where g is the acceleration of gravity at the moon's surface and R is the moon's radius (see accompanying figure). The force F is negative because it acts in the direction of decreasing s .

a. If the body is projected vertically upward from the moon's surface with an initial velocity v_0 at time $t = 0$, use Newton's second law, $F = ma$, to show that the body's velocity at position s is given by the equation

$$v^2 = \frac{2gR^2}{s} + v_0^2 - 2gR.$$

Thus, the velocity remains positive as long as $v_0 \geq \sqrt{2gR}$. The velocity $v_0 = \sqrt{2gR}$ is the moon's **escape velocity**. A body projected upward with this velocity or a greater one will escape from the moon's gravitational pull.

b. Show that if $v_0 = \sqrt{2gR}$, then

$$s = R \left(1 + \frac{3v_0 t}{2R} \right)^{2/3}.$$

42. Coasting to a stop Table 16.6 shows the distance s (meters) coasted on inline skates in t s by Johnathon Krueger. Find a model for his position in the form of Equation (2) of Section 16.3. His initial velocity was $v_0 = 0.86$ m/s, his mass $m = 30.84$ kg, and his total coasting distance was 0.97 m.

TABLE 16.6 Johnathon Krueger skating data

t (s)	s (m)	t (s)	s (m)	t (s)	s (m)
0	0	0.93	0.61	1.86	0.93
0.13	0.08	1.06	0.68	2.00	0.94
0.27	0.19	1.20	0.74	2.13	0.95
0.40	0.28	1.33	0.79	2.26	0.96
0.53	0.36	1.46	0.83	2.39	0.96
0.67	0.45	1.60	0.87	2.53	0.97
0.80	0.53	1.73	0.90	2.66	0.97

Mixture Problems

In Exercises 43 and 44, let S represent the kilograms of salt in a tank at time t minutes. Set up a differential equation representing the given information and the rate at which S changes. Then solve for S and answer the particular questions.

43. A mixture containing $\frac{1}{4}$ kg of salt per liter flows into a tank at the rate of 24 L/min, and the well-stirred mixture flows out of the tank at the rate of 16 L/min. The tank initially holds 600 liters of solution containing 6 kilograms of salt.

a. How many liters of solution are in the tank after 1 minute? after 10 minutes? after 1 hour?

b. How many kilograms of salt are in the tank after 1 minute? after 10 minutes? after 1 hour?

44. Pure water flows into a tank at the rate of 16 L/min, and the well-stirred mixture flows out of the tank at the rate of 20 L/min. The tank initially holds 800 liters of solution containing 25 kilograms of salt.

a. How many liters of solution are in the tank after 1 minute? after 10 minutes? after 200 minutes?

b. How many kilograms of salt are in the tank after 1 minute? after 30 minutes?

c. When will the tank have exactly 5 kilograms of salt, and how many liters of solution will be in the tank?

CHAPTER 16 Additional and Advanced Exercises

Theory and Applications

- 1. Transport through a cell membrane** Under some conditions, the result of the movement of a dissolved substance across a cell's membrane is described by the equation

$$\frac{dy}{dt} = k\frac{A}{V}(c - y).$$

In this equation, y is the concentration of the substance inside the cell, and dy/dt is the rate at which y changes over time. The letters k , A , V , and c stand for constants, k being the *permeability coefficient* (a property of the membrane), A the surface area of the membrane, V the cell's volume, and c the concentration of the substance outside the cell. The equation says that the rate at which the concentration within the cell changes is proportional to the difference between it and the outside concentration.

- Solve the equation for $y(t)$, using y_0 to denote $y(0)$.
 - Find the steady-state concentration, $\lim_{t \rightarrow \infty} y(t)$.
- 2. Height of a rocket** If an external force F acts upon a system whose mass varies with time, Newton's law of motion is

$$\frac{d(mv)}{dt} = F + (v + u)\frac{dm}{dt}.$$

In this equation, m is the mass of the system at time t , v is its velocity, and $v + u$ is the velocity of the mass that is entering (or leaving) the system at the rate dm/dt . Suppose that a rocket of initial mass m_0 starts from rest, but is driven upward by firing some of its mass directly backward at the constant rate of $dm/dt = -b$ units per second and at constant speed relative to the rocket $u = -c$. The only external force acting on the rocket is $F = -mg$ due to gravity. Under these assumptions, show that the height of the rocket above the ground at the end of t seconds (t small compared to m_0/b) is

$$y = c\left[t + \frac{m_0 - bt}{b} \ln \frac{m_0 - bt}{m_0}\right] - \frac{1}{2}gt^2.$$

- 3. a.** Assume that $P(x)$ and $Q(x)$ are continuous over the interval $[a, b]$. Use the Fundamental Theorem of Calculus, Part 1, to show that any function y satisfying the equation

$$v(x)y = \int v(x)Q(x) dx + C$$

for $v(x) = e^{\int P(x) dx}$ is a solution to the first-order linear equation

$$\frac{dy}{dx} + P(x)y = Q(x).$$

- b.** If $C = y_0v(x_0) - \int_{x_0}^x v(t)Q(t) dt$, then show that any solution y in part (a) satisfies the initial condition $y(x_0) = y_0$.

- 4. (Continuation of Exercise 3.)** Assume the hypotheses of Exercise 3, and assume that $y_1(x)$ and $y_2(x)$ are both solutions to the first-order linear equation satisfying the initial condition $y(x_0) = y_0$.

- a.** Verify that $y(x) = y_1(x) - y_2(x)$ satisfies the initial value problem

$$y' + P(x)y = 0, \quad y(x_0) = 0.$$

- b.** For the integrating factor $v(x) = e^{\int P(x) dx}$, show that

$$\frac{d}{dx}(v(x)[y_1(x) - y_2(x)]) = 0.$$

Conclude that $v(x)[y_1(x) - y_2(x)] \equiv \text{constant}$.

- c.** From part (a), we have $y_1(x_0) - y_2(x_0) = 0$. Since $v(x) > 0$ for $a < x < b$, use part (b) to establish that $y_1(x) - y_2(x) \equiv 0$ on the interval (a, b) . Thus $y_1(x) = y_2(x)$ for all $a < x < b$.

Homogeneous Equations

A first-order differential equation of the form

$$\frac{dy}{dx} = F\left(\frac{y}{x}\right)$$

is called *homogeneous*. It can be transformed into an equation whose variables are separable by defining the new variable $v = y/x$. Then $y = vx$ and

$$\frac{dy}{dx} = v + x\frac{dv}{dx}.$$

Substituting into the original differential equation and collecting terms with like variables then give the separable equation

$$\frac{dx}{x} + \frac{dv}{v - F(v)} = 0.$$

After solving this separable equation, we obtain the solution of the original equation when we replace v by y/x .

Solve the homogeneous equations in Exercises 5–10. First put the equation in the form of a homogeneous equation.

- $(x^2 + y^2) dx + xy dy = 0$
- $x^2 dy + (y^2 - xy) dx = 0$
- $(xe^{y/x} + y) dx - x dy = 0$
- $(x + y) dy + (x - y) dx = 0$
- $y' = \frac{y}{x} + \cos \frac{y-x}{x}$
- $\left(x \sin \frac{y}{x} - y \cos \frac{y}{x}\right) dx + x \cos \frac{y}{x} dy = 0$

CHAPTER 16 Technology Application Projects

Mathematica/Maple Projects

Projects can be found within MyLab Math.

- Drug Dosages: Are They Effective? Are They Safe?**
Formulate and solve an initial value model for the absorption of a drug in the bloodstream.
- First-Order Differential Equations and Slope Fields**
Plot slope fields and solution curves for various initial conditions to selected first-order differential equations.

Second-Order
Differential Equations

Denis Kalinichenko/Shutterstock

OVERVIEW In this chapter we extend our study of differential equations to those of *second order*, equations that involve second derivatives of a function. Second-order differential equations arise in many applications in the sciences and engineering. For instance, they can be applied to the study of vibrating springs and electric circuits. You will learn how to solve such differential equations by several methods in this chapter.

17.1 Second-Order Linear Equations

An equation of the form

$$P(x)y''(x) + Q(x)y'(x) + R(x)y(x) = G(x), \quad (1)$$

which is linear in y and its derivatives, is called a **second-order linear differential equation**. We assume that the functions P , Q , R , and G are continuous throughout some open interval I . If $G(x)$ is identically zero on I , the equation is said to be **homogeneous**; otherwise it is called **nonhomogeneous**. Therefore, the form of a second-order linear homogeneous differential equation is

$$P(x)y'' + Q(x)y' + R(x)y = 0. \quad (2)$$

We also assume that $P(x)$ is never zero for any $x \in I$.

Two fundamental results are important to solving Equation (2). The first of these says that if we know two solutions y_1 and y_2 of the linear homogeneous equation, then any **linear combination** $y = c_1y_1 + c_2y_2$ is also a solution for any constants c_1 and c_2 .

THEOREM 1 – The Superposition Principle

If $y_1(x)$ and $y_2(x)$ are two solutions to the linear homogeneous equation (2), then for any constants c_1 and c_2 , the function

$$y(x) = c_1y_1(x) + c_2y_2(x)$$

is also a solution to Equation (2).

Proof Substituting y into Equation (2), we have

$$\begin{aligned}
 P(x)y'' + Q(x)y' + R(x)y &= P(x)(c_1y_1 + c_2y_2)'' + Q(x)(c_1y_1 + c_2y_2)' + R(x)(c_1y_1 + c_2y_2) \\
 &= P(x)(c_1y_1'' + c_2y_2'') + Q(x)(c_1y_1' + c_2y_2') + R(x)(c_1y_1 + c_2y_2) \\
 &= c_1(\underbrace{P(x)y_1'' + Q(x)y_1' + R(x)y_1}_{= 0, y_1 \text{ is a solution}}) + c_2(\underbrace{P(x)y_2'' + Q(x)y_2' + R(x)y_2}_{= 0, y_2 \text{ is a solution}}) \\
 &= c_1(0) + c_2(0) = 0.
 \end{aligned}$$

Therefore, $y = c_1y_1 + c_2y_2$ is a solution of Equation (2). ■

Theorem 1 immediately establishes the following facts concerning solutions to the linear homogeneous equation.

1. A sum of two solutions $y_1 + y_2$ to Equation (2) is also a solution. (Choose $c_1 = c_2 = 1$.)
2. A constant multiple ky_1 of any solution y_1 to Equation (2) is also a solution. (Choose $c_1 = k$ and $c_2 = 0$.)
3. The **trivial solution** $y(x) \equiv 0$ is always a solution to the linear homogeneous equation. (Choose $c_1 = c_2 = 0$.)

The second fundamental result about solutions to the linear homogeneous equation concerns its **general solution**, or solution containing all solutions. This result says that there are two solutions y_1 and y_2 such that any solution is some linear combination of them for suitable values of the constants c_1 and c_2 . However, not just any pair of solutions will do. The solutions must be **linearly independent**, which means that neither y_1 nor y_2 is a constant multiple of the other. For example, the functions $f(x) = e^x$ and $g(x) = xe^x$ are linearly independent, whereas $f(x) = x^2$ and $g(x) = 7x^2$ are not (they are linearly dependent). These results on linear independence and the following theorem are proved in more advanced courses.

THEOREM 2 If P , Q , and R are continuous over the open interval I and $P(x)$ is never zero on I , then the linear homogeneous equation (2) has two linearly independent solutions y_1 and y_2 on I . Moreover, if y_1 and y_2 are *any* two linearly independent solutions of Equation (2), then the general solution is given by

$$y(x) = c_1y_1(x) + c_2y_2(x),$$

where c_1 and c_2 are arbitrary constants.

We now turn our attention to finding two linearly independent solutions to the special case of Equation (2) where P , Q , and R are constant functions.

Constant-Coefficient Homogeneous Equations

Suppose we wish to solve the second-order homogeneous differential equation

$$ay'' + by' + cy = 0, \quad (3)$$

where a , b , and c are constants. To solve Equation (3), we seek a function that, when multiplied by a constant and added to a constant times its first derivative plus a constant times its second derivative, sums identically to zero. One function that behaves this way is the exponential function $y = e^{rx}$, when r is a constant. Two differentiations of this exponential

function give $y' = re^{rx}$ and $y'' = r^2e^{rx}$, which are just constant multiples of the original exponential. If we substitute $y = e^{rx}$ into Equation (3), we obtain

$$ar^2e^{rx} + bre^{rx} + ce^{rx} = 0.$$

Since the exponential function is never zero, we can divide this last equation through by e^{rx} . Thus, $y = e^{rx}$ is a solution to Equation (3) if and only if r is a solution to the algebraic equation

$$ar^2 + br + c = 0. \quad (4)$$

Equation (4) is called the **auxiliary equation** (or **characteristic equation**) of the differential equation $ay'' + by' + cy = 0$. The auxiliary equation is a quadratic equation with roots

$$r_1 = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad r_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}.$$

There are three cases to consider, which depend on the value of the discriminant $b^2 - 4ac$.

Case 1: $b^2 - 4ac > 0$. In this case the auxiliary equation has two real and unequal roots r_1 and r_2 . Then $y_1 = e^{r_1x}$ and $y_2 = e^{r_2x}$ are two linearly independent solutions to Equation (3) because e^{r_2x} is not a constant multiple of e^{r_1x} (see Exercise 61). From Theorem 2 we conclude the following result.

THEOREM 3 If r_1 and r_2 are two real and unequal roots of the auxiliary equation $ar^2 + br + c = 0$, then

$$y = c_1e^{r_1x} + c_2e^{r_2x}$$

is the general solution to $ay'' + by' + cy = 0$.

EXAMPLE 1 Find the general solution of the differential equation

$$y'' - y' - 6y = 0.$$

Solution Substitution of $y = e^{rx}$ into the differential equation yields the auxiliary equation

$$r^2 - r - 6 = 0,$$

which factors as

$$(r - 3)(r + 2) = 0.$$

The roots are $r_1 = 3$ and $r_2 = -2$. Thus, the general solution is

$$y = c_1e^{3x} + c_2e^{-2x}. \quad \blacksquare$$

Case 2: $b^2 - 4ac = 0$. In this case $r_1 = r_2 = -b/2a$. To simplify the notation, let $r = -b/2a$. Then we have one solution $y_1 = e^{rx}$ with $2ar + b = 0$. Since multiplication of e^{rx} by a constant fails to produce a second linearly independent solution, suppose we try

multiplying by a *function* instead. The simplest such function would be $u(x) = x$, so let's see where $y_2 = xe^{rx}$ is also a solution. Substituting y_2 into the differential equation gives

$$\begin{aligned} ay_2'' + by_2' + cy_2 &= a(2re^{rx} + r^2xe^{rx}) + b(e^{rx} + rxe^{rx}) + cxe^{rx} \\ &= (2ar + b)e^{rx} + (ar^2 + br + c)xe^{rx} \\ &= 0(e^{rx}) + (0)xe^{rx} = 0. \end{aligned}$$

The first term is zero because $r = -b/2a$; the second term is zero because r solves the auxiliary equation. The functions $y_1 = e^{rx}$ and $y_2 = xe^{rx}$ are linearly independent (see Exercise 62). From Theorem 2 we conclude the following result.

THEOREM 4 If r is the only (repeated) real root of the auxiliary equation $ar^2 + br + c = 0$, then

$$y = c_1e^{rx} + c_2xe^{rx}$$

is the general solution to $ay'' + by' + cy = 0$.

EXAMPLE 2 Find the general solution to

$$y'' + 4y' + 4y = 0.$$

Solution The auxiliary equation is

$$r^2 + 4r + 4 = 0,$$

which factors into

$$(r + 2)^2 = 0.$$

Thus, $r = -2$ is a double root. Therefore, the general solution is

$$y = c_1e^{-2x} + c_2xe^{-2x}. \quad \blacksquare$$

Case 3: $b^2 - 4ac < 0$. In this case the auxiliary equation has two complex roots: $r_1 = \alpha + i\beta$ and $r_2 = \alpha - i\beta$, where α and β are real numbers and $i^2 = -1$. (These real numbers are $\alpha = -b/2a$ and $\beta = \sqrt{4ac - b^2}/2a$.) These two complex roots then give rise to two linearly independent solutions:

$$y_1 = e^{(\alpha+i\beta)x} = e^{\alpha x}(\cos \beta x + i \sin \beta x) \quad \text{and} \quad y_2 = e^{(\alpha-i\beta)x} = e^{\alpha x}(\cos \beta x - i \sin \beta x).$$

(The expressions involving the sine and cosine terms follow from Euler's identity, as seen in the discussion of Taylor series.) However, the solutions y_1 and y_2 are *complex valued* rather than real valued. Nevertheless, because of the superposition principle (Theorem 1), we can obtain from them the two real-valued solutions

$$y_3 = \frac{1}{2}y_1 + \frac{1}{2}y_2 = e^{\alpha x} \cos \beta x \quad \text{and} \quad y_4 = \frac{1}{2i}y_1 - \frac{1}{2i}y_2 = e^{\alpha x} \sin \beta x.$$

The functions y_3 and y_4 are linearly independent (see Exercise 63). From Theorem 2 we conclude the following result.

THEOREM 5 If $r_1 = \alpha + i\beta$ and $r_2 = \alpha - i\beta$ are two complex roots of the auxiliary equation $ar^2 + br + c = 0$, then

$$y = e^{\alpha x}(c_1 \cos \beta x + c_2 \sin \beta x)$$

is the general solution to $ay'' + by' + cy = 0$.

EXAMPLE 3 Find the general solution to the differential equation

$$y'' - 4y' + 5y = 0.$$

Solution The auxiliary equation is

$$r^2 - 4r + 5 = 0.$$

The roots are the complex pair $r = (4 \pm \sqrt{16 - 20})/2$, or $r_1 = 2 + i$ and $r_2 = 2 - i$. Thus, $\alpha = 2$ and $\beta = 1$ give the general solution

$$y = e^{2x}(c_1 \cos x + c_2 \sin x). \quad \blacksquare$$

Initial Value and Boundary Value Problems

To determine a unique solution to a first-order linear differential equation, it was sufficient to specify the value of the solution at a single point. Since the general solution to a second-order equation contains two arbitrary constants, it is necessary to specify two conditions. One way of doing this is to specify the value of the solution function and the value of its derivative at a single point: $y(x_0) = y_0$ and $y'(x_0) = y_1$. These conditions are called **initial conditions**. The following result is proved in more advanced texts and guarantees the existence of a unique solution for both homogeneous and nonhomogeneous second-order linear initial value problems.

THEOREM 6 If P , Q , R , and G are continuous throughout an open interval I , then there exists one and only one function $y(x)$ satisfying both the differential equation

$$P(x)y''(x) + Q(x)y'(x) + R(x)y(x) = G(x)$$

on the interval I , and the initial conditions

$$y(x_0) = y_0 \quad \text{and} \quad y'(x_0) = y_1$$

at the specified point $x_0 \in I$.

It is important to realize that any real values can be assigned to y_0 and y_1 , and Theorem 6 applies. Here is an example of an initial value problem for a homogeneous equation.

EXAMPLE 4 Find the particular solution to the initial value problem

$$y'' - 2y' + y = 0, \quad y(0) = 1, \quad y'(0) = -1.$$

Solution The auxiliary equation is

$$r^2 - 2r + 1 = (r - 1)^2 = 0.$$

The repeated real root is $r = 1$, giving the general solution

$$y = c_1 e^x + c_2 x e^x.$$

Then

$$y' = c_1 e^x + c_2(x + 1)e^x.$$

From the initial conditions we have

$$1 = c_1 + c_2 \cdot 0 \quad \text{and} \quad -1 = c_1 + c_2 \cdot 1.$$

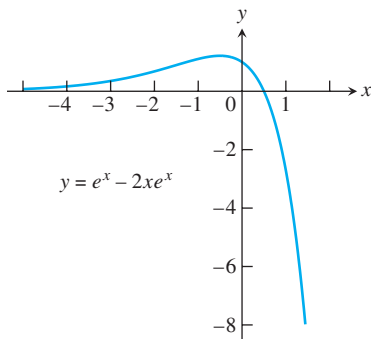

FIGURE 17.1 Particular solution curve for Example 4.

Thus, $c_1 = 1$ and $c_2 = -2$. The unique solution satisfying the initial conditions is

$$y = e^x - 2xe^x.$$

The solution curve is shown in Figure 17.1. ■

Another approach to determine the values of the two arbitrary constants in the general solution to a second-order differential equation is to specify the values of the solution function at *two different points* in the interval I . That is, we solve the differential equation subject to the **boundary values**

$$y(x_1) = y_1 \quad \text{and} \quad y(x_2) = y_2,$$

where x_1 and x_2 both belong to I . Here again the values for y_1 and y_2 can be any real numbers. The differential equation together with specified boundary values is called a **boundary value problem**. Unlike the result stated in Theorem 6, boundary value problems do not always possess a solution, or more than one solution may exist (see Exercise 65). These problems are studied in more advanced texts, but here is an example for which there is a unique solution.

EXAMPLE 5 Solve the boundary value problem

$$y'' + 4y = 0, \quad y(0) = 0, \quad y\left(\frac{\pi}{12}\right) = 1.$$

Solution The auxiliary equation is $r^2 + 4 = 0$, which has the complex roots $r = \pm 2i$. The general solution to the differential equation is

$$y = c_1 \cos 2x + c_2 \sin 2x.$$

The boundary conditions are satisfied if

$$\begin{aligned} y(0) &= c_1 \cdot 1 + c_2 \cdot 0 = 0 \\ y\left(\frac{\pi}{12}\right) &= c_1 \cos\left(\frac{\pi}{6}\right) + c_2 \sin\left(\frac{\pi}{6}\right) = 1. \end{aligned}$$

It follows that $c_1 = 0$ and $c_2 = 2$. The solution to the boundary value problem is

$$y = 2 \sin 2x. \quad \blacksquare$$

EXERCISES 17.1

In Exercises 1–30, find the general solution of the given equation.

1. $y'' - y' - 12y = 0$
3. $y'' + 3y' - 4y = 0$
5. $y'' - 4y = 0$
7. $2y'' - y' - 3y = 0$
9. $8y'' - 10y' - 3y = 0$
11. $y'' + 9y = 0$
13. $y'' + 25y = 0$
15. $y'' - 2y' + 5y = 0$
17. $y'' + 2y' + 4y = 0$
19. $y'' + 4y' + 9y = 0$
21. $y'' = 0$

2. $3y'' - y' = 0$
4. $y'' - 9y = 0$
6. $y'' - 64y = 0$
8. $9y'' - y = 0$
10. $3y'' - 20y' + 12y = 0$
12. $y'' + 4y' + 5y = 0$
14. $y'' + y = 0$
16. $y'' + 16y = 0$
18. $y'' - 2y' + 3y = 0$
20. $4y'' - 4y' + 13y = 0$
22. $y'' + 8y' + 16y = 0$

23. $\frac{d^2y}{dx^2} + 4\frac{dy}{dx} + 4y = 0$
25. $\frac{d^2y}{dx^2} + 6\frac{dy}{dx} + 9y = 0$
27. $4\frac{d^2y}{dx^2} + 4\frac{dy}{dx} + y = 0$
29. $9\frac{d^2y}{dx^2} + 6\frac{dy}{dx} + y = 0$
24. $\frac{d^2y}{dx^2} - 6\frac{dy}{dx} + 9y = 0$
26. $4\frac{d^2y}{dx^2} - 12\frac{dy}{dx} + 9y = 0$
28. $4\frac{d^2y}{dx^2} - 4\frac{dy}{dx} + y = 0$
30. $9\frac{d^2y}{dx^2} - 12\frac{dy}{dx} + 4y = 0$

In Exercises 31–40, find the unique solution of the second-order initial value problem.

31. $y'' + 6y' + 5y = 0, \quad y(0) = 0, \quad y'(0) = 3$
32. $y'' + 16y = 0, \quad y(0) = 2, \quad y'(0) = -2$
33. $y'' + 12y = 0, \quad y(0) = 0, \quad y'(0) = 1$

34. $12y'' + 5y' - 2y = 0, \quad y(0) = 1, y'(0) = -1$

35. $y'' + 8y = 0, \quad y(0) = -1, y'(0) = 2$

36. $y'' + 4y' + 4y = 0, \quad y(0) = 0, y'(0) = 1$

37. $y'' - 4y' + 4y = 0, \quad y(0) = 1, y'(0) = 0$

38. $4y'' - 4y' + y = 0, \quad y(0) = 4, y'(0) = 4$

39. $4\frac{d^2y}{dx^2} + 12\frac{dy}{dx} + 9y = 0, \quad y(0) = 2, \frac{dy}{dx}(0) = 1$

40. $9\frac{d^2y}{dx^2} - 12\frac{dy}{dx} + 4y = 0, \quad y(0) = -1, \frac{dy}{dx}(0) = 1$

In Exercises 41–55, find the general solution.

41. $y'' - 2y' - 3y = 0$

42. $6y'' - y' - y = 0$

43. $4y'' + 4y' + y = 0$

44. $9y'' + 12y' + 4y = 0$

45. $4y'' + 20y = 0$

46. $y'' + 2y' + 2y = 0$

47. $25y'' + 10y' + y = 0$

48. $6y'' + 13y' - 5y = 0$

49. $4y'' + 4y' + 5y = 0$

50. $y'' + 4y' + 6y = 0$

51. $16y'' - 24y' + 9y = 0$

52. $6y'' - 5y' - 6y = 0$

53. $9y'' + 24y' + 16y = 0$

54. $4y'' + 16y' + 52y = 0$

55. $6y'' - 5y' - 4y = 0$

In Exercises 56–60, solve the initial value problem.

56. $y'' - 2y' + 2y = 0, \quad y(0) = 0, y'(0) = 2$

57. $y'' + 2y' + y = 0, \quad y(0) = 1, y'(0) = 1$

58. $4y'' - 4y' + y = 0, \quad y(0) = -1, y'(0) = 2$

59. $3y'' + y' - 14y = 0, \quad y(0) = 2, y'(0) = -1$

60. $4y'' + 4y' + 5y = 0, \quad y(\pi) = 1, y'(\pi) = 0$

61. Prove that the two solution functions in Theorem 3 are linearly independent.

62. Prove that the two solution functions in Theorem 4 are linearly independent.

63. Prove that the two solution functions in Theorem 5 are linearly independent.

64. Prove that if y_1 and y_2 are linearly independent solutions to the homogeneous equation (2), then the functions $y_3 = y_1 + y_2$ and $y_4 = y_1 - y_2$ are also linearly independent solutions.

65. a. Show that there is no solution to the boundary value problem

$$y'' + 4y = 0, \quad y(0) = 0, y(\pi) = 1.$$

b. Show that there are infinitely many solutions to the boundary value problem

$$y'' + 4y = 0, \quad y(0) = 0, y(\pi) = 0.$$

66. Show that if a , b , and c are positive constants, then all solutions of the homogeneous differential equation

$$ay'' + by' + cy = 0$$

approach zero as $x \rightarrow \infty$.

17.2 Nonhomogeneous Linear Equations

In this section we study two methods for solving second-order linear nonhomogeneous differential equations with constant coefficients. These are the methods of *undetermined coefficients* and *variation of parameters*. We begin by considering the form of the general solution.

Form of the General Solution

Suppose we wish to solve the nonhomogeneous equation

$$ay'' + by' + cy = G(x), \quad (1)$$

where a , b , and c are constants and G is continuous over some open interval I . Let $y_c = c_1y_1 + c_2y_2$ be the general solution to the associated **complementary equation**

$$ay'' + by' + cy = 0. \quad (2)$$

(We learned how to find y_c in Section 17.1.) Now suppose we could somehow come up with a particular function y_p that solves the nonhomogeneous equation (1). Then the sum

$$y = y_c + y_p \quad (3)$$

also solves the nonhomogeneous equation (1) because

$$\begin{aligned} a(y_c + y_p)'' + b(y_c + y_p)' + c(y_c + y_p) &= (ay_c'' + by_c' + cy_c) + (ay_p'' + by_p' + cy_p) \\ &= 0 + G(x) \quad y_c \text{ solves Eq. (2) and } y_p \text{ solves Eq. (1)} \\ &= G(x). \end{aligned}$$

Moreover, if $y = y(x)$ is the general solution to the nonhomogeneous equation (1), it must have the form of Equation (3). The reason for this last statement follows from the observation that for any function y_p satisfying Equation (1), we have

$$\begin{aligned} a(y - y_p)'' + b(y - y_p)' + c(y - y_p) & \\ &= (ay'' + by' + cy) - (ay_p'' + by_p' + cy_p) \\ &= G(x) - G(x) = 0. \end{aligned}$$

Thus, $y_c = y - y_p$ is the general solution to the homogeneous equation (2). We have established the following result.

THEOREM 7 The general solution $y = y(x)$ to the nonhomogeneous differential equation (1) has the form

$$y = y_c + y_p,$$

where the **complementary solution** y_c is the general solution to the associated homogeneous equation (2), and y_p is any **particular solution** to the nonhomogeneous equation (1).

The Method of Undetermined Coefficients

This method for finding a particular solution y_p to the nonhomogeneous equation (1) applies to special cases for which $G(x)$ is a sum of terms of various polynomials $p(x)$ multiplying an exponential with possibly sine or cosine factors. That is, $G(x)$ is a sum of terms of the following forms:

$$p_1(x)e^{rx}, \quad p_2(x)e^{\alpha x} \cos \beta x, \quad p_3(x)e^{\alpha x} \sin \beta x.$$

For instance, $1 - x$, e^{2x} , xe^x , $\cos x$, and $5e^x - \sin 2x$ represent functions in this category. (Essentially these are functions solving homogeneous linear differential equations with constant coefficients, but the equations may be of order higher than two.) We now present several examples illustrating the method.

EXAMPLE 1 Solve the nonhomogeneous equation $y'' - 2y' - 3y = 1 - x^2$.

Solution The auxiliary equation for the complementary equation $y'' - 2y' - 3y = 0$ is

$$r^2 - 2r - 3 = (r + 1)(r - 3) = 0.$$

It has the roots $r = -1$ and $r = 3$, giving the complementary solution

$$y_c = c_1e^{-x} + c_2e^{3x}.$$

Now $G(x) = 1 - x^2$ is a polynomial of degree 2. It would be reasonable to assume that a particular solution to the given nonhomogeneous equation is also a polynomial of degree 2 because if y is a polynomial of degree 2, then $y'' - 2y' - 3y$ is also a polynomial of degree 2. So we seek a particular solution of the form

$$y_p = Ax^2 + Bx + C.$$

We need to determine the unknown coefficients A , B , and C . When we substitute the polynomial y_p and its derivatives into the given nonhomogeneous equation, we obtain

$$2A - 2(2Ax + B) - 3(Ax^2 + Bx + C) = 1 - x^2,$$

or, collecting terms with like powers of x ,

$$-3Ax^2 + (-4A - 3B)x + (2A - 2B - 3C) = 1 - x^2.$$

This last equation holds for all values of x if its two sides are identical polynomials of degree 2. Thus, we equate corresponding powers of x to get

$$-3A = -1, \quad -4A - 3B = 0, \quad \text{and} \quad 2A - 2B - 3C = 1.$$

These equations imply in turn that $A = 1/3$, $B = -4/9$, and $C = 5/27$. Substituting these values into the quadratic expression for our particular solution gives

$$y_p = \frac{1}{3}x^2 - \frac{4}{9}x + \frac{5}{27}.$$

By Theorem 7, the general solution to the nonhomogeneous equation is

$$y = y_c + y_p = c_1e^{-x} + c_2e^{3x} + \frac{1}{3}x^2 - \frac{4}{9}x + \frac{5}{27}. \quad \blacksquare$$

EXAMPLE 2 Find a particular solution of $y'' - y' = 2 \sin x$.

Solution If we try to find a particular solution of the form

$$y_p = A \sin x$$

and substitute the derivatives of y_p in the given equation, we find that A must satisfy the equation

$$-A \sin x + A \cos x = 2 \sin x$$

for all values of x . Since this requires A to equal both -2 and 0 at the same time, we conclude that the nonhomogeneous differential equation has no solution of the form $A \sin x$.

It turns out that the required form is the sum

$$y_p = A \sin x + B \cos x.$$

The result of substituting the derivatives of this new trial solution into the differential equation is

$$-A \sin x - B \cos x - (A \cos x - B \sin x) = 2 \sin x,$$

or

$$(B - A)\sin x - (A + B)\cos x = 2 \sin x.$$

This last equation must be an identity. Equating the coefficients for like terms on each side then gives

$$B - A = 2 \quad \text{and} \quad A + B = 0.$$

Simultaneous solution of these two equations gives $A = -1$ and $B = 1$. Our particular solution is

$$y_p = \cos x - \sin x. \quad \blacksquare$$

EXAMPLE 3 Find a particular solution of $y'' - 3y' + 2y = 5e^x$.

Solution If we substitute

$$y_p = Ae^x$$

and its derivatives into the differential equation, we find that

$$Ae^x - 3Ae^x + 2Ae^x = 5e^x,$$

or

$$0 = 5e^x.$$

However, the exponential function is never zero. The trouble can be traced to the fact that $y = e^x$ is already a solution of the related homogeneous equation

$$y'' - 3y' + 2y = 0.$$

The auxiliary equation is

$$r^2 - 3r + 2 = (r - 1)(r - 2) = 0,$$

which has $r = 1$ as a root. So we would expect Ae^x to become zero when substituted into the left-hand side of the differential equation.

The appropriate way to modify the trial solution in this case is to multiply Ae^x by x . Thus, our new trial solution is

$$y_p = Axe^x.$$

The result of substituting the derivatives of this new candidate into the differential equation is

$$(Axe^x + 2Ae^x) - 3(Axe^x + Ae^x) + 2Axe^x = 5e^x,$$

or

$$-Ae^x = 5e^x.$$

Thus, $A = -5$ gives our sought-after particular solution

$$y_p = -5xe^x. \quad \blacksquare$$

EXAMPLE 4 Find a particular solution of $y'' - 6y' + 9y = e^{3x}$.

Solution The auxiliary equation for the complementary equation

$$r^2 - 6r + 9 = (r - 3)^2 = 0$$

has $r = 3$ as a repeated root. The appropriate choice for y_p in this case is neither Ae^{3x} nor Axe^{3x} because the complementary solution contains both of those terms already. Thus, we choose a term containing the next higher power of x as a factor. When we substitute

$$y_p = Ax^2e^{3x}$$

and its derivatives into the given differential equation, we get

$$(9Ax^2e^{3x} + 12Axe^{3x} + 2Ae^{3x}) - 6(3Ax^2e^{3x} + 2Axe^{3x}) + 9Ax^2e^{3x} = e^{3x},$$

or

$$2Ae^{3x} = e^{3x}.$$

Thus, $A = 1/2$, and the particular solution is

$$y_p = \frac{1}{2}x^2e^{3x}. \quad \blacksquare$$

When we wish to find a particular solution of Equation (1) and the function $G(x)$ is the sum of two or more terms, we choose a trial function for each term in $G(x)$ and add them.

EXAMPLE 5 Find the general solution to $y'' - y' = 5e^x - \sin 2x$.

Solution We first check the auxiliary equation

$$r^2 - r = 0.$$

Its roots are $r = 1$ and $r = 0$. Therefore, the complementary solution to the associated homogeneous equation is

$$y_c = c_1e^x + c_2.$$

We now seek a particular solution y_p . That is, we seek a function that will produce $5e^x - \sin 2x$ when substituted into the left-hand side of the given differential equation. One part of y_p is to produce $5e^x$, the other $-\sin 2x$.

Since any function of the form c_1e^x is a solution of the associated homogeneous equation, we choose our trial solution y_p to be the sum

$$y_p = Axe^x + B \cos 2x + C \sin 2x,$$

including xe^x where we might otherwise have included only e^x . When the derivatives of y_p are substituted into the differential equation, the resulting equation is

$$\begin{aligned} (Axe^x + 2Ae^x - 4B \cos 2x - 4C \sin 2x) \\ - (Axe^x + Ae^x - 2B \sin 2x + 2C \cos 2x) = 5e^x - \sin 2x, \end{aligned}$$

or

$$Ae^x - (4B + 2C)\cos 2x + (2B - 4C)\sin 2x = 5e^x - \sin 2x.$$

This equation will hold if

$$A = 5, \quad 4B + 2C = 0, \quad 2B - 4C = -1,$$

or $A = 5$, $B = -1/10$, and $C = 1/5$. Our particular solution is

$$y_p = 5xe^x - \frac{1}{10}\cos 2x + \frac{1}{5}\sin 2x.$$

The general solution to the differential equation is

$$y = y_c + y_p = c_1e^x + c_2 + 5xe^x - \frac{1}{10}\cos 2x + \frac{1}{5}\sin 2x. \quad \blacksquare$$

You may find the following table helpful in solving the problems at the end of this section.

TABLE 17.1 The method of undetermined coefficients for selected equations of the form

$ay'' + by' + cy = G(x).$		
If $G(x)$ has a term that is a constant multiple of...	And if...	Then include this expression in the trial function for y_p
e^{rx}	r is not a root of the auxiliary equation	Ae^{rx}
	r is a single root of the auxiliary equation	Axe^{rx}
	r is a double root of the auxiliary equation	Ax^2e^{rx}
$\sin kx, \cos kx$	ki is not a root of the auxiliary equation	$B \cos kx + C \sin kx$
$px^2 + qx + m$	0 is not a root of the auxiliary equation	$Dx^2 + Ex + F$
	0 is a single root of the auxiliary equation	$Dx^3 + Ex^2 + Fx$
	0 is a double root of the auxiliary equation	$Dx^4 + Ex^3 + Fx^2$

The Method of Variation of Parameters

This is a general method for finding a particular solution of the nonhomogeneous equation (1) once the general solution of the associated homogeneous equation is known. The method consists of replacing the constants c_1 and c_2 in the complementary solution by functions $v_1 = v_1(x)$ and $v_2 = v_2(x)$ and requiring (in a way to be explained) that the resulting expression satisfy the nonhomogeneous equation (1). There are two functions to be determined, and requiring that Equation (1) be satisfied is only one condition. As a second condition, we also require that

$$v_1'y_1 + v_2'y_2 = 0. \quad (4)$$

Then we have

$$\begin{aligned} y &= v_1y_1 + v_2y_2, \\ y' &= v_1y_1' + v_2y_2', \\ y'' &= v_1y_1'' + v_2y_2'' + v_1'y_1' + v_2'y_2'. \end{aligned}$$

If we substitute these expressions into the left-hand side of equation (1), we obtain

$$v_1(ay_1'' + by_1' + cy_1) + v_2(ay_2'' + by_2' + cy_2) + a(v_1'y_1' + v_2'y_2') = G(x).$$

The first two parenthetical terms are zero since y_1 and y_2 are solutions of the associated homogeneous equation (2). So the nonhomogeneous equation (1) is satisfied if, in addition to equation (4), we require that

$$a(v_1'y_1' + v_2'y_2') = G(x). \quad (5)$$

Equations (4) and (5) can be solved together as a pair

$$\begin{aligned} v_1'y_1 + v_2'y_2 &= 0, \\ v_1'y_1' + v_2'y_2' &= \frac{G(x)}{a} \end{aligned}$$

for the unknown functions v_1' and v_2' . The usual procedure for solving this simple system is to use the *method of determinants* (also known as *Cramer's Rule*), which will be demonstrated in the examples to follow. Once the derivative functions v_1' and v_2' are known, the two functions $v_1 = v_1(x)$ and $v_2 = v_2(x)$ can be found by integration. Here is a summary of the method.

Variation of Parameters Procedure

To use the method of variation of parameters to find a particular solution to the nonhomogeneous equation

$$ay'' + by' + cy = G(x),$$

we can work directly with Equations (4) and (5). It is not necessary to rederive them. The steps are as follows.

1. Solve the associated homogeneous equation

$$ay'' + by' + cy = 0$$

to find the functions y_1 and y_2 .

2. Solve the equations

$$\begin{aligned} v_1'y_1 + v_2'y_2 &= 0, \\ v_1'y_1' + v_2'y_2' &= \frac{G(x)}{a} \end{aligned}$$

simultaneously for the derivative functions v_1' and v_2' .

3. Integrate v_1' and v_2' to find the functions $v_1 = v_1(x)$ and $v_2 = v_2(x)$.
4. Write down the particular solution to the nonhomogeneous equation (1) as

$$y_p = v_1y_1 + v_2y_2.$$

EXAMPLE 6 Find the general solution to the equation

$$y'' + y = \tan x.$$

Solution The solution of the homogeneous equation

$$y'' + y = 0$$

is given by

$$y_c = c_1 \cos x + c_2 \sin x.$$

Since $y_1(x) = \cos x$ and $y_2(x) = \sin x$, the conditions to be satisfied in Equations (4) and (5) are

$$\begin{aligned} v_1' \cos x + v_2' \sin x &= 0, \\ -v_1' \sin x + v_2' \cos x &= \tan x. \quad a = 1 \end{aligned}$$

Solving this system gives

$$v_1' = \frac{\begin{vmatrix} 0 & \sin x \\ \tan x & \cos x \end{vmatrix}}{\begin{vmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{vmatrix}} = \frac{-\tan x \sin x}{\cos^2 x + \sin^2 x} = \frac{-\sin^2 x}{\cos x}.$$

Likewise,

$$v_2' = \frac{\begin{vmatrix} \cos x & 0 \\ -\sin x & \tan x \end{vmatrix}}{\begin{vmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{vmatrix}} = \sin x.$$

After integrating v_1' and v_2' , we have

$$\begin{aligned} v_1(x) &= \int \frac{-\sin^2 x}{\cos x} dx \\ &= -\int (\sec x - \cos x) dx \\ &= -\ln|\sec x + \tan x| + \sin x, \end{aligned}$$

and

$$v_2(x) = \int \sin x dx = -\cos x.$$

Note that we have omitted the constants of integration in determining v_1 and v_2 . They would merely be absorbed into the arbitrary constants in the complementary solution.

Substituting v_1 and v_2 into the expression for y_p in Step 4 gives

$$\begin{aligned} y_p &= [-\ln|\sec x + \tan x| + \sin x] \cos x + (-\cos x) \sin x \\ &= (-\cos x) \ln|\sec x + \tan x|. \end{aligned}$$

The general solution is

$$y = c_1 \cos x + c_2 \sin x - (\cos x) \ln|\sec x + \tan x|. \quad \blacksquare$$

EXAMPLE 7 Solve the nonhomogeneous equation

$$y'' + y' - 2y = xe^x.$$

Solution The auxiliary equation is

$$r^2 + r - 2 = (r + 2)(r - 1) = 0,$$

giving the complementary solution

$$y_c = c_1 e^{-2x} + c_2 e^x.$$

The conditions to be satisfied in Equations (4) and (5) are

$$\begin{aligned} v_1' e^{-2x} + v_2' e^x &= 0, \\ -2v_1' e^{-2x} + v_2' e^x &= x e^x. \quad a = 1 \end{aligned}$$

Solving the above system for v_1' and v_2' gives

$$v_1' = \frac{\begin{vmatrix} 0 & e^x \\ x e^x & e^x \end{vmatrix}}{\begin{vmatrix} e^{-2x} & e^x \\ -2e^{-2x} & e^x \end{vmatrix}} = \frac{-x e^{2x}}{3e^{-x}} = -\frac{1}{3} x e^{3x}.$$

Likewise,

$$v_2' = \frac{\begin{vmatrix} e^{-2x} & 0 \\ -2e^{-2x} & x e^x \end{vmatrix}}{3e^{-x}} = \frac{x e^{-x}}{3e^{-x}} = \frac{x}{3}.$$

Integrating to obtain the parameter functions, we have

$$\begin{aligned} v_1(x) &= \int -\frac{1}{3} x e^{3x} dx \\ &= -\frac{1}{3} \left(\frac{x e^{3x}}{3} - \int \frac{e^{3x}}{3} dx \right) \\ &= \frac{1}{27} (1 - 3x) e^{3x} \end{aligned}$$

and

$$v_2(x) = \int \frac{x}{3} dx = \frac{x^2}{6}.$$

Therefore,

$$\begin{aligned} y_p &= \left[\frac{(1-3x)e^{3x}}{27} \right] e^{-2x} + \left(\frac{x^2}{6} \right) e^x \\ &= \frac{1}{27} e^x - \frac{1}{9} x e^x + \frac{1}{6} x^2 e^x. \end{aligned}$$

The general solution to the differential equation is

$$y = c_1 e^{-2x} + c_2 e^x - \frac{1}{9} x e^x + \frac{1}{6} x^2 e^x,$$

where the term $(1/27)e^x$ in y_p has been absorbed into the term $c_2 e^x$ in the complementary solution. ■

EXERCISES 17.2

Solve the equations in Exercises 1–16 by the method of undetermined coefficients.

1. $y'' - 3y' - 10y = -3$

2. $y'' - 3y' - 10y = 2x - 3$

3. $y'' - y' = \sin x$

4. $y'' + 2y' + y = x^2$

5. $y'' + y = \cos 3x$

6. $y'' + y = e^{2x}$

7. $7y'' - y' - 2y = 20 \cos x$

8. $y'' + y = 2x + 3e^x$

9. $y'' - y = e^x + x^2$

10. $y'' + 2y' + y = 6 \sin 2x$

11. $y'' - y' - 6y = e^{-x} - 7 \cos x$

12. $y'' + 3y' + 2y = e^{-x} + e^{-2x} - x$

$$13. \frac{d^2y}{dx^2} + 5\frac{dy}{dx} = 15x^2 \quad 14. \frac{d^2y}{dx^2} - \frac{dy}{dx} = -8x + 3$$

$$15. \frac{d^2y}{dx^2} - 3\frac{dy}{dx} = e^{3x} - 12x \quad 16. \frac{d^2y}{dx^2} + 7\frac{dy}{dx} = 42x^2 + 5x + 1$$

Solve the equations in Exercises 17–28 by variation of parameters.

$$17. y'' + y' = x$$

$$18. y'' + y = \tan x, \quad -\frac{\pi}{2} < x < \frac{\pi}{2}$$

$$19. y'' + y = \sin x \quad 20. y'' + 2y' + y = e^x$$

$$21. y'' + 2y' + y = e^{-x} \quad 22. y'' - y = x$$

$$23. y'' - y = e^x \quad 24. y'' - y = \sin x$$

$$25. y'' + 4y' + 5y = 10 \quad 26. y'' - y' = 2^x$$

$$27. \frac{d^2y}{dx^2} + y = \sec x, \quad -\frac{\pi}{2} < x < \frac{\pi}{2}$$

$$28. \frac{d^2y}{dx^2} - \frac{dy}{dx} = e^x \cos x, \quad x > 0$$

In each of Exercises 29–32, the given differential equation has a particular solution y_p of the form given. Determine the coefficients in y_p . Then solve the differential equation.

$$29. y'' - 5y' = xe^{5x}, \quad y_p = Ax^2e^{5x} + Bxe^{5x}$$

$$30. y'' - y' = \cos x + \sin x, \quad y_p = A \cos x + B \sin x$$

$$31. y'' + y = 2 \cos x + \sin x, \quad y_p = Ax \cos x + Bx \sin x$$

$$32. y'' + y' - 2y = xe^x, \quad y_p = Ax^2e^x + Bxe^x$$

In Exercises 33–36, solve the given differential equations (a) by variation of parameters and (b) by the method of undetermined coefficients.

$$33. \frac{d^2y}{dx^2} - \frac{dy}{dx} = e^x + e^{-x} \quad 34. \frac{d^2y}{dx^2} - 4\frac{dy}{dx} + 4y = 2e^{2x}$$

$$35. \frac{d^2y}{dx^2} - 4\frac{dy}{dx} - 5y = e^x + 4 \quad 36. \frac{d^2y}{dx^2} - 9\frac{dy}{dx} = 9e^{9x}$$

$$55. \frac{1}{2}y'' + y' + y = 4e^x(\cos x - \sin x),$$

$$y_p = 2e^x \cos x, \quad y(0) = 0, y'(0) = 1$$

Solve the differential equations in Exercises 37–46. Some of the equations can be solved by the method of undetermined coefficients, but others cannot.

$$37. y'' + y = \cot x, \quad 0 < x < \pi$$

$$38. y'' + y = \csc x, \quad 0 < x < \pi$$

$$39. y'' - 8y' = e^{8x} \quad 40. y'' + 4y = \sin x$$

$$41. y'' - y' = x^3 \quad 42. y'' + 4y' + 5y = x + 2$$

$$43. y'' + 2y' = x^2 - e^x \quad 44. y'' + 9y = 9x - \cos x$$

$$45. y'' + y = \sec x \tan x, \quad -\frac{\pi}{2} < x < \frac{\pi}{2}$$

$$46. y'' - 3y' + 2y = e^x - e^{2x}$$

The method of undetermined coefficients can sometimes be used to solve first-order ordinary differential equations. Use the method to solve the equations in Exercises 47–50.

$$47. y' - 3y = e^x \quad 48. y' + 4y = x$$

$$49. y' - 3y = 5e^{3x} \quad 50. y' + y = \sin x$$

Solve the differential equations in Exercises 51 and 52 subject to the given initial conditions.

$$51. \frac{d^2y}{dx^2} + y = \sec^2 x, \quad -\frac{\pi}{2} < x < \frac{\pi}{2}; \quad y(0) = y'(0) = 1$$

$$52. \frac{d^2y}{dx^2} + y = e^{2x}; \quad y(0) = 0, y'(0) = \frac{2}{5}$$

In Exercises 53–58, verify that the given function is a particular solution to the specified nonhomogeneous equation. Find the general solution, and evaluate its arbitrary constants to find the unique solution satisfying the equation and the given initial conditions.

$$53. y'' + y' = x, \quad y_p = \frac{x^2}{2} - x, \quad y(0) = 0, y'(0) = 0$$

$$54. y'' + y = x, \quad y_p = 2 \sin x + x, \quad y(0) = 0, y'(0) = 0$$

$$55. \frac{1}{2}y'' + y' + y = 4e^x(\cos x - \sin x),$$

$$y_p = 2e^x \cos x, \quad y(0) = 0, y'(0) = 1$$

$$56. y'' - y' - 2y = 1 - 2x, \quad y_p = x - 1, y(0) = 0, y'(0) = 1$$

$$57. y'' - 2y' + y = 2e^x, \quad y_p = x^2e^x, \quad y(0) = 1, y'(0) = 0$$

$$58. y'' - 2y' + y = x^{-1}e^x, \quad x > 0,$$

$$y_p = xe^x \ln x, \quad y(1) = e, y'(1) = 0$$

In Exercises 59 and 60, two linearly independent solutions y_1 and y_2 are given to the associated homogeneous equation of the variable-coefficient nonhomogeneous equation. Use the method of variation of parameters to find a particular solution to the nonhomogeneous equation. Assume $x > 0$ in each exercise.

$$59. x^2y'' + 2xy' - 2y = x^2, \quad y_1 = x^{-2}, y_2 = x$$

$$60. x^2y'' + xy' - y = x, \quad y_1 = x^{-1}, y_2 = x$$

17.3 Applications

In this section we apply second-order differential equations to the study of vibrating springs and electric circuits.

Vibrations

A spring has its upper end fastened to a rigid support, as shown in Figure 17.2. An object of mass m is suspended from the spring and stretches it a length s when the spring comes to rest in an equilibrium position. According to Hooke's Law (Section 6.5), the tension

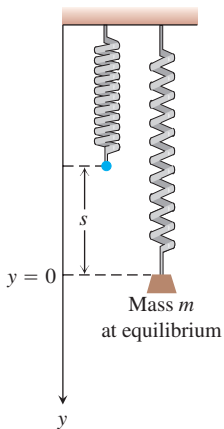

FIGURE 17.2 Mass m stretches a spring by length s to the equilibrium position at $y = 0$.

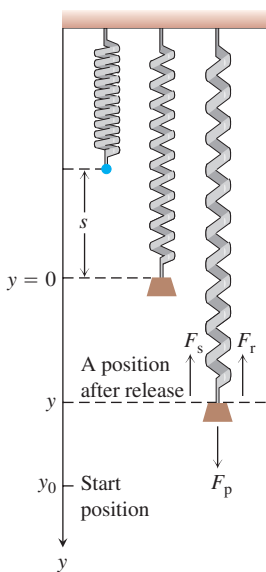

FIGURE 17.3 The propulsion force (weight) F_p pulls the mass downward, but the spring restoring force F_s and frictional force F_r pull the mass upward. The motion starts at $y = y_0$ with the mass vibrating up and down.

force in the spring is ks , where k is the spring constant. The force due to gravity pulling down on the spring is mg , and equilibrium requires that

$$ks = mg. \quad (1)$$

Suppose that the object is pulled down an additional amount y_0 beyond the equilibrium position and then released. We want to study the object's motion, that is, the vertical position of its center of mass at any future time.

Let y , with positive direction downward, denote the displacement position of the object away from the equilibrium position $y = 0$ at any time t after the motion has started. Then the forces acting on the object are (see Figure 17.3)

$$\begin{aligned} F_p &= mg, && \text{the propulsion force due to gravity,} \\ F_s &= k(s + y), && \text{the restoring force of the spring's tension,} \\ F_r &= \delta \frac{dy}{dt}, && \text{a frictional force assumed proportional to velocity.} \end{aligned}$$

The frictional force tends to slow the motion of the object. The resultant of these forces is $F = F_p - F_s - F_r$, and by Newton's second law $F = ma$, we must then have

$$m \frac{d^2y}{dt^2} = mg - ks - ky - \delta \frac{dy}{dt}.$$

By Equation (1), $mg - ks = 0$, so this last equation becomes

$$m \frac{d^2y}{dt^2} + \delta \frac{dy}{dt} + ky = 0, \quad (2)$$

subject to the initial conditions $y(0) = y_0$ and $y'(0) = 0$. (Here we use the prime notation to denote differentiation with respect to time t .)

You might expect that the motion predicted by Equation (2) will be oscillatory about the equilibrium position $y = 0$ and eventually damp to zero because of the frictional force. This is indeed the case, and we will show how the constants m , δ , and k determine the nature of the damping. You will also see that if there is no friction (so $\delta = 0$), then the object will simply oscillate indefinitely.

Simple Harmonic Motion

Suppose first that there is no frictional force. Then $\delta = 0$ and there is no damping. If we substitute $\omega = \sqrt{k/m}$ to simplify our calculations, then the second-order equation (2) becomes

$$y'' + \omega^2 y = 0, \quad \text{with} \quad y(0) = y_0 \quad \text{and} \quad y'(0) = 0.$$

The auxiliary equation is

$$r^2 + \omega^2 = 0,$$

which has the imaginary roots $r = \pm \omega i$. The general solution to the differential equation in (2) is

$$y = c_1 \cos \omega t + c_2 \sin \omega t. \quad (3)$$

To fit the initial conditions, we compute

$$y' = -c_1 \omega \sin \omega t + c_2 \omega \cos \omega t$$

and then substitute the conditions. This yields $c_1 = y_0$ and $c_2 = 0$. The particular solution

$$y = y_0 \cos \omega t \quad (4)$$

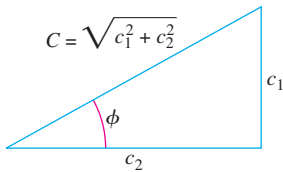

FIGURE 17.4 $c_1 = C \sin \phi$ and $c_2 = C \cos \phi$.

describes the motion of the object. Equation (4) represents **simple harmonic motion** of amplitude y_0 and period $T = 2\pi/\omega$.

The general solution given by Equation (3) can be combined into a single term by using the trigonometric identity

$$\sin(\omega t + \phi) = \cos \omega t \sin \phi + \sin \omega t \cos \phi.$$

To apply the identity, we take (see Figure 17.4)

$$c_1 = C \sin \phi \quad \text{and} \quad c_2 = C \cos \phi,$$

where

$$C = \sqrt{c_1^2 + c_2^2} \quad \text{and} \quad \phi = \tan^{-1} \frac{c_1}{c_2}.$$

Then the general solution in Equation (3) can be written in the alternative form

$$y = C \sin(\omega t + \phi). \quad (5)$$

Here C and ϕ may be taken as two new arbitrary constants, replacing the two constants c_1 and c_2 . Equation (5) represents simple harmonic motion of amplitude C and period $T = 2\pi/\omega$. The angle $\omega t + \phi$ is called the **phase angle**, and ϕ may be interpreted as its initial value. A graph of the simple harmonic motion represented by Equation (5) is given in Figure 17.5.

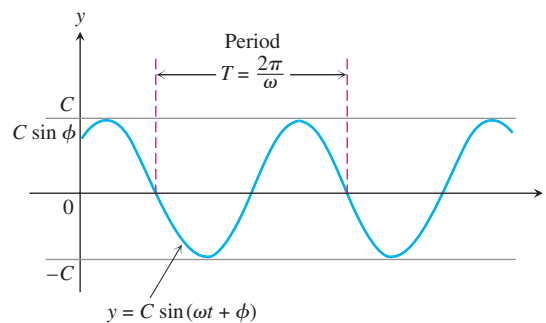

FIGURE 17.5 Simple harmonic motion of amplitude C and period T with initial phase angle ϕ (Equation 5).

Damped Motion

Assume now that there is friction in the spring system, so $\delta \neq 0$. If we substitute $\omega = \sqrt{k/m}$ and $2b = \delta/m$, then the differential equation (2) is

$$y'' + 2by' + \omega^2 y = 0. \quad (6)$$

The auxiliary equation is

$$r^2 + 2br + \omega^2 = 0,$$

with roots $r = -b \pm \sqrt{b^2 - \omega^2}$. Three cases now present themselves, depending on the relative sizes of b and ω .

Case 1: $b = \omega$. The double root of the auxiliary equation is real and equals $r = -\omega$. The general solution to Equation (6) is

$$y = (c_1 + c_2 t)e^{-\omega t}.$$

This situation of motion is called **critical damping** and is not oscillatory. Figure 17.6a shows an example of this kind of damped motion.

Case 2: $b > \omega$. The roots of the auxiliary equation are real and unequal, and they are given by $r_1 = -b + \sqrt{b^2 - \omega^2}$ and $r_2 = -b - \sqrt{b^2 - \omega^2}$. The general solution to Equation (6) is given by

$$y = c_1 e^{(-b + \sqrt{b^2 - \omega^2})t} + c_2 e^{(-b - \sqrt{b^2 - \omega^2})t}.$$

Here again the motion is not oscillatory and both r_1 and r_2 are negative. Thus y approaches zero as time goes on. This motion is referred to as **overdamping** (see Figure 17.6b).

Case 3: $b < \omega$. The roots to the auxiliary equation are complex and are given by $r = -b \pm i\sqrt{\omega^2 - b^2}$. The general solution to Equation (6) is given by

$$y = e^{-bt} (c_1 \cos \sqrt{\omega^2 - b^2} t + c_2 \sin \sqrt{\omega^2 - b^2} t).$$

This situation, called **underdamping**, represents damped oscillatory motion. It is analogous to simple harmonic motion of period $T = 2\pi/\sqrt{\omega^2 - b^2}$ except that the amplitude is not constant but damped by the factor e^{-bt} . Therefore, the motion tends to zero as t increases, so the vibrations tend to die out as time goes on. Notice that the period $T = 2\pi/\sqrt{\omega^2 - b^2}$ is larger than the period $T_0 = 2\pi/\omega$ in the friction-free system. Moreover, the larger the value of $b = \delta/(2m)$ in the exponential damping factor, the more quickly the vibrations tend to become unnoticeable. A curve illustrating underdamped motion is shown in Figure 17.6c.

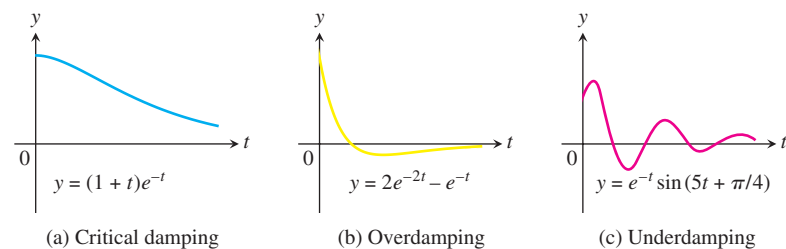

FIGURE 17.6 Three examples of damped vibratory motion for a spring system with friction, so $\delta \neq 0$.

An external force $F(t)$ can also be added to the spring system modeled by Equation (2). The forcing function may represent an external disturbance on the system. For instance, if the equation models an automobile suspension system, the forcing function might represent periodic bumps or potholes in the road affecting the performance of the suspension system. Or it might represent the effects of winds when modeling the vertical motion of a suspension bridge. Inclusion of a forcing function results in the second-order nonhomogeneous equation

$$m \frac{d^2 y}{dt^2} + \delta \frac{dy}{dt} + ky = F(t). \quad (7)$$

Such equations are studied in the theory of Differential Equations.

Electric Circuits

The basic quantity in electricity is the **charge** q (analogous to the idea of mass). In an electric field we use the flow of charge, or **current** $I = dq/dt$, as we might use velocity in a gravitational field. There are many similarities between motion in a gravitational field and the flow of electrons (the carriers of charge) in an electric field.

Consider the electric circuit shown in Figure 17.7. It consists of four components: voltage source, resistor, inductor, and capacitor. Think of electrical flow as being like a fluid flow, where the voltage source is the pump and the resistor, inductor, and capacitor tend to block the flow. A battery or generator is an example of a source, producing a

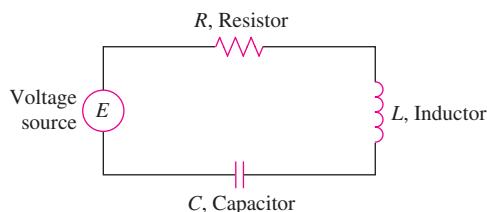

FIGURE 17.7 An electric circuit.

voltage that causes the current to flow through the circuit when the switch is closed. An electric light bulb or appliance would provide resistance. The inductance is due to a magnetic field that opposes any change in the current as it flows through a coil. The capacitance is normally created by two metal plates that alternate charges and thus reverse the current flow. The following symbols specify the quantities relevant to the circuit.

- q : charge at a cross section of a conductor, measured in **coulombs** (abbreviated c)
- I : current or rate of change of charge dq/dt (flow of electrons) at a cross section of a conductor, measured in **amperes** (abbreviated A)
- E : electric (potential) source, measured in **volts** (abbreviated V)
- V : difference in potential between two points along the conductor, measured in **volts** (V)

Ohm observed that the current I flowing through a resistor, caused by a potential difference across it, is (approximately) proportional to the potential difference (voltage drop). He named his constant of proportionality $1/R$ and called R the **resistance**. So *Ohm's law* is

$$I = \frac{1}{R}V.$$

Similarly, it is known from physics that the voltage drops across an inductor and a capacitor are, respectively,

$$L \frac{dI}{dt} \quad \text{and} \quad \frac{q}{C},$$

where L is the **inductance** and C is the **capacitance** (with q the charge on the capacitor).

The German physicist Gustav R. Kirchhoff (1824–1887) formulated the law that the sum of the voltage drops in a closed circuit is equal to the supplied voltage $E(t)$. Symbolically, this says that

$$RI + L \frac{dI}{dt} + \frac{q}{C} = E(t).$$

Since $I = dq/dt$, Kirchhoff's law becomes

$$L \frac{d^2q}{dt^2} + R \frac{dq}{dt} + \frac{1}{C}q = E(t). \quad (8)$$

The second-order differential equation (8), which models an electric circuit, has exactly the same form as Equation (7) modeling vibratory motion. Both models can be solved using the methods developed in Section 17.2.

Summary

The following chart summarizes our analogies between the physics of motion of an object in a spring system and the flow of charged particles in an electric circuit.

Linear Second-Order Constant-Coefficient Models

Mechanical System

$$my'' + \delta y' + ky = F(t)$$

y	displacement
y'	velocity
y''	acceleration
m	mass
δ	damping constant
k	spring constant
$F(t)$	forcing function

Electrical System

$$Lq'' + Rq' + \frac{1}{C}q = E(t)$$

q	charge
q'	current
q''	change in current
L	inductance
R	resistance
$1/C$	where C is the capacitance
$E(t)$	voltage source

EXERCISES 17.3

- A 70-N weight is attached to the lower end of a coil spring suspended from the ceiling and having a spring constant of 15 N/m. The resistance in the spring–mass system is numerically equal to 15 times the instantaneous velocity. At $t = 0$, the weight is set in motion from a position 0.6 m below its equilibrium position by giving it a downward velocity of 0.6 m/s. Write an initial value problem that models the given situation.
- A 36-N weight stretches a spring 1.2 m. The spring–mass system resides in a medium offering a resistance to the motion that is numerically equal to 20 times the instantaneous velocity. If the weight is released at a position 0.6 m above its equilibrium position with a downward velocity of 0.9 m/s, write an initial value problem modeling the given situation.
- A 90-N weight is hung on a 0.4-m spring and stretches it 0.15 m. The weight is pulled down 0.1 m and 30 N are added to the weight. If the weight is now released with a downward velocity of v_0 m/s, write an initial value problem modeling the vertical displacement.
- A 49-N weight is suspended by a spring that is stretched 0.05 m by the weight. Assume a resistance whose magnitude is $300/\sqrt{g}$ N times the instantaneous velocity v in meters per second. If the weight is pulled down 0.08 m below its equilibrium position and released, formulate an initial value problem modeling the behavior of the spring–mass system.
- An (open) electric circuit consists of an inductor, a resistor, and a capacitor. There is an initial charge of 2 coulombs on the capacitor. At the instant the circuit is closed, a current of 3 amperes is present and a voltage of $E(t) = 20 \cos t$ is applied. In this circuit the voltage drop across the resistor is 4 times the instantaneous change in the charge, the voltage drop across the capacitor is 10 times the charge, and the voltage drop across the inductor is 2 times the instantaneous change in the current. Write an initial value problem to model the circuit.
- An inductor of 2 henrys is connected in series with a resistor of 12 ohms, a capacitor of 1/16 farad, and a 300-volt battery. Initially, the charge on the capacitor is zero and the current is zero. Formulate an initial value problem modeling this electric circuit.
- A 49-N weight is attached to the lower end of a coil spring suspended from the ceiling and having a spring constant of 10 N/m. The resistance in the spring–mass system is numerically equal to 10 times the instantaneous velocity. At $t = 0$, the weight is set in motion from a position 0.6 m below its equilibrium position by giving it a downward velocity of 0.6 m/s. At the end of π s, determine whether the mass is above or below the equilibrium position and by what distance.
- A 29.4-N weight stretches a spring 1.225 m. The spring–mass system resides in a medium offering a resistance to the motion equal to 18 times the instantaneous velocity. If the weight is released at a position 0.6 m above its equilibrium position with a downward velocity of 0.9 m/s, find its position relative to the equilibrium position 2 s later.
- A 98-N weight is hung on a 0.6 m spring stretching it 0.2 m. The weight is pulled down 0.15 m and 49 N are added to the weight. If the weight is now released with a downward velocity of v_0 m/s, find the position of mass relative to the equilibrium in terms of v_0 and valid for any time $t \geq 0$.
- A mass of 15 kg is attached to a spring whose constant is $375/4$ N/m. Initially the mass is released 1 m above the equilibrium position with a downward velocity of 3 m/s, and the subsequent motion takes place in a medium that offers a damping force numerically equal to 45 times the instantaneous velocity. An external force $f(t)$ is driving the system, but assume that initially $f(t) \equiv 0$. Formulate and solve an initial value problem that models the given system. Interpret your results.
- A 50-N weight is suspended by a spring that is stretched 0.05 m by the weight. Assume a resistance whose magnitude is 100 N times the instantaneous velocity in meters per second. If the weight is pulled down 0.1 m below its equilibrium position and released, find the time required to reach the equilibrium position for the first time.

12. A weight stretches a spring 0.2 m. It is set in motion at a point 0.05 m below its equilibrium position with a downward velocity of 0.05 m/s.
- When does the weight return to its equilibrium position?
 - When does it reach its highest point?
 - Show that the maximum velocity is $0.05\sqrt{10g}$ m/s.
13. A weight of 50 N stretches a spring 0.25 m. The weight is drawn down 0.05 m below its equilibrium position and given an initial velocity of 0.1 m/s. An identical spring has a different weight attached to it. This second weight is drawn down from its equilibrium position a distance equal to the amplitude of the first motion and then given an initial velocity of 0.6 m/s. If the amplitude of the second motion is twice that of the first, what weight is attached to the second spring?
14. A weight stretches one spring 0.05 m and a second weight stretches another spring 0.15 m. If both weights are simultaneously pulled down 0.02 m below their respective equilibrium positions and then released, find the first time after $t = 0$ when their velocities are equal.
15. A weight of 80 N stretches a spring 1 m. The weight is pulled down 1.5 m below the equilibrium position and then released. What initial velocity v_0 given to the weight would have the effect of doubling the amplitude of the vibration?
16. A mass weighing 40 N stretches a spring 0.1 m. The spring-mass system resides in a medium with a damping constant of 32 N-s/m. If the mass is released from its equilibrium position with a velocity of 0.1 m/s in the downward direction, find the time required for the mass to return to its equilibrium position for the first time.
17. A weight suspended from a spring executes damped vibrations with a period of 2 s. If the damping factor decreases by 90% in 10 s, find the acceleration of the weight when it is 0.1 m below its equilibrium position and is moving upward with a speed of 0.8 m/s.
18. A 50-N weight stretches a spring 0.6 m. If the weight is pulled down 0.15 m below its equilibrium position and released, find the highest point reached by the weight. Assume the spring-mass system resides in a medium offering a resistance of 30 N times the instantaneous velocity in meters per second.
19. An *LRC* circuit is set up with an inductance of $1/5$ henry, a resistance of 1 ohm, and a capacitance of $5/6$ farad. Assuming the initial charge is 2 coulombs and the initial current is 4 amperes, find the solution function describing the charge on the capacitor at any time. What is the charge on the capacitor after a long period of time?
20. An (open) electric circuit consists of an inductor, a resistor, and a capacitor. There is an initial charge of 2 coulombs on the capacitor. At the instant the circuit is closed, a current of 3 amperes is present but no external voltage is being applied. In this circuit the voltage drops at three points are numerically related as follows: across the capacitor, 10 times the charge; across the resistor, 4 times the instantaneous change in the charge; and across the inductor, 2 times the instantaneous change in the current. Find the charge on the capacitor as a function of time.
21. A 78.4-N weight stretches a spring 1.225 m. This spring-mass system is in a medium with a damping constant of 72 N-s/m, and an external force given by $f(t) = 25.6 + 6.4e^{-2t}$ (in newtons) is being applied. What is the solution function describing the position of the mass at any time if the mass is released from 0.6 m below the equilibrium position with an initial velocity of 1.2 m/s downward?
22. A 10-kg mass is attached to a spring having a spring constant of 140 N/m. The mass is started in motion from the equilibrium position with an initial velocity of 1 m/s in the upward direction and with an applied external force given by $f(t) = 5 \sin t$ (in newtons). The mass is in a viscous medium with a coefficient of resistance equal to 90 N-s/m. Formulate an initial value problem that models the given system; solve the model and interpret the results.
23. A 2-kg mass is attached to the lower end of a coil spring suspended from the ceiling. The mass comes to rest in its equilibrium position thereby stretching the spring 1.96 m. The mass is in a viscous medium that offers a resistance in newtons numerically equal to 4 times the instantaneous velocity measured in meters per second. The mass is then pulled down 2 m below its equilibrium position and released with a downward velocity of 3 m/s. At this same instant an external force given by $f(t) = 20 \cos t$ (in newtons) is applied to the system. At the end of π s determine if the mass is above or below its equilibrium position and by how much.
24. A 39.2-N weight stretches a spring 1.225 m. The spring-mass system resides in a medium offering a resistance to the motion equal to 24 times the instantaneous velocity, and an external force given by $f(t) = 28.8 + 19.2e^{-t}$ (in newtons) is being applied. If the weight is released at a position 0.6 m above its equilibrium position with downward velocity of 0.9 m/s, find its position relative to the equilibrium after 2 s have elapsed.
25. Suppose $L = 10$ henrys, $R = 10$ ohms, $C = 1/500$ farads, $E = 100$ volts, $q(0) = 10$ coulombs, and $q'(0) = i(0) = 0$. Formulate and solve an initial value problem that models the given *LRC* circuit. Interpret your results.
26. A series circuit consisting of an inductor, a resistor, and a capacitor is open. There is an initial charge of 2 coulombs on the capacitor, and 3 amperes of current is present in the circuit at the instant the circuit is closed. A voltage given by $E(t) = 20 \cos t$ is applied. In this circuit the voltage drops are numerically equal to the following: across the resistor, to 4 times the instantaneous change in the charge; across the capacitor, to 10 times the charge; and across the inductor, to 2 times the instantaneous change in the current. Find the charge on the capacitor as a function of time. Determine the charge on the capacitor and the current at time $t = 10$.

17.4 Euler Equations

In Section 17.1 we introduced the second-order linear homogeneous differential equation

$$P(x)y''(x) + Q(x)y'(x) + R(x)y(x) = 0$$

and showed how to solve this equation when the coefficients P , Q , and R are constants. If the coefficients are not constant, we cannot generally solve this differential equation in terms of elementary functions we have studied in calculus. In this section you will learn how to solve the equation when the coefficients have the special forms

$$P(x) = ax^2, \quad Q(x) = bx, \quad \text{and} \quad R(x) = c,$$

where a , b , and c are constants. These special types of equations are called **Euler equations** in honor of Leonhard Euler, who studied them and showed how to solve them. Such equations arise in the study of mechanical vibrations.

The General Solution of Euler Equations

Consider the Euler equation

$$ax^2y'' + bxy' + cy = 0, \quad x > 0. \quad (1)$$

To solve Equation (1), we first make the change of variables

$$z = \ln x \quad \text{and} \quad y(x) = Y(z).$$

We next use the chain rule to find the derivatives $y'(x)$ and $y''(x)$:

$$y'(x) = \frac{d}{dx}Y(z) = \frac{d}{dz}Y(z) \frac{dz}{dx} = Y'(z) \frac{1}{x}$$

and

$$y''(x) = \frac{d}{dx}y'(x) = \frac{d}{dx}Y'(z) \frac{1}{x} = -\frac{1}{x^2}Y'(z) + \frac{1}{x}Y''(z) \frac{dz}{dx} = -\frac{1}{x^2}Y'(z) + \frac{1}{x^2}Y''(z).$$

Substituting these two derivatives into the left-hand side of Equation (1), we find

$$\begin{aligned} ax^2y'' + bxy' + cy &= ax^2 \left(-\frac{1}{x^2}Y'(z) + \frac{1}{x^2}Y''(z) \right) + bx \left(\frac{1}{x}Y'(z) \right) + cY(z) \\ &= aY''(z) + (b - a)Y'(z) + cY(z). \end{aligned}$$

Therefore, the substitutions give us the second-order linear differential equation with constant coefficients

$$aY''(z) + (b - a)Y'(z) + cY(z) = 0. \quad (2)$$

We can solve Equation (2) using the method of Section 17.1. That is, we find the roots of the associated auxiliary equation

$$ar^2 + (b - a)r + c = 0 \quad (3)$$

to find the general solution for $Y(z)$. After finding $Y(z)$, we can determine $y(x)$ from the substitution $z = \ln x$.

EXAMPLE 1 Find the general solution of the equation $x^2y'' + 2xy' - 2y = 0$.

Solution This is an Euler equation with $a = 1$, $b = 2$, and $c = -2$. The auxiliary equation (3) for $Y(z)$ is

$$r^2 + (2 - 1)r - 2 = (r - 1)(r + 2) = 0,$$

with roots $r = -2$ and $r = 1$. The solution for $Y(z)$ is given by

$$Y(z) = c_1 e^{-2z} + c_2 e^z.$$

Substituting $z = \ln x$ gives the general solution for $y(x)$:

$$y(x) = c_1 e^{-2 \ln x} + c_2 e^{\ln x} = c_1 x^{-2} + c_2 x. \quad \blacksquare$$

EXAMPLE 2 Solve the Euler equation $x^2 y'' - 5xy' + 9y = 0$.

Solution Since $a = 1$, $b = -5$, and $c = 9$, the auxiliary equation (3) for $Y(z)$ is

$$r^2 + (-5 - 1)r + 9 = (r - 3)^2 = 0.$$

The auxiliary equation has the double root $r = 3$, giving

$$Y(z) = c_1 e^{3z} + c_2 z e^{3z}.$$

Substituting $z = \ln x$ into this expression gives the general solution

$$y(x) = c_1 e^{3 \ln x} + c_2 \ln x e^{3 \ln x} = c_1 x^3 + c_2 x^3 \ln x. \quad \blacksquare$$

EXAMPLE 3 Find the particular solution to $x^2 y'' - 3xy' + 68y = 0$ that satisfies the initial conditions $y(1) = 0$ and $y'(1) = 1$.

Solution Here $a = 1$, $b = -3$, and $c = 68$ substituted into the auxiliary equation (3) give

$$r^2 - 4r + 68 = 0.$$

The roots are $r = 2 + 8i$ and $r = 2 - 8i$, giving the solution

$$Y(z) = e^{2z}(c_1 \cos 8z + c_2 \sin 8z).$$

Substituting $z = \ln x$ into this expression gives

$$y(x) = e^{2 \ln x}(c_1 \cos(8 \ln x) + c_2 \sin(8 \ln x)).$$

From the initial condition $y(1) = 0$, we see that $c_1 = 0$ and

$$y(x) = c_2 x^2 \sin(8 \ln x).$$

To fit the second initial condition, we need the derivative

$$y'(x) = c_2(8x \cos(8 \ln x) + 2x \sin(8 \ln x)).$$

Since $y'(1) = 1$, we immediately obtain $c_2 = 1/8$. Therefore, the particular solution satisfying both initial conditions is

$$y(x) = \frac{1}{8} x^2 \sin(8 \ln x).$$

Since $-1 \leq \sin(8 \ln x) \leq 1$, the solution satisfies

$$-\frac{x^2}{8} \leq y(x) \leq \frac{x^2}{8}.$$

A graph of the solution is shown in Figure 17.8. \blacksquare

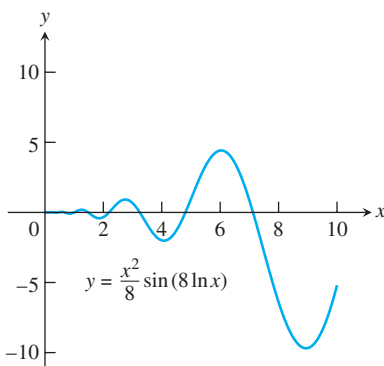

FIGURE 17.8 Graph of the solution to Example 3.

EXERCISES 17.4

In Exercises 1–24, find the general solution to the given Euler equation. Assume $x > 0$ throughout.

1. $x^2y'' + 2xy' - 2y = 0$
2. $x^2y'' + xy' - 4y = 0$
3. $x^2y'' - 6y = 0$
4. $x^2y'' + xy' - y = 0$
5. $x^2y'' - 5xy' + 8y = 0$
6. $2x^2y'' + 7xy' + 2y = 0$
7. $3x^2y'' + 4xy' = 0$
8. $x^2y'' + 6xy' + 4y = 0$
9. $x^2y'' - xy' + y = 0$
10. $x^2y'' - xy' + 2y = 0$
11. $x^2y'' - xy' + 5y = 0$
12. $x^2y'' + 7xy' + 13y = 0$
13. $x^2y'' + 3xy' + 10y = 0$
14. $x^2y'' - 5xy' + 10y = 0$
15. $4x^2y'' + 8xy' + 5y = 0$
16. $4x^2y'' - 4xy' + 5y = 0$
17. $x^2y'' + 3xy' + y = 0$
18. $x^2y'' - 3xy' + 9y = 0$
19. $x^2y'' + xy' = 0$
20. $4x^2y'' + y = 0$

21. $9x^2y'' + 15xy' + y = 0$
22. $16x^2y'' - 8xy' + 9y = 0$
23. $16x^2y'' + 56xy' + 25y = 0$
24. $4x^2y'' - 16xy' + 25y = 0$

In Exercises 25–30, solve the given initial value problem.

25. $x^2y'' + 3xy' - 3y = 0$, $y(1) = 1$, $y'(1) = -1$
26. $6x^2y'' + 7xy' - 2y = 0$, $y(1) = 0$, $y'(1) = 1$
27. $x^2y'' - xy' + y = 0$, $y(1) = 1$, $y'(1) = 1$
28. $x^2y'' + 7xy' + 9y = 0$, $y(1) = 1$, $y'(1) = 0$
29. $x^2y'' - xy' + 2y = 0$, $y(1) = -1$, $y'(1) = 1$
30. $x^2y'' + 3xy' + 5y = 0$, $y(1) = 1$, $y'(1) = 0$

17.5 Power-Series Solutions

In this section we extend our study of second-order linear homogeneous equations with variable coefficients. With the Euler equations in Section 17.4, the power of the variable x in the nonconstant coefficient had to match the order of the derivative with which it was paired: x^2 with y'' , x^1 with y' , and $x^0 (=1)$ with y . Here we drop that requirement so we can solve more general equations.

Method of Solution

The **power-series method** for solving a second-order homogeneous differential equation consists of finding the coefficients of a power series

$$y(x) = \sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + \cdots \quad (1)$$

which solves the equation. To apply the method we substitute the series and its derivatives into the differential equation to determine the coefficients c_0, c_1, c_2, \dots . The technique for finding the coefficients is similar to that used in the method of undetermined coefficients presented in Section 17.2.

In our first example we demonstrate the method in the setting of a simple equation whose general solution we already know. This is to help you become more comfortable with solutions expressed in series form.

EXAMPLE 1 Solve the equation $y'' + y = 0$ by the power-series method.

Solution We assume the series solution takes the form of

$$y = \sum_{n=0}^{\infty} c_n x^n$$

and calculate the derivatives

$$y' = \sum_{n=1}^{\infty} n c_n x^{n-1} \quad \text{and} \quad y'' = \sum_{n=2}^{\infty} n(n-1) c_n x^{n-2}.$$

Substitution of these forms into the second-order equation gives us

$$\sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} + \sum_{n=0}^{\infty} c_n x^n = 0.$$

Next, we equate the coefficients of each power of x to zero as summarized in the following table.

Power of x	Coefficient equation
x^0	$2(1)c_2 + c_0 = 0$ or $c_2 = -\frac{1}{2}c_0$
x^1	$3(2)c_3 + c_1 = 0$ or $c_3 = -\frac{1}{3 \cdot 2}c_1$
x^2	$4(3)c_4 + c_2 = 0$ or $c_4 = -\frac{1}{4 \cdot 3}c_2$
x^3	$5(4)c_5 + c_3 = 0$ or $c_5 = -\frac{1}{5 \cdot 4}c_3$
x^4	$6(5)c_6 + c_4 = 0$ or $c_6 = -\frac{1}{6 \cdot 5}c_4$
\vdots	\vdots
x^{n-2}	$n(n-1)c_n + c_{n-2} = 0$ or $c_n = -\frac{1}{n(n-1)}c_{n-2}$

From the table we notice that the coefficients with even indices ($n = 2k$, $k = 1, 2, 3, \dots$) are related to each other and the coefficients with odd indices ($n = 2k + 1$) are also inter-related. We treat each group in turn.

Even indices: Here $n = 2k$, so the power is x^{2k-2} . From the last line of the table, we have

$$2k(2k-1)c_{2k} + c_{2k-2} = 0$$

or

$$c_{2k} = -\frac{1}{2k(2k-1)}c_{2k-2}.$$

From this recursive relation we find

$$\begin{aligned} c_{2k} &= \left[-\frac{1}{2k(2k-1)} \right] \left[-\frac{1}{(2k-2)(2k-3)} \right] \cdots \left[-\frac{1}{4(3)} \right] \left[-\frac{1}{2} \right] c_0 \\ &= \frac{(-1)^k}{(2k)!} c_0. \end{aligned}$$

Odd indices: Here $n = 2k + 1$, so the power is x^{2k-1} . Substituting this into the last line of the table yields

$$(2k+1)(2k)c_{2k+1} + c_{2k-1} = 0$$

or

$$c_{2k+1} = -\frac{1}{(2k+1)(2k)}c_{2k-1}.$$

Thus,

$$\begin{aligned} c_{2k+1} &= \left[-\frac{1}{(2k+1)(2k)} \right] \left[-\frac{1}{(2k-1)(2k-2)} \right] \cdots \left[-\frac{1}{5(4)} \right] \left[-\frac{1}{3(2)} \right] c_1 \\ &= \frac{(-1)^k}{(2k+1)!} c_1. \end{aligned}$$

Writing the power series by grouping its even and odd powers together and substituting for the coefficients yields

$$\begin{aligned} y &= \sum_{n=0}^{\infty} c_n x^n \\ &= \sum_{k=0}^{\infty} c_{2k} x^{2k} + \sum_{k=0}^{\infty} c_{2k+1} x^{2k+1} \\ &= c_0 \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} x^{2k} + c_1 \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} x^{2k+1}. \end{aligned}$$

From our study of Taylor series, we see that the first series on the right-hand side of the last equation represents the cosine function, and the second series represents the sine. Thus, the general solution to $y'' + y = 0$ is

$$y = c_0 \cos x + c_1 \sin x. \quad \blacksquare$$

EXAMPLE 2 Find the general solution to $y'' + xy' + y = 0$.

Solution We assume the series solution form

$$y = \sum_{n=0}^{\infty} c_n x^n$$

and calculate the derivatives

$$y' = \sum_{n=1}^{\infty} n c_n x^{n-1} \quad \text{and} \quad y'' = \sum_{n=2}^{\infty} n(n-1) c_n x^{n-2}.$$

Substitution of these forms into the second-order equation yields

$$\sum_{n=2}^{\infty} n(n-1) c_n x^{n-2} + \sum_{n=1}^{\infty} n c_n x^n + \sum_{n=0}^{\infty} c_n x^n = 0.$$

We equate the coefficients of each power of x to zero as summarized in the following table.

Power of x	Coefficient equation
x^0	$2(1)c_2 + c_0 = 0$ or $c_2 = -\frac{1}{2}c_0$
x^1	$3(2)c_3 + c_1 + c_1 = 0$ or $c_3 = -\frac{1}{3}c_1$
x^2	$4(3)c_4 + 2c_2 + c_2 = 0$ or $c_4 = -\frac{1}{4}c_2$
x^3	$5(4)c_5 + 3c_3 + c_3 = 0$ or $c_5 = -\frac{1}{5}c_3$
x^4	$6(5)c_6 + 4c_4 + c_4 = 0$ or $c_6 = -\frac{1}{6}c_4$
\vdots	\vdots
x^n	$(n+2)(n+1)c_{n+2} + (n+1)c_n = 0$ or $c_{n+2} = -\frac{1}{n+2}c_n$

From the table notice that the coefficients with even indices are interrelated and the coefficients with odd indices are also interrelated.

Even indices: Here $n = 2k - 2$, so the power is x^{2k-2} . From the last line in the table, we have

$$c_{2k} = -\frac{1}{2k}c_{2k-2}.$$

From this recurrence relation we obtain

$$\begin{aligned} c_{2k} &= \left(-\frac{1}{2k}\right)\left(-\frac{1}{2k-2}\right)\cdots\left(-\frac{1}{6}\right)\left(-\frac{1}{4}\right)\left(-\frac{1}{2}\right)c_0 \\ &= \frac{(-1)^k}{(2)(4)(6)\cdots(2k)}c_0. \end{aligned}$$

Odd indices: Here $n = 2k - 1$, so the power is x^{2k-1} . From the last line in the table, we have

$$c_{2k+1} = -\frac{1}{2k+1}c_{2k-1}.$$

From this recurrence relation we obtain

$$\begin{aligned} c_{2k+1} &= \left(-\frac{1}{2k+1}\right)\left(-\frac{1}{2k-1}\right)\cdots\left(-\frac{1}{5}\right)\left(-\frac{1}{3}\right)c_1 \\ &= \frac{(-1)^k}{(3)(5)\cdots(2k+1)}c_1. \end{aligned}$$

Writing the power series by grouping its even and odd powers and substituting for the coefficients yields

$$\begin{aligned} y &= \sum_{k=0}^{\infty} c_{2k}x^{2k} + \sum_{k=0}^{\infty} c_{2k+1}x^{2k+1} \\ &= c_0 \sum_{k=0}^{\infty} \frac{(-1)^k}{(2)(4)\cdots(2k)}x^{2k} + c_1 \sum_{k=0}^{\infty} \frac{(-1)^k}{(3)(5)\cdots(2k+1)}x^{2k+1}. \end{aligned} \quad \blacksquare$$

EXAMPLE 3 Find the general solution to

$$(1-x^2)y'' - 6xy' - 4y = 0, \quad |x| < 1.$$

Solution Notice that the leading coefficient is zero when $x = \pm 1$. Thus, we assume the solution interval I : $-1 < x < 1$. Substitution of the series form

$$y = \sum_{n=0}^{\infty} c_n x^n$$

and its derivatives gives us

$$\begin{aligned} (1-x^2) \sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} - 6 \sum_{n=1}^{\infty} n c_n x^n - 4 \sum_{n=0}^{\infty} c_n x^n &= 0, \\ \sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} - \sum_{n=2}^{\infty} n(n-1)c_n x^n - 6 \sum_{n=1}^{\infty} n c_n x^n - 4 \sum_{n=0}^{\infty} c_n x^n &= 0. \end{aligned}$$

Next, we equate the coefficients of each power of x to zero as summarized in the following table.

Power of x	Coefficient equation
x^0	$2(1)c_2 - 4c_0 = 0$ or $c_2 = \frac{4}{2}c_0$
x^1	$3(2)c_3 - 6(1)c_1 - 4c_1 = 0$ or $c_3 = \frac{5}{3}c_1$
x^2	$4(3)c_4 - 2(1)c_2 - 6(2)c_2 - 4c_2 = 0$ or $c_4 = \frac{6}{4}c_2$
x^3	$5(4)c_5 - 3(2)c_3 - 6(3)c_3 - 4c_3 = 0$ or $c_5 = \frac{7}{5}c_3$
\vdots	\vdots
x^n	$(n+2)(n+1)c_{n+2} - [n(n-1) + 6n + 4]c_n = 0$ $(n+2)(n+1)c_{n+2} - (n+4)(n+1)c_n = 0$ or $c_{n+2} = \frac{n+4}{n+2}c_n$

Again we notice that the coefficients with even indices are interrelated and those with odd indices are interrelated.

Even indices: Here $n = 2k - 2$, so the power is x^{2k} . From the right-hand column and the last line of the table, we get

$$\begin{aligned} c_{2k} &= \frac{2k+2}{2k} c_{2k-2} \\ &= \left(\frac{2k+2}{2k}\right) \left(\frac{2k}{2k-2}\right) \left(\frac{2k-2}{2k-4}\right) \cdots \frac{6}{4} \left(\frac{4}{2}\right) c_0 \\ &= (k+1)c_0. \end{aligned}$$

Odd indices: Here $n = 2k - 1$, so the power is x^{2k+1} . The right-hand column and the last line of the table give us

$$\begin{aligned} c_{2k+1} &= \frac{2k+3}{2k+1} c_{2k-1} \\ &= \left(\frac{2k+3}{2k+1}\right) \left(\frac{2k+1}{2k-1}\right) \left(\frac{2k-1}{2k-3}\right) \cdots \frac{7}{5} \left(\frac{5}{3}\right) c_1 \\ &= \frac{2k+3}{3} c_1. \end{aligned}$$

The general solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} c_n x^n \\ &= \sum_{k=0}^{\infty} c_{2k} x^{2k} + \sum_{k=0}^{\infty} c_{2k+1} x^{2k+1} \\ &= c_0 \sum_{k=0}^{\infty} (k+1) x^{2k} + c_1 \sum_{k=0}^{\infty} \frac{2k+3}{3} x^{2k+1}. \end{aligned}$$

EXAMPLE 4 Find the general solution to $y'' - 2xy' + y = 0$.

Solution Assuming that

$$y = \sum_{n=0}^{\infty} c_n x^n,$$

substitution into the differential equation gives us

$$\sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} - 2 \sum_{n=1}^{\infty} n c_n x^n + \sum_{n=0}^{\infty} c_n x^n = 0.$$

We next determine the coefficients, listing them in the following table.

Power of x	Coefficient equation
x^0	$2(1)c_2 + c_0 = 0$ or $c_2 = -\frac{1}{2}c_0$
x^1	$3(2)c_3 - 2c_1 + c_1 = 0$ or $c_3 = \frac{1}{3 \cdot 2}c_1$
x^2	$4(3)c_4 - 4c_2 + c_2 = 0$ or $c_4 = \frac{3}{4 \cdot 3}c_2$
x^3	$5(4)c_5 - 6c_3 + c_3 = 0$ or $c_5 = \frac{5}{5 \cdot 4}c_3$
x^4	$6(5)c_6 - 8c_4 + c_4 = 0$ or $c_6 = \frac{7}{6 \cdot 5}c_4$
\vdots	\vdots
x^n	$(n+2)(n+1)c_{n+2} - (2n-1)c_n = 0$ or $c_{n+2} = \frac{2n-1}{(n+2)(n+1)}c_n$

From the recursive relation

$$c_{n+2} = \frac{2n-1}{(n+2)(n+1)}c_n,$$

we write out the first few terms of each series for the general solution:

$$y = c_0 \left(1 - \frac{1}{2}x^2 - \frac{3}{4!}x^4 - \frac{21}{6!}x^6 - \dots \right) + c_1 \left(x + \frac{1}{3!}x^3 + \frac{5}{5!}x^5 + \frac{45}{7!}x^7 + \dots \right).$$

EXERCISES 17.5

In Exercises 1–18, use power series to find the general solution of the differential equation.

- $y'' + 2y' = 0$
- $y'' + 2y' + y = 0$
- $y'' + 4y = 0$
- $y'' - 3y' + 2y = 0$
- $x^2 y'' - 2xy' + 2y = 0$
- $y'' - xy' + y = 0$
- $(1+x)y'' - y = 0$
- $(1-x^2)y'' - 4xy' + 6y = 0$
- $(x^2-1)y'' + 2xy' - 2y = 0$
- $y'' + y' - x^2y = 0$
- $(x^2-1)y'' - 6y = 0$
- $xy'' - (x+2)y' + 2y = 0$
- $(x^2-1)y'' + 4xy' + 2y = 0$
- $y'' - 2xy' + 4y = 0$
- $y'' - 2xy' + 3y = 0$
- $(1-x^2)y'' - xy' + 4y = 0$
- $y'' - xy' + 3y = 0$
- $x^2 y'' - 4xy' + 6y = 0$

ANSWERS TO ODD-NUMBERED EXERCISES

Chapter 17

SECTION 17.1, pp. 17-6-17-7

1. $y = c_1e^{-3x} + c_2e^{4x}$ 3. $y = c_1e^{-4x} + c_2e^x$
 5. $y = c_1e^{-2x} + c_2e^{2x}$ 7. $y = c_1e^{-x} + c_2e^{3x/2}$
 9. $y = c_1e^{-x/4} + c_2e^{3x/2}$ 11. $y = c_1 \cos 3x + c_2 \sin 3x$
 13. $y = c_1 \cos 5x + c_2 \sin 5x$ 15. $y = e^x(c_1 \cos 2x + c_2 \sin 2x)$
 17. $y = e^{-x}(c_1 \cos \sqrt{3}x + c_2 \sin \sqrt{3}x)$
 19. $y = e^{-2x}(c_1 \cos \sqrt{5}x + c_2 \sin \sqrt{5}x)$
 21. $y = c_1 + c_2x$ 23. $y = c_1e^{-2x} + c_2xe^{-2x}$
 25. $y = c_1e^{-3x} + c_2xe^{-3x}$ 27. $y = c_1e^{-x/2} + c_2xe^{-x/2}$
 29. $y = c_1e^{-x/3} + c_2xe^{-x/3}$ 31. $y = -\frac{3}{4}e^{-5x} + \frac{3}{4}e^{-x}$
 33. $y = \frac{1}{2\sqrt{3}} \sin 2\sqrt{3}x$
 35. $y = -\cos 2\sqrt{2}x + \frac{1}{\sqrt{2}} \sin 2\sqrt{2}x$
 37. $y = (1 - 2x)e^{2x}$ 39. $y = 2(1 + 2x)e^{-3x/2}$
 41. $y = c_1e^{-x} + c_2e^{3x}$ 43. $y = c_1e^{-x/2} + c_2xe^{-x/2}$
 45. $y = c_1 \cos \sqrt{5}x + c_2 \sin \sqrt{5}x$ 47. $y = c_1e^{-x/5} + c_2xe^{-x/5}$
 49. $y = e^{-x/2}(c_1 \cos x + c_2 \sin x)$ 51. $y = c_1e^{3x/4} + c_2xe^{3x/4}$
 53. $y = c_1e^{-4x/3} + c_2xe^{-4x/3}$ 55. $y = c_1e^{-x/2} + c_2e^{4x/3}$
 57. $y = (1 + 2x)e^{-x}$ 59. $y = \frac{15}{13}e^{-7x/3} + \frac{11}{13}e^{2x}$

SECTION 17.2, pp. 17-14-17-15

1. $y = c_1e^{5x} + c_2e^{-2x} + \frac{3}{10}$
 3. $y = c_1 + c_2e^x + \frac{1}{2} \cos x - \frac{1}{2} \sin x$
 5. $y = c_1 \cos x + c_2 \sin x - \frac{1}{8} \cos 3x$
 7. $y = c_1e^{2x} + c_2e^{-x} - 6 \cos x - 2 \sin x$
 9. $y = c_1e^x + c_2e^{-x} - x^2 - 2 + \frac{1}{2}xe^x$
 11. $y = c_1e^{3x} + c_2e^{-2x} - \frac{1}{4}e^{-x} + \frac{49}{50} \cos x + \frac{7}{50} \sin x$
 13. $y = c_1 + c_2e^{-5x} + x^3 + \frac{3}{5}x^2 - \frac{6}{25}x$
 15. $y = c_1 + c_2e^{3x} + 2x^2 + \frac{4}{3}x + \frac{1}{3}xe^{3x}$
 17. $y = c_1 + c_2e^{-x} + \frac{1}{2}x^2 - x$
 19. $y = c_1 \cos x + c_2 \sin x - \frac{1}{2}x \cos x$
 21. $y = (c_1 + c_2x)e^{-x} + \frac{1}{2}x^2e^{-x}$
 23. $y = c_1e^x + c_2e^{-x} + \frac{1}{2}xe^x$
 25. $y = e^{-2x}(c_1 \cos x + c_2 \sin x) + 2$
 27. $y = A \cos x + B \sin x + x \sin x + \cos x \ln(\cos x)$
 29. $y = c_1 + c_2e^{5x} + \frac{1}{10}x^2e^{5x} - \frac{1}{25}xe^{5x}$
 31. $y = c_1 \cos x + c_2 \sin x - \frac{1}{2}x \cos x + x \sin x$

33. $y = c_1 + c_2e^x + \frac{1}{2}e^{-x} + xe^x$
 35. $y = c_1e^{5x} + c_2e^{-x} - \frac{1}{8}e^x - \frac{4}{5}$
 37. $y = c_1 \cos x + c_2 \sin x - (\sin x)[\ln(\csc x + \cot x)]$
 39. $y = c_1 + c_2e^{8x} + \frac{1}{8}xe^{8x}$
 41. $y = c_1 + c_2e^x - x^4/4 - x^3 - 3x^2 - 6x$
 43. $y = c_1 + c_2e^{-2x} - \frac{1}{3}e^x + x^3/6 - x^2/4 + x/4$
 45. $y = c_1 \cos x + c_2 \sin x + (x - \tan x) \cos x - \sin x \ln(\cos x)$
 $= c_1 \cos x + c_2' \sin x + x \cos x - (\sin x) \ln(\cos x)$
 47. $y = ce^{3x} - \frac{1}{2}e^x$
 49. $y = ce^{3x} + 5xe^{3x}$
 51. $y = 2 \cos x + \sin x - 1 + \sin x \ln(\sec x + \tan x)$
 53. $y = -e^{-x} + 1 + \frac{1}{2}x^2 - x$
 55. $y = 2(e^x - e^{-x}) \cos x - 3e^{-x} \sin x$
 57. $y = (1 - x + x^2)e^x$
 59. $y_p = \frac{1}{4}x^2$

SECTION 17.3, pp. 17-20-17-21

1. $\frac{1}{2}y'' + y' + y = 0, \quad y(0) = 0.6, \quad y'(0) = 0.6$
 3. $\frac{120}{9.8}y'' + 600y = 0, \quad y(0) = 0.05, \quad y'(0) = v_0$
 5. $2q'' + 4q' + 10q = 20 \cos t, \quad q(0) = 2, \quad q'(0) = 3$
 7. 0.0259 m (above equilibrium)

Complex Functions

INTRODUCTION The study of derivatives, integrals, and series can be extended from the real to the complex numbers, where it is called *complex analysis*. The study of complex functions is far from a straightforward extension of the study of real variable functions. Differentiable functions of a complex variable have many properties not found in their real relatives. For example, while we can find real functions that are once but not twice differentiable, this is not true for complex functions. If a complex function is differentiable once on an open region, then its second, third, and all higher order derivatives also exist. In Chapter 9 we saw differentiable functions that are not equal to any power series. In contrast, a complex differentiable function can always be expressed as a convergent power series. The study of complex functions gives profound new insights into the properties of the real-valued functions we have already encountered and opens the way to many new applications. The study of complex functions, particularly in higher dimensions, remains an active area of mathematical research. In this chapter we introduce the complex numbers and then study some of the many beautiful aspects of complex differentiable functions.

18.1 Complex Numbers

Complex numbers are expressed in the form $a + ib$, or $a + bi$, where a and b are real numbers and i is a symbol for a new type of number whose square equals -1 ; that is, $i^2 = -1$. We refer to a as the *real* part of the complex number and to b as the *imaginary* part. The words “real” and “imaginary” have connotations that tend to place $\sqrt{-1}$ in a less favorable position in our minds than a real number such as $\sqrt{2}$. In fact, a good deal of imagination, or inventiveness, was required to construct the real number system, which forms the basis of calculus (see Appendix A.7). We begin this chapter with a review of the successive stages of invented number systems.

The Hierarchy of Numbers

The first stage of number development was the recognition of the counting numbers $1, 2, 3, \dots$, which we now call the natural numbers or the positive integers. Certain arithmetical operations on the positive integers, such as addition and multiplication, keep us entirely within this system. That is, if m and n are any positive integers, then their sum $m + n$ and product mn are also positive integers. Some equations can be solved entirely within the system of positive integers. For example, we can solve $3 + x = 7$ using only positive integers. But other simple equations, such as $7 + x = 3$, cannot be solved if only positive integers are at our disposal. The invention of the number zero and the negative numbers allowed the solution of equations such as $7 + x = 3$. Using the integers

$$\dots, -3, -2, -1, 0, 1, 2, 3, \dots$$

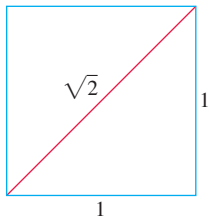

FIGURE 18.1 The diagonal of the unit square has irrational length.

we can always find the missing integer x that solves the equation $m + x = p$ when we are given the other two integers m and p in the equation. Addition and multiplication of integers always keep us within the system of integers. However, division does not, and so fractions m/n , where m and n are integers with n nonzero, were invented. The resulting system is called the rational numbers and is rich enough to perform all of the rational operations of arithmetic, including addition, subtraction, multiplication, and division (although division by zero is excluded since it is meaningless). Yet there are still simple polynomial equations that cannot be solved within the system of rational numbers. The ancient Greeks realized that there is no rational number that solves the equation $x^2 = 2$, even though the Pythagorean Theorem implies that the length x of the diagonal of the unit square satisfies this equation. (See Figure 18.1.)

To see why $x^2 = 2$ has no rational solution, consider the following argument. Suppose that there did exist some positive integers p and q with no common factor other than 1 such that the fraction $x = p/q$ satisfies $x^2 = 2$. Writing this out, we see that $p^2/q^2 = 2$, and therefore

$$p^2 = 2q^2.$$

Then p^2 is also an even integer. Since the square of an odd number is odd, we conclude that p itself must be an even number (for if p were odd, then p^2 would also be odd). So p is divisible by 2, and $p = 2k$ for some integer k . Hence $p^2 = 4k^2$. Since we already saw that $p^2 = 2q^2$, it follows that $2q^2 = p^2 = 4k^2$, and therefore $q^2 = 2k^2$.

Consequently, q^2 is an even number and this requires in turn that q itself be even. Therefore, both p and q are divisible by 2, which is contrary to our assumption that they contain no common factors other than 1. Since we have arrived at a contradiction, there cannot exist any such integers p and q , and therefore there is no rational number that solves the equation $x^2 = 2$.

The invention of real numbers addressed this issue (and others). Using real numbers, we can represent every possible physical length. Each real number can be represented as an infinite decimal $a.d_1d_2d_3d_4\dots$, where a is an integer followed by a sequence of decimal digits each between 0 and 9 (Appendix A.7). If the sequence stops or repeats in a periodic pattern, then the decimal represents a rational number. An irrational number is represented by a nonterminating and nonrepeating decimal. The rational and irrational numbers together make up the real number system. Unlike the rational numbers, the real numbers have the completeness property, meaning that there are no “holes” or “gaps” in the real line. This property is essential in calculus, implying for example that continuous functions on a closed interval have an absolute maximum value and an absolute minimum value (Extreme Value Theorem, Section 4.1), and that an increasing and bounded sequence converges (Monotonic Sequence Theorem, Section 9.1). Yet for all of its utility, there are simple equations that cannot be solved when working only within the real number system. As an example, the polynomial equation $x^2 + 1 = 0$ has no real solutions.

The Complex Numbers

We have discussed three systems of numbers that form a hierarchy, with each system containing the previous system. Each system is richer than its predecessor in that it permits additional operations to be performed without going outside the system.

1. Using the integer system, we can solve all equations of the form

$$x + a = 0, \tag{1}$$

where a is an integer.

2. Using the rational numbers, we can solve all equations of the form

$$ax + b = 0, \tag{2}$$

provided that a and b are rational numbers and $a \neq 0$.

3. Using the real numbers, we can solve all of Equations (1) and (2) and, in addition, all quadratic equations

$$ax^2 + bx + c = 0, \quad (3)$$

provided that $a \neq 0$ and $b^2 - 4ac \geq 0$.

The quadratic formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad (4)$$

gives the solutions to Equation (3). When $b^2 - 4ac$ is negative, there are no real number solutions to the equation $ax^2 + bx + c = 0$. In particular, the simple quadratic equation $x^2 + 1 = 0$ cannot be solved using any of the three invented systems of numbers that we have discussed. Thus we are led to the fourth system of numbers, the set of complex numbers $a + ib$. The symbol i represents a new number whose square equals -1 . We call a the *real part* and b the *imaginary part* of the complex number $a + ib$.

Real and Imaginary parts

For a complex number $z = a + ib$, we write

$$\operatorname{Re} z = a$$

and

$$\operatorname{Im} z = b.$$

Sometimes it is convenient to write $a + bi$ instead of $a + ib$; both notations describe the same complex number. We define equality and addition for complex numbers in the following way.

Equality $a + ib = c + id$ if and only if $a = c$ and $b = d$.

Two complex numbers $a + ib$ and $c + id$ are equal if and only if their real parts are equal and their imaginary parts are equal.

Addition $(a + ib) + (c + id) = (a + c) + i(b + d)$

We sum the real parts and separately sum the imaginary parts.

To multiply two complex numbers, we multiply using the distributive rule and then simplify using $i^2 = -1$.

Multiplication $(a + ib)(c + id)$
 $= ac + iad + ibc + i^2bd$
 $= (ac - bd) + i(ad + bc) \quad i^2 = -1$

EXAMPLE 1 Basic arithmetic operations with complex numbers

- a. The set of all complex numbers $a + i0$, where the second number b is zero, has all of the properties of the set of real numbers. For example, addition and multiplication as complex numbers give

$$(a + i0) + (c + i0) = (a + c) + i0, \quad (a + i0)(c + i0) = ac + i0,$$

which are numbers of the same type with imaginary part zero. We usually just write a instead of $a + i0$, and in this sense the complex number system contains the real number system.

- b. If we multiply a real number $a = a + i0$ by a complex number $c + id$, we get $a(c + id) = (a + i0)(c + id) = ac + iad$.

- c. The number $0 = 0 + i0$ plays the role of zero in the complex number system, and the complex number $1 = 1 + i0$ plays the role of unity, or one.
- d. The complex number $i = 0 + i1$, which has real part zero and imaginary part one, has the property that its square is $i^2 = (0 + i1)^2 = (0 + i1)(0 + i1) = (-1) + i0 = -1$. So $x = i$ is a solution to the quadratic equation $x^2 + 1 = 0$. In the complex number system there are exactly two solutions to this equation, the other solution being $x = -i = 0 + i(-1)$.
- e. We can divide any two complex numbers, as long as we do not divide by the number $0 = 0 + i0$. When $a + ib \neq 0$ (meaning that either $a \neq 0$ or $b \neq 0$ or both $a \neq 0$ and $b \neq 0$), we carry out division as follows:

$$\frac{c + id}{a + ib} = \frac{(c + id)(a - ib)}{(a + ib)(a - ib)} = \frac{(ac + bd) + i(ad - bc)}{a^2 + b^2} = \frac{ac + bd}{a^2 + b^2} + i\frac{ad - bc}{a^2 + b^2}.$$

In this way we express the quotient in the standard form $x + iy$, where $x = (ac + bd)/(a^2 + b^2)$ and $y = (ad - bc)/(a^2 + b^2)$ are real numbers. Note that $a^2 + b^2 \neq 0$ since we stipulated that a and b cannot both be zero.

- f. The number $a - ib$ that was used in part (e) as the multiplier to clear the i from the denominator is called the *complex conjugate* of $a + ib$. If we denote the original complex number by $z = a + ib$, then it is customary to write \bar{z} (read “z bar”) to denote its complex conjugate:

$$z = a + ib, \quad \bar{z} = a - ib.$$

Multiplying the numerator and denominator of a fraction $(c + id)/(a + ib)$ by the complex conjugate of the denominator will always replace the denominator by a real number. ■

EXAMPLE 2 Computations with complex numbers

- a. $(2 + 3i) + (6 - 2i) = (2 + 6) + (3 - 2)i = 8 + i$
- b. $(2 + 3i) - (6 - 2i) = (2 - 6) + (3 - (-2))i = -4 + 5i$
- c. $(2 + 3i)(6 - 2i) = (2)(6) + (2)(-2i) + (3i)(6) + (3i)(-2i)$
 $= 12 - 4i + 18i - 6i^2 = 12 + 14i + 6 = 18 - 14i$
- d. $\frac{2 + 3i}{6 - 2i} = \frac{(2 + 3i)(6 + 2i)}{(6 - 2i)(6 + 2i)} = \frac{12 + 4i + 18i + 6i^2}{36 + 12i - 12i - 4i^2} = \frac{6 + 22i}{40} = \frac{3}{20} + \frac{11}{20}i$ ■

The Complex Plane

We can use the usual xy -coordinate system to represent complex numbers as points or vectors in the plane. In this context we call it the *complex plane*. There are now two geometric representations of a complex number $z = x + iy$:

1. as a point $P(x, y)$ in the xy -plane,
2. as a vector \overrightarrow{OP} from the origin to P .

In each representation, the x -axis is called the *real axis* and the y -axis is the *imaginary axis*, as in Figure 18.2. Geometric representations of complex numbers are sometimes called *Argand Diagrams*.

In polar coordinates we have

$$x = r \cos \theta, \quad y = r \sin \theta,$$

and

$$z = x + iy = r(\cos \theta + i \sin \theta). \quad (5)$$

The number 0, or $0 + i0$ is a special case, with $r = 0$ but no specified θ .

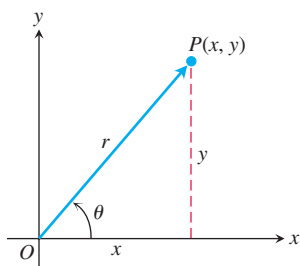

FIGURE 18.2 The complex number $z = x + iy$ can be represented both as a point $P(x, y)$ and as a vector.

We define the *absolute value* (or *magnitude*) of a complex number $x + iy$ to be the length r of a vector \overline{OP} from the origin to $P(x, y)$. We denote the absolute value by vertical bars; thus,

$$|x + iy| = \sqrt{x^2 + y^2}.$$

We always choose the polar coordinates r and θ so that r is nonnegative, and then

$$r = |x + iy|.$$

The polar angle θ is called the *argument* of z and is written $\theta = \arg z$. There is more than one choice for the argument. Any integer multiple of 2π may be added to θ to produce another appropriate angle. The following equation gives a useful formula connecting a complex number z , its conjugate \bar{z} , and its absolute value $|z|$:

$$z \cdot \bar{z} = |z|^2.$$

Euler's Formula

The identity

$$e^{i\theta} = \cos \theta + i \sin \theta \quad (6)$$

is called Euler's Formula. The origins of this formula will be seen in Section 18.6. We show a vector representing $e^{i\theta}$ in Figure 18.3. Using Equation (6), we can write Equation (5) as

$$z = re^{i\theta}.$$

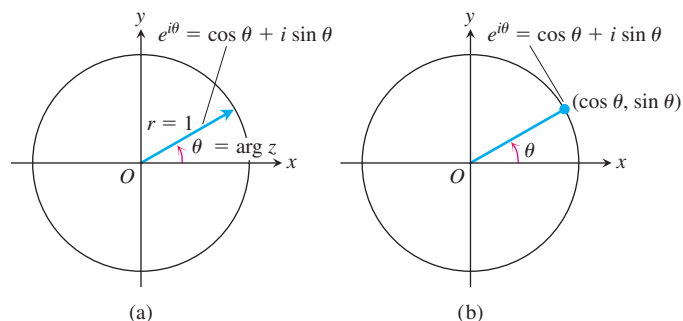

FIGURE 18.3 The complex number $z = e^{i\theta}$ as a vector and as a point.

The notation $\exp(A)$ is also used for e^A , so we could write $z = r \exp(i\theta)$.

Euler's formula leads to the following rules for calculating products, quotients, powers, and roots of complex numbers in polar form.

Products

To multiply two complex numbers in polar form, we multiply their absolute values and add their arguments. To see why, let

$$z_1 = r_1 e^{i\theta_1} \quad \text{and} \quad z_2 = r_2 e^{i\theta_2}, \quad (7)$$

so that

$$|z_1| = r_1, \quad \arg z_1 = \theta_1; \quad |z_2| = r_2, \quad \arg z_2 = \theta_2.$$

In the Cartesian $a + bi$ form we have

$$z_1 = r_1 \cos \theta_1 + ir_1 \sin \theta_1$$

and

$$z_2 = r_2 \cos \theta_2 + ir_2 \sin \theta_2.$$

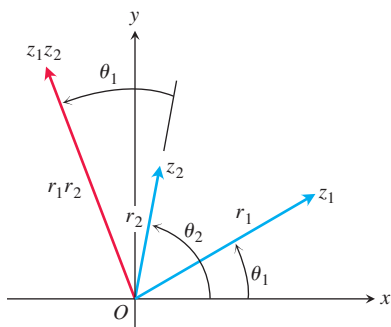

FIGURE 18.4 When z_1 and z_2 are multiplied, $|z_1 z_2| = r_1 \cdot r_2$ and $\arg(z_1 z_2) = \theta_1 + \theta_2$.

Their product is then

$$\begin{aligned} z_1 z_2 &= r_1 e^{i\theta_1} r_2 e^{i\theta_2} \\ &= r_1 r_2 (\cos \theta_1 + i \sin \theta_1)(\cos \theta_2 + i \sin \theta_2) \\ &= r_1 r_2 [\cos \theta_1 \cos \theta_2 - \sin \theta_1 \sin \theta_2] + i [\cos \theta_1 \sin \theta_2 + \sin \theta_1 \cos \theta_2] \\ &= r_1 r_2 (\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)) \quad \text{Angle sum formulas} \\ &= r_1 r_2 e^{i(\theta_1 + \theta_2)}. \end{aligned}$$

Therefore

$$r_1 e^{i\theta_1} r_2 e^{i\theta_2} = r_1 r_2 e^{i(\theta_1 + \theta_2)}. \quad (8)$$

The absolute value of the product is $r_1 r_2$ and the argument of the product is the sum of the arguments of z_1 and z_2 . We have shown that the product of two complex numbers is represented by a vector whose length is the product of the lengths of the two factors and whose angle with the x -axis is the sum of the corresponding angles of the factors. (Figure 18.4.) In particular, Equation (8) implies that multiplying a vector by $e^{i\theta}$ causes its vector representation to be rotated counterclockwise through an angle θ . Multiplication by i rotates 90° , by -1 rotates 180° , by $-i$ rotates 270° , and so on.

EXAMPLE 3 We compute the product of $z_1 = 1 + i$ and $z_2 = \sqrt{3} - i$. We first plot these complex numbers in Figure 18.5, and we can then read off their polar representations

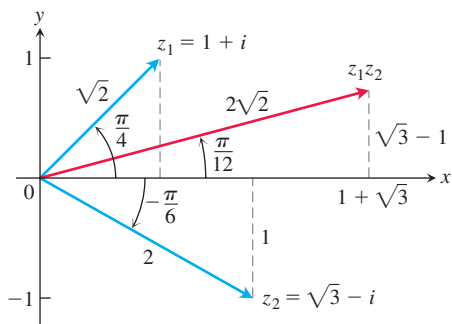

FIGURE 18.5 To multiply two complex numbers, multiply their absolute values and add their arguments.

$$\begin{aligned} z_1 \cdot z_2 &= \sqrt{2} \exp\left(\frac{i\pi}{4}\right) \cdot 2 \exp\left(-\frac{i\pi}{6}\right) \\ &= 2\sqrt{2} \exp\left(\frac{i\pi}{4} - \frac{i\pi}{6}\right) \\ &= 2\sqrt{2} \exp\left(\frac{i\pi}{12}\right) \\ &= 2\sqrt{2} \left(\cos \frac{\pi}{12} + i \sin \frac{\pi}{12}\right) \\ &\approx 2.73 + 0.73i. \end{aligned}$$

EXAMPLE 4 **Computing Reciprocals** Show that if $z = re^{i\theta}$ and $r > 0$, then

$$\frac{1}{z} = \frac{1}{r} e^{-i\theta}.$$

Solution Applying the formula for products, Equation (8), we see that

$$(re^{i\theta})\left(\frac{1}{r}e^{-i\theta}\right) = 1 \cdot e^{i0} = 1.$$

Dividing both sides by $z = re^{i\theta}$ gives

$$\frac{1}{r}e^{-i\theta} = \frac{1}{re^{i\theta}} = \frac{1}{z}.$$

Quotients

We now look at how to divide $z_1 = r_1 e^{i\theta_1}$ by $z_2 = r_2 e^{i\theta_2}$ in polar form. We assume that $r_2 > 0$ so that we are not dividing by zero. To compute the quotient z_1/z_2 we multiply z_1 by $1/z_2$. This gives

$$\frac{z_1}{z_2} = z_1 \left(\frac{1}{z_2}\right) = r_1 e^{i\theta_1} \left(\frac{1}{r_2} e^{-i\theta_2}\right) = \frac{r_1}{r_2} e^{i(\theta_1 - \theta_2)}, \quad \text{Equation (8)}$$

so that

$$\left| \frac{z_1}{z_2} \right| = \frac{|z_1|}{|z_2|}$$

and

$$\arg\left(\frac{z_1}{z_2}\right) = \theta_1 - \theta_2 = \arg z_1 - \arg z_2.$$

That is, we divide lengths and subtract angles to compute the quotient of complex numbers.

EXAMPLE 5 Let $z_1 = 1 + i$ and $z_2 = \sqrt{3} - i$, as in Example 3. Then

$$\frac{1+i}{\sqrt{3}-i} = \frac{\sqrt{2}e^{i\pi/4}}{2e^{-i\pi/6}} = \frac{\sqrt{2}}{2}e^{5\pi i/12} \approx 0.707\left(\cos\frac{5\pi}{12} + i\sin\frac{5\pi}{12}\right) \approx 0.183 + 0.683i. \quad \blacksquare$$

Powers

If n is a positive integer, we can apply the product formulas in Equation (8) to find the polar form of a power

$$z^n = z \cdot z \cdot \cdots \cdot z. \quad n \text{ factors}$$

With $z = re^{i\theta}$, we obtain

$$\begin{aligned} z^n &= (re^{i\theta})^n = r^n e^{i(\theta+\cdots+\theta)} \\ &= r^n e^{in\theta}. \quad n \text{ summands} \end{aligned} \quad (9)$$

The length $r = |z|$ is raised to the n th power, and the angle $\theta = \arg z$ is multiplied by n .

If we take $r = 1$ in Equation (9), we obtain De Moivre's Theorem.

De Moivre's Theorem

$$(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta \quad (10)$$

If we expand the left side of the equation in De Moivre's Theorem using the Binomial Theorem and reduce it to the form $a + ib$, we obtain trigonometric identities, namely formulas for $\cos n\theta$ and $\sin n\theta$ as polynomials of degree n in $\cos \theta$ and $\sin \theta$.

EXAMPLE 6 If $n = 3$ in Equation (10), we have

$$(\cos \theta + i \sin \theta)^3 = \cos(3\theta) + i \sin(3\theta).$$

The left side of this equation expands to

$$\cos^3 \theta + 3i \cos^2 \theta \sin \theta - 3 \cos \theta \sin^2 \theta - i \sin^3 \theta.$$

The real part of this must equal $\cos(3\theta)$ and the imaginary part must equal $\sin(3\theta)$. Therefore,

$$\begin{aligned} \cos(3\theta) &= \cos^3 \theta - 3 \cos \theta \sin^2 \theta, \\ \sin(3\theta) &= 3 \cos^2 \theta \sin \theta - \sin^3 \theta. \end{aligned} \quad \blacksquare$$

Roots

If x is a positive real number, then it has exactly one real n th root if n is an odd integer and exactly two n th roots if n is even. If x is a negative real number, then x has exactly one real n th root if n is an odd integer and no real n th root if n is even. In contrast, if $z = re^{i\theta}$ is a

complex number different from zero, then there are precisely n different complex numbers, w_0, w_1, \dots, w_{n-1} , that are n th roots of z . To see why, let $w = \rho e^{i\alpha}$ be an n th root of $z = re^{i\theta}$. Then

$$w^n = z$$

or

$$\rho^n e^{in\alpha} = re^{i\theta}.$$

Since both r and ρ are positive real numbers, this implies that $\rho^n = r$, and so

$$\rho = \sqrt[n]{r}$$

is the real, positive n th root of r . Although we cannot say that $n\alpha$ and θ must be equal, since the argument of a complex number is only defined up to multiples of 2π , we can say that they may differ only by an integer multiple of 2π . That is,

$$n\alpha = \theta + 2k\pi, \quad k = 0, \pm 1, \pm 2, \dots$$

Therefore,

$$\alpha = \frac{\theta}{n} + k \frac{2\pi}{n}.$$

This gives the following collection of n distinct complex numbers,

$$\sqrt[n]{re^{i\theta}} = \sqrt[n]{r} \exp\left[i\left(\frac{\theta}{n} + k \frac{2\pi}{n}\right)\right], \quad k = 0, \pm 1, \pm 2, \dots \quad (11)$$

Each of these has the property that its n th power equals z , so these n complex numbers give all of the n th roots of $z = re^{i\theta}$.

The expression $\sqrt[n]{re^{i\theta}}$ on the left of Equation (11) defines a new concept, the n th root of a complex number, while the term $\sqrt[n]{r}$ on the right refers to the real n th root. There is exactly one positive real number whose n th power equals the positive real number r , and that number gives the value of $\sqrt[n]{r}$. On the other hand, the expression $\sqrt[n]{re^{i\theta}}$ refers to a collection of n distinct numbers. In practice we often want to pick out a particular n th root, the *principal* n th root. We can do that by requiring that $z = re^{i\theta}$ have $-\pi < \theta \leq \pi$, and then taking the *principal* n th root to be

$$\sqrt[n]{r} \exp\left[i\left(\frac{\theta}{n}\right)\right].$$

There might appear to be infinitely many different answers in Equation (11), corresponding to the infinitely many possible values of k , but $k = m + n$ gives the same complex number as $k = m$. This is true because the complex number

$$\exp\left[i\left(\frac{\theta}{n} + 2\pi \frac{m+n}{n}\right)\right] = \exp\left[i\left(\frac{\theta}{n} + 2\pi \frac{m}{n} + 2\pi\right)\right]$$

and the complex number

$$\exp\left[i\left(\frac{\theta}{n} + 2\pi \frac{m}{n}\right)\right],$$

are equal, since they have arguments that differ by 2π . Therefore we need only take n consecutive values for k to obtain all the different complex numbers that are n th roots of z . For convenience, we take

$$k = 0, 1, 2, \dots, n-1.$$

All the n th roots of $re^{i\theta}$ lie on a circle centered at the origin and having radius equal to the real, positive n th root of r . One of them has argument $w_0 = \theta/n$. The others are uniformly spaced around the circle, each being separated from its neighbors by an angle equal to $2\pi/n$. (Figure 18.6 illustrates the placement of the three cube roots, w_0, w_1, w_2 , of the complex number $z = re^{i\theta}$.)

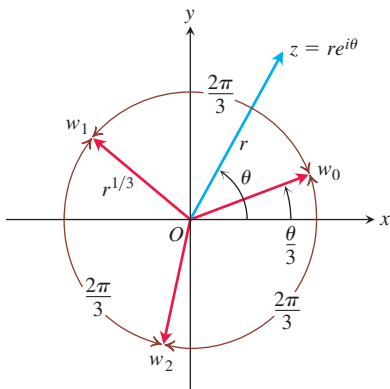

FIGURE 18.6 The three cube roots of $z = re^{i\theta}$

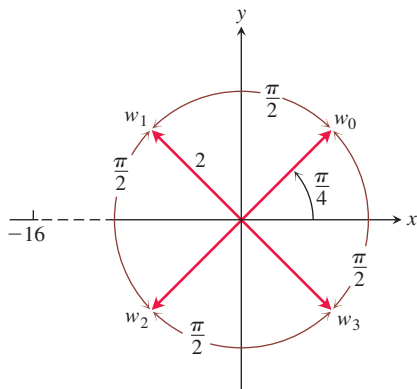

FIGURE 18.7 The four fourth roots of -16

EXAMPLE 7 Find the four fourth roots of -16 .

Solution As our first step, we plot the number -16 in the complex plane (Figure 18.7) and determine its polar representation $re^{i\theta}$. Here, $z = -16$, $r = +16$, and $\theta = \pi$. One of the fourth roots of $16e^{i\pi}$ is $2e^{i\pi/4}$. We obtain others by successive additions of $2\pi/4 = \pi/2$ to the argument of this first one. Hence,

$$\sqrt[4]{16e^{i\pi}} = 2e^{ik\pi/4}, \quad k = 1, 3, 5, 7, \quad (12)$$

and the four roots are

$$w_0 = 2 \left[\cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right] = \sqrt{2}(1 + i),$$

$$w_1 = 2 \left[\cos \frac{3\pi}{4} + i \sin \frac{3\pi}{4} \right] = \sqrt{2}(-1 + i),$$

$$w_2 = 2 \left[\cos \frac{5\pi}{4} + i \sin \frac{5\pi}{4} \right] = \sqrt{2}(-1 - i),$$

$$w_3 = 2 \left[\cos \frac{7\pi}{4} + i \sin \frac{7\pi}{4} \right] = \sqrt{2}(1 - i). \quad \blacksquare$$

The Fundamental Theorem of Algebra

One might say that the invention of $\sqrt{2}$ is all well and good and leads to a number system that is richer than the rational number system alone, and the complex number system is richer still, but where will this process end? Will we need to develop still more systems so as to obtain $\sqrt[4]{-1}$ (a solution of $x^4 = -1$), $\sqrt[6]{-1}$ (a solution of $x^6 = -1$), and so on? It turns out this is not necessary. These numbers are already expressible in the complex number system as $a + ib$ for appropriate a and b . In fact, the Fundamental Theorem of Algebra says that with the introduction of the complex numbers, we now have enough numbers to factor every polynomial into a product of linear factors. We have enough numbers to solve every possible polynomial equation.

The Fundamental Theorem of Algebra

Every polynomial equation of the form

$$a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0 = 0,$$

in which the coefficients $a_0, a_1, \dots, a_{n-1}, a_n$ are any complex numbers, whose degree n is greater than or equal to one, and whose leading coefficient a_n is not zero, has exactly n roots in the complex number system, provided each multiple root of multiplicity m is counted as m roots.

A proof of this theorem can be found in most texts on the theory of functions of a complex variable.

EXERCISES 18.1

Operations with Complex Numbers

1. Express the following products of complex numbers in the form $a + ib$ where a and b are real numbers.

a. $(2 + 3i)(4 - 2i)$

b. $(2 - i)(-2 - 3i)$

c. $(-1 - 2i)(2 + i)$

2. Solve the following equations for the real numbers x and y .

a. $(3 + 4i)^2 - 2(x - iy) = x + iy$

b. $\left(\frac{1+i}{1-i}\right)^2 + \frac{1}{x+iy} = 1 + i$

c. $(3 - 2i)(x + iy) = 2(x - 2iy) + 2i - 1$

Graphing and Geometry

3. How may the following complex numbers be obtained from $z = x + iy$ geometrically? Sketch.
- a. \bar{z} b. $-\bar{z}$ c. $-z$ d. $1/z$
4. Show that the distance between the two points z_1 and z_2 in the complex plane is $|z_1 - z_2|$.

In Exercises 5–10, graph the points $z = x + iy$ that satisfy the given conditions.

5. a. $|z| = 2$ b. $|z| < 2$ c. $|z| > 2$
6. $|z - 1| = 2$ 7. $|z + 1| = 1$
8. $|z + 1| = |z - 1|$ 9. $|z + i| = |z - 1|$
10. $|z + 1| \geq |z - 1|$

Express the complex numbers in Exercises 11–14 in the form $re^{i\theta}$, with $r \geq 0$ and $-\pi < \theta \leq \pi$, and for each of them draw a diagram in the complex plane.

11. $(1 + \sqrt{-3})^2$ 12. $\frac{1+i}{1-i}$
13. $\frac{1 + \sqrt{-3}}{1 - \sqrt{-3}}$ 14. $(2 + 3i)(1 - 2i)$

Powers and Roots

Use De Moivre's Theorem to express the trigonometric functions in Exercises 15 and 16 in terms of $\cos \theta$ and $\sin \theta$.

15. $\cos 4\theta$ 16. $\sin 4\theta$
17. Find the three cube roots of 1.
18. Find the two square roots of i .
19. Find the three cube roots of $-8i$.
20. Find the six sixth roots of 64.
21. Find the four solutions of the equation $z^4 - 2z^2 + 4 = 0$.
22. Find the six solutions of the equation $z^6 + 2z^3 + 2 = 0$.

23. Find all solutions of the equation $x^4 + 4x^2 + 16 = 0$.
24. Solve the equation $x^4 + 1 = 0$.

Theory and Examples

25. **Complex numbers and vectors in the plane** Show with a diagram in the complex plane that the law for adding complex numbers is the same as the parallelogram law for adding vectors.
26. **Complex arithmetic with conjugates** Show that the conjugate of the sum (product, or quotient) of two complex numbers, z_1 and z_2 , is the same as the sum (product, or quotient) of their conjugates.
27. **Complex roots of polynomials with real coefficients come in complex-conjugate pairs**

- a. Extend the results of Exercise 26 to show that $f(\bar{z}) = \overline{f(z)}$ when

$$f(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0$$

is a polynomial with real coefficients a_0, \dots, a_n .

- b. If z is a root of the equation $f(z) = 0$, where $f(z)$ is a polynomial with real coefficients as in part (a), show that the conjugate \bar{z} is also a root of the equation. (Hint: Let $f(z) = u + iv = 0$; then both u and v are zero. Use the fact that $f(\bar{z}) = \overline{f(z)} = u - iv$.)

28. **Absolute value of a conjugate** Show that $|\bar{z}| = |z|$.
29. **When $z = \bar{z}$** If z and \bar{z} are equal, what can you say about the location of the point z in the complex plane?
30. **Real and imaginary parts** Show that the following relations hold for any complex numbers z , z_1 , and z_2 .
- a. $z + \bar{z} = 2\operatorname{Re}(z)$
- b. $z - \bar{z} = 2i\operatorname{Im}(z)$
- c. $2\operatorname{Re}(z) \leq |z|$
- d. $|z_1 + z_2|^2 = |z_1|^2 + |z_2|^2 + 2\operatorname{Re}(z_1\bar{z}_2)$
- e. $|z_1 + z_2| \leq |z_1| + |z_2|$

18.2 Functions of a Complex Variable

Complex Domains

The domains of the real variable functions discussed in Chapter 1 consisted of subsets of the real line, such as $[0, 1]$ or $(0, \infty)$. The domain of a complex function is a subset of the complex numbers, which we can visualize as a region in the complex plane.

EXAMPLE 1 Examples of complex domains

- a. The set of complex numbers z for which $|z| \leq 1$
The corresponding region in the complex plane is the set of points lying inside or on a circle of radius 1 centered at the origin O , shown in Figure 18.8(a).
- b. The set of complex numbers with $|z - z_0| \leq 1$
This corresponds to the region inside or on a circle of radius 1 centered at a complex number $z_0 = a_0 + b_0i$, as in Figure 18.8b.
- c. A complex region can have a more general shape. Three more examples of complex domains are shown in Figure 18.8c.

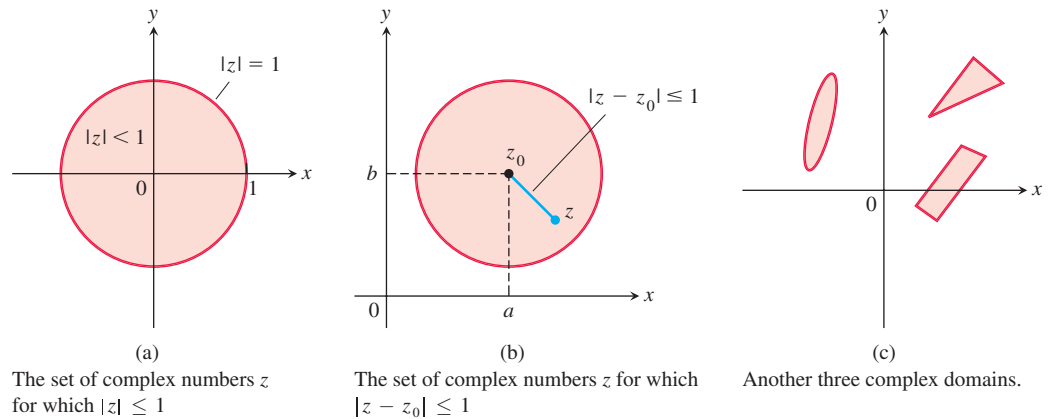

FIGURE 18.8 Some complex domains. ■

We usually use the letter z for a variable that describes a point in the domain of a complex function, just as we used x for a real function. We write $w = f(z)$ to describe a function that takes as input a complex number z and gives as output a complex number w .

Complex Limits

To understand complex limits, we take advantage of the fact that a complex number $z = x + iy$ can be identified with a point (x, y) in the xy -plane. This identification allows us to extend our knowledge of real limits to complex numbers.

We first consider the case where a complex number $z = z(t)$ is a function of a real variable t , which we often consider to be time. So we think of a vector whose position in the complex plane changes with time. We can write $z(t) = x(t) + iy(t)$, and then each t describes a vector $(x(t), y(t))$ in the complex plane. By describing $z(t)$ as a vector-valued function we are able to understand limits of $z(t)$ similarly to the limits of vector functions seen in Section 12.1. The meaning of an expression such as

$$\lim_{t \rightarrow 1} z(t) = z_0,$$

which states that $z(t)$ is approaching $z_0 = x_0 + iy_0$ as t approaches 1 is that

$$\lim_{t \rightarrow 1} |z(t) - z_0| = 0.$$

More specifically, we make the following definition.

DEFINITION We say that the complex-valued function $z(t) = x(t) + iy(t)$ has limit z_0 as t approaches t_0 , and write

$$\lim_{t \rightarrow t_0} z(t) = z_0$$

if, for every number $\epsilon > 0$, there exists a corresponding number $\delta > 0$ such that

$$|z(t) - z_0| < \epsilon \text{ whenever } 0 < |t - t_0| < \delta. \quad (13)$$

One way of interpreting Equation (13) is that $|z(t) - z_0|$ is small when $|t - t_0|$ is small. In other words, if we draw a circle around the complex number z_0 in the complex plane, as small as we like, then the point $z(t) = x(t) + iy(t)$ will be inside that circle if we choose t sufficiently close to t_0 . Since

$$|z(t) - z_0| = |(x(t) + iy(t)) - (x_0 + iy_0)| \leq |x(t) - x_0| + |y(t) - y_0|, \quad \text{Figure 18.9}$$

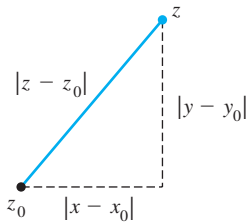

FIGURE 18.9

$$|z - z_0|^2 = |(x - x_0)|^2 + |(y - y_0)|^2$$

we see that if $x(t) - x_0 \rightarrow 0$ and $y(t) - y_0 \rightarrow 0$, then also $z(t) - z_0 \rightarrow 0$. So $z(t)$ converges to z_0 when its real part converges to the real part of z_0 and its imaginary part converges to the imaginary part of z_0 .

On the other hand, since $|z - z_0| \geq |x - x_0|$ and $|z - z_0| \geq |y - y_0|$, it follows that if $z(t) \rightarrow z_0$, then also $x(t) \rightarrow x_0$ and $y(t) \rightarrow y_0$. In summary, as $t \rightarrow t_0$, $z(t)$ approaches z_0 if and only if both $x(t)$ approaches x_0 and $y(t)$ approaches y_0 ,

$$z(t) \rightarrow z_0 \Leftrightarrow x(t) \rightarrow x_0 \text{ and } y(t) \rightarrow y_0. \quad (14)$$

This gives a practical formula that can be used to compute the complex limit of a function $z(t) = x(t) + iy(t)$:

$$\lim_{t \rightarrow t_0} z(t) = \lim_{t \rightarrow t_0} x(t) + i \lim_{t \rightarrow t_0} y(t).$$

EXAMPLE 2 For the function $z(t) = \cos t + i \sin t$, find $\lim_{t \rightarrow \pi} z(t)$.

Solution

$$\lim_{t \rightarrow \pi} z(t) = \lim_{t \rightarrow \pi} \cos t + i \lim_{t \rightarrow \pi} \sin t = -1. \quad \blacksquare$$

Functions of a Complex Variable

We say that f is a complex function on a domain S in the complex plane if to each z in S , the function f assigns a single complex number $f(z)$.

EXAMPLE 3 The function taking z to z^2

For this function, the domain S is the set of all complex numbers, or the complex plane \mathbb{C} , and the function sends a complex number z to the complex number z^2 .

As before, we write $f(z) = z^2$ to give an explicit name f to the function that inputs a complex number z and outputs a new complex number $f(z)$. For each point $z = x + iy$, this function f outputs the complex number $u + iv$ where

$$u + iv = (x + iy)^2 = x^2 + i(2xy) + i^2y^2 = (x^2 - y^2) + i(2xy). \quad (15)$$

The real part of the complex variable $u + iv$ is given by a real function of x and y , $u(x, y) = x^2 - y^2$, and the imaginary part by a second real function $v(x, y) = 2xy$. \blacksquare

We cannot draw the graph of such a function, as we did with real functions whose graphs were curves or surfaces, since both the domain and the range in this case are the complex plane. We would need four dimensions, or four perpendicular directions, to graph a complex function, but we only have three dimensions to work with. Instead, we can set $w = f(z)$ and get a feeling for what this function is doing by drawing some lines or curves in the z -plane and looking at their images in the w -plane. We can visualize the behavior of a complex function by thinking of the domain as a rubber sheet that has a grid of lines drawn on it, parallel to the x and y axes. By drawing the image of this grid under the map, we can get an understanding of how the complex function maps one domain to another.

EXAMPLE 4 Compute where $f(z) = z^2$ maps the vertical line $x = 1$. More generally, compute where it maps the vertical line $x = a$ and the horizontal line $y = b$.

Solution Looking at u and v in Equation (15), and setting the value of x to be $x = a$, we see that

$$u(a, y) = a^2 - y^2 \text{ and } v(a, y) = 2ay.$$

When $a \neq 0$ we obtain $y = v/(2a)$ in Equation (15); we have that the vertical line $x = a$ is mapped to the curve

$$u = a^2 - \frac{v^2}{4a^2}. \quad (16)$$

For each nonzero choice of constant a , this equation describes a parabola. For $a = 1$ the parabola $u = 1 - v^2/4$ in the complex w -plane is the image of the line $x = 1$ in the complex z -plane. If we chose $a = -1$ in Equation (16), the image of the line $x = -1$ is the same parabola. This is to be expected since the squares of $-z$ and z coincide under the map $z \rightarrow z^2$.

In the case $a = 0$, corresponding to the y -axis, we have $u(0, y) = -y^2$ and $v(0, y) = 0$. Thus the point $(0, y)$ on the y -axis is mapped to the point $(-y^2, 0)$. The y -axis is folded at 0 so that the positive y -axis and the negative y -axis each map onto the negative real axis.

We can get further insight into the behavior of the map $f(z) = z^2$ by examining the images of some horizontal lines. The line $y = b$ in the complex z -plane has image points satisfying

$$u(x, b) = x^2 - b^2 \text{ and } v(x, b) = 2xb.$$

We can solve for x , and when $b \neq 0$, we see that $x = v/(2b)$ and

$$u = \frac{v^2}{4b^2} - b^2. \quad (17)$$

Again this gives us a parabola for each nonzero choice of b . As before, the lines $y = \pm b$ map to the same parabola. The x -axis, corresponding to $b = 0$, is folded over at the origin. The positive real axis is mapped to itself, while the negative real axis is mapped not to itself, but also to the positive real axis. Four parabolas obtained as the images of horizontal and vertical lines are shown in Figure 18.10.

The images of two squares in the first quadrant are seen in Figure 18.11 and Figure 18.13. Green stripes are taken to green, and red to red. These figures give us a feeling for the behavior of the complex function $f(z) = z^2$. ■

Limits of a function of a complex variable $f(z) = u(x, y) + iv(x, y)$ are defined by considering the limits of the real and imaginary parts. Each of u and v is a real-valued function of two variables, and we extend the definition of limits developed for such functions in Section 13.2.

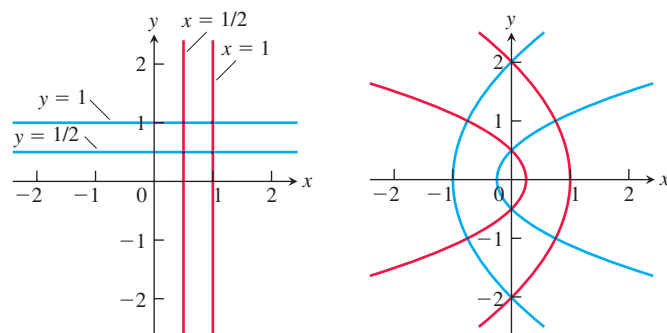

FIGURE 18.10 The images of the horizontal lines $y = 1/2$ and $y = 1$, and of the vertical lines $x = 1/2$ and $x = 1$, under the complex map $f(z) = z^2$.

DEFINITION We say that the complex-valued function $f(z) = u(x, y) + iv(x, y)$ has **limit** $w_0 = u_0 + iv_0$ as z approaches $z_0 = x_0 + iy_0$, and write

$$\lim_{z \rightarrow z_0} f(z) = w_0$$

if, for every number $\varepsilon > 0$, there exists a corresponding number $\delta > 0$ such that

$$|f(z) - w_0| < \varepsilon \text{ whenever } 0 < |z - z_0| < \delta. \quad (18)$$

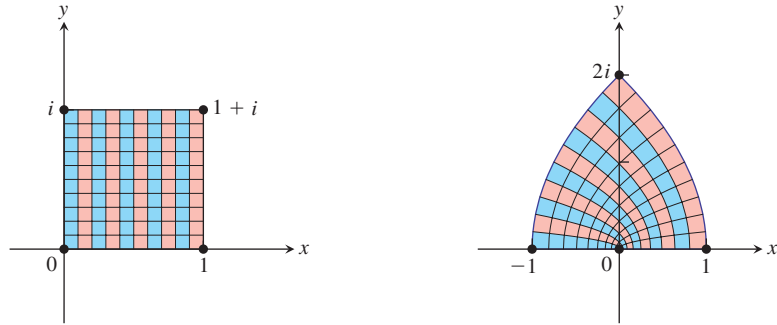

FIGURE 18.11 The image of a square with vertices at $0, 1, 1 + i$ under the complex map $f(z) = z^2$

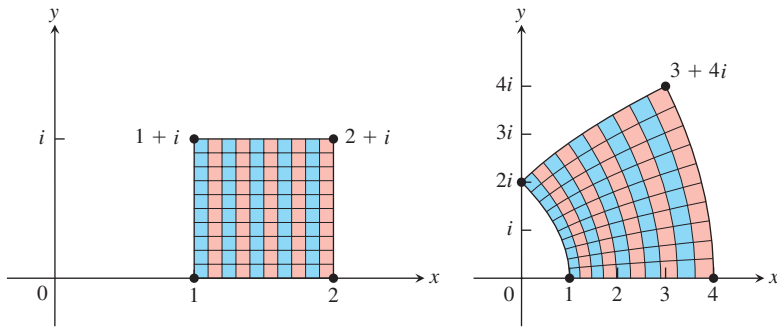

FIGURE 18.12 The image of a square with vertices at $1, 2, 1 + i, 2 + i$ under the same map

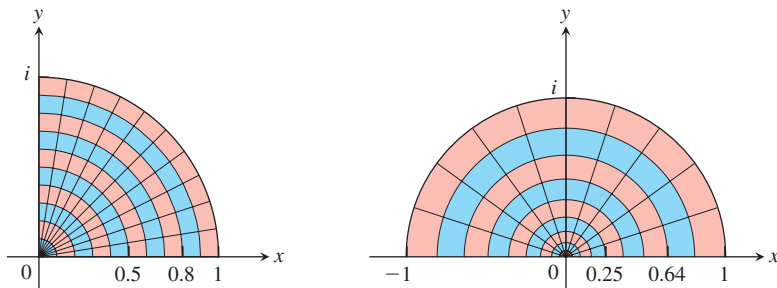

FIGURE 18.13 A quarter of the unit disk in the complex plane and its image under the complex map $f(z) = z^2$. Radial lines at angle θ are taken to new radial lines at angle 2θ , and circular arcs of radius r to circular arcs of radius r^2 .

If we express f in the form $f(x + iy) = u(x, y) + iv(x, y)$, then we have

$$|f(z) - w_0| = \sqrt{(u(x, y) - u_0)^2 + (v(x, y) - v_0)^2}.$$

For a point in the complex plane $w_0 = u_0 + iv_0$, the definition implies (Exercise 7) that $\lim_{z \rightarrow z_0} f(z) = w_0$ exactly when both

$$\lim_{(x, y) \rightarrow (x_0, y_0)} u(x, y) = u_0$$

and

$$\lim_{(x, y) \rightarrow (x_0, y_0)} v(x, y) = v_0.$$

We often use this formulation in computations. Namely the limit of a function $f(x + iy) = u(x, y) + iv(x, y)$ as $x + iy \rightarrow x_0 + iy_0$ exists if and only if the limit of $u(x, y)$ and of $v(x, y)$ each exists as $(x, y) \rightarrow (x_0, y_0)$.

EXAMPLE 5 Show that

a. $\lim_{z \rightarrow z_0} z = z_0$, **b.** $\lim_{z \rightarrow z_0} z^2 = z_0^2$, **c.** $\lim_{z \rightarrow 0} \bar{z}/z$ does not exist.

Solution

a. We express $f(z) = z$ in the form $f(z) = u(x, y) + iv(x, y)$, where $u(x, y) = x$ and $v(x, y) = y$, and compute the limit as z approaches $z_0 = x_0 + iy_0$. Then since the real-valued functions $u(x, y) = x$ and $v(x, y) = y$ are continuous,

$$\lim_{(x, y) \rightarrow (x_0, y_0)} u(x, y) = x_0$$

and

$$\lim_{(x, y) \rightarrow (x_0, y_0)} v(x, y) = y_0.$$

So $\lim_{z \rightarrow z_0} z = x_0 + iy_0 = z_0$ as claimed.

b. We express $f(z) = z^2$ as $f(z) = u(x, y) + iv(x, y)$, where $u(x, y) = x^2 - y^2$ and $v(x, y) = 2xy$ (Equation 15). Then since the real-valued function $u(x, y) = x^2 - y^2$ is continuous,

$$\lim_{(x, y) \rightarrow (x_0, y_0)} u(x, y) = x_0^2 - y_0^2$$

and similarly, since the real-valued function $v(x, y) = 2xy$ is continuous,

$$\lim_{(x, y) \rightarrow (x_0, y_0)} v(x, y) = 2x_0y_0.$$

So $\lim_{z \rightarrow z_0} z^2 = x_0^2 - y_0^2 + i2x_0y_0 = z_0^2$ as claimed.

c. We express $f(z) = \bar{z}/z$ in the form $f(x + iy) = u(x, y) + iv(x, y)$.

$$f(x + iy) = \frac{x - iy}{x + iy} = \frac{(x - iy)(x - iy)}{(x + iy)(x - iy)} = \frac{x^2 - y^2}{x^2 + y^2} + i \frac{-2xy}{x^2 + y^2}.$$

The function

$$u(x, y) = \frac{x^2 - y^2}{x^2 + y^2}$$

is not continuous at $(0, 0)$ since it has limit equal to 1 if $(x, y) \rightarrow (0, 0)$ along the x -axis (with $y = 0$), and it has limit equal to -1 if $(x, y) \rightarrow (0, 0)$ along the y -axis (with $x = 0$). Since different limits are obtained as $(x, y) \rightarrow (0, 0)$ from different directions, no limit exists for $u(x, y)$ and therefore no limit exists for $f(z)$. ■

Continuity

A function $w = f(z)$ that is defined throughout an open set containing a point $z = z_0$ is said to be **continuous** at z_0 if

$$\lim_{z \rightarrow z_0} |f(z) - f(z_0)| = 0. \quad (19)$$

Intuitively, this means that as the point z approaches z_0 , its image $f(z)$ approaches $f(z_0)$, as shown in Figure 18.14. The notion of continuity for real-valued functions of two variables u and v was defined in Section 13.2. If we write f as a sum of its real and imaginary parts, $f(z) = u(x, y) + iv(x, y)$, then f is continuous at z_0 if and only if $u(x, y)$ and $v(x, y)$ are each continuous at (x_0, y_0) (Exercise 8).

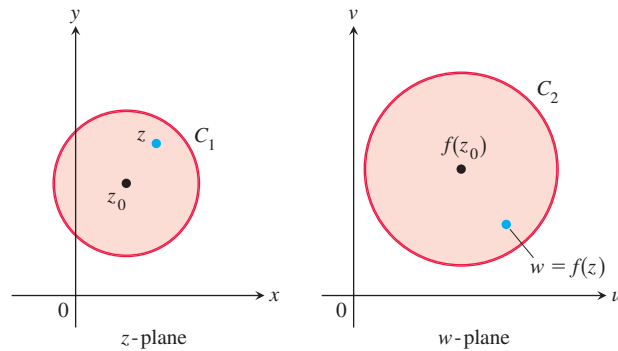

FIGURE 18.14 Choose any circle C_2 around $f(z_0)$ in the w -plane. A continuous function takes points in the z -plane that lie inside a small enough circle C_1 around z_0 to points inside C_2 .

As with functions of a real variable, polynomial functions are continuous. The proof is similar to the real case, and while we do not give it in full, we illustrate the idea with two examples.

EXAMPLE 6 Show that at any point z_0 in the complex plane, the function $f(z) = z$ is continuous.

Solution The definition of continuity given in Equation (19) requires us to show that the limit

$$\lim_{z \rightarrow z_0} |f(z) - f(z_0)| = \lim_{z \rightarrow z_0} |z - z_0| = 0.$$

Using the definition of limit in Equation (18), our challenge is to find a δ so that

$$|z - z_0| < \varepsilon \text{ whenever } 0 < |z - z_0| < \delta.$$

For this very simple function we can choose $\delta = \varepsilon$. So the requirement for continuity is satisfied, and we conclude that f is continuous at any point z_0 . ■

By similar arguments we can show that sums and products of continuous functions are continuous, as are quotients of continuous functions wherever the denominator is nonzero. These arguments combine to show that polynomial functions and rational functions are continuous on their domains. We illustrate such an argument for the function $f(z) = z^2$.

EXAMPLE 7 Show that at any point z_0 in the complex plane, the function $f(z) = z^2$ is continuous.

Solution For the function $f(z) = z^2$ we have

$$\begin{aligned} \lim_{z \rightarrow z_0} |f(z) - f(z_0)| &= \lim_{z \rightarrow z_0} |z^2 - z_0^2| \\ &= \lim_{z \rightarrow z_0} |z - z_0| |z + z_0| && \text{Factor.} \\ &= \lim_{z \rightarrow z_0} |z - z_0| \lim_{z \rightarrow z_0} |z + z_0| \\ &= 0 \cdot |2z_0| && \text{Example 1 and Exercise 9} \\ &= 0. \end{aligned}$$

The requirement for continuity given by Equation (19) is satisfied, and we conclude that f is continuous at any point z_0 . ■

Although we will not prove it here, the arguments of Examples 1 and 2 can be extended to show that all complex polynomials are continuous, as are all quotients of complex polynomials where the denominator is nonzero.

EXERCISES 18.2

- For each of the following regions in the complex plane, describe the image of the region under the map $w = z^2$. (Hint: Use polar coordinates.)
 - $|z| = 1, 0 \leq \arg z \leq \pi$
 - $|z| = 2, \pi/2 \leq \arg z \leq \pi$
 - $\arg z = \pi/4$
 - $|z| < 1, -\pi \leq \arg z \leq 0$
 - The x -axis
 - The y -axis
- Show that the two parabolas in the w -plane in Figure 18.10 intersect orthogonally (at right angles) if neither a nor b is zero.
- Show that the function $w = z^3$ maps the wedge $0 < \arg z < \pi/3$ in the z -plane onto the upper half-plane of the w -plane, the half-plane whose imaginary part satisfies $\text{Im}(w) > 0$. Use polar coordinates and sketch.
- Show that $f(z) = z^3$ is continuous at $z = z_0$ for any z_0 .
- Show that $f(z) = 1/z$ is continuous at $z = z_0$ if $z_0 \neq 0$.
- The function $w = z^3$ maps the square with vertices at $0, 1, i$, and $1 + i$ to the region shown in Figure 18.15.

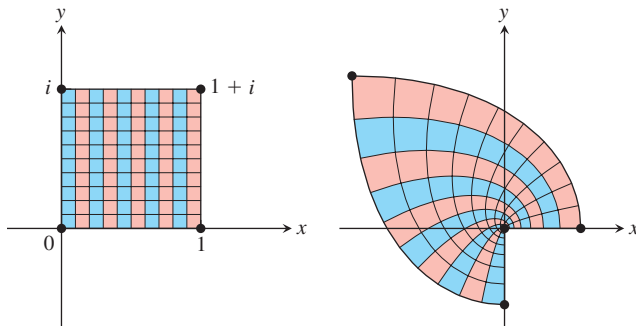

FIGURE 18.15 The image under the complex map $f(z) = z^3$ of a square with vertices at $0, 1, i$, and $1 + i$

- Determine the four complex numbers to which the vertices of the square are mapped.
 - Give parameterizations of the four curves to which the sides of the square are mapped.
- Use Formula (18) with $f(z) = u(x, y) + iv(x, y)$, $z_0 = x_0 + iy_0$, and $w_0 = u_0 + iv_0$ to show that

$$\lim_{z \rightarrow z_0} f(z) = w_0$$

exactly when both

$$\lim_{(x, y) \rightarrow (x_0, y_0)} u(x, y) = u_0$$

and

$$\lim_{(x, y) \rightarrow (x_0, y_0)} v(x, y) = v_0.$$

- Suppose that $f(z) = u(x, y) + iv(x, y)$ is defined on an open set containing the point $z_0 = x_0 + iy_0$. Show that $f(z)$ is continuous at z_0 if and only if $u(x, y)$ and $v(x, y)$ are each continuous at (x_0, y_0) .
- Show that the constant function $f(z) = z_0$ is continuous.
 - Show that if $f(z)$ and $g(z)$ are continuous, then so is $(f + g)(z)$.

18.3 Derivatives

The derivative of a complex function $w = f(z)$ at z_0 is defined in the same way as for a real-valued function of a real variable.

DEFINITION The derivative of a complex-valued function f at $z = z_0$ is

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}, \quad (20)$$

provided that this limit exists. When this limit exists we say that f is **complex differentiable** at z_0 .

As usual, we also use the equivalent notation

$$\frac{df}{dz}(z_0)$$

to denote the derivative of f at z_0 . A function that has a complex derivative at every point in its domain D is said to be *complex differentiable* or *holomorphic* on D . Due to a property of complex differentiable functions, that they are equal to their Taylor series where the Taylor series converges, they are also often called *analytic* functions.

The derivative of a real-valued function exists at a point x_0 if the derivative from the left and from the right exist and agree at x_0 . For a complex differentiable function the derivative from *any* direction must exist and agree with the derivative computed from any other direction.

There are many ways in which z can approach z_0 . It can approach z_0 on a horizontal path from the left, from the right, or along a vertical path coming from above or from below. And there are many other possibilities. It is possible for z to approach z_0 along a line coming from any direction, or even along a curved path or spiral that ends at z_0 . The existence of a single limiting value for

$$\frac{f(z) - f(z_0)}{z - z_0}$$

says that no matter how z_0 is approached, the same value is obtained. Despite this very restrictive condition, there is still a large collection of complex differentiable functions. The very special implications of differentiability and the large number of such functions make the use of complex differentiable functions an extremely powerful tool.

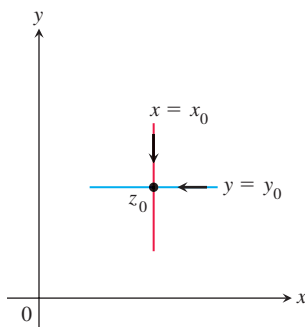

FIGURE 18.16 The limit defining a differentiable function has the same value as z approaches z_0 from any direction, including the horizontal and vertical.

EXAMPLE 1 The complex conjugation function $f(z) = \bar{z}$ takes a point $z = x + iy$ to its complex conjugate $\bar{z} = x - iy$. Show that at any point z_0 in the complex plane, this function is *not* complex differentiable.

Solution We compute the limit defining the derivative as we approach the point $z_0 = x_0 + iy_0$ from two different directions:

- along the vertical line $x = x_0$ and
- along the horizontal line $y = y_0$. See Figure 18.16.

In case (a), we fix $x = x_0$ and consider what happens as $y \rightarrow y_0$. On the vertical line $x = x_0$ we have that z approaches z_0 only from above or below. On this line $z \rightarrow z_0$ exactly when $y \rightarrow y_0$. The limit defining a derivative, Equation (20), gives

$$\begin{aligned} \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} &= \lim_{z \rightarrow z_0} \frac{\bar{z} - \bar{z}_0}{z - z_0} \\ &= \lim_{y \rightarrow y_0} \frac{\overline{(x_0 + iy)} - \overline{(x_0 + iy_0)}}{(x_0 + iy) - (x_0 + iy_0)} \\ &= \lim_{y \rightarrow y_0} \frac{(x_0 - iy) - (x_0 - iy_0)}{i(y - y_0)} \\ &= \lim_{y \rightarrow y_0} \frac{-i(y - y_0)}{i(y - y_0)} \\ &= \lim_{y \rightarrow y_0} \frac{-i}{i} \\ &= -1. \end{aligned}$$

In case (b), we fix $y = y_0$ and consider what happens along this horizontal line. With y fixed at y_0 , we have $z \rightarrow z_0$ exactly when $x \rightarrow x_0$, and Equation (20) becomes

$$\begin{aligned}\lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} &= \lim_{z \rightarrow z_0} \frac{\bar{z} - \bar{z}_0}{z - z_0} \\ &= \lim_{x \rightarrow x_0} \frac{\overline{(x + iy_0)} - \overline{(x_0 + iy_0)}}{(x + iy_0) - (x_0 + iy_0)} \\ &= \lim_{x \rightarrow x_0} \frac{(x - iy_0) - (x_0 - iy_0)}{x - x_0} \\ &= \lim_{x \rightarrow x_0} \frac{x - x_0}{x - x_0} \\ &= 1.\end{aligned}$$

Two different paths along which z approaches z_0 lead to two different answers. So, there is no single complex number that is equal to the limit, no matter which path is chosen. There is no number that we can call $f'(z_0)$, and we conclude that the function $w = \bar{z}$ does not have a derivative at any point z_0 in the complex plane. ■

Rules for Finding Complex Derivatives

The formulas for differentiating sums, products, quotients, and powers of the complex variable z are the same as those for a real variable x . For example, if c is any complex number, and if $f(z)$ and $g(z)$ are functions that have derivatives at $z = z_0$, then at $z = z_0$ we have:

- | | |
|---|------------------------------|
| (1) $(c)' = 0$ | Derivative of a constant c |
| (2) $(cf)'(z) = cf'(z)$ | Constant Multiple Rule |
| (3) $(f + g)'(z) = f'(z) + g'(z)$ | Sum Rule |
| (4) $(fg)'(z) = f'(z)g(z) + f(z)g'(z)$ | Product Rule |
| (5) $(f/g)'(z) = [g(z)f'(z) - f(z)g'(z)]/g(z)^2$, if $g(z) \neq 0$ | Quotient Rule |
| (6) $(z^n)' = nz^{n-1}$, where n is any integer | Power Rule |
| (7) $(g \circ f)'(z) = g'(f(z))f'(z)$, for $f(z)$ in domain of g | Chain Rule |

These formulas are derived in the same manner as the formulas for functions of a real variable. We give an idea of the techniques used to prove them by establishing one case of the power rule.

EXAMPLE 2 Show from the definition that $f(z) = z^3$ has derivative

$$f'(z) = 3z^2.$$

Solution We compute the limit defining a derivative,

$$\begin{aligned}\lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} &= \lim_{z \rightarrow z_0} \frac{z^3 - z_0^3}{z - z_0} && \text{Factor numerator.} \\ &= \lim_{z \rightarrow z_0} \frac{(z - z_0)(z^2 + zz_0 + z_0^2)}{z - z_0} \\ &= \lim_{z \rightarrow z_0} z^2 + zz_0 + z_0^2 && \text{Each of the three terms approaches } z_0^2. \\ &= 3z_0^2.\end{aligned}$$

Note that no matter how z approaches z_0 , the terms z^2 and zz_0 each approaches z_0^2 , and the limit is $3z_0^2$. So $f'(z_0) = 3z_0^2$. ■

EXERCISES 18.3

In Exercises 1–3, find the derivative with respect to z of the given function at the point z_0 .

1. $f(z) = \frac{z+1}{z-1}$, $z_0 = 1+i$

2. $f(z) = z^3 + 3z^2 + 3z + 2$, $z_0 = -1+2i$

3. $f(z) = \sqrt{z^2 + 1}$, $z_0 = \frac{1+i}{\sqrt{2}}$

(Here we get two answers depending on our choice of the square root. Give the answer using the principal square root, as defined in Section 18.1.)

4. Use the definition of a complex derivative to find $f'(z_0)$ if $f(z) = 1/z$ and $z \neq 0$.

Theory and Examples

5. The directional derivative of a real-valued function f in the complex plane in the direction of a unit vector w is given by

$$D_w f(z_0) = \lim_{t \rightarrow 0} \frac{f(z_0 + tw) - f(z_0)}{t}. \quad (21)$$

Compare this to the derivative of a complex function $f(z)$ by computing the complex derivative of f as z approaches z_0 along the line $z = z_0 + tw$, where w now represents a complex number with magnitude 1. What are the differences between these two formulas?

18.4 The Cauchy-Riemann Equations

When we write $z = x + iy$ and the complex function $w = f(z) = u + iv$ is differentiable, the real part of f , $u(x, y)$, and the imaginary part of f , $v(x, y)$, are real-valued differentiable functions of the real variables x and y . We can compute the derivative of f at a point $z_0 = x_0 + iy_0$ by approaching z_0 from any direction we choose. By comparing the derivative $f'(z_0)$ obtained from approaching z_0 along horizontal and vertical directions, we obtain equations relating the partial derivatives of u and v .

If we approach along the horizontal line $y = y_0$, then

$$z - z_0 = (x + iy_0) - (x_0 + iy_0) = x - x_0$$

and therefore

$$\begin{aligned} f'(z_0) &= \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \\ &= \lim_{x \rightarrow x_0} \frac{f(x + iy_0) - f(x_0 + iy_0)}{x - x_0} \\ &= \lim_{x \rightarrow x_0} \frac{u(x, y_0) + iv(x, y_0) - (u(x_0, y_0) + iv(x_0, y_0))}{x - x_0} \\ &= \lim_{x \rightarrow x_0} \frac{u(x, y_0) - u(x_0, y_0)}{x - x_0} + i \lim_{x \rightarrow x_0} \frac{v(x, y_0) - v(x_0, y_0)}{x - x_0} \\ &= \frac{\partial u}{\partial x}(x_0, y_0) + i \frac{\partial v}{\partial x}(x_0, y_0). \end{aligned}$$

Though we have approached z_0 in only one of the many possible ways, we obtained a useful formula for the derivative, equal to what we would get if we approached z_0 from any other direction. For $f(z) = u(x + iy) + iv(x + iy)$, we obtain the following explicit formula for the complex derivative of a function that has a complex derivative at z_0 .

Formula for the Complex Derivative

$$f'(z_0) = \frac{\partial u}{\partial x}(x_0, y_0) + i \frac{\partial v}{\partial x}(x_0, y_0) \quad (22)$$

The formula in Equation (22) does not depend on which direction is taken to approach z_0 . Instead of approaching z_0 along the x -axis, we can approach along the vertical line $x = x_0$, on which

$$z - z_0 = (x_0 + iy) - (x_0 + iy_0) = i(y - y_0).$$

In this case we have

$$\begin{aligned}
 f'(z_0) &= \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0} \\
 &= \lim_{y \rightarrow y_0} \frac{f(x_0 + iy) - f(x_0 + iy_0)}{i(y - y_0)} \\
 &= \lim_{y \rightarrow y_0} \frac{u(x_0, y) + iv(x_0, y) - (u(x_0, y_0) + iv(x_0, y_0))}{i(y - y_0)} \\
 &= \lim_{y \rightarrow y_0} \frac{u(x_0, y) - u(x_0, y_0)}{i(y - y_0)} + \lim_{y \rightarrow y_0} \frac{i[v(x_0, y) - v(x_0, y_0)]}{i(y - y_0)} \\
 &= \frac{\partial v}{\partial y}(x_0, y_0) - i \frac{\partial u}{\partial y}(x_0, y_0). \quad 1/i = -i
 \end{aligned}$$

Since f is complex differentiable, these two computations must give the same value for the derivative. The two real parts in the two equations must be equal, and the imaginary parts in the two equations must be the same. This gives relations between the partial derivatives of u and v that hold at any point where $f(z) = u(x, y) + iv(x, y)$ has a complex derivative.

The Cauchy-Riemann Equations

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

EXAMPLE 1 Show that the function $f(z) = 1/z$ satisfies the Cauchy-Riemann Equations at any point in the complex plane where $z \neq 0$.

Solution Let $z = x + iy$ be a nonzero point in the complex plane, and let

$$w = f(z) = 1/z.$$

Then

$$w = u + iv = \frac{1}{x + iy} = \frac{1}{x + iy} \cdot \frac{x - iy}{x - iy} = \frac{x - iy}{x^2 + y^2},$$

and therefore

$$u = \frac{x}{x^2 + y^2}, v = \frac{-y}{x^2 + y^2}. \quad x^2 + y^2 \neq 0 \text{ since } z \neq 0.$$

After computing partial derivatives four times and simplifying, we find that

$$\frac{\partial u}{\partial x} = \frac{y^2 - x^2}{(x^2 + y^2)^2} = \frac{\partial v}{\partial y}$$

and

$$\frac{\partial u}{\partial y} = \frac{-2xy}{(x^2 + y^2)^2} = -\frac{\partial v}{\partial x}.$$

This shows that the Cauchy-Riemann Equations are satisfied at all points where $x^2 + y^2 \neq 0$. ■

The Cauchy-Riemann Equations give relationships between u and v that must be satisfied by a complex differentiable function. We cannot independently specify functions

$u(x, y)$ and $v(x, y)$ and expect the function $w = u + iv$ to be complex differentiable. However if we take functions u and v , which have continuous partial derivatives

$$\frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial v}{\partial x}, \text{ and } \frac{\partial v}{\partial y}$$

on a region R and satisfy the Cauchy-Riemann Equations on R , then a theorem that we will not prove here states that the function $w = u + iv$ is complex differentiable on R . This is a very powerful conclusion, since it means that by checking agreement of the computation of the limit

$$\lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}$$

only as $z \rightarrow z_0$ in the horizontal and vertical directions, we know the derivative is the same as $z \rightarrow z_0$ in every direction.

EXERCISES 18.4

For the following functions, find the real and imaginary parts of the function $w = f(z)$, $w = u + iv$, $z = x + iy$, and show that they satisfy the Cauchy-Riemann equations.

1. z^2
2. z^3
3. z^4
4. $1/z^2, z \neq 0$
5. A real-valued function with continuous second partial derivatives $g(x, y)$ is called *harmonic* if it satisfies Laplace's Equation,

$$\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} = 0.$$

Show that both the real part $u = u(x, y)$ and the imaginary part $v = v(x, y)$ of a complex differentiable function $w = f(z)$ satisfy Laplace's Equation.

6. Verify that Laplace's Equation in Exercise 5 is satisfied by the real and imaginary parts of the functions
 - a. z ,
 - b. z^2 ,
 - c. z^3 .
7. Show that the following functions are complex differentiable on the complex plane by verifying that their real and imaginary parts have continuous partial derivatives and satisfy the Cauchy-Riemann Equations.
 - a. $f(z) = e^x \cos y + ie^x \sin y$
 - b. $f(z) = \sin x \cosh y + i \cos x \sinh y$

18.5 Complex Power Series

Applying the rules for finding the derivatives of sums, products, and quotients of complex functions, we can see that polynomials and rational functions (quotients of polynomials) are complex differentiable on their domains. We have extended these functions from differentiable functions on the real line to differentiable functions on the complex plane \mathbb{C} . We now investigate how to extend other elementary functions such as $\sin z$, $\cos z$, e^z , $\cosh z$, and so on that are defined on the real line to functions that are differentiable on \mathbb{C} . To do this we will need to make sense of expressions such as $\sin(2 + 3i)$ and e^{3-i} . When evaluating $\sin(2 + 3i)$ it is not helpful to try to think of $2 + 3i$ as an angle whose sine is evaluated, as we did when evaluating the sine of a real number. Rather we define the value of the sine function evaluated on a complex number by extending the expression of the sine function as a power series from real to complex numbers. In Chapter 9 we derived the Taylor series expression

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$$

When we use this series to calculate a value such as $\sin 2$, we don't think of $x = 2$ as a radian measure of an angle, but just consider it as a number that is input into the series. This leads us to *define* the function $f(z) = \sin z$ for a complex variable z by the formula

$$\sin z = z - \frac{z^3}{3!} + \frac{z^5}{5!} - \frac{z^7}{7!} + \dots = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n+1}}{(2n+1)!}. \quad (23)$$

For real z , for which $z = x + iy$ with $y = 0$, this gives the familiar series for $\sin x$. So this new definition of $\sin z$ for complex numbers z is consistent with our previous understanding of the sine function. We now consider what it means for such a series to converge.

Sequences

As we did with real numbers, we base the concept of convergence of a complex series on the more basic concept of the convergence of complex sequences. A **complex sequence** is defined to be a function from the positive integers to the complex numbers. These sequences are often presented as an infinite list of complex numbers,

$$\{z_n\} = z_1, z_2, \dots, z_n, \dots$$

We say that a sequence $\{z_n\}$ **converges** to a complex number L if for every positive number ϵ there corresponds an integer N such that

$$|z_n - L| < \epsilon \text{ whenever } n > N.$$

If no such number exists we say that $\{z_n\}$ **diverges**.

While each number z_n in the sequence and the limiting number L is complex, the conditions for convergence involve the real numbers $|z_n - L|$, ϵ , and δ . Because of this, many of the arguments for convergence of sequences given in Section 9.1 carry over to complex sequences.

Series

A complex power series

$$\sum_{n=0}^{\infty} a_n z^n = a_0 + a_1 z + a_2 z^2 + \dots \quad (24)$$

converges at a point z if the sequence of partial sums

$$s_n = a_0 + a_1 z + a_2 z^2 + \dots + a_n z^n$$

has a limit $S = u + iv$ as $n \rightarrow \infty$.

If we separate s_n into its real and imaginary parts, by writing

$$s_n = u_n(x, y) + iv_n(x, y),$$

then

$$s_n \rightarrow S \text{ if and only if } u_n \rightarrow u \text{ and } v_n \rightarrow v. \quad \text{As in Equation (14)}$$

Many properties of real series proved in Chapter 9 carry over to complex series. For example, sums of convergent series converge. If

$$\sum_{n=0}^{\infty} c_n = L \quad \text{and} \quad \sum_{n=0}^{\infty} d_n = M$$

are two convergent complex series, then the series $\sum_{n=0}^{\infty} (c_n + d_n)$ also converges, and

$$\sum_{n=0}^{\infty} (c_n + d_n) = L + M.$$

Proofs of these properties are very similar to the proofs for real series.

The series $\sum_{n=0}^{\infty} a_n z^n$ is said to *converge absolutely* if the corresponding series of absolute values

$$\sum_{n=0}^{\infty} |a_n z^n| = |a_0| + |a_1 z| + |a_2 z^2| + \dots \quad (25)$$

converges. The sum in Equation (25) is a series of real numbers, so we can apply the tests developed in Chapter 9, such as the Ratio Test, Comparison Test, or Integral Test, to verify its convergence. If the series of absolute values does converge, then the following theorem tells us that the original series also converges.

THEOREM 1—The Absolute Convergence Test for Complex Series

If a series converges absolutely, then it converges.

Proof Separate each term of the series into its real and imaginary part by writing

$$a_k z^k = c_k + id_k, \quad k = 0, 1, 2, \dots$$

where c_k and d_k are real numbers. Suppose that the series of absolute values in Equation (25) converges. Then, since

$$|c_k| = \sqrt{c_k^2} \leq \sqrt{c_k^2 + d_k^2} = |a_k z^k| \quad \text{and} \quad |d_k| = \sqrt{d_k^2} \leq \sqrt{c_k^2 + d_k^2} = |a_k z^k|,$$

the Direct Comparison Test tells us that the series

$$\sum_{k=0}^{\infty} |c_k| \quad \text{and} \quad \sum_{k=0}^{\infty} |d_k|$$

both converge (Theorem 10 in Chapter 9). From this we can conclude that each of the series

$$\sum_{k=0}^{\infty} c_k \quad \text{and} \quad \sum_{k=0}^{\infty} d_k,$$

computed without taking absolute values, also converge. Therefore the series

$$\sum_{k=0}^{\infty} (c_k + id_k) = \sum_{k=0}^{\infty} c_k + i \sum_{k=0}^{\infty} d_k$$

converges. ■

EXAMPLE 1 Show that the series for $\sin z$ in Equation (23) converges for all complex numbers z .

Solution We test the series of real numbers

$$\sum_{n=0}^{\infty} \left| (-1)^n \frac{z^{2n+1}}{(2n+1)!} \right| \tag{26}$$

for absolute convergence. For this series we apply the Ratio Test. Set

$$w_n = \left| (-1)^n \frac{z^{2n+1}}{(2n+1)!} \right|.$$

Then we calculate

$$\left| \frac{w_{n+1}}{w_n} \right| = \frac{|z|^2}{(2n+3)(2n+2)},$$

and

$$\lim_{n \rightarrow \infty} \left| \frac{w_{n+1}}{w_n} \right| = \lim_{n \rightarrow \infty} \frac{|z|^2}{(2n+3)(2n+2)} = 0. \quad \text{As } n \rightarrow \infty, \text{ denominator } \rightarrow \infty.$$

Since this limit is less than one, the Ratio Test implies that the series in Equation (26) converges absolutely. By Theorem 1, the series in Equation (26) itself converges, without the absolute value signs, and we have shown that the complex series for $\sin z$, the series in Equation (23), converges at every point z in the complex plane. ■

EXERCISES 18.5

In Exercises 1–5, find the regions in which each of the series converges. Sketch the region of absolute convergence.

1. $1 + z + z^2 + z^3 + \dots$

2. $1 - 2z + 3z^2 - 4z^3 + \dots$

3. $(z - 1) - \frac{(z - 1)^2}{2} + \frac{(z - 1)^3}{3} - \frac{(z - 1)^4}{4} + \dots$

4. $(z + i) + \frac{(z + i)^2}{2} + \frac{(z + i)^3}{3} + \frac{(z + i)^4}{4} + \dots$

5. $1 - \frac{(z + 1)}{2} + \frac{(z + 1)^2}{4} - \frac{(z + 1)^3}{8} + \frac{(z + 1)^4}{16} - \dots$

6. Show that the series $\sum_{k=0}^{\infty} \frac{z^k}{k!}$ converges absolutely for all z .

7. Show that the series $\sum_{k=0}^{\infty} (-1)^k \frac{z^{2k}}{(2k)!}$ converges absolutely for all z .

8. Show that the series $\sum_{k=1}^{\infty} (-1)^{k-1} \frac{z^k}{k}$ converges absolutely for $|z| < 1$.

T 9. Use the series in Equation (23) for $\sin z$ to compute $\sin(0.2 + 0.3i)$ to three decimals.

18.6 Some Complex Functions

We have seen how to define the sine function as a complex series by extending the series expansion for real numbers to complex numbers. We can similarly define other basic complex functions by extending the series formulas developed for a real variable x to complex numbers.

$$e^z = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots = \sum_{n=0}^{\infty} \frac{z^n}{n!}$$

$$\cos z = 1 - \frac{z^2}{2!} + \frac{z^4}{4!} - \frac{z^6}{6!} + \dots = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n}}{(2n)!}$$

$$\text{Arctan } z = z - \frac{z^3}{3} + \frac{z^5}{5} - \frac{z^7}{7} + \dots = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n+1}}{2n+1}$$

Using the Ratio Test as in Example 1 of Section 18.5, we can show that the series for e^z and $\cos z$ converge absolutely for all z in the complex plane. To define $\text{Arctan } z$ as an inverse function for the function $\tan z$, we need to restrict the domain of $\tan z$ to a region on which it is one-to-one. The formula for $\text{Arctan } z$ in the above power series corresponds to one choice for such a restricted domain and is called the *principal value* of $\text{arctan } z$. The Ratio Test shows that this series for $\text{Arctan } z$ converges when $|z| < 1$, and diverges when $|z| > 1$. We will explore this idea in more detail when we look at the complex logarithmic function later in this section.

If there is an open region of the complex plane containing a point z in which all points except for z are in the domain of a complex differentiable function, then z is called an *isolated singularity* of f . For example, the point $z = 0$ is not in the domain of $f(z) = 1/z$ and is an isolated singularity of this complex differentiable function.

A basic theorem in the theory of complex functions says that a power series $\sum_{n=0}^{\infty} a_n z^n$ either

- (1) converges for all z , or
- (2) converges inside a circle $|z| < R$ and diverges for $|z| > R$, or
- (3) converges only at $z = 0$.

This theorem closely resembles Theorem 18 in Chapter 9, and its proof, based on the Ratio Test, is similar.

THEOREM 2—The Convergence Theorem for Complex Power Series

If a series $\sum_{n=0}^{\infty} a_n z^n$ converges at a point $z = z_0$, then it converges absolutely for all z with $|z| < |z_0|$. If the series diverges at $z = z_0$, then it diverges for all z with $|z| > |z_0|$.

EXAMPLE 1 Show that the largest radius circle centered at 0 inside which the series

$$1 - z^2 + z^4 - z^6 + \dots$$

converges is the circle of radius $R = 1$.

Solution The absolute value of the n th term $a_n = z^{2n}$ of this series is $|z|^{2n}$. By Theorem 1, the Absolute Convergence Test, this converges for all z with $|z| < 1$. For $z = i$ the series becomes

$$1 - i^2 + i^4 - i^6 + \dots = 1 + 1 + 1 + 1 + \dots,$$

which diverges. By Theorem 2 the series diverges for all z with $|z| > 1$. So the largest radius circle centered at zero inside which the series converges is the circle of radius one. ■

The largest radius circle around a point z_0 inside of which a series converges is called the *circle of convergence* for z_0 . The series converges for all points inside this circle and diverges at any point outside it. Understanding the convergence for points lying on the circle of convergence is a more difficult problem that we will not discuss. The circle $|z| = 1$ is the circle of convergence centered at zero for the function in Example 1.

Many of the basic properties of trigonometric and exponential functions extend to the complex versions of these functions that are defined using series.

EXAMPLE 2 Using the series definition of the exponential function

$$e^z = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots = \sum_{n=0}^{\infty} \frac{z^n}{n!},$$

show that

$$e^z e^w = e^{z+w}. \quad (27)$$

Solution We multiply the series for e^z and the series for e^w , and gather terms to get a series for the product:

$$\begin{aligned} & \left(1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \dots\right) \left(1 + w + \frac{w^2}{2!} + \frac{w^3}{3!} + \dots\right) \\ &= 1 + (z + w) + \left(\frac{z^2}{2!} + z \cdot w + \frac{w^2}{2!}\right) + \dots \end{aligned}$$

The general form for the terms whose degree is n is given by

$$\frac{z^n}{n!} \cdot 1 + \frac{z^{n-1}}{(n-1)!} \cdot w + \frac{z^{n-2}}{(n-2)!} \cdot \frac{w^2}{2!} + \dots + \frac{z^{n-k}}{(n-k)!} \cdot \frac{w^k}{k!} + \dots + 1 \cdot \frac{w^n}{n!},$$

which in summation form equals

$$\sum_{k=0}^n \frac{z^{n-k}}{(n-k)!} \frac{w^k}{k!}. \quad (28)$$

On the other hand, the series expression for e^{z+w} is

$$e^{z+w} = 1 + z + \frac{(z+w)^2}{2!} + \frac{(z+w)^3}{3!} + \dots = \sum_{n=0}^{\infty} \frac{(z+w)^n}{n!},$$

and the term of degree n is

$$\frac{(z+w)^n}{n!}.$$

By noticing that

$$\frac{n(n-1)\dots(n-k+1)}{k!} \cdot \frac{(n-k)!}{(n-k)!} = \frac{n!}{k!(n-k)!}$$

we may also write this in summation form as

$$\begin{aligned}\frac{(z+w)^n}{n!} &= \frac{1}{n!} \left[z^n + nz^{n-1}w + \frac{n(n-1)}{2}z^{n-2}w^2 + \frac{n(n-1)(n-2)}{3!}z^{n-3}w^3 + \cdots + w^n \right] \\ &= \frac{1}{n!} \sum_{k=0}^n \frac{n!}{(n-k)!k!} z^{n-k}w^k \\ &= \sum_{k=0}^n \frac{z^{n-k}}{(n-k)!} \frac{w^k}{k!}.\end{aligned}$$

This last expression is identical to the one that appeared in Equation (28). We have shown that e^ze^w and e^{z+w} have power series whose terms of degree n are equal for each value of n . It follows that the power series themselves are equal, and so $e^ze^w = e^{z+w}$. ■

In a similar way, we can multiply and add power series term by term to show that

$$\sin(z+w) = \sin(z)\cos(w) + \cos(z)\sin(w)$$

and

$$\cos(z+w) = \cos(z)\cos(w) - \sin(z)\sin(w).$$

When we substitute iz for z in the series expansion for e^z , we obtain

$$\begin{aligned}e^{iz} &= 1 + iz + \frac{(iz)^2}{2!} + \frac{(iz)^3}{3!} + \frac{(iz)^4}{4!} + \cdots \\ &= 1 + iz - \frac{z^2}{2!} - i\frac{z^3}{3!} + \frac{z^4}{4!} + \cdots && i^2 = -1, i^3 = -i, \\ &= \left(1 - \frac{z^2}{2!} + \frac{z^4}{4!} - \frac{z^6}{6!} + \cdots\right) + i\left(z - \frac{z^3}{3!} + \frac{z^5}{5!} - \frac{z^7}{7!} + \cdots\right) && i^4 = 1, \dots \\ &= \cos z + i \sin z. && \text{Series expansions for } \cos z \text{ and } \sin z\end{aligned}$$

This establishes **Euler's Formula**, which we stated in Section 18.1,

$$e^{iz} = \cos z + i \sin z. \quad (29)$$

Euler's formula tells us how to make sense of a complex exponent. Namely if we write $z = x + iy$, then

$$e^z = e^{x+iy} = e^xe^{iy} = e^x(\cos y + i \sin y). \quad (30)$$

Thus the value of e^z is expressed in terms of sines and cosines of the real numbers x and y .

With this formula, we can begin to understand the behavior of the exponential function on the complex plane. The image of a rectangle in the complex plane under the exponential map, computed using Euler's formula, is shown in Figure 18.17. The rectangle is wrapped around the origin, which is not in the range of e^z . If the rectangle is translated upwards by or downwards by a multiple of $2\pi i$, then the formula for e^z yields the same value, as can be seen in Equation (30). The height of the rectangle in Figure 18.17 is 6, just

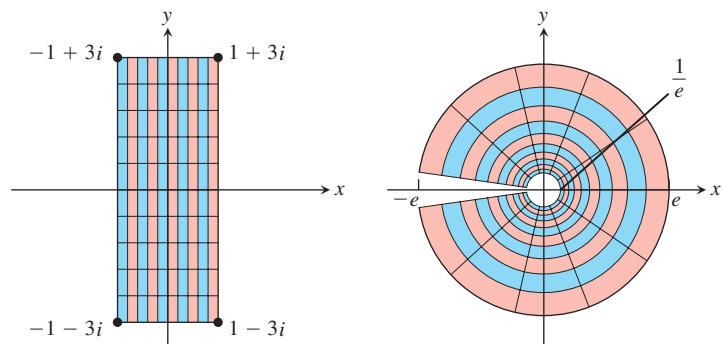

FIGURE 18.17 The image under the map $f(z) = e^z$ of a rectangle with vertices at $-1 - 3i$, $1 - 3i$, $-1 + 3i$, and $1 + 3i$

short of 2π . The top and bottom edges are wrapped around by the exponential function and almost coincide. A slightly taller rectangle with height 2π would have its top and bottom edges mapped by $w = e^z$ to coinciding radial segments.

If we replace z by $-iz$ in Euler's formula, we get the companion equation

$$e^{-iz} = \cos z - i \sin z. \quad (31)$$

By adding these two equations and dividing by two, we obtain a formula for $\cos z$,

$$\cos z = \frac{e^{iz} + e^{-iz}}{2}. \quad (32)$$

If we subtract Equation (31) from Equation (29), then we obtain a formula for $\sin z$,

$$\sin z = \frac{e^{iz} - e^{-iz}}{2i}. \quad (33)$$

The complex versions of the other trigonometric functions are derived from $\sin z$ and $\cos z$ in the usual way. For example

$$\tan z = \frac{\sin z}{\cos z} = \frac{1}{i} \frac{e^{iz} - e^{-iz}}{e^{iz} + e^{-iz}}. \quad (34)$$

The usual trigonometric identities can be established by expressing the trigonometric functions as exponentials and then making use of the properties of the exponential function.

EXAMPLE 3 Show that

$$\cos^2 z + \sin^2 z = 1.$$

Solution We square both sides of Equation (32) and Equation (33) and add:

$$\begin{aligned} \cos^2 z + \sin^2 z &= \frac{e^{2iz} + 2e^0 + e^{-2iz}}{4} - \frac{e^{2iz} - 2e^0 + e^{-2iz}}{4} \\ &= \frac{4e^0}{4} = 1. \end{aligned}$$

Equations (32) and (33) also reveal the close relationship between the trigonometric and hyperbolic functions. We define the complex hyperbolic functions by extending the series formulas for the real case, so that

$$\begin{aligned} \cosh z &= \frac{e^z + e^{-z}}{2} = 1 + \frac{z^2}{2!} + \frac{z^4}{4!} + \frac{z^6}{6!} + \cdots, \\ \sinh z &= \frac{e^z - e^{-z}}{2} = z + \frac{z^3}{3!} + \frac{z^5}{5!} + \frac{z^7}{7!} + \cdots. \end{aligned}$$

Then Equations (32) and (33) say that

$$\cos z = \cosh iz \quad \text{and} \quad i \sin z = \sinh iz. \quad (35)$$

These relationships explain the similarities between trigonometric identities such as

$$\cos^2 z + \sin^2 z = 1,$$

and the corresponding identities for hyperbolic functions, such as

$$\cosh^2 z - \sinh^2 z = 1. \quad \blacksquare$$

The Logarithmic Function

We now define the logarithm of a complex number, extending the familiar notion of the logarithm of a real positive number. It is convenient to work with the extension of the natural logarithm, $\ln x$, and we will assume this choice of base. However we will reserve usage of the notation $\ln x$ to the case where the x is a real number.

If x is a positive real number, then the logarithm arises as the inverse of the exponential function, so that $\ln x = y$ if and only if $x = e^y$. We wish to have the complex logarithmic function be the inverse of the exponential function in a similar manner. However, when we replace x with an arbitrary complex number z , we are faced with a problem because

$$e^{z+2\pi i} = e^z e^{2\pi i} = e^z (\cos 2\pi + i \sin 2\pi) = e^z.$$

The function $w = e^z$ is not one-to-one, and therefore does not have an inverse if the domain of the exponential function is the entire complex plane. We ran into this type of problem when we defined inverse functions, such as $\arcsin x$, because $\sin x$ is not one-to-one. We handled the issue by restricting the domain of $\sin x$ to an interval on which it is one-to-one, namely $[-\pi/2, \pi/2]$. We do the same now, restricting the domain of e^z to a subset on which it is one-to-one. This allows for defining an unambiguous inverse for e^z , which we call $\text{Log } z$, written with a capital “L.” While there are many possibilities for such a subset of the complex plane, we make a choice that gives what is called the *principal branch* of the logarithm function. Other choices of notation, such as $\text{Ln } z$, are sometimes used for this function.

The idea behind the definition of $\text{Log } z$ is most easily understood if we represent a complex number using its polar coordinate form, $z = re^{i\theta}$, where $r = |z|$ and $\theta = \arg(z)$. Now recall the property $\ln ab = \ln a + \ln b$ that is satisfied by the real logarithmic function, whose domain is the positive real numbers. If we retain this property, we are led to define the complex logarithm of a nonzero complex number z to be

$$\log z = \ln r + i\theta. \quad (36)$$

There is still an ambiguity to resolve, because $\theta = \arg(z)$ is only defined up to multiples of 2π . The description of the complex number z could also have been given as $z = re^{i(\theta+2\pi)}$, or $z = re^{i(\theta+4\pi)}$, or in general

$$z = re^{i(\theta+2n\pi)}, \quad n = 0, \pm 1, \pm 2, \dots$$

The definition in Equation (36) could be applied to any of these choices that describe z , leading to infinitely many possible values for the logarithm of z , with any pair differing by a multiple of $2\pi i$. To pin down one choice, we require that the angle θ used to specify z should be chosen to satisfy $-\pi < \theta \leq \pi$. (We always take $r > 0$, which implies that 0 is not in the domain of the logarithmic function.) We call the resulting complex number $\ln r + i\theta$, $-\pi < \theta \leq \pi$, the *principal value* of the complex logarithmic function. The definition of the complex logarithmic function now becomes unambiguous,

$$\text{Log } z = \ln r + i\theta, \quad -\pi < \theta \leq \pi.$$

If we do not require that θ satisfy $-\pi < \theta \leq \pi$, then we get multiple values for $\ln r + i\theta$. We use $\log z$ to denote this entire collection of values. So $\log z$ denotes all complex numbers w satisfying $e^w = z$. A value of $\log z$ other than the principal value differs from it by a multiple of $2\pi i$. Thus all possible values w for the logarithm of z are related to the principal value by

$$w = \text{Log } z + 2n\pi i, \quad n = 0, \pm 1, \pm 2, \dots$$

EXAMPLE 4 Find all possible values for the logarithm of $1 + i$.

Solution The complex number $1 + i$ is described with polar coordinates $r = \sqrt{2}$, $\theta = \pi/4$ (Figure 18.18). Since $-\pi < \pi/4 \leq \pi$, the principal value $\text{Log}(1 + i)$ is

$$\text{Log}(1 + i) = \ln\sqrt{2} + (\pi/4)i.$$

So the possible values w for the logarithm of $1 + i$ are

$$w = \text{Log}(1 + i) + (2n\pi)i = \ln\sqrt{2} + (\pi/4)i + (2n\pi)i, \quad n = 0, \pm 1, \pm 2, \dots \quad \blacksquare$$

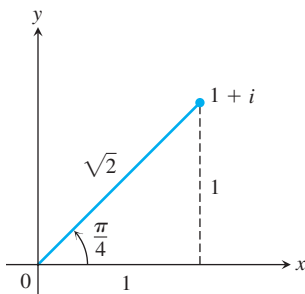

FIGURE 18.18 The polar description of $1 + i$

EXERCISES 18.6

- T** 1. Estimate $e^{(1+i)/\sqrt{2}}$ by using the first four terms of the series expansion for e^z .
2. Express the sines and cosines in the following identity in terms of exponentials and thereby show that

$$\sin(A + B) = \sin(A)\cos(B) + \cos(A)\sin(B)$$

is a consequence of the exponential law $e^{z_1}e^{z_2} = e^{z_1+z_2}$.

3. Establish the following differentiation formulas by differentiating the appropriate series term-by-term.

a. $\frac{de^z}{dz} = e^z$

b. $\frac{d \sin z}{dz} = \cos z$

c. $\frac{d \cos z}{dz} = -\sin z$

d. $\frac{d \operatorname{Arctan} z}{dz} = \frac{1}{1+z^2}$

4. The derivative of a complex-valued function $f(x) = u(x) + iv(x)$ whose input is a real variable x is defined to be $f'(x) = u'(x) + iv'(x)$.

- a. Show that $y = e^{i\omega x}$ and $y = e^{-i\omega x}$ are solutions of the differential equation

$$\frac{d^2y}{dx^2} + \omega^2 y = 0.$$

- b. Show that $y = e^{(a+ib)x}$ and $y = e^{(a-ib)x}$ are solutions of the differential equation

$$\frac{d^2y}{dx^2} + 2a\frac{dy}{dx} + (a^2 + b^2)y = 0.$$

- c. Assuming that a and b are real in part 4(b), show that both

$$e^{ax} \cos bx = \operatorname{Re}(e^{(a+ib)x})$$

and

$$e^{ax} \sin bx = \operatorname{Im}(e^{(a+ib)x})$$

are solutions of the given differential equation.

5. Find values of a such that $y = e^{ax}$ is a solution of the differential equation

a. $\frac{d^2y}{dx^2} + 2\frac{dy}{dx} + 5y = 0,$

b. $\frac{d^4y}{dx^4} + 4y = 0,$

c. $\frac{d^3y}{dx^3} - 8y = 0.$

6. Show that the point $z(t)$ traverses a unit circle with angular velocity ω if $z(t) = e^{i\omega t}$ and ω is a real constant.

7. If x and y are real, show that $|e^{x+iy}| = e^x$.

8. Show that the real and imaginary parts of $w = e^z$ satisfy the Cauchy-Riemann Equations.

9. Show using the relevant series that

a. $\sin(iz) = i \sinh z,$

b. $\cos(iz) = \cosh z.$

10. Show using the results of Exercises 2 and 9 that $\sin(x + iy) = \sin x \cosh y + i \cos x \sinh y$, and find a value of z such that $\sin z = 2$.

11. Show that the real and imaginary parts of $w = \sin z$ in Exercise 10 satisfy the Cauchy-Riemann equations.

12. Show that $|\sin(x + iy)| = \sqrt{\sin^2 x + \sinh^2 y}$ if x and y are real.

13. Let $z = x + iy, w = u + iv,$ and $w = \sin z$. Show that for any nonzero real constant b , the line segment $\{-\pi < x \leq \pi, y = b\}$ in the z -plane maps to the ellipse

$$\frac{u^2}{\cosh^2 b} + \frac{v^2}{\sinh^2 b} = 1$$

in the w -plane.

14. Show that the only complex roots $z = x + iy$ (x and y real) of the equation $\sin z = 0$ are at points on the real axis ($y = 0$) at which $\sin x = 0$.

15. Show that $\cosh(x + iy) = \cosh x \cos y + i \sinh x \sin y$.

16. Show that $|\cosh(x + iy)| = \sqrt{\cos^2 y + \sinh^2 x}$ if x and y are real.

17. If x and y are real and $\cosh(x + iy) = 0$, show that $x = 0$ and $\cos y = 0$.

18. What is the image in the w -plane of a line $x = \text{constant}$ in the z -plane if

a. $w = e^z,$

b. $w = \sin z?$ Sketch.

19. The integral of a complex-valued function of a real variable x , $f(x) = u(x) + iv(x)$, is defined to be $\int f(x) dx = \int u(x) dx + i \int v(x) dx$. Evaluate $\int e^{(a+ib)x} dx$ and by equating real and imaginary parts, obtain formulas for $\int e^{ax} \cos bx dx$ and $\int e^{ax} \sin bx dx$.

Logarithms

20. Find the principal value of $\log z$ for each of the following complex numbers z :

a. $2 - 2i,$

b. $\sqrt{3} + i,$

c. $-4,$

d. $4,$

e. $2i,$

f. $\frac{1+i}{1-i}.$

21. Find all values of $\log z$ for each of the following complex numbers z :

a. $2,$

b. $-2,$

c. $2i,$

d. $-2i,$

e. $i - \sqrt{3}.$

22. Express $w = \tan z$ in terms of exponentials; then solve for z in terms of w and thereby show that

$$\arctan w = \frac{1}{2i} \log \frac{1+iw}{1-iw}.$$

23. a. Show that

$$\arcsin z = -i \log(iz + \sqrt{1-z^2}).$$

- b. Use part (a) to find a complex number z satisfying $\sin z = 3$. Note that since $\sin z = \sin(z + 2\pi)$ there are infinitely many choices for such a z .

24. Sketch the images in the w -plane of the following sets in the z -plane, under the mapping function $w = \ln z$:
- $|z| = \text{constant}$, $-\pi < \arg z < \pi$,
 - $\arg z = \text{constant}$, $0 < |z| < \infty$.
25. Figure 18.19 shows the image under the complex map $f(z) = \text{Log } z$ of a square with vertices at 1 , e , $1 + (e - 1)i$, and $e + (e - 1)i$.
- Find the complex number to which each of the four vertices is mapped.
 - Find parameterizations of the four curves forming the boundary of the image.

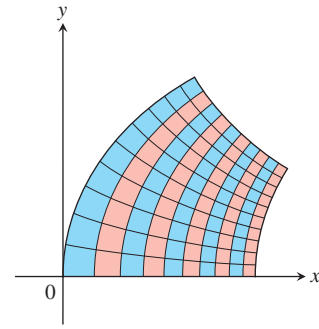

FIGURE 18.19 The map $w = \text{Log } z$ maps a square to this region.

18.7 Conformal Maps

In this section we will introduce the concept of a conformal map. Informally, these maps are functions on open regions in the plane that preserve the angles between curves. There is a close connection between this idea and properties of complex functions. It turns out that complex differentiable functions with nonzero derivative are conformal. This geometric concept plays an important role in many applications.

To measure the angle between two differentiable curves that meet at a point z_0 , we take the angle between their tangent vectors, as we did in Chapter 12. We now look at what a map $f(x, y) = (u(x, y), v(x, y))$ does to such angles. We can compare the angle between two curves $a(t)$ and $b(t)$ intersecting at z_0 with the angle between the two curves $c(t) = f(a(t))$ and $d(t) = f(b(t))$ that they are sent to by f , as in Figure 18.20. When these angles are unchanged for all choices of curves, we say that the map f is *conformal*.

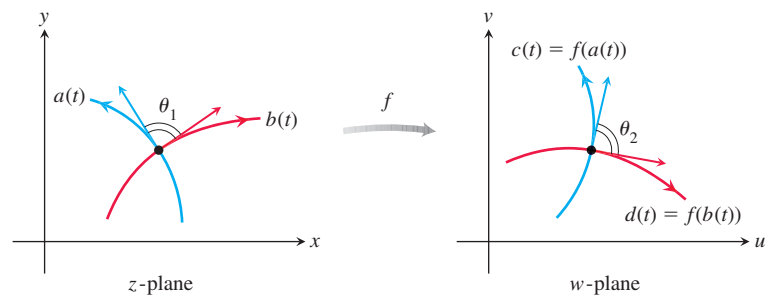

FIGURE 18.20 A conformal map preserves angles, meaning that $\theta_1 = \theta_2$ for any pair of curves in the domain of f .

Intuitively, conformal maps act at infinitesimal scales by stretching or contracting equally in all directions, and by rotating. Since angles are preserved, a conformal map f rotates the tangent vector of all curves through a point z_0 by the same angle. The length of a tangent vector can be changed by a conformal map, but any two tangent vectors are stretched or compressed by the same factor. It is a rather amazing fact, shown in Theorem 3, that all complex differentiable maps have this powerful and useful geometric property wherever their derivative is nonzero.

Figure 18.21 shows the square domain $A = \{(x, y) : 0 < x < 1, 0 < y < 1\}$, which is mapped by $f(z) = z^2$ to the domain B in the complex w -plane.

Blue stripes in A are sent by f to blue stripes in B , and red stripes to red. Notice that the edges of the red and blue stripes in A meet at right angles, as do their images in B . The angle between these curves is preserved. Even though the region A itself is stretched and distorted when mapped to B , the angle between any two curves in A is the same as the angle between the images of these curves in B .

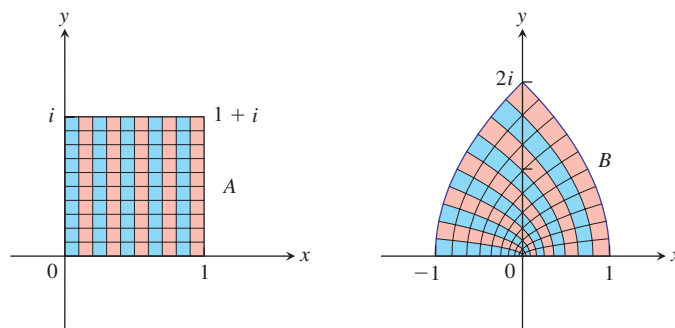

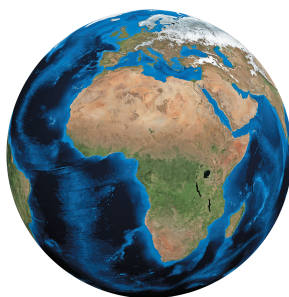

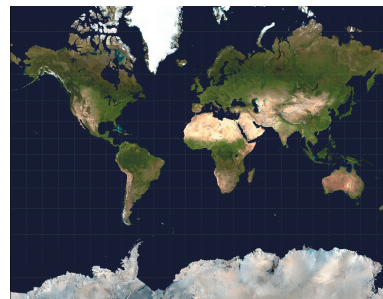

FIGURE 18.21 The map $f(z) = z^2$ takes the perpendicular horizontal and vertical lines in A to perpendicular curves in B . It preserves the angle between any pair of curves, at all points other than $z = 0$.

Cartographers making maps of the earth for navigational purposes made use of conformal maps. The most commonly used method for displaying a map of the earth, the Mercator Projection, shown in Figure 18.22, is conformal. It maps the surface of the earth, cut open from the north to the south pole along a longitude, to a rectangle in the plane. To set a course to a distant port, a navigator could draw a straight line on the Mercator map between their location and the destination. This would give a heading to follow, such as south 10 degrees west, or due east. If they then sailed their ship in that direction, they would follow the line drawn on the map till they reached their goal. This was very useful before the days of GPS. Note that while it preserves angles, the Mercator conformal map distorts lengths, and can give a distorted impression of the size of two regions. Antarctica and Greenland appear large relative to regions near the equator in this representation.

Qimono/Pixabay

NASA

FIGURE 18.22 The Mercator projection preserves angles, but distorts area. Regions near the poles are highly stretched.

Since they preserve angles, conformal maps give an accurate representation of shapes at a small scale. This makes them useful for computer graphics, shape recognition, alignment algorithms, and many other applications. Conformal maps also have many uses in solving problems in electromagnetism and heat distribution.

To compute angles between two curves, we use their tangent vectors. If $a(t) = (x(t), y(t))$ is a curve with $a(0) = (x_0, y_0)$ and $a'(0) \neq 0$, the vector $a'(0) = \langle x'(0), y'(0) \rangle$ gives the tangent vector. A second curve $b(t)$ has tangent vector $b'(0)$ at the point (x_0, y_0) . The angle between these two vectors at z_0 gives the angle between the two curves.

A complex-valued map f whose domain includes a disk around $z_0 = x_0 + iy_0$ maps $a(t)$ to a new curve, $c(t) = f(a(t))$, with tangent vector $c'(0)$ at $f(z_0)$. Similarly $d(t) = f(b(t))$ has tangent vector $d'(0)$ at $f(z_0)$. We can compare the angle between the vectors $c'(0)$ and $d'(0)$ at $f(z_0)$ with the angle between $a'(0)$ and $b'(0)$ at z_0 . In general there is no reason to expect these angles to be the same. However when f is a complex differentiable map and $f'(z_0) \neq 0$, then it turns out that these angles are indeed equal, no matter which point z_0 and which curves a and b are considered. Theorem 3 explains why this is true.

THEOREM 3 Suppose that a map $f = u + iv$ is complex differentiable and $f'(z) \neq 0$ on a domain A . Then f is conformal.

Proof We will show that f preserves the angle between the tangent vectors of any pair of differentiable curves. Suppose that $a(t)$ and $b(t)$ are two differentiable curves with $a(0) = b(0) = z_0$ and that their tangent vectors meet at an angle α . Take a_r to be a point on $a(t)$, $t > 0$, that has distance r from z_0 , and pick b_r to be a point on $b(t)$ at the same distance r from z_0 . Then we can write

$$a_r - z_0 = re^{i\theta_1} \quad \text{and} \quad b_r - z_0 = re^{i\theta_2}.$$

The quotient satisfies

$$\frac{a_r - z_0}{b_r - z_0} = e^{i(\theta_1 - \theta_2)}.$$

As $r \rightarrow 0$, the angle $\theta_1 - \theta_2$ approaches the angle α between the tangent vectors to the two curves,

$$\alpha = \lim_{r \rightarrow 0} \arg \left(\frac{a_r - z_0}{b_r - z_0} \right).$$

Set $c(t)$ and $d(t)$ to be the images of $a(t)$ and $b(t)$ under f so that this pair of curves intersects at $f(z_0)$.

The angle β at which $c(t)$ and $d(t)$ intersect at $f(z_0)$ is

$$\beta = \lim_{r \rightarrow 0} \arg \left(\frac{f(a_r) - f(z_0)}{f(b_r) - f(z_0)} \right)$$

as this limit gives the angle between tangent vectors to the two image curves. We can rewrite this limit as

$$\begin{aligned} \beta &= \lim_{r \rightarrow 0} \arg \left(\frac{f(a_r) - f(z_0)}{f(b_r) - f(z_0)} \right) \\ &= \lim_{r \rightarrow 0} \arg \left(\frac{\left(\frac{f(a_r) - f(z_0)}{a_r - z_0} \right)}{\left(\frac{f(b_r) - f(z_0)}{b_r - z_0} \right)} \right) \left(\frac{a_r - z_0}{b_r - z_0} \right). \end{aligned}$$

As $r \rightarrow 0$ we have

$$\lim_{r \rightarrow 0} \frac{f(a_r) - f(z_0)}{a_r - z_0} = f'(z_0) \quad \text{and} \quad \frac{f(b_r) - f(z_0)}{b_r - z_0} = f'(z_0)$$

since the complex derivative can be computed as we approach z_0 from any direction. We assumed $f'(z_0) \neq 0$, so we can cancel these terms. Then

$$\beta = \lim_{r \rightarrow 0} \arg \left(\frac{a_r - z_0}{b_r - z_0} \right).$$

This is the same as the formula giving α , so the two angles are equal. ■

EXAMPLE 1 Conformal maps of a square

We consider the square $\{0 < x < 1, 0 < y < 1\}$, shown in Figure 18.23a, and its image under three conformal maps:

The image under the map $f(z) = \sin z$ is shown in Figure 18.23b.

The image under the map $f(z) = \cos z$ is shown in Figure 18.23c.

The image under the map $f(z) = \text{Arctan } z$ is shown in Figure 18.23d.

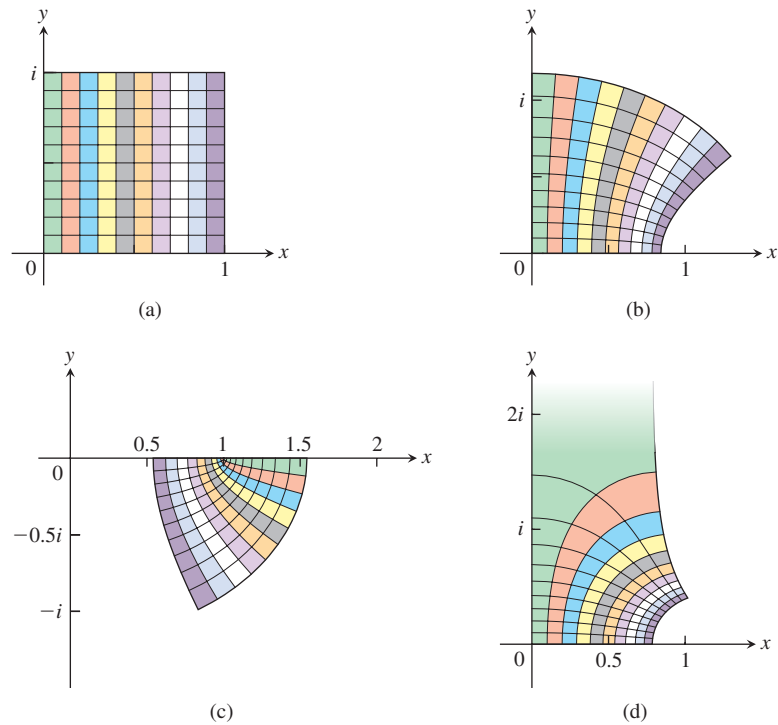

FIGURE 18.23 Conformal images of (a) a square region divided into ten vertical stripes under the conformal maps (b) $\sin z$, (c) $\cos z$, and (d) $\text{Arctan } z$.

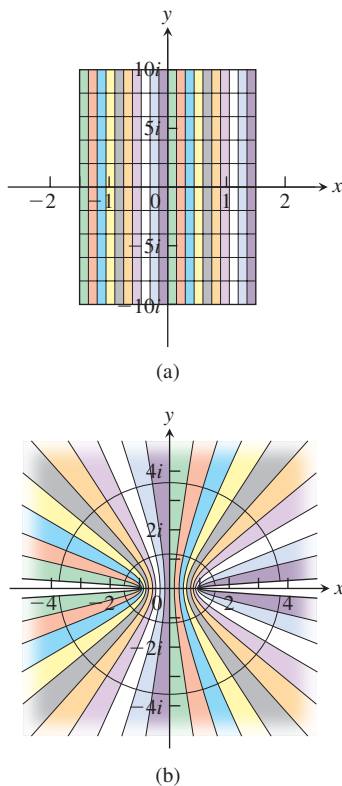

FIGURE 18.24. (a) A rectangle divided into 20 vertical stripes and (b) its image under the conformal map $f(z) = \sin z$

Only part of the image of the vertical green stripe in the square is shown in Figure 18.23d. As $z \rightarrow i$ the values of $\text{Arctan } z$ diverge, and $\text{Arctan } z$ is not defined at $z = i$. The image of the green stripe is not bounded. This illustrates that conformal maps can stretch bounded domains such as the square to unbounded domains.

Since these maps are conformal, the images of perpendicular, vertical, and horizontal lines in the square remain perpendicular in the image. In fact, all angles between pairs of curves are preserved by these conformal maps. ■

In Example 1 we see three regions in the plane that are the images of a square under a conformal map. It turns out that these types of region are not so special, and *any* simply connected open region in the plane is the image of an open square under a conformal map, with one exception. The exception is the entire complex plane. The existence of a conformal map between any other pair of simply connected open regions is given by the Riemann Mapping Theorem, a deep result from the theory of conformal maps.

EXAMPLE 2 The sine function $f(z) = \sin(z)$ has nonzero derivative when restricted to the rectangle $\{-1.5 < x < 1.5, -10 < y < 10\}$, shown in Figure 18.24a. The image of this rectangle lying within the square $\{-2.5 < x < 2.5, -2.5 < y < 2.5\}$ is shown in Figure 18.24b. If the rectangle is enlarged to the infinite rectangle $\{-\pi/2 < x < \pi/2, -\infty < y < \infty\}$, then its image under the sine function fills up the entire complex plane except for two “slits”, the intervals $(-\infty, -1]$ and $[1, \infty)$ on the x -axis.

EXERCISES 18.7

- Does the map $f(z) = z^2$ preserve the angles between the intersecting lines $y = 0$ and $y = x$? How does this fit into Theorem 3?
- For which z is the map $f(z) = e^z$ conformal?
- For which z is the map $f(z) = z^3$ conformal? What happens to angles at points where it is not conformal?
- For the map $f(x, y) = (2x, y)$, compute the angle of intersection of the images under f of the horizontal line $\{x = 1\}$ and the vertical line $\{y = 1\}$. Is this map conformal?
- Is the map $f(x, y) = (x, x + y)$ conformal? If not, find two intersecting curves whose angles are not preserved by f .
- Show that the map $f(z) = (z - i)/(z + i)$ is a conformal map from the upper half-plane $\{(x, y): y > 0\}$ to the open unit disk $\{(x, y): x^2 + y^2 < 1\}$. A deep result, the Riemann Mapping Theorem, shows that this is not unusual. Any simply connected region in the plane can be conformally mapped to the open unit disk, with the exception of the entire complex plane.
- Find the angle by which a curve through the point z_0 is rotated by the map $f(z) = z^2$ if **a.** $z_0 = 1$, **b.** $z_0 = i$, **c.** $z_0 = 1 + i$, **d.** $z_0 = -i$, **e.** $z_0 = 2i$, and **f.** $z_0 = -1$.
- The *conformal factor* of f at z_0 is the amount by which it stretches tangent vectors. Where is the conformal factor of $f(z) = z^2$ smaller than one?
- Given two complex numbers a and b , the map $f(z) = az + b$ rotates all vectors by the same angle. What is this angle?
- Given two complex numbers a and b , the map $f(z) = az + b$ stretches all vectors by the same factor. What is this factor?
- The most basic conformal maps have the form $f(z) = az + b$. Show that such a map is conformal when $a \neq 0$. When a is not real show that f has a fixed point z_0 satisfying $f(z_0) = z_0$. If $a = 1$ and $b \neq 0$, show that f does not have a fixed point.
- What is the fixed point in Exercise 11 when **a.** $f(z) = 3z + i$, **b.** $f(z) = (1 + i)z + 4 - 2i$?

CHAPTER 18 Questions to Guide Your Review

- Define the set of complex numbers.
- Define, for complex numbers, the concepts of equality, addition, multiplication, and division.
- A set of numbers is said to be *closed* under an operation \otimes if $a \otimes b$ is in the set whenever a and b are. Is the set of complex numbers closed under the operations of addition, subtraction, multiplication, division, and raising to a power (including complex exponents)? (Be careful to consider all complex numbers in formulating your answer, including 0.)
- How may the complex number $a + ib$ be represented graphically in the complex plane?
- Illustrate in the complex plane how the absolute values and arguments of the product and quotient of two complex numbers z_1 and z_2 are related to the absolute values and the arguments of z_1 and z_2 .
- State De Moivre's theorem and explain how to find the n distinct complex n th roots of a nonzero complex number $a + ib$.
- Prove that if n is an even positive integer, then $\cos n\theta$ may be expressed as a polynomial with integer coefficients, in $\cos^2 \theta$. (Example: $\cos 2\theta = 2\cos^2 \theta - 1$.)
- Using vectors in the complex plane, illustrate geometrically how to find the n complex n th roots of any complex number $a + ib$.
- Using the complex plane, illustrate geometrically how the conjugate and the reciprocal of a complex number $a + ib$ are related to that number.
- If z is a complex number such that $z = \bar{z}$, what else can you conclude about z ?
- If z is a complex number such that $z = -\bar{z}$, what else can you conclude about z ?
- Describe the sets of complex numbers z satisfying the following equalities or inequalities, where $z_0 = a + ib$ is a given complex number and k is a positive real constant.
 - $|z - z_0| = k$,
 - $|z - z_0| < k$,
 - $|z - z_0| > k$.
- Define the concept of continuity for a function of a complex variable z . Define the derivative of f at $z = a + ib$.
- What are the Cauchy-Riemann Equations and when are they known to be satisfied?
- Define the convergence of a series of complex numbers.
- How do we define e^z , $\sin z$, $\cos z$, and $\tan z$ for a complex number $z = a + ib$?
- What is a conformal map and what is its relationship to a complex differentiable map?

CHAPTER 18 Additional and Advanced Exercises

1. Let $z = 2 - 2i$.
 - a. Plot the points z , \bar{z} , and z^2 .
 - b. Plot the three complex cube roots of z^2 (that is, $z^{2/3}$).
2. Express each of the following complex numbers in the form $re^{i\theta}$ with $r \geq 0$ and $-\pi < \theta \leq \pi$. Sketch
 - a. $(1+i)(1-i\sqrt{3})^2$,
 - b. $\sqrt[3]{2-2i}$ (three answers).
3. Express the four 4th roots of $-16i$ in the form $a + bi$.
4. a. Solve the equation $z^4 + 16 = 0$, obtaining four distinct roots.
 b. Express the five roots of the equation $z^5 + 32 = 0$ in polar form.
5. a. Find all complex numbers z such that $z^4 + 1 + i\sqrt{3} = 0$.
 b. Express the number $e^{2+\pi i/4}$ in the form $a + bi$.
6. Plot the complex number $2 - 2\sqrt{3}i$ in the complex plane and find
 - a. its two square roots,
 - b. the principal value of its logarithm.
7. Find the values of r and θ such that $3 + 4i = re^{i\theta}$.
8. If $z = 3 - 3i$, find all values of $\log z$.
9. Find a complex number $a + ib$ that satisfies the equation

$$e^{a+ib} = 1 - i\sqrt{3}.$$
10. Express the following in the form $a + bi$:
 - a. $(-1 - i)^{1/3}$ (write down all the roots).
 - b. $\log(3 + i\sqrt{3})$. (There are infinitely many possible answers. Give an answer that expresses all of these.)
 - c. $e^{2+\pi i}$.
11. Let $f(z) = \bar{z}$ (the conjugate of z).
 - a. Study the behavior of the quotient

$$\frac{f(z) - f(z_1)}{z - z_1}$$
 when $z \rightarrow z_1$ along straight lines of slope m .
 b. From the results of **part (a)** what can you conclude about the derivative of $f(z)$?
12. If $f(z) = \sum_{n=0}^{\infty} a_n z^n$ and $f(\bar{z}) = \overline{f(z)}$, for $|z| < R$, show that the a_n are real.
13. If $f(z) = \sum_{n=0}^{\infty} a_n z^n$ and $f(\bar{z}) = f(z)$, for $|z| < R$, show that $f(z)$ is a constant.
14. Show that $\frac{d^n}{d\theta^n}(\cos \theta + i \sin \theta) = i^n(\cos \theta + i \sin \theta)$.
15. Draw the set of points in the complex plane that satisfy
 - a. $\operatorname{Re}(z) > 0$,
 - b. $\operatorname{Im}(z) = 2, (z - i) \leq 0$,
 - c. $\left| \frac{z-i}{z+i} \right| < 1$,
 - d. $|e^z| \geq 1$,
 - e. $|\sin z| \leq 1$.
16. If $u(x, y)$ and $v(x, y)$ are the real and imaginary parts of a complex differentiable function of $z = x + iy$, show that the family of curves $u = \text{constant}$ is orthogonal (perpendicular) to the family $v = \text{constant}$ at every point of intersection where $f'(z) \neq 0$.
17. Given that $z = e^{\operatorname{Log} z}$ and $(e^{z_1})^{z_2} = e^{z_1 z_2}$, how would you compute z^w for complex numbers z and w ? Compute z^w for $z = 1 + i, w = 2i$.

ANSWERS TO ODD-NUMBERED EXERCISES

Chapter 18

SECTION 18.1, pp. 18-9-18-10

- (a) $14 + 8i$ (b) $-7 - 4i$ (c) $-5i$
- (a) By reflecting z across the real axis
(b) By reflecting z across the imaginary axis
(c) By reflecting z through the origin, or equivalently, rotating it by 180 degrees.
(d) By reflecting z across the real axis and then multiplying the length of the vector by $1/|z|^2$
- (a) Points on the circle $x^2 + y^2 = 4$
(b) Points inside the circle $x^2 + y^2 = 4$
(c) Points outside the circle $x^2 + y^2 = 4$
- Points on a circle of radius 1, center $(-1, 0)$
- Points on the line $y = -x$ 11. $4e^{2\pi i/3}$ 13. $1e^{2\pi i/3}$
- $\cos^4 \theta - 6 \cos^2 \theta \sin^2 \theta + \sin^4 \theta$
- $1, -\frac{1}{2} \pm \frac{\sqrt{3}}{2}i$ 19. $2i, -\sqrt{3} - i, \sqrt{3} - i$
- $\frac{\sqrt{6}}{2} \pm \frac{\sqrt{2}}{2}i, -\frac{\sqrt{6}}{2} \pm \frac{\sqrt{2}}{2}i$ 23. $1 \pm \sqrt{3}i, -1 \pm \sqrt{3}i$

SECTION 18.2, p. 18-17

- (a) $|w| = 1, 0 \leq \arg w \leq 2\pi$
(b) $|w| = 4, \pi \leq \arg w \leq 2\pi$
(c) $\arg w = \pi/2$
(d) $|w| < 1, -2\pi < \arg w \leq 0$
(e) The u -axis, $u \geq 0$
(f) The u -axis, $u \leq 0$

SECTION 18.3, p. 18-20

- $\frac{-2}{(z_0 - 1)^2} = +2$
- $f'(z_0) = \frac{z_0}{\sqrt{z_0^2 + 1}}$, which gives two values;
 $\frac{1}{\sqrt[3]{2}} \exp\left(\frac{\pi}{8}i\right)$ and $\frac{1}{\sqrt[3]{2}} \exp\left(\frac{9\pi}{8}i\right)$.

SECTION 18.4, p. 18-22

- $u = x^2 - y^2, v = 2xy$
- $u = x^4 - 6x^2y^2 + y^4, v = 4x^3y - 4xy^3$

SECTION 18.5, p. 18-25

- $|z| < 1$ 3. $|z - 1| < 1$ 5. $|z + 1| < 2$
- $0.208 + 0.298i$

SECTION 18.6, pp. 18-30-18-31

- $1.59 + 1.32i$
- (a) $-1 \pm 2i$ (b) $1 \pm i, -1 \pm i$ (c) $2, -1 \pm i\sqrt{3}$
- $\int e^{ax} \cos bx \, dx = \frac{e^{ax}}{a^2 + b^2}(a \cos bx + b \sin bx) + C$
 $\int e^{ax} \sin bx \, dx = \frac{e^{ax}}{a^2 + b^2}(a \sin bx - b \cos bx) + C$
- (a) $\ln 2 + 2n\pi i$
(b) $\ln 2 + (2n + 1)\pi i$
(c) $\ln 2 + (2n + \frac{1}{2})\pi i$
(d) $\ln 2 + (2n - \frac{1}{2})\pi i$
(e) $\ln 2 + (2n + \frac{5}{6})\pi i$,
($n = 0, \pm 1, \pm 2, \dots$)
- (b) $\left(\frac{\pi}{2} + 2n\pi\right) - i \ln(3 + 2\sqrt{2})$

SECTION 18.7, p. 18-35

- No. The angle between the lines is 90° , but the angle between their images is 180° . This is the case in Theorem 3 where $f'(z_0) = 0$.
- All $z \neq 0$ since $f'(z) \neq 0$ except at $z = 0$ and f is analytic. At $z = 0$ angles multiply by 3.
- No. The angle between $y = 0$ and $x = 0$ is $\pi/2$. These two lines are taken by f to $y = x$ and $x = 0$, which intersect at an angle of $\pi/4$.
- (a) 0 (b) $\pi/2$ (c) $\pi/4$ (d) $3\pi/2$ (e) $\pi/2$ (f) π
- $\arg a$ 11. $z_0 = b/(1 - a)$

ADDITIONAL AND ADVANCED EXERCISES, p. 18-36

- (a) $\pm(\sqrt{2 + \sqrt{2}} - i\sqrt{2 - \sqrt{2}})$, $\pm(\sqrt{2 - \sqrt{2}} + i\sqrt{2 + \sqrt{2}})$
(b) $\sin^{-1} 5 = 2n\pi + \pi/2 - i \ln(5 + \sqrt{24})$,
($n = 0, \pm 1, \pm 2, \dots$)
- (a) $2^{1/4} e^{in(2+3n)/6}$ ($n = 0, 1, 2, 3$) (b) $e^2/\sqrt{2} + i(e^2/\sqrt{2})$
- $r = 5, \theta = \tan^{-1} \frac{4}{3}$ 9. $\ln 2 - i\pi/3$
- (b) Derivative doesn't exist.

Fourier Series and Wavelets

BIOGRAPHY

Jean-Baptiste Joseph Fourier (1768–1830)

Fourier was a French mathematician, who as a young boy aspired to become an army officer. He was denied that opportunity for military service and, therefore, switched his passion to mathematics.

To know more, visit the companion Website.

In Section 9.8 we saw that if a function f has derivatives $f^{(k)}$ of order $k = 1, 2, \dots, n$, then we can create a polynomial function P_n that approximates f near a chosen point. This *Taylor polynomial* gives a close fit to f near that particular point, but the error in the approximation can be large at points that are far away. In this chapter we will introduce *Fourier series*, which provide a way to approximate a function over an interval, rather than near a single point. Instead of involving polynomials, a Fourier series approximation is a sum of multiples of the functions $\sin kx$ and $\cos kx$. In a sense that we will describe, a Fourier series approximation minimizes an error that is distributed over an interval. Additionally, while Taylor polynomials cannot be used to approximate discontinuous functions, Fourier series approximations will often be applicable to such functions.

Fourier series, introduced by Joseph Fourier, are well-suited to analyzing periodic functions, such as radio signals and alternating currents. They can also be used to solve heat transfer problems; indeed, this was the problem that motivated Fourier. A large field of mathematics called *harmonic analysis* began with Fourier series. Fourier series and harmonic analysis have applications to electrical engineering, acoustics, optics, signal processing, image processing, quantum mechanics, econometrics, and many other areas in science and engineering.

19.1 Periodic Functions

For some periodic functions, such as the constant function $f(x) = 1$, there is no smallest $P > 0$ such that $f(x + P) = f(x)$ for every x .

Let f be a function whose domain is the real line. We say that f is **periodic** if there is a positive real number P such that $f(x + P) = f(x)$ for every real number x . In Section 1.3 we defined the period of f to be the smallest such number P . In this chapter we will call the smallest P the **fundamental period** of f , and say that any other positive number P that satisfies $f(x + P) = f(x)$ for every x is a **period** for f . We will focus in this chapter on functions with period $P = 2\pi$, but it is not difficult to adapt to other periods.

EXAMPLE 1

- (a) The function $f(x) = \sin x$ is periodic with period 2π because for every real number x we have

$$f(x + 2\pi) = \sin(x + 2\pi) = \sin x = f(x).$$

Likewise, $\cos x$ is periodic with period 2π , and 2π is the fundamental period for both functions.

- (b) Let k be any positive integer. Then the function $g(x) = \sin kx$ has period $2\pi/k$ because if x is any real number, then

$$g\left(x + \frac{2\pi}{k}\right) = \sin\left[k\left(x + \frac{2\pi}{k}\right)\right] = \sin(kx + 2\pi) = \sin kx = g(x).$$

The number $2\pi/k$ is the fundamental period of g , but it is not the only period. Any positive integer multiple of $2\pi/k$ is also a period. For example, 2π is a period for g because for every x we have

$$g(x + 2\pi) = \sin[k(x + 2\pi)] = \sin(kx + 2\pi k) = \sin kx = g(x).$$

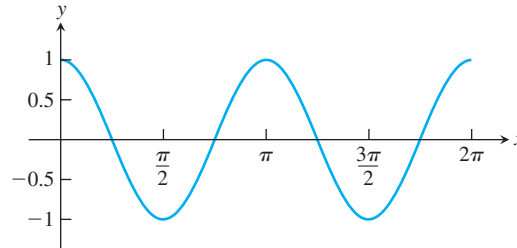

Similarly, $g(x) = \cos kx$ has fundamental period $2\pi/k$, and it is also periodic with period 2π .

- (c) We will let $\mathbf{1}$ denote the constant function that takes the value 1 at every point:

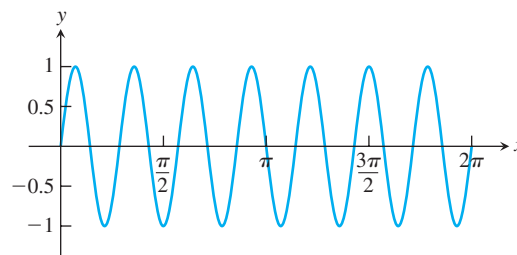

$$\mathbf{1}(x) = 1 \quad \text{for every real number } x.$$

The function $\mathbf{1}$ is periodic, and every positive real number P is a period. There is no smallest period P , so $\mathbf{1}$ does not have a fundamental period. ■

We will use the functions $\sin kx$ and $\cos kx$, along with the constant function $\mathbf{1}$, to define the Fourier series approximation of a function. Each of these functions is periodic with period 2π . The oscillatory nature of these functions is one reason that they are well-suited for forming approximations. We say that $\sin kx$ and $\cos kx$ have **frequency** k , because their graphs show k complete oscillations within the interval $[0, 2\pi]$ (Figure 19.1). Since $\cos 0x = 1 = \mathbf{1}(x)$ for every x , we say that the constant function $\mathbf{1}$ has **frequency zero**. We introduce a name for this set of functions.

(a) Graph of $\cos 2x$ over the interval $[0, 2\pi]$

(b) Graph of $\sin 7x$ over the interval $[0, 2\pi]$

FIGURE 19.1 Two functions in the trigonometric system.

DEFINITION The collection of functions

$$\mathbf{1}, \cos x, \sin x, \cos 2x, \sin 2x, \cos 3x, \sin 3x, \dots$$

is called the **trigonometric system**.

EXERCISES 19.1

Periodic Functions

In Exercises 1–6, determine whether the given function is periodic. If it is, find its fundamental period P .

1. $1 + \sin x$
2. x
3. $|x|$
4. $e^{\cos x}$
5. $\sin^2 x \cos x$
6. $\sin x^2$

Theory and Examples

7. Show that if $f(x)$ and $g(x)$ are both periodic with the same period P , then the following functions are also periodic with period P .
 - a. $f(x) + g(x)$
 - b. $cf(x)$, where c is a real number

c. $f(x)g(x)$

d. $e^{f(x)}$

8. **Periodic extension** Suppose that the values of $f(x)$ are specified for $0 \leq x < 2\pi$. Then for each $0 \leq x < 2\pi$ and every nonzero integer k , define $f(x + 2k\pi) = f(x)$. Show that this extends the definition of f to the entire real line, and that the resulting function is periodic with period 2π .

19.2 Summing Sines and Cosines

We discussed *Taylor series* and *Taylor polynomials* in Section 9.8. If a function f has derivatives of order k for $k = 1, 2, \dots, n$ then the **Taylor polynomial of order n** at $x = 0$ is

$$P_n(x) = a_0 + a_1x + a_2x^2 + \cdots + a_nx^n \quad \text{where } a_k = \frac{f^{(k)}(0)}{k!}.$$

By choosing the coefficients a_k in this way we obtain a polynomial P_n that approximates f near the point $x = 0$.

Taylor series are based on the functions $1, x, x^2, x^3, \dots$, while Fourier series are instead based on sines and cosines. Just as a Taylor polynomial is a combination of finitely many of the functions $1, x, x^2, x^3, \dots$, we seek a combination of finitely many elements of the trigonometric system that will approximate a function. We refer to such a finite combination of sines and cosines as a **trigonometric polynomial**.

EXAMPLE 1 Define a periodic function f by letting its values on the interval $[0, 2\pi]$ be

$$f(x) = \begin{cases} x - \pi, & 0 \leq x < 2\pi, \\ -\pi, & x = 2\pi, \end{cases} \quad (1)$$

and then let those values repeat every 2π units (Figure 19.2). This gives us a function f that is periodic on the real line with period 2π . Observe that f has a jump discontinuity at $x = 2\pi k$ for every integer k .

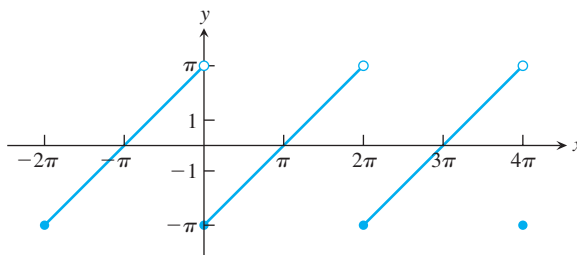

FIGURE 19.2 Graph of the periodic function f defined in Equation (1) over the interval $[-2\pi, 4\pi]$

We would like to approximate f by a trigonometric polynomial, which is a sum of finitely many multiples of the functions in the trigonometric system (the real number that we multiply $\mathbf{1}$ or $\sin kx$ or $\cos kx$ by is called the **amplitude** of that term). We cannot do a very good job using only one function from the trigonometric system (see Figure 19.3a, which compares the graphs of f and $-2 \sin x$). However, we can make a better approximation by using more elements of the trigonometric system. Figure 19.3b shows a trigonometric polynomial that is a sum of two scaled sines, while Figure 19.3c shows that we can do a better approximation using a sum of three scaled sines. As seen in Figure 19.3d, a certain combination of 9 terms gives us a trigonometric polynomial that appears to be a good approximation over most of the domain, though still not close at points near integer multiples of 2π . If we use yet more terms, we can improve the approximation. In particular, the trigonometric polynomial

$$p_n(x) = -2 \sin x - \sin 2x - \frac{2}{3} \sin 3x - \cdots - \frac{2}{n} \sin nx \quad (2)$$

is a good approximation to f using a sum of n sines. We will explain below how we knew what amplitudes to choose for the sines in this sum, and why no cosine terms are used. ■

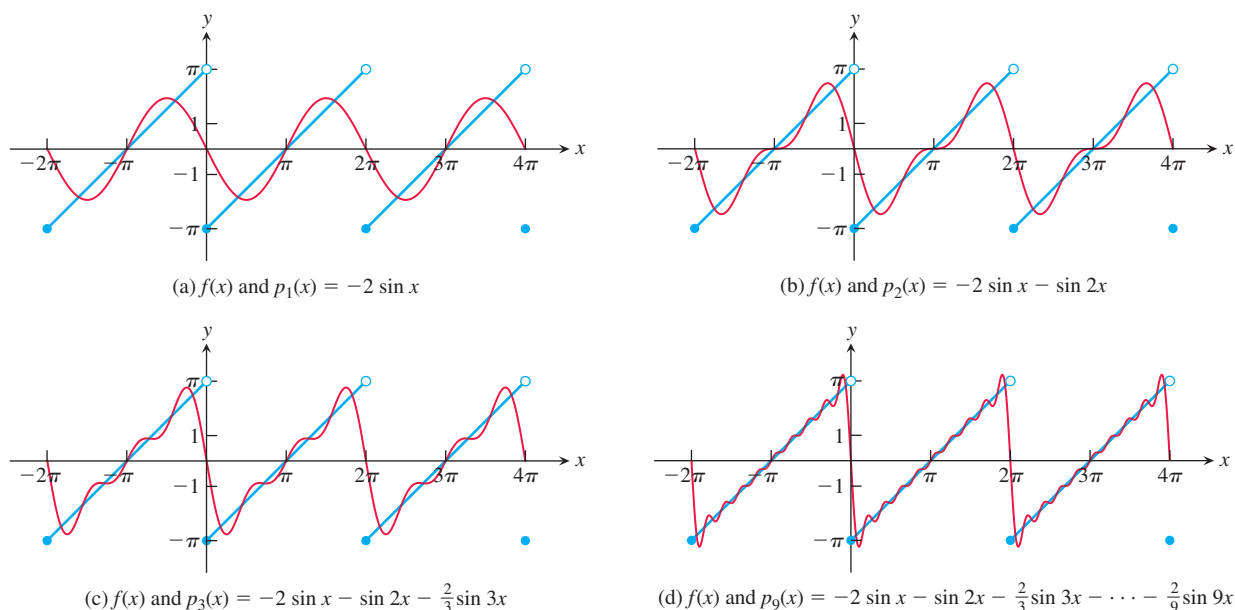

FIGURE 19.3 Trigonometric polynomial approximations to the function f defined in Equation (1) over the interval $[-2\pi, 4\pi]$, using sums of scaled sines.

We see in Example 1 that we can closely approximate a particular function over most of the interval $[0, 2\pi]$ by using sines and cosines from the trigonometric system (for that function we only needed sines). We would like to approximate other functions in a similar way. Given a function f that has period 2π , we seek a function

$$p_n(x) = a_0 + a_1 \cos x + a_2 \cos 2x + \cdots + a_n \cos nx + b_1 \sin x + b_2 \sin 2x + \cdots + b_n \sin nx \quad (3)$$

that approximates f across the interval $[0, 2\pi]$. We refer to p_n as a **trigonometric polynomial** (Exercises 5–18 will explain why we use the word “polynomial” in this context). We say that a_k is the amplitude of the term $a_k \cos kx$, and similarly b_k is the amplitude of the term $b_k \sin kx$. Since $a_0 = a_0 \cos 0x$, this number is the amplitude of the zero frequency term. Recalling the constant function $\mathbf{1}$, which satisfies $\mathbf{1}(x) = 1$ for every x , we have $a_0 = a_0 \mathbf{1}(x)$. Thus we also say that a_0 is the amplitude of the constant term in the sum in Equation (3).

We can write Equation (3) more succinctly using sigma notation:

$$p_n(x) = a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx. \quad (4)$$

We will show how to choose the amplitudes a_k and b_k so that p_n is the “best approximation” to f that is a sum of constant multiples of the constant function, the n cosines $\cos x$, $\cos 2x$, ..., $\cos nx$ and the n sines $\sin x$, $\sin 2x$, ..., $\sin nx$. To do this, we will demonstrate how to approximate vectors in three and higher dimensions in Section 19.3, and then show in Section 19.4 that ideas that work for approximating vectors by other vectors also work for functions.

EXERCISES 19.2

Theory and Examples

- Show that a function of the form $p_n(x) = \sum_{k=1}^n b_k \sin kx$ is odd, that is, $p_n(-x) = -p_n(x)$ for every x .
- Show that a function of the form $p_n(x) = a_0 + \sum_{k=1}^n a_k \cos kx$ is even, that is, $p_n(-x) = p_n(x)$ for every x .

Sums of Sines and Cosines

In Exercises 3 and 4, the values of a_0 , a_k , and b_k that define a trigonometric polynomial $p_n(x) = a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx$ are given. Use a CAS to plot p_n for various values of n over the domain $[-2\pi, 4\pi]$. Does it appear that $p_n(x)$ is converging to some limit function $f(x)$ as n increases? If so, what function? Is the convergence “fast” (the limit is apparent even for small values of n) or “slow” (you must use a large value of n before the graph of p_n appears to be close to the graph of f)?

- T** 3. $a_0 = \frac{\pi}{2}$, $a_{2k-1} = \frac{4}{(2k-1)^2\pi}$, $a_{2k} = 0$, $b_k = 0$
- T** 4. $a_0 = \frac{1}{2}$, $a_{2k-1} = (-1)^k \frac{2}{(2k-1)\pi}$, $a_{2k} = 0$, $b_k = 0$

Complex Numbers and Trigonometric Polynomials

The exercises below illustrate the connection between trigonometric polynomials and complex polynomials in the variable $z = e^{ix}$. Some knowledge of complex numbers is required. In particular, we will use **Euler’s Formula** $e^{ix} = \cos x + i \sin x$ and **De Moivre’s Theorem**,

$$e^{inx} = (\cos x + i \sin x)^n = \cos nx + i \sin nx, \quad n \geq 0,$$

which are derived in Chapter 18, and we will use the fact that $(z^m)^n = z^{mn}$. These exercises will show that trigonometric polynomials equal “generalized” polynomials

$$a_n z^n + \cdots + a_1 z + a_0 + a_{-1} z^{-1} + \cdots + a_{-n} z^{-n}$$

that use both positive and negative powers of $z = e^{ix}$ with complex numbers a_k .

Prove the identities stated in Exercises 5–18. We assume that $z = e^{ix}$ where x is a real number.

- $z^0 = 1$
- $z + 1 + i = (1 + \cos x) + i(1 + \sin x)$
- $2z^2 + 3z - 5 = (2 \cos 2x + 3 \cos x - 5) + i(2 \sin 2x + 3 \sin x)$
- $\sum_{k=0}^n a_k z^k = a_0 + \sum_{k=0}^n a_k \cos kx + i \sum_{k=0}^n a_k \sin kx$
- $z^{-1} = e^{-ix} = \cos x - i \sin x$
- $z^{-n} = e^{-inx} = \cos nx - i \sin nx, \quad n \geq 0$
- $z + z^{-1} = 2 \cos x$
- $z - z^{-1} = 2i \sin x$
- $z^n + z^{-n} = 2 \cos nx, \quad n \geq 0$
- $z^n - z^{-n} = 2i \sin nx, \quad n \geq 0$
- $2z^2 + 3z - 5 + 3z^{-1} + 2z^{-2} = 4 \cos 2x + 6 \cos x - 5$
- $4iz^2 - 2iz + 2iz^{-1} - 4iz^{-2} = -8 \sin 2x + 4 \sin x$
- $\cos x + 2 \sin x - 3 = (0.5 - i)z - 3 + (0.5 + i)z^{-1}$
- $2 \cos 3x - 6 \cos 2x + 8 \sin 3x - 5 = (1 - 4i)z^3 - 3z^2 - 5 - 3z^{-2} + (1 + 4i)z^{-3}$

19.3 Vectors and Approximation in Three and More Dimensions

Vectors in two and three dimensions were introduced in Chapter 11. If \mathbf{v} is a three-dimensional vector equal to the vector with initial point at the origin and terminal point (v_1, v_2, v_3) , then the *component form* of \mathbf{v} is

$$\mathbf{v} = \langle v_1, v_2, v_3 \rangle.$$

Vectors in Three Dimensions

We review some definitions and facts about vectors in three dimensions.

DEFINITION

1. The **length** of a vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is

$$|\mathbf{v}| = \sqrt{v_1^2 + v_2^2 + v_3^2}.$$

If $|\mathbf{v}| = 1$, then we say that \mathbf{v} is a **unit vector**.

2. The **distance** between two vectors $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is

$$|\mathbf{u} - \mathbf{v}| = \sqrt{(u_1 - v_1)^2 + (u_2 - v_2)^2 + (u_3 - v_3)^2}.$$

Observe that $|\mathbf{u} - \mathbf{v}| = |\mathbf{v} - \mathbf{u}|$.

DEFINITION The **dot product** of $\mathbf{u} = \langle u_1, u_2, u_3 \rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is the number

$$\mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + u_3v_3.$$

An important fact is that the length squared of a vector equals the dot product of the vector with itself:

$$|\mathbf{v}|^2 = v_1^2 + v_2^2 + v_3^2 = \mathbf{v} \cdot \mathbf{v}.$$

Some other properties of dot products and lengths are laid out in Exercises 21–30.

Theorem 1 in Section 11.3 shows that the dot product of two nonzero vectors satisfies

$$\mathbf{u} \cdot \mathbf{v} = |\mathbf{u}||\mathbf{v}|\cos\theta,$$

where θ is the angle between \mathbf{u} and \mathbf{v} . If \mathbf{u} and \mathbf{v} are perpendicular then $\theta = \pi/2$ and therefore $\mathbf{u} \cdot \mathbf{v} = 0$. The converse is also true. That is, if \mathbf{u} and \mathbf{v} are nonzero vectors with $\mathbf{u} \cdot \mathbf{v} = |\mathbf{u}||\mathbf{v}|\cos\theta = 0$, then $\cos\theta = 0$ and therefore $\theta = \arccos 0 = \pi/2$. The following definition also allows for one or both of the vectors to be the zero vector.

DEFINITION Vectors \mathbf{u} and \mathbf{v} are **orthogonal** if $\mathbf{u} \cdot \mathbf{v} = 0$. They are **orthonormal** if $\mathbf{u} \cdot \mathbf{v} = 0$ and additionally $|\mathbf{u}| = |\mathbf{v}| = 1$.

Often we deal with more than two vectors. We say that three vectors \mathbf{u} , \mathbf{v} , \mathbf{w} are orthogonal if the dot product of any two of them is zero: $\mathbf{u} \cdot \mathbf{v} = 0$, $\mathbf{u} \cdot \mathbf{w} = 0$, and $\mathbf{v} \cdot \mathbf{w} = 0$. If in addition each of \mathbf{u} , \mathbf{v} , and \mathbf{w} is a unit vector, then we say that the vectors \mathbf{u} , \mathbf{v} , \mathbf{w} are orthonormal. Sometimes we will use the longer but more precise phrasing that $\{\mathbf{u}, \mathbf{v}, \mathbf{w}\}$ is an *orthogonal set of vectors* (or *orthonormal set of vectors*). In three-dimensional space, it is not possible to have a set of more than three orthonormal vectors, but we will see below that it is possible to have larger collections in higher-dimensional space.

We will derive some formulas that relate lengths, distances, and dot products. Statement 3 of the next result is the **Pythagorean Theorem** for vectors. Exercise 25 shows that the converse of the Pythagorean Theorem holds as well.

THEOREM 1 Let \mathbf{u} and \mathbf{v} be three-dimensional vectors.

1. $|\mathbf{u} - \mathbf{v}|^2 = |\mathbf{u}|^2 - 2(\mathbf{u} \cdot \mathbf{v}) + |\mathbf{v}|^2$.
2. $|\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + 2(\mathbf{u} \cdot \mathbf{v}) + |\mathbf{v}|^2$.
3. If \mathbf{u} and \mathbf{v} are orthogonal, then $|\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2$.

Proof Statement 1 follows because

$$\begin{aligned} |\mathbf{u} - \mathbf{v}|^2 &= (u_1 - v_1)^2 + (u_2 - v_2)^2 + (u_3 - v_3)^2 \\ &= u_1^2 - 2u_1v_1 + v_1^2 + u_2^2 - 2u_2v_2 + v_2^2 + u_3^2 - 2u_3v_3 + v_3^2 \\ &= (u_1^2 + u_2^2 + u_3^2) - 2(u_1v_1 + u_2v_2 + u_3v_3) + (v_1^2 + v_2^2 + v_3^2) \\ &= |\mathbf{u}|^2 - 2(\mathbf{u} \cdot \mathbf{v}) + |\mathbf{v}|^2, \end{aligned}$$

and the proof of Statement 2 is similar. If \mathbf{u} and \mathbf{v} are orthogonal then $\mathbf{u} \cdot \mathbf{v} = 0$, so Statement 3 follows from Statement 2. ■

We need one additional definition.

DEFINITION A **linear combination** of finitely many vectors $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$ is a sum where we scale each vector \mathbf{u}_k by a real number a_k and add those terms together, giving the vector

$$a_1\mathbf{u}_1 + a_2\mathbf{u}_2 + \cdots + a_n\mathbf{u}_n.$$

EXAMPLE 1 The *standard unit vectors* in three-dimensional space were introduced in Section 11.2. They are

$$\mathbf{i} = \langle 1, 0, 0 \rangle, \quad \mathbf{j} = \langle 0, 1, 0 \rangle, \quad \mathbf{k} = \langle 0, 0, 1 \rangle.$$

We can form linear combinations of one, two, or three of the standard unit vectors by multiplying the vectors by real numbers and adding them together. For example, using two of the vectors we can create linear combinations such as

$$\begin{aligned} 2\mathbf{i} + 4\mathbf{j} &= \langle 2, 0, 0 \rangle + \langle 0, 4, 0 \rangle = \langle 2, 4, 0 \rangle, \\ 5\mathbf{i} - 7\mathbf{k} &= \langle 5, 0, 0 \rangle - \langle 0, 0, 7 \rangle = \langle 5, 0, -7 \rangle, \\ -3\mathbf{j} - 2\mathbf{k} &= -\langle 0, 3, 0 \rangle - \langle 0, 0, 2 \rangle = \langle 0, -3, -2 \rangle. \end{aligned}$$

Some linear combinations of all three of the standard unit vectors are

$$\begin{aligned} 5\mathbf{i} + 2\mathbf{j} - 7\mathbf{k} &= \langle 5, 0, 0 \rangle + \langle 0, 2, 0 \rangle - \langle 0, 0, 7 \rangle = \langle 5, 2, -7 \rangle, \\ \pi\mathbf{i} + 6\mathbf{j} - \mathbf{k} &= \langle \pi, 0, 0 \rangle + \langle 0, 6, 0 \rangle - \langle 0, 0, 1 \rangle = \langle \pi, 6, -1 \rangle, \\ \mathbf{i} - \sqrt{2}\mathbf{j} - 2\mathbf{k} &= \langle 1, 0, 0 \rangle - \langle 0, \sqrt{2}, 0 \rangle - \langle 0, 0, 2 \rangle = \langle 1, -\sqrt{2}, -2 \rangle. \end{aligned}$$

To create a linear combination of one vector, we simply multiply that vector by a real number:

$$\begin{aligned} 3\mathbf{i} &= \langle 3, 0, 0 \rangle, \\ \sqrt{5}\mathbf{j} &= \langle 0, \sqrt{5}, 0 \rangle, \\ -9\mathbf{k} &= \langle 0, 0, -9 \rangle. \end{aligned}$$

We are not restricted to using just three vectors. For example, one linear combination of $\mathbf{u} = \langle 1, -1, 0 \rangle$, $\mathbf{v} = \langle 2, 0, 2 \rangle$, $\mathbf{w} = \langle 3, 1, 2 \rangle$, and $\mathbf{y} = \langle 0, 1, -3 \rangle$ is

$$2\mathbf{u} + 3\mathbf{v} - \mathbf{w} - 3\mathbf{y} = \langle 2, -2, 0 \rangle + \langle 6, 0, 6 \rangle - \langle 3, 1, 2 \rangle - \langle 0, 3, -9 \rangle = \langle 5, -6, 13 \rangle. \quad \blacksquare$$

Orthonormal Bases in Three Dimensions

Any vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ can be written as a linear combination of the standard unit vectors:

$$\mathbf{v} = \langle v_1, v_2, v_3 \rangle = v_1\langle 1, 0, 0 \rangle + v_2\langle 0, 1, 0 \rangle + v_3\langle 0, 0, 1 \rangle = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}.$$

The dot product between any two of the standard basis vectors is zero: $\mathbf{i} \cdot \mathbf{j} = 0$, $\mathbf{i} \cdot \mathbf{k} = 0$, and $\mathbf{j} \cdot \mathbf{k} = 0$. Further, each of \mathbf{i} , \mathbf{j} , and \mathbf{k} is a unit vector. Therefore, \mathbf{i} , \mathbf{j} , \mathbf{k} are orthonormal vectors.

Now choose any other orthonormal vectors \mathbf{r} , \mathbf{s} , \mathbf{t} . For example, we might take the standard unit vectors \mathbf{i} , \mathbf{j} , \mathbf{k} and rotate them in space around some axis that passes through the origin to obtain new vectors \mathbf{r} , \mathbf{s} , \mathbf{t} . The lengths of the vectors and the angles between them remain unchanged under a rotation, so this process gives us orthonormal vectors. However we obtain them, if we have three orthonormal vectors \mathbf{r} , \mathbf{s} , \mathbf{t} , then we can write any vector \mathbf{v} as a linear combination of them (this is proved in texts on linear algebra). That is, if we choose a vector \mathbf{v} , then there must be real numbers c_1, c_2 , and c_3 so that

$$\mathbf{v} = c_1\mathbf{r} + c_2\mathbf{s} + c_3\mathbf{t}.$$

We now determine these coefficients. Taking the dot product of \mathbf{v} with \mathbf{r} gives us

$$\begin{aligned} \mathbf{v} \cdot \mathbf{r} &= (c_1\mathbf{r} + c_2\mathbf{s} + c_3\mathbf{t}) \cdot \mathbf{r} & \mathbf{v} &= c_1\mathbf{r} + c_2\mathbf{s} + c_3\mathbf{t} \\ &= c_1(\mathbf{r} \cdot \mathbf{r}) + c_2(\mathbf{s} \cdot \mathbf{r}) + c_3(\mathbf{t} \cdot \mathbf{r}) & \text{distributive property of the dot product} \\ &= c_1|\mathbf{r}|^2 + 0 + 0 & \mathbf{r} \cdot \mathbf{r} &= |\mathbf{r}|^2, \mathbf{s} \cdot \mathbf{r} = 0, \mathbf{t} \cdot \mathbf{r} = 0 \\ &= c_1. & \mathbf{r} & \text{has unit length.} \end{aligned}$$

A similar calculation shows that $c_2 = \mathbf{v} \cdot \mathbf{s}$ and $c_3 = \mathbf{v} \cdot \mathbf{t}$. We state these facts as a theorem.

THEOREM 2 Let \mathbf{r} , \mathbf{s} , \mathbf{t} be orthonormal vectors in three-dimensional space. Then every vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ can be written as

$$\mathbf{v} = (\mathbf{v} \cdot \mathbf{r})\mathbf{r} + (\mathbf{v} \cdot \mathbf{s})\mathbf{s} + (\mathbf{v} \cdot \mathbf{t})\mathbf{t}.$$

Using the standard unit vectors, we can write $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ as $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$. Theorem 2 tells us that if \mathbf{r} , \mathbf{s} , \mathbf{t} are three orthonormal vectors, then \mathbf{v} is also a linear combination of \mathbf{r} , \mathbf{s} , and \mathbf{t} , namely $\mathbf{v} = c_1\mathbf{r} + c_2\mathbf{s} + c_3\mathbf{t}$ where $c_1 = \mathbf{v} \cdot \mathbf{r}$, $c_2 = \mathbf{v} \cdot \mathbf{s}$ and $c_3 = \mathbf{v} \cdot \mathbf{t}$. Because every vector \mathbf{v} can be written as a unique linear combination of \mathbf{r} , \mathbf{s} , and \mathbf{t} , this collection of vectors is called a **basis**. Since the vectors are also orthonormal, we use the following name.

DEFINITION A set of three orthonormal vectors $\{\mathbf{r}, \mathbf{s}, \mathbf{t}\}$ in three-dimensional space is called an **orthonormal basis** for three-dimensional space.

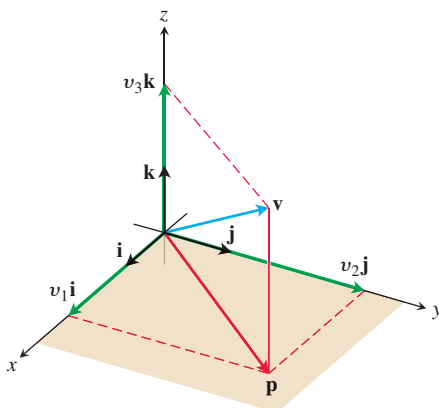

FIGURE 19.4 The vector in the xy -plane that is closest to $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ is $\mathbf{p} = v_1\mathbf{i} + v_2\mathbf{j}$.

Approximation Using an Orthonormal Basis in Three Dimensions

Suppose that $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is a vector. Out of all the vectors $\mathbf{p} = \langle p_1, p_2, 0 \rangle$ in the xy -plane, which one is closest to \mathbf{v} ? It is the vector \mathbf{p} that we obtain by dropping \mathbf{v} straight down onto the xy -plane. That is, $\mathbf{p} = \langle v_1, v_2, 0 \rangle$ is the vector in the xy -plane that is closest to \mathbf{v} (Figure 19.4). Expressing this in terms of linear combinations, if we choose any vector \mathbf{v} and write it as $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$, then the vector in the xy -plane that is closest to \mathbf{v} is $\mathbf{p} = v_1\mathbf{i} + v_2\mathbf{j}$. The distance from \mathbf{v} to the xy -plane is the length of $\mathbf{v} - \mathbf{p} = v_3\mathbf{k}$, which is $|v_3|$.

We saw in Section 5 of Chapter 11 how to find the distance from a point to a generic plane in space. Now we formulate that discussion in terms of orthonormal vectors and best approximation. Suppose that \mathbf{r} , \mathbf{s} , \mathbf{t} are three orthonormal vectors in three-dimensional space. If we fix a vector \mathbf{v} , then Theorem 2 tells us that $\mathbf{v} = (\mathbf{v} \cdot \mathbf{r})\mathbf{r} + (\mathbf{v} \cdot \mathbf{s})\mathbf{s} + (\mathbf{v} \cdot \mathbf{t})\mathbf{t}$. How closely can we approximate \mathbf{v} by a linear combination of just \mathbf{r} and \mathbf{s} ? The set of all possible linear combinations $a_1\mathbf{r} + a_2\mathbf{s}$ forms a plane in three-dimensional space, which

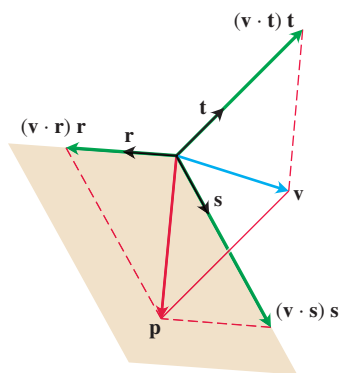

FIGURE 19.5 The vector in the plane determined by orthonormal vectors \mathbf{r} and \mathbf{s} that is closest to \mathbf{v} is $\mathbf{p} = (\mathbf{v} \cdot \mathbf{r})\mathbf{r} + (\mathbf{v} \cdot \mathbf{s})\mathbf{s}$.

we call the plane **determined by** or **spanned by** \mathbf{r} and \mathbf{s} . We seek to find the vector \mathbf{p} in this plane that minimizes the error between \mathbf{v} and \mathbf{p} . This error is the distance between \mathbf{v} and \mathbf{p} , so we want to find the vector \mathbf{p} in the plane that is closest to \mathbf{v} . We saw above how to solve this *optimization problem* for the case where our orthonormal vectors are the standard unit vectors \mathbf{i} , \mathbf{j} , and \mathbf{k} . A similar approach works here. As shown in Figure 19.5, we obtain the closest point by dropping \mathbf{v} down perpendicularly onto the plane determined by \mathbf{r} and \mathbf{s} , landing on the point $\mathbf{p} = (\mathbf{v} \cdot \mathbf{r})\mathbf{r} + (\mathbf{v} \cdot \mathbf{s})\mathbf{s}$. If the vector \mathbf{v} happens to actually be in the plane determined by \mathbf{r} and \mathbf{s} , then we will have $\mathbf{p} = \mathbf{v}$.

THEOREM 3 If $\{\mathbf{r}, \mathbf{s}, \mathbf{t}\}$ is an orthonormal basis for three-dimensional space and \mathbf{v} is a vector, then the linear combination of \mathbf{r} and \mathbf{s} that is closest to \mathbf{v} is

$$\mathbf{p} = (\mathbf{v} \cdot \mathbf{r})\mathbf{r} + (\mathbf{v} \cdot \mathbf{s})\mathbf{s}. \quad (5)$$

The vector $\mathbf{v} - \mathbf{p}$ is orthogonal to both \mathbf{r} and \mathbf{s} .

Proof Let \mathbf{v} be a vector and let \mathbf{p} be given by Equation (5). Consider any linear combination $\mathbf{w} = a_1\mathbf{r} + a_2\mathbf{s}$ of \mathbf{r} and \mathbf{s} . We want to show that the distance from \mathbf{v} to \mathbf{p} is less than or equal to the distance from \mathbf{v} to \mathbf{w} (less than or equal to because \mathbf{w} could possibly equal \mathbf{p}). That is, we must prove that $|\mathbf{v} - \mathbf{p}| \leq |\mathbf{v} - \mathbf{w}|$.

Observe that $\mathbf{v} - \mathbf{w} = (\mathbf{v} - \mathbf{p}) + (\mathbf{p} - \mathbf{w})$. Since \mathbf{p} and \mathbf{w} are each linear combinations of \mathbf{r} and \mathbf{s} , their difference $\mathbf{p} - \mathbf{w}$ is also a linear combination of \mathbf{r} and \mathbf{s} . Therefore, since \mathbf{r} and \mathbf{s} are each orthogonal to \mathbf{t} , the vector $\mathbf{p} - \mathbf{w}$ is orthogonal to \mathbf{t} , and hence it is also orthogonal to $\mathbf{v} - \mathbf{p} = (\mathbf{v} \cdot \mathbf{t})\mathbf{t}$. Consequently,

$$\begin{aligned} |\mathbf{v} - \mathbf{w}|^2 &= |(\mathbf{v} - \mathbf{p}) + (\mathbf{p} - \mathbf{w})|^2 && \text{Add and subtract.} \\ &= |\mathbf{v} - \mathbf{p}|^2 + |\mathbf{p} - \mathbf{w}|^2 && \text{Pythagorean Theorem} \\ &\geq |\mathbf{v} - \mathbf{p}|^2. \end{aligned}$$

Taking square roots gives $|\mathbf{v} - \mathbf{p}| \leq |\mathbf{v} - \mathbf{w}|$. This shows that \mathbf{p} is the linear combination of \mathbf{r} and \mathbf{s} that is closest to \mathbf{v} . Finally, $\mathbf{v} - \mathbf{p} = (\mathbf{v} \cdot \mathbf{t})\mathbf{t}$ is a multiple of \mathbf{t} , which is orthogonal to both \mathbf{r} and \mathbf{s} . ■

Vectors in Higher Dimensions

Written in component form, a two-dimensional vector $\mathbf{v} = \langle v_1, v_2 \rangle$ is an ordered pair of real numbers, while a three-dimensional vector $\mathbf{v} = \langle v_1, v_2, v_3 \rangle$ is an ordered triple of real numbers. Although we cannot easily visualize vectors in higher dimensions, we can still define and understand them. A vector in four dimensions is an ordered quadruple $\mathbf{v} = \langle v_1, v_2, v_3, v_4 \rangle$ of real numbers. The length of such a vector is

$$|\mathbf{v}| = \sqrt{v_1^2 + v_2^2 + v_3^2 + v_4^2}.$$

There are four axis directions, and the number v_k is the component of \mathbf{v} in the direction of the k th axis.

Higher-dimensional vectors are similar. If d is a positive integer, then a d -dimensional vector is an ordered list $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ of d real numbers (also called a d -tuple of numbers). Its length is

$$|\mathbf{v}| = \sqrt{v_1^2 + v_2^2 + \dots + v_d^2} = \sqrt{\sum_{k=1}^d v_k^2}. \quad (6)$$

The distance between two d -dimensional vectors \mathbf{u} and \mathbf{v} is $|\mathbf{u} - \mathbf{v}|$, the length of the difference of \mathbf{u} and \mathbf{v} . The dot product of $\mathbf{u} = \langle u_1, u_2, \dots, u_d \rangle$ with $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ is

$$\mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + \dots + u_dv_d = \sum_{k=1}^d u_kv_k.$$

The length of a vector is related to the dot product of the vector with itself by the formula

$$\mathbf{v} \cdot \mathbf{v} = v_1^2 + v_2^2 + \cdots + v_d^2 = |\mathbf{v}|^2.$$

Vectors \mathbf{u} and \mathbf{v} are orthogonal if $\mathbf{u} \cdot \mathbf{v} = 0$. In this case, the Pythagorean Theorem holds (Exercise 24):

$$\text{If } \mathbf{u} \cdot \mathbf{v} = 0, \text{ then } |\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2.$$

The converse of the Pythagorean Theorem also holds (Exercise 25).

As a reminder, dot products are defined in any dimension, but cross products are special to dimension 3.

Orthonormal Bases and Approximation in Higher Dimensions

The standard unit vectors in d dimensions are the d vectors

$$\begin{aligned} \mathbf{e}_1 &= \langle 1, 0, 0, \dots, 0 \rangle, \\ \mathbf{e}_2 &= \langle 0, 1, 0, \dots, 0 \rangle, \\ &\vdots \\ \mathbf{e}_d &= \langle 0, 0, 0, \dots, 1 \rangle. \end{aligned}$$

The k th vector \mathbf{e}_k has a 1 as its k th component, while all other components are zero. The set of unit vectors $\{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_d\}$ is orthonormal, and additionally every vector \mathbf{v} in d -dimensional space is a linear combination of these vectors. Therefore, we say that $\{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_d\}$ forms an orthonormal basis for d -dimensional space.

Likewise, any collection of d orthonormal vectors is an orthonormal basis for d -dimensional space, and we have the following explicit formula for writing any vector as a linear combination of the basis vectors (this theorem is proved in texts on linear algebra). The coefficients in this representation are dot products of \mathbf{v} with the vectors \mathbf{u}_k .

THEOREM 4 If $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d$ are d orthonormal vectors in d -dimensional space (so $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis for d -dimensional space), then every vector $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ can be written as

$$\mathbf{v} = (\mathbf{v} \cdot \mathbf{u}_1) \mathbf{u}_1 + (\mathbf{v} \cdot \mathbf{u}_2) \mathbf{u}_2 + \cdots + (\mathbf{v} \cdot \mathbf{u}_d) \mathbf{u}_d = \sum_{k=1}^d (\mathbf{v} \cdot \mathbf{u}_k) \mathbf{u}_k.$$

Now fix an integer $1 \leq n < d$. If $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis and \mathbf{v} is a vector in d dimensions, how close can we get to \mathbf{v} using a linear combination of only the first n vectors $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$? This type of optimization problem occurs widely throughout mathematics, science, and engineering. The answer (which is often called the *least squares solution*) is given in the next theorem. The proof is similar to the proof of Theorem 3 (Exercise 31).

THEOREM 5 Assume that $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis for d -dimensional space. If \mathbf{v} is a vector and $1 \leq n < d$, then the linear combination of $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$ that is closest to \mathbf{v} is

$$\mathbf{p} = (\mathbf{v} \cdot \mathbf{u}_1) \mathbf{u}_1 + (\mathbf{v} \cdot \mathbf{u}_2) \mathbf{u}_2 + \cdots + (\mathbf{v} \cdot \mathbf{u}_n) \mathbf{u}_n = \sum_{k=1}^n (\mathbf{v} \cdot \mathbf{u}_k) \mathbf{u}_k. \quad (7)$$

The vector $\mathbf{v} - \mathbf{p}$ is orthogonal to $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$.

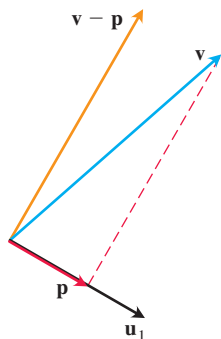

FIGURE 19.6 The vector on the line through \mathbf{u}_1 that is closest to \mathbf{v} is $\mathbf{p} = (\mathbf{v} \cdot \mathbf{u}_1)\mathbf{u}_1$. The vector $\mathbf{v} - \mathbf{p}$ is orthogonal to \mathbf{u}_1 .

The set of all possible linear combinations $a_1\mathbf{u}_1 + a_2\mathbf{u}_2 + \cdots + a_n\mathbf{u}_n$ of vectors $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$ is called the **subspace** spanned by $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$. The vector \mathbf{p} given in Equation (7) is the vector in this subspace that is closest to \mathbf{v} . It is the vector in that subspace that *minimizes the distance* between \mathbf{v} and the vectors in the subspace, and it is called the **orthogonal projection of \mathbf{v} onto the span of $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$** . Geometrically, Theorem 5 tells us that to find the closest vector \mathbf{p} , we should simply drop down perpendicularly from \mathbf{v} onto the subspace spanned by $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$.

EXAMPLE 2 Assume that \mathbf{u}_1 is a unit vector in d -dimensional space. A linear combination of the single vector \mathbf{u}_1 is simply a multiple $a\mathbf{u}_1$, where a is a real number. Therefore, the subspace spanned by \mathbf{u}_1 is the set of all multiples $a\mathbf{u}_1$ of \mathbf{u}_1 . We also call this the **line through \mathbf{u}_1** . If \mathbf{v} is a vector in d -dimensional space, what is the vector \mathbf{p} on the line through \mathbf{u}_1 that is closest to \mathbf{v} ?

Solution We will apply Theorem 5 with $n = 1$. By results from linear algebra, starting with a unit vector \mathbf{u}_1 we can find vectors $\mathbf{u}_2, \dots, \mathbf{u}_d$ so that $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d$ forms an orthonormal basis for d -dimensional space. Then, by Equation (7) with $n = 1$, the vector on the line through \mathbf{u}_1 that is closest to \mathbf{v} is

$$\mathbf{p} = (\mathbf{v} \cdot \mathbf{u}_1)\mathbf{u}_1.$$

This agrees with the formula that we found in Section 11.3 for vectors in two- or three-dimensional space, where we denoted the vector \mathbf{p} by $\text{proj}_{\mathbf{u}_1}\mathbf{v}$ (compare Figure 19.6 to Figure 11.27). ■

EXERCISES 19.3

Orthogonal Vectors in Three Dimensions

In Exercises 1–6, find

- the dot products $\mathbf{r} \cdot \mathbf{s}$, $\mathbf{r} \cdot \mathbf{t}$, and $\mathbf{s} \cdot \mathbf{t}$,
- the lengths $|\mathbf{r}|$, $|\mathbf{s}|$, $|\mathbf{t}|$.

Also determine whether $\{\mathbf{r}, \mathbf{s}, \mathbf{t}\}$ is

- an orthogonal set of vectors,
- an orthonormal set of vectors.

- $\mathbf{r} = \langle 1, 1, 0 \rangle$, $\mathbf{s} = \langle 1, -1, 0 \rangle$, $\mathbf{t} = \langle 0, 0, 1 \rangle$.
- $\mathbf{r} = \langle 1/\sqrt{2}, 1/\sqrt{2}, 0 \rangle$, $\mathbf{s} = \langle 1/\sqrt{2}, -1/\sqrt{2}, 0 \rangle$, $\mathbf{t} = \langle 0, 0, 1 \rangle$.
- $\mathbf{r} = \langle 1, 1, 1 \rangle$, $\mathbf{s} = \langle 1, 1, -2 \rangle$, $\mathbf{t} = \langle 0, -1, 1 \rangle$.
- $\mathbf{r} = \langle 1/\sqrt{3}, 1/\sqrt{3}, 1/\sqrt{3} \rangle$, $\mathbf{s} = \langle 1/\sqrt{6}, 1/\sqrt{6}, -\sqrt{2}/\sqrt{3} \rangle$,
 $\mathbf{t} = \langle 0, -1/\sqrt{2}, 1/\sqrt{2} \rangle$.
- $\mathbf{r} = \langle 1/\sqrt{3}, 1/\sqrt{3}, 1/\sqrt{3} \rangle$, $\mathbf{s} = \langle 1/\sqrt{6}, 1/\sqrt{6}, -\sqrt{2}/\sqrt{3} \rangle$,
 $\mathbf{t} = \langle 1/\sqrt{2}, -1/\sqrt{2}, 0 \rangle$.
- $\mathbf{r} = \langle 2/3, -2/3, 1/3 \rangle$, $\mathbf{s} = \langle 1/\sqrt{2}, 1/\sqrt{2}, 0 \rangle$,
 $\mathbf{t} = \langle -1/(3\sqrt{2}), 1/(3\sqrt{2}), 2\sqrt{2}/3 \rangle$.

Closest Point in a Plane

In Exercises 7–10,

- verify that $\{\mathbf{r}, \mathbf{s}, \mathbf{t}\}$ is an orthonormal basis for three-dimensional space,
- find the linear combination \mathbf{p} of \mathbf{r} and \mathbf{s} that is closest to \mathbf{v} ,
- find the distance from \mathbf{v} to \mathbf{p} .

- $\mathbf{r} = \langle 1, 0, 0 \rangle$, $\mathbf{s} = \langle 0, -1, 0 \rangle$, $\mathbf{t} = \langle 0, 0, -1 \rangle$, $\mathbf{v} = \langle 1, 2, 3 \rangle$.
- $\mathbf{r} = \langle 2/3, -2/3, -1/3 \rangle$, $\mathbf{s} = \langle 1/3, 2/3, -2/3 \rangle$,
 $\mathbf{t} = \langle 2/3, 1/3, 2/3 \rangle$, $\mathbf{v} = \langle 3, 6, 3 \rangle$.
- $\mathbf{r} = \langle 2/3, -2/3, 1/3 \rangle$, $\mathbf{s} = \langle 1/\sqrt{2}, 1/\sqrt{2}, 0 \rangle$,
 $\mathbf{t} = \langle -1/(3\sqrt{2}), 1/(3\sqrt{2}), 2\sqrt{2}/3 \rangle$, and $\mathbf{v} = \langle 3, 0, 3 \rangle$.
- $\mathbf{r} = \langle 3/5, 3/5, \sqrt{7}/5 \rangle$, $\mathbf{s} = \langle -\sqrt{7}/4, 0, 3/4 \rangle$,
 $\mathbf{t} = \langle 9/20, -4/5, 3\sqrt{7}/20 \rangle$, $\mathbf{v} = \langle 0, 1, 0 \rangle$.

Vectors in Five Dimensions

In Exercises 11–14, let $\mathbf{u} = \langle 2, 0, -1, 3, 2 \rangle$, $\mathbf{v} = \langle -1, 1, 1, -1, 0 \rangle$, and $\mathbf{w} = \langle 3, -1, 2, -1, 1 \rangle$.

- Find the linear combinations $2\mathbf{u} + \mathbf{v} - 3\mathbf{w}$ and $-\mathbf{u} + 5\mathbf{v} - \mathbf{w}$.
- Find the lengths $|\mathbf{u}|$, $|\mathbf{v}|$, and $|\mathbf{w}|$.
- Find the dot products $\mathbf{u} \cdot \mathbf{v}$, $\mathbf{u} \cdot \mathbf{w}$, and $\mathbf{v} \cdot \mathbf{w}$.
- Find the linear combination $(2\mathbf{w} \cdot \mathbf{u})\mathbf{u} - (\mathbf{w} \cdot 3\mathbf{v})\mathbf{v} + (\mathbf{u} \cdot \mathbf{v})4\mathbf{w}$.

In Exercises 15–20, let $\mathbf{u}_1 = \langle 1/\sqrt{2}, 1/\sqrt{2}, 0, 0, 0 \rangle$,
 $\mathbf{u}_2 = \langle 1/\sqrt{2}, -1/\sqrt{2}, 0, 0, 0 \rangle$, $\mathbf{u}_3 = \langle 0, 0, 1/\sqrt{2}, 1/\sqrt{2}, 0 \rangle$,
 $\mathbf{u}_4 = \langle 0, 0, 1/\sqrt{2}, -1/\sqrt{2}, 0 \rangle$, $\mathbf{u}_5 = \langle 0, 0, 0, 0, 1 \rangle$, and
 $\mathbf{v} = \langle 2, -4, 4, 2, 1 \rangle$.

- Verify that $\{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3, \mathbf{u}_4, \mathbf{u}_5\}$ is an orthonormal basis for five-dimensional space.
- Find the vector \mathbf{p} on the line through \mathbf{u}_1 that is closest to \mathbf{v} , and find the distance from \mathbf{v} to \mathbf{p} . Verify that $\mathbf{v} - \mathbf{p}$ is orthogonal to \mathbf{u}_1 .

17. Find the linear combination \mathbf{p} of \mathbf{u}_1 and \mathbf{u}_2 that is closest to \mathbf{v} , and find the distance from \mathbf{v} to \mathbf{p} . Verify that $\mathbf{v} - \mathbf{p}$ is orthogonal to both \mathbf{u}_1 and \mathbf{u}_2 .
18. Find the linear combination \mathbf{p} of \mathbf{u}_1 , \mathbf{u}_2 , and \mathbf{u}_3 that is closest to \mathbf{v} , and find the distance from \mathbf{v} to \mathbf{p} . Verify that $\mathbf{v} - \mathbf{p}$ is orthogonal to \mathbf{u}_1 , \mathbf{u}_2 , and \mathbf{u}_3 .
19. Find the linear combination \mathbf{p} of \mathbf{u}_1 , \mathbf{u}_2 , \mathbf{u}_3 , and \mathbf{u}_4 that is closest to \mathbf{v} , and find the distance from \mathbf{v} to \mathbf{p} . Verify that $\mathbf{v} - \mathbf{p}$ is orthogonal to \mathbf{u}_1 , \mathbf{u}_2 , \mathbf{u}_3 , and \mathbf{u}_4 .
20. Verify that
- $$(\mathbf{v} \cdot \mathbf{u}_1)\mathbf{u}_1 + (\mathbf{v} \cdot \mathbf{u}_2)\mathbf{u}_2 + (\mathbf{v} \cdot \mathbf{u}_3)\mathbf{u}_3 + (\mathbf{v} \cdot \mathbf{u}_4)\mathbf{u}_4 + (\mathbf{v} \cdot \mathbf{u}_5)\mathbf{u}_5$$
- equals \mathbf{v} .
- Theory and Examples**
- In Exercises 21–30, $\mathbf{u} = \langle u_1, u_2, \dots, u_d \rangle$, $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$, and $\mathbf{w} = \langle w_1, w_2, \dots, w_d \rangle$ are d -dimensional vectors.
21. **Symmetry** Prove that $\mathbf{u} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{u}$.
22. **Distributive properties** Prove that if a and b are real numbers, then
- $$(\mathbf{a}\mathbf{u} + b\mathbf{v}) \cdot \mathbf{w} = a(\mathbf{u} \cdot \mathbf{w}) + b(\mathbf{v} \cdot \mathbf{w}) \quad \text{and}$$
- $$\mathbf{u} \cdot (\mathbf{a}\mathbf{v} + b\mathbf{w}) = a(\mathbf{u} \cdot \mathbf{v}) + b(\mathbf{u} \cdot \mathbf{w}).$$
23. Prove that $|\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + 2(\mathbf{u} \cdot \mathbf{v}) + |\mathbf{v}|^2$.
24. **Pythagorean Theorem** Prove that if $\mathbf{u} \cdot \mathbf{v} = 0$, then $|\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2$.
25. **Converse of the Pythagorean Theorem** Prove that if $|\mathbf{u} + \mathbf{v}|^2 = |\mathbf{u}|^2 + |\mathbf{v}|^2$, then $\mathbf{u} \cdot \mathbf{v} = 0$.
26. **Parallelogram Law** Prove that $|\mathbf{u} + \mathbf{v}|^2 + |\mathbf{u} - \mathbf{v}|^2 = 2|\mathbf{u}|^2 + 2|\mathbf{v}|^2$.
27. **Cauchy–Schwarz Inequality** Let $a = |\mathbf{u}|^2$, $b = |\mathbf{v}|^2$, and $c = \mathbf{u} \cdot \mathbf{v}$. Set $\mathbf{w} = b\mathbf{u} - c\mathbf{v}$, so $b\mathbf{u} = \mathbf{w} + c\mathbf{v}$.
- Prove that \mathbf{w} and $c\mathbf{v}$ are orthogonal.
 - Prove that $b^2a = |\mathbf{w} + c\mathbf{v}|^2$, and use the Pythagorean Theorem to show that $|\mathbf{w} + c\mathbf{v}|^2 = |\mathbf{w}|^2 + c^2|\mathbf{v}|^2 \geq c^2b$.
 - Prove that $|\mathbf{u} \cdot \mathbf{v}| \leq |\mathbf{u}||\mathbf{v}|$.
28. **Triangle Inequality** Use Exercises 23 and 27 to prove that $|\mathbf{u} + \mathbf{v}| \leq |\mathbf{u}| + |\mathbf{v}|$.
29. **Reverse Triangle Inequality** Prove that $|\mathbf{u}| = |\mathbf{u} - \mathbf{v} + \mathbf{v}| \leq |\mathbf{u} - \mathbf{v}| + |\mathbf{v}|$ and $|\mathbf{v}| = |\mathbf{v} - \mathbf{u} + \mathbf{u}| \leq |\mathbf{v} - \mathbf{u}| + |\mathbf{u}|$. Use these facts to prove that
- $$\left| |\mathbf{u}| - |\mathbf{v}| \right| \leq |\mathbf{u} - \mathbf{v}|.$$
30. **Parseval Equality** Assume that $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis for d -dimensional space. Use Theorem 4 to prove that
- $$|\mathbf{v}|^2 = (\mathbf{v} \cdot \mathbf{u}_1)^2 + (\mathbf{v} \cdot \mathbf{u}_2)^2 + \dots + (\mathbf{v} \cdot \mathbf{u}_d)^2$$
- $$= \sum_{k=1}^d (\mathbf{v} \cdot \mathbf{u}_k)^2.$$
31. Prove Theorem 5.

19.4 Approximation of Functions

The Norm of a Function

The main goal of Fourier series is to find the best approximation of a function by a trigonometric polynomial. We have seen that for vectors, it is easy to find best approximations when we have an orthonormal collection $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d$ of vectors. If we had an *orthonormal collection of functions*, then we could use similar ideas to find the best approximation. We will show below that the trigonometric system is, after being appropriately rescaled, an analogue of such an orthonormal basis. Before doing this, we must explain what we mean by the *norm of a function* (because we need unit functions) and the *inner product of two functions* (because we need orthogonal functions). We will assume that the functions we are working with are periodic with period 2π . Any such function simply repeats the values that it takes in the interval $[0, 2\pi]$ in any other interval $[2n\pi, 2(n+1)\pi]$ with n an integer.

Vectors and functions are more similar than might be apparent at first glance. A vector $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ in d dimensions is an ordered list of numbers v_1, v_2, \dots, v_d . For each integer $k = 1, 2, \dots, d$ we have an associated number v_k . If f is a function on $[0, 2\pi]$, then for each real number x in $[0, 2\pi]$ we have an associated number $f(x)$.

Many of the things that we have done with vectors can also be done with functions if we use the analogy that the function values $f(x)$ are like the components v_k of a vector. There are infinitely many function values instead of finitely many components, so where we used *sums* before, we now use “continuous sums,” or *integrals*.

There is one technical issue here that does not arise with vectors. While we can always sum up finitely many numbers, there are functions whose integrals do not exist. We cannot define the norm of such functions. Instead, we restrict our attention to *integrable* functions, those whose integral does exist. Fortunately, most of the functions that we encounter in real world problems are integrable. All of the functions that we will see in later examples or exercises will be integrable. In particular, any function that is continuous on a finite interval $[a, b]$ is integrable. More generally, any function that is bounded and piecewise continuous on $[a, b]$ (continuous at all but finitely many points) is integrable.

The norm of a function is analogous to the length of a vector. The length of a vector $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ is

$$|\mathbf{v}| = \sqrt{\sum_{k=1}^d v_k^2}.$$

We define the norm of a function using a similar formula, replacing components v_k with function values $f(x)$, and a finite sum with an integral.

DEFINITION

1. The **norm** of an integrable function f on the domain $[0, 2\pi]$ is

$$\|f\| = \sqrt{\int_0^{2\pi} f(x)^2 dx}.$$

We say that f is a **unit function** if $\|f\| = 1$.

2. The **distance** between two integrable functions f and g on the domain $[0, 2\pi]$ is

$$\|f - g\| = \sqrt{\int_0^{2\pi} (f(x) - g(x))^2 dx}.$$

Our definition of the norm of a function is suited to the applications that we consider in this chapter, but it is only one of many ways to extend the idea of length from vectors to functions. The notion of a norm is explored in the mathematical subject called Real Analysis.

We compute the norms of some functions, including the functions that belong to the trigonometric system.

EXAMPLE 1

- (a) Let f be the function defined in Equation (1). Observe that $f(x) = x - \pi$ for all but one point in the interval $[0, 2\pi]$. Since changing the value of a function at a single point does not change the value of its integral, we can ignore that exceptional point and compute that

$$\|f\|^2 = \int_0^{2\pi} |f(x)|^2 dx = \int_0^{2\pi} (x - \pi)^2 dx = \frac{2\pi^3}{3}.$$

Taking square roots, $\|f\| = \sqrt{2/3} \pi^{3/2} \approx 4.55$.

- (b) Let k be any positive integer. The norm of the function $\sin kx$ is

$$\|\sin kx\| = \sqrt{\int_0^{2\pi} \sin^2 kx dx}.$$

We can use trigonometric identities to evaluate this integral, but an easier way is to note that the graph of $\cos kx$ equals the graph of $\sin kx$ translated $\pi/(2k)$ units to the left, and therefore the area under the graph of $\cos^2 kx$ over $[0, 2\pi]$ is the same as the area under the graph of $\sin^2 kx$ over $[0, 2\pi]$; see Figure 19.7. Therefore, using the identity $\sin^2 x + \cos^2 x = 1$, we see that

$$\begin{aligned} 2\|\sin kx\|^2 &= \int_0^{2\pi} \sin^2 kx dx + \int_0^{2\pi} \sin^2 kx dx \\ &= \int_0^{2\pi} \sin^2 kx dx + \int_0^{2\pi} \cos^2 kx dx \\ &= \int_0^{2\pi} (\sin^2 kx + \cos^2 kx) dx \\ &= \int_0^{2\pi} 1 dx = 2\pi. \end{aligned}$$

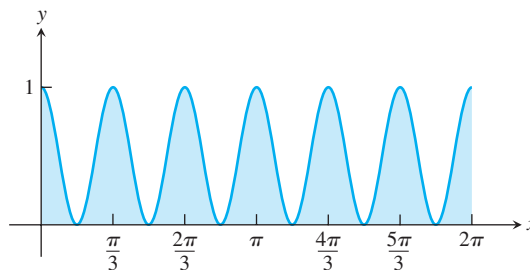

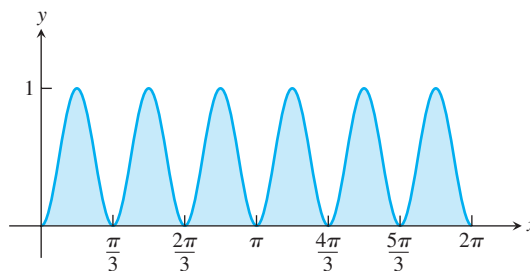

(a) Graph of $\cos^2 3x$ over the interval $[0, 2\pi]$ (b) Graph of $\sin^2 3x$ over the interval $[0, 2\pi]$

FIGURE 19.7 The area under the graph of $\cos^2 3x$ between 0 and 2π is the same as the area under the graph of $\sin^2 3x$ between 0 and 2π .

The norm of the constant function $\mathbf{1}$ is not 1 because the length of the interval $[0, 2\pi]$ is 2π , not 1.

Therefore, $\|\sin kx\|^2 = \pi$ for each positive integer k . A similar computation applies to $\cos kx$, so by taking square roots we conclude that $\|\sin kx\| = \sqrt{\pi} = \|\cos kx\|$.

(c) The norm of the constant function $\mathbf{1}$ on the domain $[0, 2\pi]$ is

$$\|\mathbf{1}\| = \sqrt{\int_0^{2\pi} \mathbf{1}(x)^2 dx} = \sqrt{\int_0^{2\pi} 1^2 dx} = \sqrt{2\pi}. \quad \blacksquare$$

The Inner Product of Functions

The inner product of functions is analogous to the dot product of vectors. The dot product of a vector $\mathbf{u} = \langle u_1, u_2, \dots, u_d \rangle$ with $\mathbf{v} = \langle v_1, v_2, \dots, v_d \rangle$ is the number

$$\mathbf{u} \cdot \mathbf{v} = u_1 v_1 + u_2 v_2 + \dots + u_d v_d = \sum_{k=1}^d u_k v_k.$$

The inner product of two functions is a number that is defined by a similar formula. However, because the notation $f \cdot g$ resembles the definition of the product function $f(x)g(x)$ rather than a number, we denote the inner product of f and g by $\langle f, g \rangle$.

The notation $\mathbf{u} = \langle u_1, u_2 \rangle$ denotes the components of a two-dimensional vector, while $\langle f, g \rangle$ denotes the inner product of functions f and g . Despite the similar notation, we can tell from context which meaning is intended.

DEFINITION The **inner product** of two integrable functions f and g on $[0, 2\pi]$ is

$$\langle f, g \rangle = \int_0^{2\pi} f(x)g(x) dx.$$

The properties of the inner product of functions are similar to the properties of the dot product of vectors. For example, just as the dot product of a vector with itself is the square of its length, the inner product of a function with itself is the square of its norm:

$$\langle f, f \rangle = \int_0^{2\pi} f(x)^2 dx = \|f\|^2. \quad (8)$$

Hence f is a unit function if and only if $\langle f, f \rangle = 1$.

The definition of orthogonality for functions is similar to the definition for vectors.

DEFINITION Let f and g be integrable functions on $[0, 2\pi]$. Then f and g are **orthogonal** if $\langle f, g \rangle = 0$. They are **orthonormal** if they are orthogonal and, additionally, $\|f\| = \|g\| = 1$.

Often we deal with more than two functions. We say that a collection of functions is orthogonal if any two distinct functions in the collection are orthogonal. If in addition each function in the collection is a unit function, then we say that the collection is orthonormal.

The next theorem is the analogue for functions of Theorem 1 in Section 19.3. Statement 3 of this theorem is the **Pythagorean Theorem** for functions.

THEOREM 6 Let f and g be integrable functions on $[0, 2\pi]$.

1. $\|f - g\|^2 = \|f\|^2 - 2\langle f, g \rangle + \|g\|^2$
2. $\|f + g\|^2 = \|f\|^2 + 2\langle f, g \rangle + \|g\|^2$
3. If f and g are orthogonal, then $\|f + g\|^2 = \|f\|^2 + \|g\|^2$.

Proof Statement 1 follows because

$$\begin{aligned} \|f - g\|^2 &= \int_0^{2\pi} (f(x) - g(x))^2 dx \\ &= \int_0^{2\pi} f(x)^2 dx - 2 \int_0^{2\pi} f(x)g(x) dx + \int_0^{2\pi} g(x)^2 dx \\ &= \|f\|^2 - 2\langle f, g \rangle + \|g\|^2, \end{aligned}$$

and the proof of Statement 2 is similar. If f and g are orthogonal, then $\langle f, g \rangle = 0$, so Statement 3 follows from Statement 2. ■

Orthogonality of the Trigonometric System

We will show that the trigonometric system is an orthogonal collection of functions. It is not an orthonormal collection because the functions $\mathbf{1}$, $\cos kx$ and $\sin kx$ do not have norm 1.

EXAMPLE 2

(a) If k is any positive integer, then the inner product of the constant function $\mathbf{1}$ with $\sin kx$ is

$$\langle \mathbf{1}, \sin kx \rangle = \int_0^{2\pi} 1 \cdot \sin kx dx = \int_0^{2\pi} \sin kx dx.$$

We see by looking at the graph of $\sin kx$ on the interval $[0, 2\pi]$ that this integral is zero since it has as much area below as above the x -axis, and therefore the signed areas cancel. We demonstrate this explicitly by computing that

$$\langle \mathbf{1}, \sin kx \rangle = \int_0^{2\pi} \sin kx dx = -\frac{\cos kx}{k} \Big|_0^{2\pi} = \frac{-\cos 2k\pi}{k} + \frac{\cos 0}{k} = \frac{-1}{k} + \frac{1}{k} = 0.$$

Consequently, the constant function is orthogonal to $\sin kx$ for every integer $k > 0$. A similar calculation shows that $\mathbf{1}$ is orthogonal to $\cos kx$ for every positive k .

- (b) We show next that $\sin x$ and $\cos x$ are orthogonal. Using the u -substitution $u = \sin x$, their inner product is

$$\langle \sin x, \cos x \rangle = \int_0^{2\pi} \sin x \cos x \, dx = \frac{\sin^2 x}{2} \Big|_0^{2\pi} = \frac{\sin^2 2\pi - \sin^2 0}{2} = 0.$$

Looking at their graphs, there is no obvious reason why we should expect that $\sin x$ and $\cos x$ should be orthogonal. We can understand visually what it means for two vectors \mathbf{u} and \mathbf{v} in three-dimensional space to be perpendicular (there is a 90-degree angle between them), but there is no easy way to see from their graphs why two functions are orthogonal.

- (c) We compute another special case. The inner product of $\sin x$ and $\sin 2x$ is zero because

$$\langle \sin x, \sin 2x \rangle = \int_0^{2\pi} \sin x (2 \sin x \cos x) \, dx = 2 \frac{\sin^3 x}{3} \Big|_0^{2\pi} = 2 \frac{\sin^3 2\pi - \sin^3 0}{3} = 0.$$

Therefore, $\sin x$ and $\sin 2x$ are orthogonal.

- (d) We have shown that the constant function $\mathbf{1}$ is orthogonal to $\sin kx$ and $\cos kx$ for every positive integer k . To complete the proof that the trigonometric system is a collection of orthogonal functions, it remains to prove that for all positive integers m and n we have:

$$\langle \sin mx, \sin nx \rangle = \int_0^{2\pi} \sin mx \sin nx \, dx = 0 \quad \text{whenever } m \neq n,$$

$$\langle \cos mx, \cos nx \rangle = \int_0^{2\pi} \cos mx \cos nx \, dx = 0 \quad \text{whenever } m \neq n,$$

$$\langle \sin mx, \cos nx \rangle = \int_0^{2\pi} \sin mx \cos nx \, dx = 0 \quad \text{for all } m \text{ and } n.$$

This can be done through the use of trigonometric identities (Exercises 31–33). ■

The functions in the trigonometric system do not have unit norm. However, if we divide each function by its norm, then we obtain functions whose norm is 1. We set

$$u_0(x) = \frac{\mathbf{1}}{\sqrt{2\pi}},$$

and for each integer $k > 0$ let

$$u_k(x) = \frac{\cos kx}{\sqrt{\pi}} \quad \text{and} \quad v_k(x) = \frac{\sin kx}{\sqrt{\pi}}.$$

Each function u_0 , u_k , and v_k is a unit function, and the set of these functions is orthonormal.

DEFINITION The **normalized trigonometric system** is the collection of orthonormal functions $u_0, u_1, v_1, u_2, v_2, \dots$. Explicitly, these are

$$\frac{\mathbf{1}}{\sqrt{2\pi}}, \frac{\cos x}{\sqrt{\pi}}, \frac{\sin x}{\sqrt{\pi}}, \frac{\cos 2x}{\sqrt{\pi}}, \frac{\sin 2x}{\sqrt{\pi}}, \frac{\cos 3x}{\sqrt{\pi}}, \frac{\sin 3x}{\sqrt{\pi}}, \dots$$

Approximation of Functions

Now we find the best approximation to a function using the normalized constant function u_0 , the first n normalized cosine functions u_1, u_2, \dots, u_n , and the first n normalized sine functions v_1, v_2, \dots, v_n . That is, out of all of the linear combinations

$$w = a_0 u_0 + \sum_{k=1}^n a_k u_k + \sum_{k=1}^n b_k v_k, \quad (9)$$

we identify the one whose distance from f is the smallest. We let p_n denote this closest function.

THEOREM 7 If f is an integrable function on $[0, 2\pi]$ and n is a positive integer, then the linear combination of u_0 and u_1, u_2, \dots, u_n and v_1, v_2, \dots, v_n that is closest to f is

$$p_n = \langle f, u_0 \rangle u_0 + \sum_{k=1}^n \langle f, u_k \rangle u_k + \sum_{k=1}^n \langle f, v_k \rangle v_k. \quad (10)$$

Proof Let p_n be the function in Equation (10), and let w be any linear combination of the form given in Equation (9). We must prove that $\|f - p_n\| \leq \|f - w\|$.

To simplify the notation, let

$$q = f - p_n \quad \text{and} \quad z = p_n - w.$$

Also let $c_0 = \langle f, u_0 \rangle$, and for each positive integer k set $c_k = \langle f, u_k \rangle$ and $d_k = \langle f, v_k \rangle$, so

$$p_n = c_0 u_0 + \sum_{k=1}^n c_k u_k + \sum_{k=1}^n d_k v_k.$$

The inner product satisfies a distributive law, just as the dot product of vectors does (Exercise 24). Using this and the fact that u_0 is orthogonal to all of the other functions u_k and v_k with $k > 0$, the inner product of p_n with u_0 is

$$\begin{aligned} \langle p_n, u_0 \rangle &= \langle c_0 u_0 + \sum_{k=1}^n c_k u_k + \sum_{k=1}^n d_k v_k, u_0 \rangle && \text{Substitute} \\ &= c_0 \langle u_0, u_0 \rangle + \sum_{k=1}^n c_k \langle u_k, u_0 \rangle + \sum_{k=1}^n d_k \langle v_k, u_0 \rangle && \text{Distributive laws} \\ &= c_0 \|u_0\|^2 + \sum_{k=1}^n c_k \cdot 0 + \sum_{k=1}^n d_k \cdot 0 && \text{Orthogonality} \\ &= c_0 \cdot 1 + 0 + 0 = c_0. && u_0 \text{ is a unit function} \end{aligned}$$

It follows from this that q is orthogonal to u_0 because $q = f - p_n$, and therefore

$$\langle q, u_0 \rangle = \langle f - p_n, u_0 \rangle = \langle f, u_0 \rangle - \langle p_n, u_0 \rangle = c_0 - c_0 = 0.$$

A similar calculation holds for inner products of q with each of the functions u_1, u_2, \dots, u_n and each of v_1, v_2, \dots, v_n . That is, q is orthogonal to every one of these functions. Using the distributive law again, it follows that q is orthogonal to every linear combination of u_0 and u_1, u_2, \dots, u_n and v_1, v_2, \dots, v_n . Now, p_n is a linear combination of those functions, and so is w , so q is orthogonal to both p_n and w . Hence

$$\langle q, z \rangle = \langle q, p_n - w \rangle = \langle q, p_n \rangle - \langle q, w \rangle = 0 - 0 = 0,$$

and so we see that q and z are orthogonal. Therefore, we can apply the Pythagorean Theorem for functions:

$$\begin{aligned} \|f - w\|^2 &= \|q + z\|^2 && q = f - p_n, z = p_n - w \\ &= \|q\|^2 + \|z\|^2 && \text{Pythagorean Theorem} \\ &\geq \|q\|^2 + 0 && \|z\|^2 \geq 0 \\ &= \|f - p_n\|^2. && q = f - p_n \end{aligned}$$

Taking square roots, it follows that $\|f - p_n\| \leq \|f - w\|$. ■

We now show how to write the function p_n that is closest to f directly in terms of sines and cosines. We call the function p_n given in Equation (11) a **trigonometric polynomial of degree n** . The numbers a_0 , a_k , and b_k defined in this theorem are called the **Fourier coefficients** of f .

THEOREM 8 Let f be an integrable function on $[0, 2\pi]$ and let n be a positive integer. Define real numbers

$$\begin{aligned} a_0 &= \frac{1}{2\pi} \langle f, \mathbf{1} \rangle = \frac{1}{2\pi} \int_0^{2\pi} f(x) dx, \\ a_k &= \frac{1}{\pi} \langle f, \cos kx \rangle = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos kx dx, \\ b_k &= \frac{1}{\pi} \langle f, \sin kx \rangle = \frac{1}{\pi} \int_0^{2\pi} f(x) \sin kx dx, \end{aligned}$$

where k is a positive integer. Then the best approximation to f by a linear combination of $\mathbf{1}$, $\cos x$, ..., $\cos nx$, $\sin x$, ..., $\sin nx$ is

$$p_n(x) = a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx. \quad (11)$$

Proof By Theorem 7, the best approximation is the function p_n given in Equation (10). Expanding and simplifying shows that this function satisfies Equation (11):

$$\begin{aligned} p_n(x) &= \langle f, u_0 \rangle u_0(x) + \sum_{k=1}^n \langle f, u_k \rangle u_k(x) + \sum_{k=1}^n \langle f, v_k \rangle v_k(x) \\ &= \left\langle f, \frac{\mathbf{1}}{\sqrt{2\pi}} \right\rangle \frac{\mathbf{1}}{\sqrt{2\pi}} + \sum_{k=1}^n \left\langle f, \frac{\cos kx}{\sqrt{\pi}} \right\rangle \frac{\cos kx}{\sqrt{\pi}} + \sum_{k=1}^n \left\langle f, \frac{\sin kx}{\sqrt{\pi}} \right\rangle \frac{\sin kx}{\sqrt{\pi}} \\ &= \frac{1}{2\pi} \langle f, \mathbf{1} \rangle \mathbf{1} + \sum_{k=1}^n \frac{1}{\pi} \langle f, \cos kx \rangle \cos kx + \sum_{k=1}^n \frac{1}{\pi} \langle f, \sin kx \rangle \sin kx \\ &= a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx. \quad \blacksquare \end{aligned}$$

EXAMPLE 3 Let f be the function defined in Equation (1). We will verify that the function p_n given in Equation (2) is the best approximation to f by a trigonometric polynomial of degree n . We must compute the numbers a_0 , a_k , and b_k given in Theorem 8. If k is a positive integer, then we use Equation 86 from the Table of Integrals to compute that

$$\begin{aligned} b_k &= \frac{1}{\pi} \int_0^{2\pi} (x - \pi) \sin kx dx \\ &= \frac{1}{\pi} \int_0^{2\pi} x \sin kx dx - \int_0^{2\pi} \sin kx dx \\ &= \frac{1}{\pi} \left[\frac{\sin kx}{k^2} - \frac{x \cos kx}{k} \right]_0^{2\pi} - 0 = \frac{1}{\pi} \left(\frac{-2\pi}{k} \right) = -\frac{2}{k}. \end{aligned}$$

A similar calculation shows that $a_0 = 0$ and $a_k = 0$ for every $k > 0$. Therefore, the best approximation uses amplitude zero for the constant term and the cosine terms, and amplitude $-2/k$ for the sine term of frequency k , so

$$p_n(x) = -2 \left(\sin x + \frac{\sin 2x}{2} + \cdots + \frac{\sin nx}{n} \right) = -2 \sum_{k=1}^n \frac{\sin kx}{k}.$$

This is the trigonometric polynomial given in Equation (2). ■

EXAMPLE 4 Let f be the step function

$$f(x) = \begin{cases} 1, & 0 \leq x < \pi \text{ or } x = 2\pi, \\ 2, & \pi \leq x < 2\pi. \end{cases}$$

Find the best approximation to f by a trigonometric polynomial of degree n .

Solution We compute the Fourier coefficients for f . If k is a positive integer, then

$$\begin{aligned} b_k &= \frac{1}{\pi} \int_0^{2\pi} f(x) \sin kx \, dx \\ &= \frac{1}{\pi} \int_0^{\pi} \sin kx \, dx + \frac{1}{\pi} \int_{\pi}^{2\pi} 2 \sin kx \, dx \\ &= \frac{1}{\pi} \left(\left[\frac{-\cos kx}{k} \right]_0^{\pi} + \left[\frac{-2 \cos kx}{k} \right]_{\pi}^{2\pi} \right) \\ &= \frac{\cos k\pi - 1}{k\pi} = \frac{(-1)^k - 1}{k\pi} = \begin{cases} -\frac{2}{k\pi}, & k \text{ odd,} \\ 0, & k \text{ even.} \end{cases} \end{aligned}$$

A similar calculation shows that $a_0 = 3/2$, but $a_k = 0$ for every $k > 0$. Therefore, the best approximation to f uses only a constant term and sine terms with odd frequencies. Specifically, if n is odd then the linear combination of $\mathbf{1}$, $\sin x$, \dots , $\sin nx$ that is closest to f is

$$p_n(x) = \frac{3}{2} - \frac{2}{\pi} \left(\sin x + \frac{\sin 3x}{3} + \frac{\sin 5x}{5} + \dots + \frac{\sin nx}{n} \right).$$

At the point $x = \pi$, where $f(x)$ jumps from 1 to 2, all of the sine terms vanish, so $p_n(\pi) = 3/2$ for every n . This is not the value of $f(\pi)$, nor does it approach closer to $f(\pi)$ as n increases. This does not contradict the fact that p_n is the best approximation to f because best does not mean that $p_n(x)$ is close to $f(x)$ at every point. Instead, p_n is the best approximation because the *error* is being measured here by an integral. The error in the approximation is the distance between f and p_n , which is

$$\|f - p_n\| = \sqrt{\int_0^{2\pi} (f(x) - p_n(x))^2 \, dx}.$$

Out of all linear combinations using frequencies of at most n , the trigonometric polynomial p_n minimizes this error, which is defined by an integral that takes all of the values of $f(x)$ and $p_n(x)$ across the entire domain $[0, 2\pi]$ into account (see Figure 19.8). ■

Convergence of Fourier Series

If f is an integrable function on $[0, 2\pi]$, then Theorem 8 gives us the best approximation p_n to f by a linear combination of $\mathbf{1}$, $\cos x$, \dots , $\cos nx$, $\sin x$, \dots , $\sin nx$. The only information that we needed to prove this theorem is that the functions in the trigonometric system are orthogonal. Looking at Figures 19.3 and 19.7, it appears that the approximation p_n becomes closer to f in some sense as n increases. The next theorem makes this precise. Specifically, it is the distance $\|f - p_n\|$ between f and p_n that converges to zero as $n \rightarrow \infty$.

THEOREM 9 Let f be an integrable function on $[0, 2\pi]$ and for each positive integer n let p_n be the function defined in Equation (11). Then the distance between f and p_n converges to zero as $n \rightarrow \infty$:

$$\lim_{n \rightarrow \infty} \|f - p_n\| = \lim_{n \rightarrow \infty} \sqrt{\int_0^{2\pi} (f(x) - p_n(x))^2 \, dx} = 0.$$

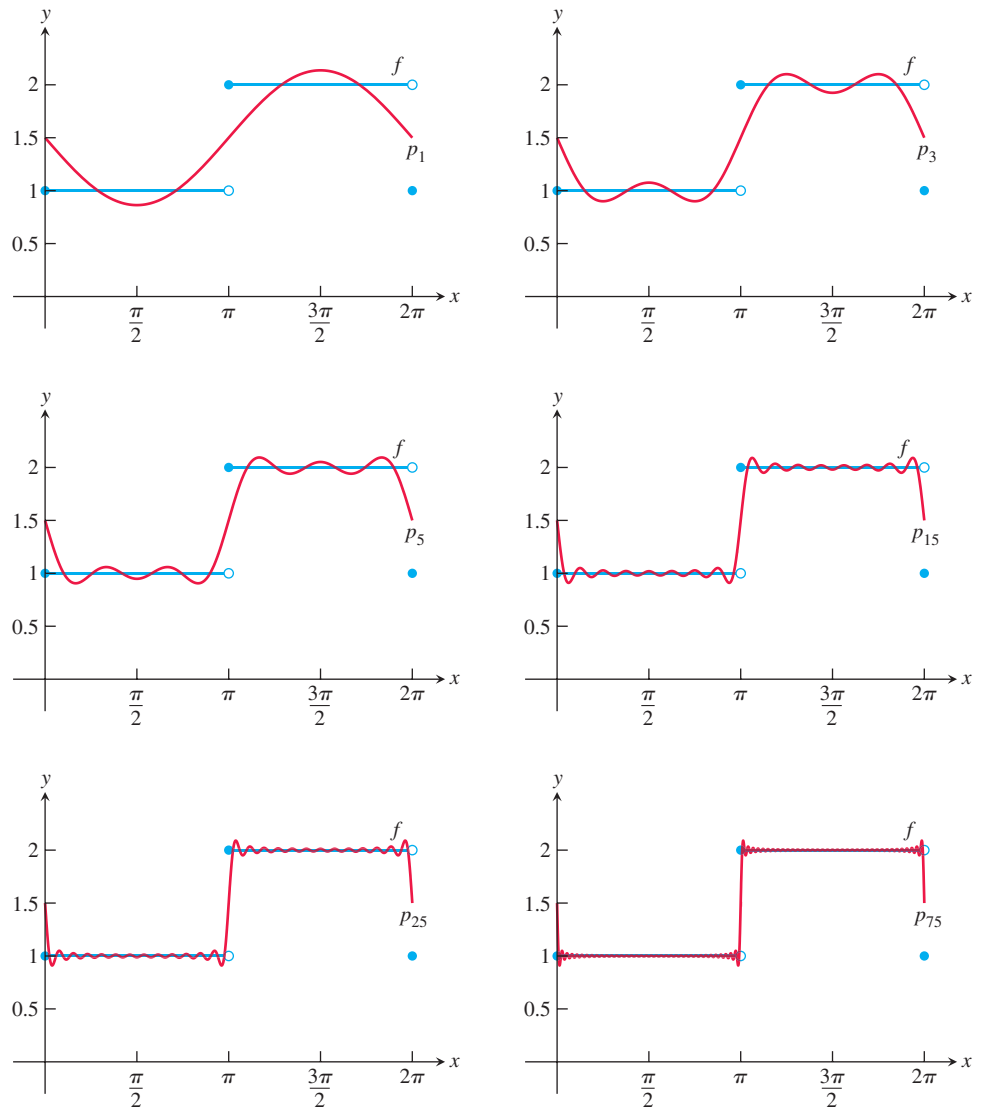

FIGURE 19.8 The trigonometric polynomials p_1 , p_3 , p_5 , p_{15} , p_{25} , and p_{75} approximating the function f from Example 4

The proof of Theorem 9 is harder than the proof of Theorem 8. It can be found in advanced texts on real analysis. We can get some insight into why the proof is difficult by recalling our discussion of orthonormal bases in three dimensions. Whenever we have three orthonormal vectors \mathbf{r} , \mathbf{s} , \mathbf{t} in three-dimensional space, we know that these three vectors form an orthonormal basis, and therefore every vector \mathbf{v} can be written as a linear combination of those three vectors, as shown in Theorem 2. A similar fact holds in higher-dimensional space. That is, a set of d orthonormal vectors in d -dimensional space will be an orthonormal basis for that space (Theorem 4). However, the normalized trigonometric system is a set of *infinitely many* orthonormal functions. Just having infinitely many orthonormal functions is not enough to ensure that they form the correct analogue of an orthonormal basis. For example, the cosine functions $\cos x$, $\cos 2x$, $\cos 3x$, ... are infinitely many orthogonal functions, but they are only “half” of the trigonometric system. The difficulty in the proof of Theorem 9 is in showing that the trigonometric system contains “enough” functions.

Let a_0 , a_k , and b_k be the Fourier coefficients of f as given in Theorem 8, and let

$$p_n(x) = a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx$$

be the trigonometric polynomial defined in Equation (11). Theorem 9 says that if f is an integrable function, then p_n converges to f in the sense that the distance $\|f - p_n\| = \sqrt{\int_0^{2\pi} (f(x) - p_n(x))^2 dx}$ between p_n and f converges to zero as $n \rightarrow \infty$. This does not imply that $p_n(x)$ must converge to $f(x)$ at each point x . We often call

$$a_0 + \sum_{k=1}^{\infty} a_k \cos kx + \sum_{k=1}^{\infty} b_k \sin kx \quad (12)$$

the **Fourier series** for f , but it is important to note that this series need not converge. Under the right hypothesis, it will be true that $p_n(x)$ converges to $f(x)$, and hence $f(x)$ will equal its Fourier series at x . Loosely speaking, the smoother that f is, the “better” the convergence of $p_n(x)$ to $f(x)$ will be. The following result, whose proof we will omit, states that if f is smooth enough as a periodic function on the real line, then convergence will hold at every point, and the maximum difference between $f(x)$ and $p_n(x)$ shrinks as n increases.

THEOREM 10 Let f be a function on $[0, 2\pi]$ such that $f(0) = f(2\pi)$, and extend f to be a periodic function on the real line by repeating values every 2π units. If f is differentiable at every point and f' is continuous, then we have for every x that

$$f(x) = \lim_{n \rightarrow \infty} p_n(x) = a_0 + \sum_{k=1}^{\infty} a_k \cos kx + \sum_{k=1}^{\infty} b_k \sin kx.$$

Further, if for each n we let M_n be the maximum value of $|f(x) - p_n(x)|$ over all x , then

$$\lim_{n \rightarrow \infty} M_n = 0.$$

The function f pictured in Figure 19.8 does not satisfy the hypotheses of Theorem 10, and it can be shown that for that function the maximum M_n defined in Theorem 10 does not decrease to zero as n increases (this is known as the **Gibbs phenomenon**).

The Parseval Equality for Fourier Series

By Exercise 30 of Section 19.3, if $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis for d -dimensional space, then the *Parseval Equality* holds for every vector \mathbf{v} in d -dimensional space:

$$|\mathbf{v}|^2 = \sum_{k=1}^d (\mathbf{v} \cdot \mathbf{u}_k)^2.$$

We will prove an analogous result for Fourier series.

THEOREM 11 – The Parseval Equality

If f is an integrable function on $[0, 2\pi]$, then

$$\|f\|^2 = 2\pi a_0^2 + \pi \sum_{k=1}^{\infty} a_k^2 + \pi \sum_{k=1}^{\infty} b_k^2.$$

Proof Let p_n be the trigonometric polynomial of degree n given in Equation (11). According to Exercise 34, we have $\langle p_n, \mathbf{1} \rangle = 2\pi a_0$, while $\langle p_n, \cos kx \rangle = \pi a_k$ and $\langle p_n, \sin kx \rangle = \pi b_k$ for $k = 1, \dots, n$. Therefore,

$$\|p_n\|^2 = \langle p_n, p_n \rangle \quad \text{Equation (8)}$$

$$= \left\langle p_n, a_0 + \sum_{k=1}^n a_k \cos kx + \sum_{k=1}^n b_k \sin kx \right\rangle \quad \text{Equation (11)}$$

$$= \langle p_n, a_0 \mathbf{1} \rangle + \sum_{k=1}^n a_k \langle p_n, \cos kx \rangle + \sum_{k=1}^n b_k \langle p_n, \sin kx \rangle \quad \text{Distributive property}$$

$$= a_0 \langle p_n, \mathbf{1} \rangle + \sum_{k=1}^n a_k \pi a_k + \sum_{k=1}^n b_k \pi b_k. \quad \text{Exercise 34}$$

$$= 2\pi a_0^2 + \pi \sum_{k=1}^n a_k^2 + \pi \sum_{k=1}^n b_k^2. \quad \text{Exercise 34 and simplify}$$

Since Theorem 9 tells us that $\|f - p_n\| \rightarrow 0$, it follows that

$$\|f\|^2 = \lim_{n \rightarrow \infty} \|p_n\|^2 \quad \text{Exercise 28}$$

$$= \lim_{n \rightarrow \infty} \left(2\pi a_0^2 + \pi \sum_{k=1}^n a_k^2 + \pi \sum_{k=1}^n b_k^2 \right) \quad \text{Calculated above}$$

$$= 2\pi a_0^2 + \pi \sum_{k=1}^{\infty} a_k^2 + \pi \sum_{k=1}^{\infty} b_k^2. \quad \text{Monotonic Sequence Theorem (Theorem 6 in Section 9.1)} \quad \blacksquare$$

EXAMPLE 5 Let f be the function from Example 4. The square of the norm of f is

$$\|f\|^2 = \int_0^\pi 1^2 dx + \int_\pi^{2\pi} 2^2 dx = 5\pi.$$

We saw in Example 4 that $a_0 = 3/2$, $a_k = 0$ for all $k > 0$, $b_k = -2/(k\pi)$ if k is odd, and $b_k = 0$ if k is even. Theorem 10 therefore implies that

$$\begin{aligned} 5\pi = \|f\|^2 &= 2\pi a_0^2 + \pi \sum_{k=1}^{\infty} a_k^2 + \pi \sum_{k=1}^{\infty} b_k^2 \\ &= 2\pi \frac{9}{4} + 0 + \pi \sum_{k \text{ odd}} \left(\frac{-2}{k\pi} \right)^2 \\ &= \frac{18\pi}{4} + 0 + \frac{4}{\pi} \sum_{k \text{ odd}} \frac{1}{k^2}. \end{aligned}$$

Simplifying, we obtain

$$\sum_{k=1}^{\infty} \frac{1}{(2k-1)^2} = \sum_{k \text{ odd}} \frac{1}{k^2} = \frac{\pi^2}{8}.$$

Therefore,

$$\sum_{k=1}^{\infty} \frac{1}{k^2} = \sum_{k=1}^{\infty} \frac{1}{(2k-1)^2} + \sum_{k=1}^{\infty} \frac{1}{(2k)^2} = \frac{\pi^2}{8} + \frac{1}{4} \sum_{k=1}^{\infty} \frac{1}{k^2}.$$

This gives us

$$\frac{3}{4} \sum_{k=1}^{\infty} \frac{1}{k^2} = \frac{\pi^2}{8},$$

and hence

$$\sum_{k=1}^{\infty} \frac{1}{k^2} = \frac{\pi^2}{6}. \quad (13) \quad \blacksquare$$

EXERCISES 19.4

Norms of Functions

In Exercises 1–6, a periodic function with period 2π is defined by specifying its values on the interval $[0, 2\pi]$. Find the norm of each function.

$$1. f(x) = \begin{cases} x, & 0 \leq x \leq \pi \\ 2\pi - x, & \pi < x \leq 2\pi \end{cases}$$

$$2. g(x) = \begin{cases} 1, & \pi/2 < x < 3\pi/2 \\ 0, & 0 \leq x \leq \pi/2 \text{ or } 3\pi/2 \leq x \leq 2\pi \end{cases}$$

$$3. h(x) = (x - \pi)^2$$

$$4. j(x) = \begin{cases} x^2, & 0 \leq x \leq \pi \\ 0, & \pi < x \leq 2\pi \end{cases}$$

$$5. k(x) = \begin{cases} e^x, & 0 \leq x < 2\pi \\ 1, & x = 2\pi \end{cases}$$

$$6. \ell(x) = \begin{cases} \cos x, & 0 \leq x \leq \pi \\ 1, & \pi < x \leq 2\pi \end{cases}$$

Inner Product of Functions

In Exercises 7–12, use the functions defined in Exercises 1–6 to compute the given inner product. Are the two functions orthogonal?

$$7. \langle g, j \rangle \qquad 8. \langle k, \cos x \rangle$$

$$9. \langle h, \mathbf{1} \rangle \qquad 10. \langle \ell, \mathbf{1} \rangle$$

$$11. \langle f, \sin 3x \rangle \qquad 12. \langle \ell, \cos x \rangle$$

Finding Fourier Series

In Exercises 13–18, find the Fourier coefficients a_0 , a_k , and b_k and the trigonometric polynomial p_n of degree n for the given function. If available, use a CAS to plot p_n for various values of n over the domain $[-2\pi, 4\pi]$.

13. The function f from Exercise 1.

14. The function g from Exercise 2.

15. The function h from Exercise 3.

16. The function j from Exercise 4.

17. The function k from Exercise 5.

18. The function ℓ from Exercise 6.

The Parseval Equality

19. Apply the Parseval Equality to the function f defined in Equation (11) to give another proof that $\sum_{k=1}^{\infty} 1/k^2 = \pi^2/6$.

20. Apply the Parseval Equality to the function f from Exercise 1 to prove that

$$\sum_{k=1}^{\infty} \frac{1}{(2k-1)^4} = \frac{\pi^4}{96}.$$

Use that equality to prove that

$$\sum_{k=1}^{\infty} \frac{1}{k^4} = \frac{\pi^4}{90}.$$

21. Apply the Parseval Equality to the function h from Exercise 3 to give another proof of the equalities specified in Exercise 20.

22. Define a function f on $[0, 2\pi]$ by

$$f(x) = \begin{cases} x(\pi - x), & 0 \leq x \leq \pi \\ (x - \pi)(x - 2\pi), & \pi < x \leq 2\pi \end{cases}$$

Apply the Parseval Equality to this function f to prove that

$$\sum_{k=1}^{\infty} \frac{1}{(2k-1)^6} = \frac{\pi^6}{960}.$$

Use that equality to prove that

$$\sum_{k=1}^{\infty} \frac{1}{k^6} = \frac{\pi^6}{945}.$$

Theory and Examples

In Exercises 23–28, f , g , and h denote integrable functions on $[0, 2\pi]$.

23. **Symmetry** Prove that $\langle f, g \rangle = \langle g, f \rangle$.

24. **Distributive properties** Prove that if a and b are real numbers, then

$$\langle af + bg, h \rangle = a \langle f, h \rangle + b \langle g, h \rangle \quad \text{and} \\ \langle f, ag + bh \rangle = a \langle f, g \rangle + b \langle f, h \rangle.$$

25. **Cauchy–Schwarz Inequality** Prove that $|\langle f, g \rangle| \leq \|f\| \|g\|$. (Hint: Follow the approach given in Exercise 27 of Section 19.3.)

26. **Triangle Inequality** Prove that $\|f + g\| \leq \|f\| + \|g\|$. (Hint: Compare Exercise 28 in Section 19.3.)

27. **Reverse Triangle Inequality** Prove that $\left| \|f\| - \|g\| \right| \leq \|f - g\|$. (Hint: Compare Exercise 29 in Section 19.3.)

28. **Convergence of norms** Use Theorem 9 and the Reverse Triangle Inequality (Exercise 27) to prove that $\lim_{n \rightarrow \infty} \|p_n\| = \|f\|$.

29. Let $f(x) = 1 + \cos x + \sin x$. Find the Fourier coefficients a_0 , a_k , and b_k and the trigonometric polynomial p_n of degree n corresponding to f .

30. Suppose that $f(x) = c_0 + \sum_{j=1}^m c_j \cos jx + \sum_{j=1}^m d_j \sin jx$. What are the Fourier coefficients a_0 , a_k , and b_k for f ? Prove that p_n is equal to f for all $n \geq m$.

Establish the identities stated in Exercises 31–33, where m and n are positive integers.

31. If $m \neq n$, then $\langle \sin mx, \sin nx \rangle = \int_0^{2\pi} \sin mx \sin nx \, dx = 0$. (Hint: $\sin A \sin B = (\cos(A - B) - \cos(A + B))/2$.)

32. If $m \neq n$, then $\langle \cos mx, \cos nx \rangle = \int_0^{2\pi} \cos mx \cos nx \, dx = 0$. (Hint: $\cos A \cos B = (\cos(A + B) + \cos(A - B))/2$.)

33. $\langle \sin mx, \cos nx \rangle = \int_0^{2\pi} \sin mx \cos nx \, dx = 0$. (Hint: $\sin A \cos B = (\sin(A + B) + \sin(A - B))/2$.)

34. Let f be an integrable function on $[0, 2\pi]$, and let p_n be the trigonometric polynomial defined in Equation (11). Prove that:

$$\mathbf{a.} \langle p_n, \mathbf{1} \rangle = 2\pi a_0.$$

$$\mathbf{b.} \langle p_n, \cos jx \rangle = \pi a_k \text{ for } j = 1, \dots, n.$$

$$\mathbf{c.} \langle p_n, \sin jx \rangle = \pi b_k \text{ for } j = 1, \dots, n.$$

19.5 Advanced Topic: The Haar System and Wavelets

Fourier series approximations are based on the trigonometric system, which is an orthogonal collection of functions. Today many sets of orthonormal functions are used in mathematics, science, and engineering. We will discuss a family of systems collectively known as *wavelets*, which are especially useful in signal and image processing, data analysis, and related areas. The JPEG 2000 image compression standard uses wavelets.

In contrast to Fourier series approximations, which are best suited to applications involving periodic functions, wavelets can be used to approximate functions that are not periodic. The domain of the functions in the wavelet systems that we will discuss will be the entire real line, but each individual wavelet function that we will consider is identically zero outside of some finite interval, and is integrable on that interval.

We say that a function that is integrable on an interval $[a, b]$ and identically zero outside of that interval is **supported in** $[a, b]$. The function may be zero at points within $[a, b]$. If f is supported in $[a, b]$, then its **norm** is

$$\|f\| = \sqrt{\int_a^b |f(x)|^2 dx}.$$

Since f is zero outside of $[a, b]$, we often write this integral as

$$\|f\| = \sqrt{\int_{-\infty}^{\infty} |f(x)|^2 dx}.$$

We say that f is a **unit function** if $\|f\| = 1$.

If g is another integrable function that is supported in an interval $[c, d]$ (which need not equal $[a, b]$), then the **inner product** of f and g is

$$\langle f, g \rangle = \int_{-\infty}^{\infty} f(x) g(x) dx. \quad (14)$$

The product $f(x)g(x)$ is identically zero outside of the intersection of the intervals $[a, b]$ and $[c, d]$.

We say that two functions f and g are **orthogonal** if $\langle f, g \rangle = 0$. Functions f and g are **orthonormal** if they are orthogonal and both are unit functions ($\|f\| = \|g\| = 1$). A collection of functions is orthogonal if any two different functions from the collection are orthogonal, and the collection is orthonormal if it is orthogonal and every function in the collection is a unit function.

The Haar System

The first wavelet system was introduced by Alfréd Haar (1885–1933). The construction is based on two simple functions that are each supported in the interval $[0, 1]$. The first is the **box function** or **Haar scaling function**,

$$\varphi(x) = \begin{cases} 1, & 0 \leq x < 1, \\ 0, & x < 0 \text{ or } x \geq 1, \end{cases}$$

and the second is the **square wave** or **Haar wavelet**,

$$\psi(x) = \begin{cases} 1, & 0 \leq x < \frac{1}{2}, \\ -1, & \frac{1}{2} \leq x < 1, \\ 0, & x < 0 \text{ or } x \geq 1. \end{cases}$$

These functions are shown in Figure 19.9.

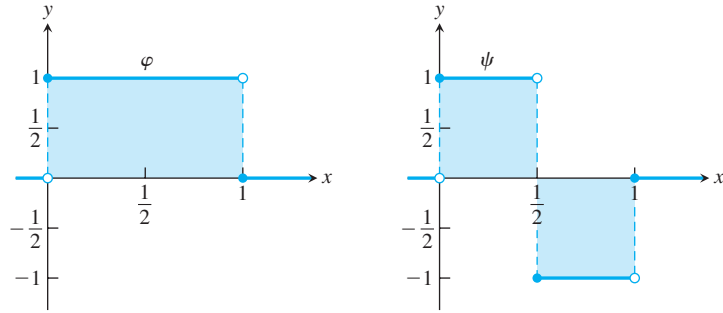

FIGURE 19.9 The Haar scaling function φ and the Haar wavelet ψ . The region between the graphs and the x -axis is shaded.

We have $\|\varphi\| = 1$ and $\|\psi\| = 1$, so φ and ψ are unit functions. Further, they are orthogonal, because their inner product is zero:

$$\begin{aligned} \langle \varphi, \psi \rangle &= \int_{-\infty}^{\infty} \varphi(x) \psi(x) dx \\ &= \int_0^1 \varphi(x) \psi(x) dx \\ &= \int_0^{1/2} 1 \cdot 1 dx + \int_{1/2}^1 1 \cdot (-1) dx = \frac{1}{2} - \frac{1}{2} = 0. \end{aligned}$$

Now we create more functions based on φ and ψ . For each integer k , we horizontally translate φ by k units to obtain the function

$$\varphi_k(x) = \varphi(x - k) = \begin{cases} 1, & k \leq x < k + 1, \\ 0, & x < k \text{ or } x \geq k + 1. \end{cases}$$

We say that φ_k is the **box function on** $[k, k + 1)$. If $j \neq k$, then the product $\varphi_j(x) \varphi_k(x)$ is identically zero. Therefore, $\langle \varphi_j, \varphi_k \rangle = 0$ whenever $j \neq k$.

Next, we translate and also *dilate* (stretch or compress) the Haar wavelet to create new functions $\psi_{n,k}$, where n and k are integers. For $n = 0$ there is no dilation, only translation:

$$\psi_{0,k}(x) = \psi(x - k) = \begin{cases} 1, & k \leq x < k + \frac{1}{2}, \\ -1, & k + \frac{1}{2} \leq x < k + 1, \\ 0, & x < k \text{ or } x \geq k + 1. \end{cases}$$

For $n = 1$ we horizontally shrink ψ by a factor of 2 and horizontally translate by $k/2$ units, also vertically rescaling so that the resulting function has norm 1:

$$\psi_{1,k}(x) = 2^{1/2} \psi(2x - k) = 2^{1/2} \psi(2(x - k/2)) = \begin{cases} \sqrt{2}, & \frac{k}{2} \leq x < \frac{k}{2} + \frac{1}{4}, \\ -\sqrt{2}, & \frac{k}{2} + \frac{1}{4} \leq x < \frac{k}{2} + \frac{1}{2}, \\ 0, & x < \frac{k}{2} \text{ or } x \geq \frac{k}{2} + \frac{1}{2}. \end{cases}$$

The functions $\psi_{1,k}$ for $k = 0, 1, 2, 3$ are shown in Figure 19.10.

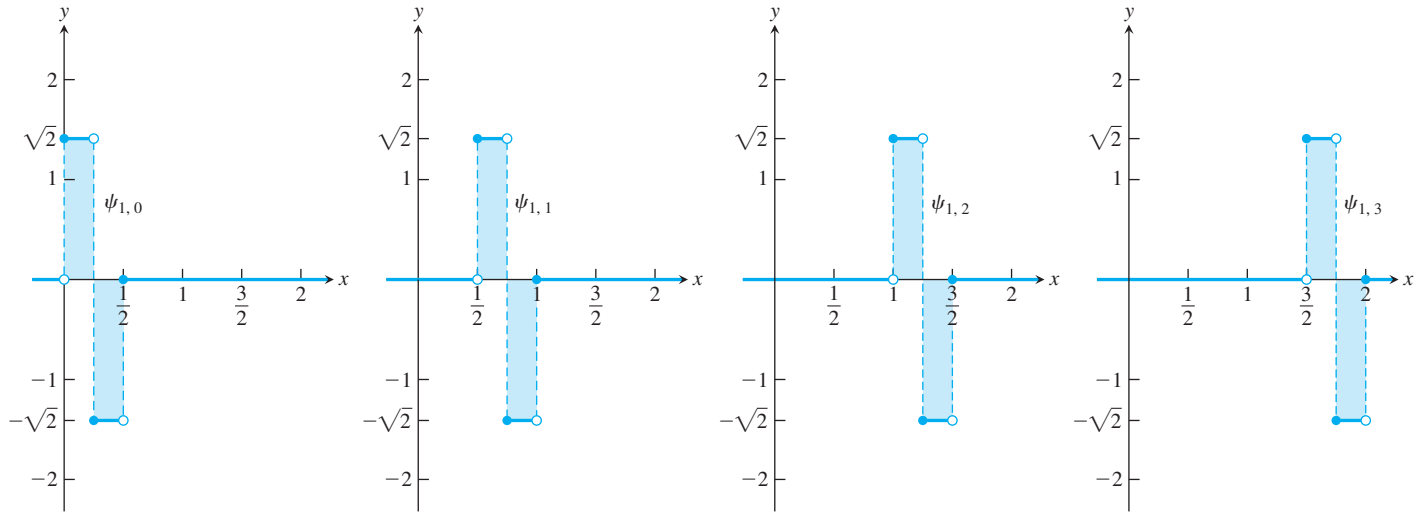

FIGURE 19.10 The functions $\psi_{1,0}$, $\psi_{1,1}$, $\psi_{1,2}$, and $\psi_{1,3}$.

For arbitrary integers n and k we define

$$\psi_{n,k}(x) = 2^{n/2} \psi(2^n x - k) = \begin{cases} 2^{n/2}, & 2^{-n}k \leq x < 2^{-n}\left(k + \frac{1}{2}\right), \\ -2^{n/2}, & 2^{-n}\left(k + \frac{1}{2}\right) \leq x < 2^{-n}(k + 1), \\ 0, & x < 2^{-n}k \text{ or } x \geq 2^{-n}(k + 1). \end{cases}$$

We refer to $\psi_{n,k}$ as a **wavelet**. It is supported in the interval $[2^{-n}k, 2^{-n}(k + 1)]$, which has length 2^{-n} . We have $\psi_{n,k}$ take the values $\pm 2^{n/2}$ instead of ± 1 so that it is a unit function (Exercise 19).

For $n \geq 0$, the wavelet $\psi_{n,k}$ is obtained by compressing the Haar wavelet ψ and translating and rescaling it, while $n < 0$ corresponds to a stretching of ψ along with a translation and rescaling. It is useful in some applications to consider $\psi_{n,k}$ with negative n , but for our purposes we will define the Haar system using only $n \geq 0$. The functions $\psi_{2,k}$ for $k = 0, 1, 2, 3$ are shown in Figure 19.11.

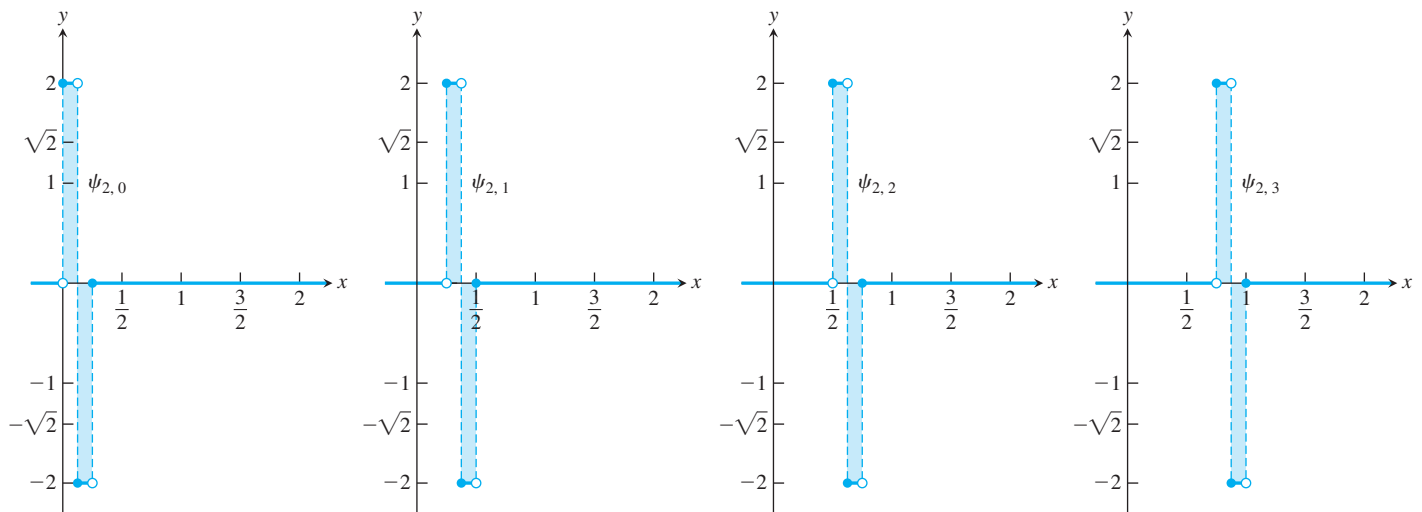

FIGURE 19.11 The functions $\psi_{2,0}$, $\psi_{2,1}$, $\psi_{2,2}$, and $\psi_{2,3}$.

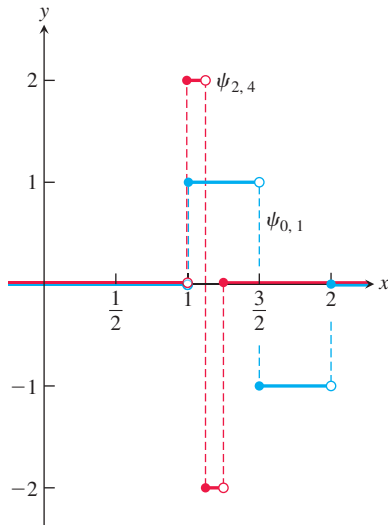

FIGURE 19.12 The functions $\psi_{0,1}$ and $\psi_{2,4}$. The second function completes its oscillation on an interval where the first function is constant.

DEFINITION The **Haar system** is the collection of functions φ_k for integers k , together with $\psi_{n,k}$ for integers k and integers $n \geq 0$.

Each function in the Haar system is a unit function. Further, any two different elements are orthogonal. To illustrate why this is, consider the specific two wavelets $\psi_{0,1}$ and $\psi_{2,4}$ shown in Figure 19.12. The wavelet $\psi_{0,1}$ is supported in the interval $[1, 2]$, while $\psi_{2,4}$ is supported in $[1, 5/4]$. Therefore, their product is $\psi_{0,1}(x)\psi_{2,4}(x) = 0$ for every x outside $[1, 5/4]$. For all x inside $[1, 5/4)$ we have $\psi_{0,1}(x) = 1$, so for these x the product is $\psi_{0,1}(x)\psi_{2,4}(x) = \psi_{2,4}(x)$. Consequently, their inner product is

$$\langle \psi_{0,1}, \psi_{2,4} \rangle = \int_{-\infty}^{\infty} \psi_{0,1}(x)\psi_{2,4}(x) dx = \int_1^{5/4} \psi_{2,4}(x) dx = 0.$$

This shows that $\psi_{0,1}$ and $\psi_{2,4}$ are orthogonal. A similar argument shows that any two different functions $\psi_{n,k}$ and $\psi_{m,j}$ are orthogonal, and that $\psi_{n,k}$ is orthogonal to every function φ_j (Exercise 20). Therefore, the Haar system is an orthonormal collection of functions.

DEFINITION Let f be an integrable function that is supported in a finite interval. The **Haar coefficients** of f are the numbers

$$\begin{aligned} a_k &= \langle f, \varphi_k \rangle \quad \text{for integer } k, \\ b_{n,k} &= \langle f, \psi_{n,k} \rangle \quad \text{for integer } k \text{ and nonnegative integer } n. \end{aligned}$$

Since φ_k is identically 1 on $[k, k+1)$ and 0 elsewhere, the Haar coefficient a_k is given by

$$a_k = \langle f, \varphi_k \rangle = \int_{-\infty}^{\infty} f(x)\varphi_k(x) dx = \int_k^{k+1} f(x) dx. \quad (15)$$

This is the average value of f on the interval $[k, k+1)$.

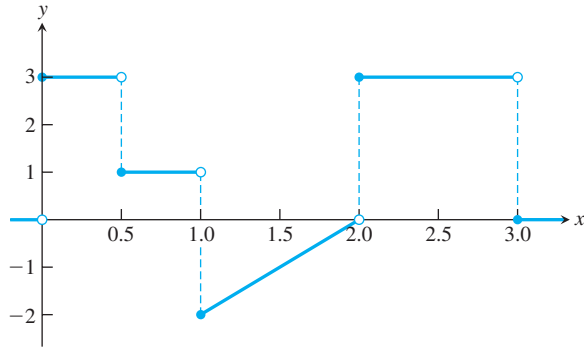

The function $\psi_{n,k}(x)$ takes the value $2^{n/2}$ for $2^{-n}k \leq x < 2^{-n}(k + \frac{1}{2})$, the value $-2^{n/2}$ for $2^{-n}(k + \frac{1}{2}) \leq x < 2^{-n}(k+1)$, and 0 elsewhere. Therefore, the Haar coefficient $b_{n,k}$ is given by

$$\begin{aligned} b_{n,k} &= \langle f, \psi_{n,k} \rangle = \int_{-\infty}^{\infty} f(x)\psi_{n,k}(x) dx \\ &= 2^{n/2} \int_{2^{-n}k}^{2^{-n}(k+1/2)} f(x) dx - 2^{n/2} \int_{2^{-n}(k+1/2)}^{2^{-n}(k+1)} f(x) dx. \end{aligned} \quad (16)$$

EXAMPLE 1 Find the Haar coefficients for the function

$$f(x) = \begin{cases} 3, & 0 \leq x < 1/2 \\ 1, & 1/2 \leq x < 1 \\ 2x - 4, & 1 \leq x < 2 \\ 3, & 2 \leq x < 3 \\ 0, & \text{otherwise.} \end{cases}$$

This function is pictured in Figure 19.13.

FIGURE 19.13 The function f from Example 1.

Solution By Equation (15), the Haar coefficient $a_k = \langle f, \varphi_k \rangle$ is the average value of f on $[k, k + 1]$. Since f is supported in the interval $[0, 3]$, the coefficient $\langle f, \varphi_k \rangle$ can only be nonzero for $k = 0, 1$, and 2 . For these k we compute that

$$\begin{aligned} a_0 &= \langle f, \varphi_0 \rangle = \int_0^1 f(x) dx = \int_0^{1/2} 3 dx + \int_{1/2}^1 1 dx = 2 \\ a_1 &= \langle f, \varphi_1 \rangle = \int_1^2 f(x) dx = \int_1^2 (2x - 4) dx = -1 \\ a_2 &= \langle f, \varphi_2 \rangle = \int_2^3 f(x) dx = \int_2^3 3 dx = 3. \end{aligned}$$

Now consider the coefficients $b_{n,k} = \langle f, \psi_{n,k} \rangle$ with $n = 0$. The function $\psi_{0,k}$ is supported in $[k, k + 1]$ while f is supported in $[0, 3]$, so $\langle f, \psi_{0,k} \rangle$ can only be nonzero for $k = 0, 1$, and 2 . For these k we use Equation (16) to compute that

$$\begin{aligned} b_{0,0} &= \langle f, \psi_{0,0} \rangle = \int_0^{1/2} f(x) dx - \int_{1/2}^1 f(x) dx = \int_0^{1/2} 3 dx - \int_{1/2}^1 1 dx = 1 \\ b_{0,1} &= \langle f, \psi_{0,1} \rangle = \int_1^{3/2} f(x) dx - \int_{3/2}^2 f(x) dx = \int_1^{3/2} (2x - 4) dx - \int_{3/2}^2 (2x - 4) dx = -\frac{1}{2} \\ b_{0,2} &= \langle f, \psi_{0,2} \rangle = \int_2^{5/2} f(x) dx - \int_{5/2}^3 f(x) dx = \int_2^{5/2} 3 dx - \int_{5/2}^3 3 dx = 0. \end{aligned}$$

Notice that $b_{0,2}$ is zero because f is constant on the interval $[2, 3)$ while $\psi_{0,2}$ is a square wave on that interval.

Next we compute $b_{n,k} = \langle f, \psi_{n,k} \rangle$ for $n = 1$. Since f is supported in $[0, 3]$ while $\psi_{1,k}$ is supported in $[k/2, (k + 1)/2]$, this coefficient will be zero if these intervals do not overlap. Hence $b_{1,k} = 0$ for all $k < 0$ and $k > 5$. However, even for k between 0 and 5 the Haar coefficient could be zero. For example, f is constant on $[0, 1/2)$ while $\psi_{1,0}$ is a square wave on $[0, 1/2)$, so

$$\begin{aligned} b_{1,0} &= \langle f, \psi_{1,0} \rangle = 2^{1/2} \int_0^{1/4} f(x) dx - 2^{1/2} \int_{1/4}^{1/2} f(x) dx \\ &= 2^{1/2} \int_0^{1/4} 3 dx - 2^{1/2} \int_{1/4}^{1/2} 3 dx = 0. \end{aligned}$$

For the same reason, $b_{1,1}$, $b_{1,4}$, and $b_{1,5}$ are all zero. For $k = 2$ we have

$$\begin{aligned} b_{1,2} &= \langle f, \psi_{1,2} \rangle = 2^{1/2} \int_1^{5/4} f(x) dx - 2^{1/2} \int_{5/4}^{3/2} f(x) dx \\ &= 2^{1/2} \int_1^{5/4} (2x - 4) dx - 2^{1/2} \int_{5/4}^{3/2} (2x - 4) dx = -\frac{1}{4\sqrt{2}}, \end{aligned}$$

and for $k = 3$,

$$\begin{aligned} b_{1,3} &= \langle f, \psi_{1,3} \rangle = 2^{1/2} \int_{3/2}^{7/4} f(x) dx - 2^{1/2} \int_{7/4}^2 f(x) dx \\ &= 2^{1/2} \int_{3/2}^{7/4} (2x - 4) dx - 2^{1/2} \int_{7/4}^2 (2x - 4) dx = -\frac{1}{4\sqrt{2}}. \end{aligned}$$

For larger n , most of the Haar coefficients $b_{n,k} = \langle f, \psi_{n,k} \rangle$ are zero; in particular, this includes all of those for which the support of $\psi_{n,k}$ intersects $[0, 1]$ or $[2, 3]$. The coefficient $b_{n,k}$ is nonzero only for those k for which the support of $\psi_{n,k}$ intersects $[1, 2]$. ■

Approximation Using the Haar System

Now we describe how to use Haar system to create approximations of a function f . We do this in a series of steps where we first create a “low-resolution” approximation to f and then iteratively add finer and finer “details” to improve the approximation.

In the first step we find the linear combination of box functions φ_k that is closest to f . Since φ_k is 1 on $[k, k + 1)$ and zero elsewhere, this approximation, which we call p_0 , is a step function with jumps at integer points k . Because the φ_k are orthonormal functions, we know how to compute p_0 .

THEOREM 12 If f is an integrable function that is supported in a finite interval, then the linear combination of the box functions φ_k that is closest to f is

$$p_0(x) = \sum_{k=-\infty}^{\infty} a_k \varphi_k(x), \quad (17)$$

$$\text{where } a_k = \langle f, \varphi_k \rangle = \int_k^{k+1} f(x) dx.$$

The proof of Theorem 12 is similar to the proof of Theorem 7. Because f is identically zero outside of a finite interval, only finitely many Haar coefficients a_k will be nonzero, so the series in Equation (17) is actually a finite sum. In fact, if $M < N$ are integers and f is identically zero outside of the interval $[M, N]$, then $a_k = 0$ for all $k < M$ and $k \geq N$, so in this case the series in Equation (17) becomes

$$p_0(x) = \sum_{k=M}^{N-1} a_k \varphi_k(x).$$

Consider the function f from Example 1. Since f is identically zero outside of $[0, 3]$, all Haar coefficients a_k with $k < 0$ and $k \geq 3$ are zero. Using the values for a_0 , a_1 , and a_2 that we computed in that example, the best approximation p_0 to f is

$$p_0(x) = \sum_{k=0}^2 a_k \varphi_k(x) = 2\varphi_0(x) - \varphi_1(x) + 3\varphi_2(x).$$

This function is shown in Figure 19.14. As we can see, p_0 takes the average value of f on each interval $[k, k + 1]$. It is the best approximation to f by a step function that has jumps at integers. Since f is constant on the interval $[2, 3)$, the approximation p_0 equals f on that interval.

The function p_0 gives only a coarse approximation to f , analogous to representing an image using very large pixels. We refer to p_0 as the *approximation at resolution level zero*. The approximation p_0 to a function g that varies considerably across the interval $[0, 3]$ is shown in Figure 19.15.

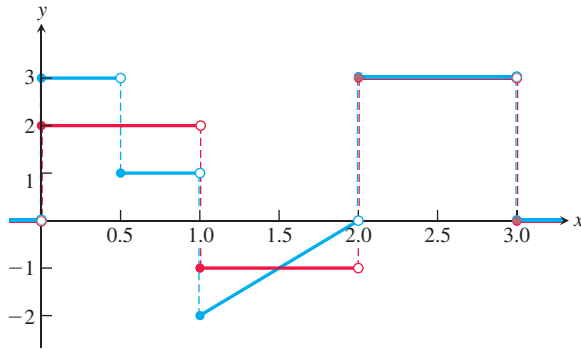

FIGURE 19.14 The function f from Example 1 (blue) and its approximation $p_0 = 2\varphi_0 - \varphi_1 + 3\varphi_2$ (red) at resolution level zero. The two functions are equal on the interval $[2, 3)$.

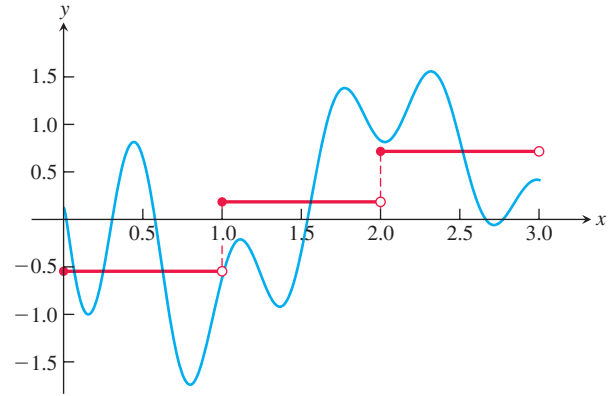

FIGURE 19.15 A function g (blue) and its approximation p_0 (red) at resolution level zero. p_0 takes the average value of g on each interval $[k, k + 1)$.

Adding Details at Resolution Level Zero

Now we will see how to create an approximation p_1 at *resolution level 1* that is better than the approximation p_0 at resolution level zero. To do this, we first create a function q_0 that represents the “details in f ” at resolution level zero. This function is

$$q_0(x) = \sum_{k=-\infty}^{\infty} b_{0,k} \psi_{0,k}(x), \quad (18)$$

where $b_{0,k} = \langle f, \psi_{0,k} \rangle$. Since f is supported in a finite interval, only finitely many of the Haar coefficients $b_{0,k}$ can be nonzero, so the series in Equation (18) is actually a finite sum. Hence the detail function q_0 is a linear combination of finitely many of the wavelets $\psi_{0,k}$.

In Example 1 we computed the Haar coefficients $b_{0,k}$ for the function f shown in Figure 19.13. Using those coefficients, we see that the detail function for this f is

$$q_0(x) = b_{0,0} \psi_{0,0}(x) + b_{0,1} \psi_{0,1}(x) + b_{0,2} \psi_{0,2}(x) = \psi_{0,0}(x) - \frac{1}{2} \psi_{0,1}(x).$$

This function is shown in Figure 19.16.

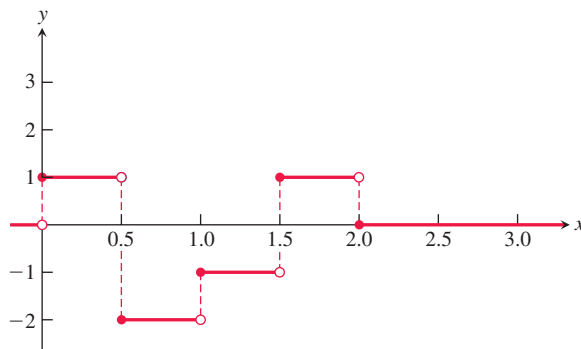

FIGURE 19.16 The detail function $q_0 = \psi_{0,0} - \frac{1}{2}\psi_{0,1}$ for the function f from Example 1.

The detail function q_0 is not itself a good approximation to f ; instead, it gives us the information needed to move from the coarse approximation p_0 to a better approximation p_1 . Specifically, p_1 is obtained by adding the detail function q_0 to the approximation p_0 :

$$p_1(x) = p_0(x) + q_0(x) = \sum_{k=-\infty}^{\infty} a_k \varphi_k(x) + \sum_{k=-\infty}^{\infty} b_{0,k} \psi_{0,k}(x).$$

As before, only finitely many terms in each series can be nonzero, so these are actually finite sums. This function p_1 is the best approximation to f using both the box functions φ_k and the Haar wavelets $\psi_{0,k}$. We say that p_1 is the approximation to f at resolution level 1.

The improved approximation p_1 for the function f from Example 1 is shown in Figure 19.17. Like p_0 , it is a step function. However, while p_0 is a step function with jumps at integers k , the new approximation p_1 is a step function with jumps at points $k/2$ where k is an integer. Because f is constant on each of the intervals $[0, 1/2)$, $[1/2, 1)$, $[2, 5/2)$, and $[5/2, 3)$, the approximation p_1 equals f on those intervals. On the intervals $[1, 3/2)$ and $[3/2, 2)$ it takes the average value of f on those intervals.

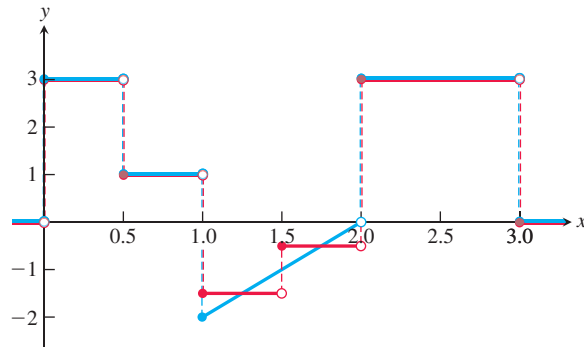

FIGURE 19.17 The approximation p_1 (red) to the function f (blue) from Example 1.

Figure 19.18 shows a superposition of p_0 and p_1 . Comparing this to Figure 19.16, we see how p_1 is obtained by adding scaled Haar wavelets $b_{0,k} \psi_{0,k}$ to p_0 .

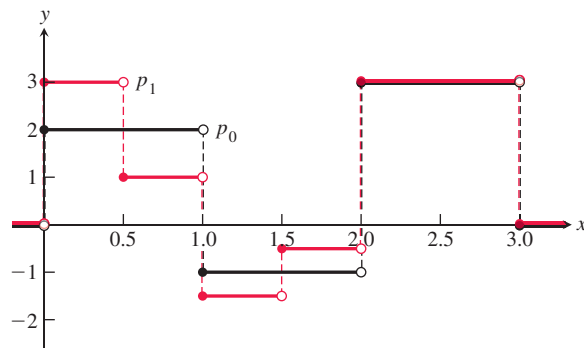

FIGURE 19.18 The approximations p_0 (black) and p_1 (red) to the function f from Example 1. We obtain p_1 by adding $q_0 = \psi_{0,0} - \frac{1}{2}\psi_{0,1}$ to p_0 .

The Multiresolution Recursion

We iterate the process described above to further improve the level of resolution in the approximation to f . The function p_1 gave us the approximation at resolution level 1. The detail function at this level is

$$q_1(x) = \sum_{k=-\infty}^{\infty} b_{1,k} \psi_{1,k}(x),$$

where $b_{1,k} = \langle f, \psi_{1,k} \rangle$. Adding q_1 to p_1 gives us the best approximation to f at resolution level 2:

$$\begin{aligned} p_2(x) &= p_1(x) + q_1(x) \\ &= p_0(x) + q_0(x) + q_1(x) \\ &= \sum_{k=-\infty}^{\infty} a_k \varphi_k(x) + \sum_{k=-\infty}^{\infty} b_{0,k} \psi_{0,k}(x) + \sum_{k=-\infty}^{\infty} b_{1,k} \psi_{1,k}(x). \end{aligned}$$

This is a step function with jumps at points $k/4$ where k is an integer. The approximation p_0 at resolution level zero for a function g was shown in Figure 19.15. Figure 19.19 shows the approximation p_1 at resolution level 1 and the approximation p_2 at resolution level 2 for this same function g .

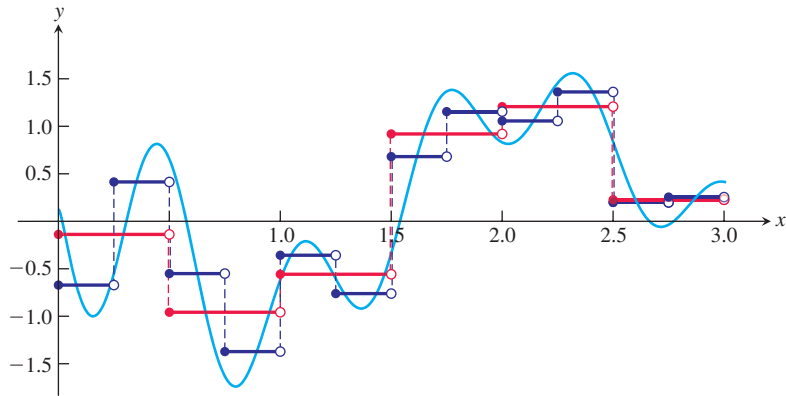

FIGURE 19.19 The approximations p_1 (red) and p_2 (dark blue) for the function g from Figure 19.15.

In general, once we have the approximation p_n at resolution level n , the detail function at that resolution level is

$$q_n(x) = \sum_{k=-\infty}^{\infty} b_{n,k} \psi_{n,k}(x) = \sum_{k=-\infty}^{\infty} \langle f, \psi_{n,k} \rangle \psi_{n,k}(x),$$

and the best approximation at the next resolution level $n + 1$ is

$$p_{n+1}(x) = p_n(x) + q_n(x).$$

Expanding,

$$p_{n+1}(x) = p_0(x) + q_0(x) + q_1(x) + \cdots + q_n(x).$$

We see that the approximation $p_{n+1}(x)$ is obtained by progressively adding finer and finer details to $p_0(x)$. The next theorem states that the distance between f and the approximation p_n at resolution level n converges to zero as $n \rightarrow \infty$. The proof of Theorem 13 can be found in more advanced texts on wavelets or real analysis.

THEOREM 13 Let f be an integrable function on the real line that is supported in a finite interval, and for each positive integer n let p_n be the function defined by the recursive process given above. That is, p_n is the linear combination of the functions $\varphi_k, \psi_{0,k}, \psi_{1,k}, \dots, \psi_{n-1,k}$ (k integer) that is closest to f . Then the distance between f and p_n converges to zero as $n \rightarrow \infty$:

$$\lim_{n \rightarrow \infty} \|f - p_n\| = \lim_{n \rightarrow \infty} \sqrt{\int_{-\infty}^{\infty} (f(x) - p_n(x))^2 dx} = 0.$$

Wavelets

The Haar system and the trigonometric system are not well-suited to every application. Each system is better suited for certain types of applications than the other. Fourier series often provide good approximations when dealing with periodic functions. The Haar system is typically a better choice when an application has a multiresolution aspect. However, there are other wavelet systems that can be even more advantageous in such applications.

One drawback of the Haar system is that the box functions φ_k and the wavelets $\psi_{n,k}$ are discontinuous. To explain another drawback, consider the function

$$f(x) = \begin{cases} 1, & 0 \leq x < m, \\ 0, & x < 0 \text{ or } x \geq m, \end{cases}$$

where m is an integer. Using the Haar system, the approximation to f at resolution level zero is f itself. Specifically,

$$p_0(x) = \sum_{k=0}^{m-1} \varphi_k(x) = f(x).$$

However, only functions that, like this f , are “locally constant” can be well represented at this low resolution level. In contrast, the approximation p_0 to

$$g(x) = \begin{cases} x, & 0 \leq x < m, \\ 0, & x < 0 \text{ or } x \geq m, \end{cases}$$

is not g itself, but rather a step function with jumps at integer points.

Today we have constructions of orthonormal wavelet systems that consist of continuous, differentiable, or smoother functions, and these systems provide good representations of functions that are locally linear, locally quadratic, or locally polynomial of higher order. In particular, for each even integer $2N$ (where $N = 1, 2, 3, \dots$), Ingrid Daubechies constructed functions D_{2N} and W_{2N} that can be used instead of the box function φ and the Haar wavelet ψ to generate orthonormal systems. Indeed, φ and ψ are precisely the functions D_2 and W_2 that correspond to $N = 1$. The function D_{2N} is called a **Daubechies scaling function** and W_{2N} is a **Daubechies wavelet**. The functions D_4 and W_4 , corresponding to $N = 2$, are shown in Figures 19.20 and 19.21. They cannot be given by closed-form formulas, but Exercises 11–15 in the Additional and Advanced Exercises discuss the recursive process by which they are defined.

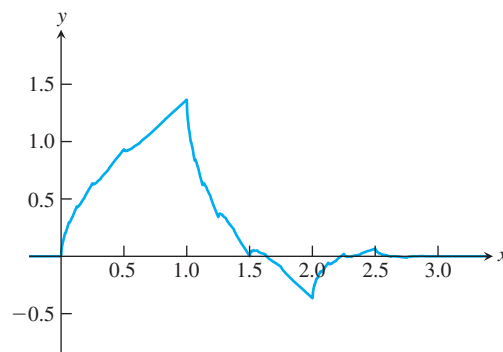

FIGURE 19.20 The Daubechies scaling function D_4 . This function is identically zero outside of the interval $[0, 3]$.

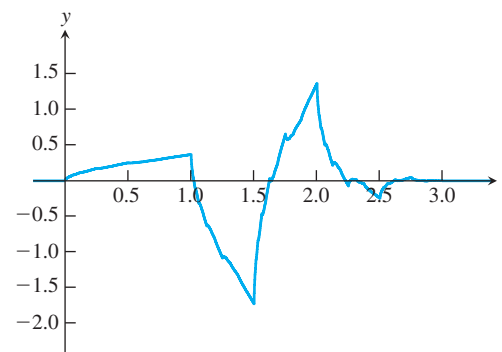

FIGURE 19.21 The Daubechies wavelet W_4 . This function is identically zero outside of the interval $[0, 3]$.

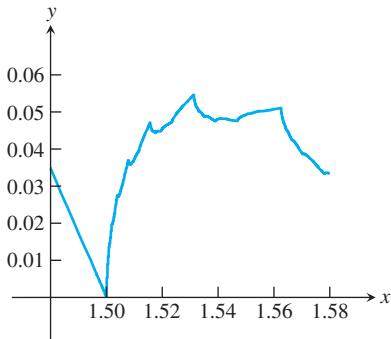

FIGURE 19.22 An enlargement of the graph of D_4 .

It is not apparent from their graphs, but D_4 and W_4 satisfy the same orthogonality relations as the box function φ and the Haar wavelet ψ . The translated box functions $\varphi_k(x) = \varphi(x - k)$ are orthogonal, and likewise the translated functions $D_4(x - k)$ are orthogonal. It is easy to see that the functions φ_k are orthogonal because their supports do not overlap. In contrast, the supports of the functions $D_4(x - k)$ do overlap, but even so the inner product $\langle D_4(x - j), D_4(x - k) \rangle$ is zero whenever $j \neq k$. Further, the collection of translates and dilates $2^{n/2}W_4(2^n x - k)$ over all integer k and nonnegative n is orthonormal, and we can substitute D_4 and W_4 for φ and ψ in the multiresolution approximation process that we described earlier.

The Daubechies scaling function D_4 and wavelet W_4 are each supported in the interval $[0, 3]$, and they are continuous, but not differentiable. Indeed, their graphs have a fractal appearance in the sense that no matter how much they are magnified, they are still jagged. Figure 19.22 shows an enlargement of the graph of D_4 centered on the interval $[1.48, 1.58]$. Linear combinations of the translates $D_4(x - k)$ can represent functions that are locally constant as well as functions that are locally linear. As N increases, D_{2N} and W_{2N} become smoother but more spread out (supported in $[0, 2N - 1]$), and can locally represent polynomials of higher order. The proof of these facts about Daubechies' constructions are much more involved than for the Haar wavelets, and can be found in texts on wavelet theory.

EXERCISES 19.5

Norms of Functions

In Exercises 1–6, the values of a function on the interval $[0, 2]$ are given, and we assume that the function is identically zero outside of that interval. Find the norm of each function.

$$1. f(x) = \begin{cases} 5, & 0 \leq x < 1 \\ 1, & 1 \leq x \leq 2 \end{cases}$$

$$2. g(x) = \begin{cases} 5, & 0 \leq x < 1/2 \\ 1, & 1/2 \leq x < 1 \\ -1, & 1 \leq x \leq 2 \end{cases}$$

$$3. h(x) = x, \quad 0 \leq x \leq 2$$

$$4. j(x) = x^2, \quad 0 \leq x \leq 2$$

$$5. \ell(x) = \begin{cases} 1, & 0 \leq x < 1 \\ \sin 2\pi x, & 1 \leq x \leq 2 \end{cases}$$

$$6. m(x) = \begin{cases} 2, & 0 \leq x < 1/2 \\ -2, & 1/2 \leq x < 1 \\ \cos 2\pi x, & 1 \leq x \leq 2 \end{cases}$$

Inner Product of Functions

In Exercises 7–12, use the functions defined in Exercises 1–6 to compute the given inner product. Are the two functions orthogonal?

$$7. \langle g, j \rangle$$

$$8. \langle \ell, \psi \rangle$$

$$9. \langle g, m \rangle$$

$$10. \langle h, \psi_{2,1} \rangle$$

$$11. \langle f, \varphi_1 \rangle$$

$$12. \langle m, \psi_{2,3} \rangle$$

Finding Haar Coefficients

In Exercises 13–18, find the Haar coefficients $a_k = \langle f, \varphi_k \rangle$ and $b_{n,k} = \langle f, \psi_{n,k} \rangle$ for the given function. If available, use a CAS to plot the approximation p_n at resolution levels $n = 0, 1$, and 2 over the domain $[0, 2]$.

13. The function f from Exercise 1.

14. The function g from Exercise 2.

15. The function h from Exercise 3.

16. The function j from Exercise 4.

17. The function ℓ from Exercise 5.

18. The function m from Exercise 6.

Theory and Examples

19. Explain why the Haar wavelet $\psi_{n,k}$ is supported in the interval $[2^{-n}k, 2^{-n}(k+1)]$ and why it is a unit function.

20. Prove that for integers j and k and nonnegative integers m and n we have

$$\text{a. } \langle \varphi_j, \varphi_k \rangle = 0 \quad \text{for all } j \neq k,$$

$$\text{b. } \langle \varphi_j, \psi_{n,k} \rangle = 0 \quad \text{for all } n, j, \text{ and } k,$$

$$\text{c. } \langle \psi_{n,j}, \psi_{n,k} \rangle = 0 \quad \text{for all } n \text{ and all } j \neq k,$$

$$\text{d. } \langle \psi_{m,j}, \psi_{n,k} \rangle = 0 \quad \text{for all } j \text{ and } k \text{ and all } m \neq n.$$

Explain why this implies that the Haar system is an orthonormal collection of functions.

CHAPTER 19 Questions to Guide Your Review

Vectors

Questions 1–5 are about vectors in d -dimensional space.

1. What is the length of a vector in d -dimensional space?
2. How do you determine the dot product of vectors in d -dimensional space? Which algebraic properties are satisfied by the dot product?
3. What does it mean for a collection of vectors in d -dimensional space to be orthogonal? orthonormal?
4. What is an orthonormal basis of vectors for d -dimensional space?
5. Assume that $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_d\}$ is an orthonormal basis for d -dimensional space and $1 \leq n < d$. If \mathbf{v} is a vector in d -dimensional space, what is the linear combination of $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$ that is closest to \mathbf{v} ?

Periodic Functions

Questions 6–11 are about periodic functions.

6. What is a periodic function?
7. What is the norm of an integrable function on the domain $[0, 2\pi]$? What is a unit function?
8. What is the inner product of two integrable functions on the domain $[0, 2\pi]$? When are two such functions orthogonal? orthonormal?

9. What does it mean for a collection of integrable functions on the domain $[0, 2\pi]$ to be orthogonal? orthonormal?
10. What are the Fourier coefficients of an integrable function f that is periodic with period 2π ?
11. If f is an integrable function on $[0, 2\pi]$, how do you find the trigonometric polynomial p_n that is the best approximation to f by a linear combination of $1, \cos x, \dots, \cos nx, \sin x, \dots, \sin nx$?

Functions on the Real Line

Questions 12–16 are about functions whose domain is the real line.

12. What does it mean to say that an integrable function f is supported in an interval $[a, b]$? What is the norm of f ? What is a unit function?
13. What is the inner product of two integrable functions that are each supported in a finite interval? When are two such functions orthogonal? orthonormal?
14. What interval is the function φ_k supported in? $\psi_{n,k}$?
15. What are the Haar coefficients of an integrable function f that is supported in a finite interval?
16. If f is an integrable function that is supported in a finite interval, how do you find the Haar approximation p_n to f at resolution level n ? What is the detail function q_n at resolution level n ?

CHAPTER 19 Additional and Advanced Exercises

Finding More Orthonormal Vectors

1. Let $\mathbf{u}_1 = \langle 1/\sqrt{5}, 2/\sqrt{5} \rangle$ and $\mathbf{v} = \langle 3, -1 \rangle$.
 - a. Show that \mathbf{u}_1 is a unit vector.
 - b. Find the vector \mathbf{p} on the line through \mathbf{u}_1 that is closest to \mathbf{v} .
 - c. Verify that $\mathbf{q} = \mathbf{v} - \mathbf{p}$ is orthogonal to \mathbf{u}_1 .
 - d. Set $\mathbf{u}_2 = \mathbf{q}/\|\mathbf{q}\|$, and explain why $\{\mathbf{u}_1, \mathbf{u}_2\}$ is an orthonormal basis for two-dimensional space.
2. Let $\mathbf{u}_1 = \langle 1/\sqrt{6}, -1/\sqrt{6}, \sqrt{2}/\sqrt{3} \rangle$, $\mathbf{u}_2 = \langle 1/\sqrt{2}, 1/\sqrt{2}, 0 \rangle$, and $\mathbf{v} = \langle 3, -1, 1 \rangle$.
 - a. Show that \mathbf{u}_1 and \mathbf{u}_2 are orthonormal.
 - b. Find the linear combination \mathbf{p} of \mathbf{u}_1 and \mathbf{u}_2 that is closest to \mathbf{v} .
 - c. Verify that $\mathbf{q} = \mathbf{v} - \mathbf{p}$ is orthogonal to both \mathbf{u}_1 and \mathbf{u}_2 .
 - d. Set $\mathbf{u}_3 = \mathbf{q}/\|\mathbf{q}\|$, and explain why $\{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3\}$ is an orthonormal basis for three-dimensional space.

Orthogonal Polynomials

The functions in Exercises 3–9 are all supported in the interval $[-1, 1]$. The norm of such a function f is

$$\|f\| = \sqrt{\int_{-1}^1 f(x)^2 dx},$$

and the inner product of f with g is

$$\langle f, g \rangle = \int_{-1}^1 f(x)g(x) dx.$$

For each integer $n \geq 0$ we let v_n be the function defined by $v_n(x) = x^n$ for $-1 \leq x \leq 1$ and $v_n(x) = 0$ for $|x| > 1$.

3. Find the norm of v_n for each $n \geq 0$.
4. Find the inner product of v_m with v_n for $m, n \geq 0$. For which m and n is v_m orthogonal to v_n ? Is $\{v_n\}_{n \geq 0}$ an orthogonal collection of functions?

In Exercises 5–9, for $-1 \leq x \leq 1$ define

$$q_0(x) = 1, \quad q_1(x) = x, \quad q_2(x) = 3x^2 - 1,$$

and set $q_0(x) = q_1(x) = q_2(x) = 0$ for $|x| > 1$. Also define

$$u_0(x) = \frac{q_0(x)}{\|q_0\|}, \quad u_1(x) = \frac{q_1(x)}{\|q_1\|}, \quad u_2(x) = \frac{q_2(x)}{\|q_2\|}.$$

5. Find $\|q_n\|$ for $n = 0, 1, 2$.
6. Prove that $\{q_0, q_1, q_2\}$ is an orthogonal set of functions.
7. Find explicit formulas for u_0, u_1 , and u_2 , and prove that $\{u_0, u_1, u_2\}$ is an orthonormal set of functions.
8. Find the function

$$w_3(x) = \langle v_3, u_0 \rangle u_0(x) + \langle v_3, u_1 \rangle u_1(x) + \langle v_3, u_2 \rangle u_2(x).$$

This is the linear combination of u_0, u_1 , and u_2 that is closest to the function v_3 .

9. Using the function w_3 from Exercise 8, let

$$q_3(x) = v_3(x) - w_3(x).$$

Find $\|q_3\|$, and set

$$u_3(x) = \frac{q_3(x)}{\|q_3\|}.$$

Prove that $\{u_0, u_1, u_2, u_3\}$ is an orthonormal set of functions.

The Haar System

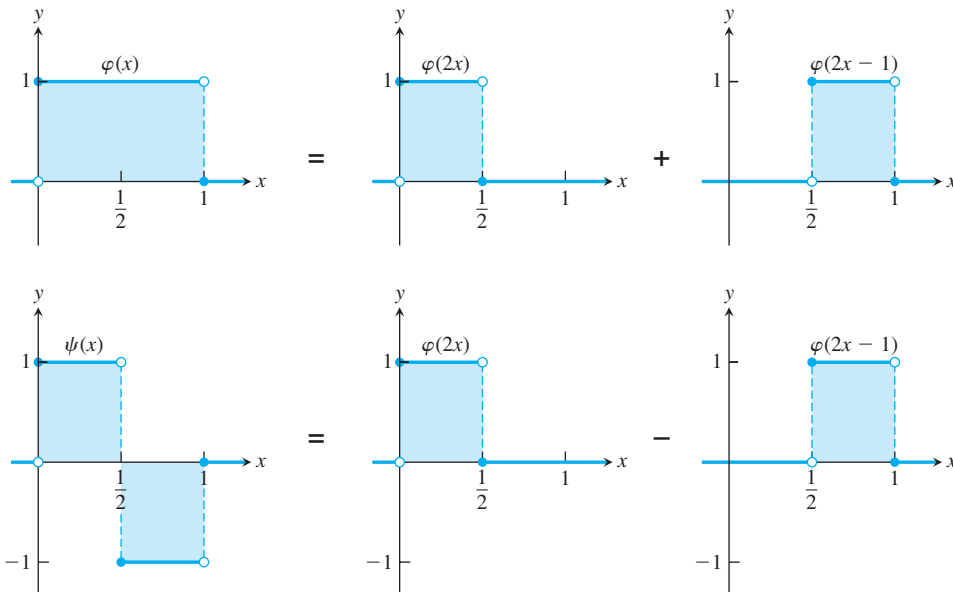

10. Prove that the box function φ satisfies the **refinement equation**

$$\varphi(x) = \varphi(2x) + \varphi(2x - 1),$$

and the Haar wavelet ψ can be obtained from the box function φ by

$$\psi(x) = \varphi(2x) - \varphi(2x - 1).$$

See the accompanying figure.

The Daubechies Scaling Function D_4

It is proved on texts in wavelet theory that the Daubechies scaling function D_4 is a continuous function that is supported in a finite interval and satisfies the refinement equation

$$D_4(x) = c_0 D_4(2x) + c_1 D_4(2x - 1) + c_2 D_4(2x - 2) + c_3 D_4(2x - 3),$$

where

$$c_0 = \frac{1 + \sqrt{3}}{4}, \quad c_1 = \frac{3 + \sqrt{3}}{4}, \quad c_2 = \frac{3 - \sqrt{3}}{4}, \quad c_3 = \frac{1 - \sqrt{3}}{4}.$$

We will use this refinement equation in Exercises 11–15.

11. The Daubechies scaling function D_4 is supported in some finite interval $[a, b]$. Use the refinement equation given above to prove that D_4 is actually supported in the interval $[0, 3]$. (*Hint:* Let $[a, b]$ be the smallest interval such that $D_4(x) = 0$ for every x outside of $[a, b]$. Use the refinement equation to prove that if $x \notin [a/2, (b+3)/2]$, then $2x < a$ and $2x - 3 > b$, and therefore $D_4(x) = 0$.)

12. Since D_4 is continuous and supported in the interval $[0, 3]$, we have $D_4(0) = D_4(3) = 0$. Let $a = D_4(1)$ and $b = D_4(2)$, and use the refinement equation to show that a and b satisfy the equations

$$\begin{aligned} a &= c_0 b + c_1 a, \\ b &= c_3 b + c_2 a. \end{aligned}$$

Prove that

$$a = \frac{1 + \sqrt{3}}{2}, \quad b = \frac{1 - \sqrt{3}}{2}$$

solves this system of equations and also satisfies $a + b = 1$.

13. Exercise 12 computed the values $D_4(1)$ and $D_4(2)$. Since D_4 is continuous and identically zero outside of $[0, 3]$, we know that $D_4(k) = 0$ for every integer k other than $k = 1$ and $k = 2$. Use the refinement equation to compute $D_4(k/2)$ for integer k .

T 14. This exercise will explain how Figure 19.20 was generated. Exercises 12 and 13 computed the values $D_4(k)$ and $D_4(k/2)$ for integer k . Use a CAS to compute the values $D_4(k/4)$ for integer k and plot the result. Then compute $D_4(k/8)$ for integer k and plot the result. Iterate this process until a sufficiently detailed plot of the graph of D_4 is obtained.

T 15. The Daubechies wavelet W_4 is derived from the Daubechies scaling function D_4 by the equation

$$W_4(x) = -c_3 D_4(2x) + c_2 D_4(2x - 1) - c_1 D_4(2x - 2) + c_0 D_4(2x - 3).$$

Use the values for $D_4(x)$ obtained in Exercise 14 to make a plot of the graph of W_4 .

T 16. Using the values for $D_4(x)$ obtained in Exercise 14, plot the function

$$F(x) = \sum_{k=-2}^4 D_4(x - k)$$

on the interval $[-2, 7]$ (remember that $D_4(x) = 0$ if $x \leq 0$ or $x \geq 3$). Numerically, it appears that $F(x)$ is constant on the interval $[0, 5]$.

T 17. Using the values for $D_4(x)$ obtained in Exercise 14, plot the function

$$G(x) = \sum_{k=-2}^4 k D_4(x - k)$$

on the interval $[-2, 7]$ (remember that $D_4(x) = 0$ if $x \leq 0$ or $x \geq 3$). Numerically, it appears that $G(x)$ is linear on the interval $[0, 5]$; that is, there are constants c and d such that $G(x) = cx + d$ for $0 \leq x \leq 5$.

ANSWERS TO ODD-NUMBERED EXERCISES

Chapter 19

SECTION 19.1, p. 19-3

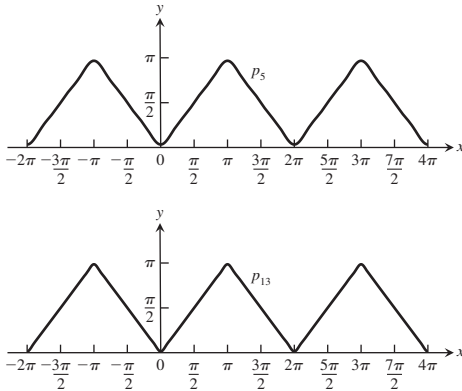

1. 2π 3. Not periodic 5. 2π
 7. (a) Since $f(x + P) = f(x)$ and $g(x + P) = g(x)$ for every x , it follows that $f(x + P) + g(x + P) = f(x) + g(x)$ for every x .

SECTION 19.2, p. 19-5

1. This follows from the fact that $\sin(-kx) = -\sin kx$.
 3. The graphs of p_5 and p_{13} are shown in the accompanying figure. It appears that p_n is converging to the function f whose values on the domain $[0, 2\pi]$ are

$$f(x) = \begin{cases} x, & 0 \leq x \leq \pi, \\ 2\pi - x, & \pi < x \leq 2\pi, \end{cases}$$

with these values then repeated every 2π units. The convergence is "fast" since the graph of p_n is already close to the graph of f when n is small.

5. $z^0 = \cos 0x + i \sin 0x = 1$
 7. $2z^2 + 3z - 5 = 2e^{i2x} + 3e^{ix} - 5$
 $= 2(\cos 2x + i \sin 2x) + 3(\cos x + i \sin x) - 5$
 9. $z^{-1} = (e^{ix})^{-1} = e^{-ix} = \cos(-x) + i \sin(-x) = \cos x - i \sin x$
 11. $z + z^{-1} = (\cos x + i \sin x) + (\cos x - i \sin x) = 2 \cos x$
 13. $z^n + z^{-n} = (\cos nx + i \sin nx) + (\cos nx - i \sin nx) = 2 \cos nx$
 15. $2z^2 + 3z - 5 + 3z^{-1} + 2z^{-2} = 2(z^2 + z^{-2}) + 3(z + z^{-1}) - 5 = 2 \cdot 2 \cos 2x + 3 \cdot 2 \cos x - 5$
 17. $\cos x + 2 \sin x - 3 = \frac{1}{2}(z + z^{-1}) - i(z - z^{-1}) - 3$
 $= (0.5 - i)z - 3 + (0.5 + i)z^{-1}$

SECTION 19.3, pp. 19-11-19-12

1. (a) $\mathbf{r} \cdot \mathbf{s} = 0$, $\mathbf{r} \cdot \mathbf{t} = 0$, $\mathbf{s} \cdot \mathbf{t} = 0$
 (b) $|\mathbf{r}| = \sqrt{2}$, $|\mathbf{s}| = \sqrt{2}$, $|\mathbf{t}| = 1$
 (c) Yes (d) No
 3. (a) $\mathbf{r} \cdot \mathbf{s} = 0$, $\mathbf{r} \cdot \mathbf{t} = 0$, $\mathbf{s} \cdot \mathbf{t} = -3$
 (b) $|\mathbf{r}| = \sqrt{3}$, $|\mathbf{s}| = \sqrt{6}$, $|\mathbf{t}| = \sqrt{2}$
 (c) No (d) No

5. (a) $\mathbf{r} \cdot \mathbf{s} = 0$, $\mathbf{r} \cdot \mathbf{t} = 0$, $\mathbf{s} \cdot \mathbf{t} = 0$

(b) $|\mathbf{r}| = 1$, $|\mathbf{s}| = 1$, $|\mathbf{t}| = 1$

(c) Yes (d) Yes

7. (b) $\mathbf{p} = \langle 1, 2, 0 \rangle$ (c) 3

9. (b) $\mathbf{p} = \langle 7/2, -1/2, 1 \rangle$ (c) $3/\sqrt{2}$

11. $2\mathbf{u} + \mathbf{v} - 3\mathbf{w} = \langle -6, 4, -7, 8, 1 \rangle$,
 $-\mathbf{u} + 5\mathbf{v} - \mathbf{w} = \langle -10, 6, 4, -7, -3 \rangle$

13. $\mathbf{u} \cdot \mathbf{v} = -6$, $\mathbf{u} \cdot \mathbf{w} = 3$, $\mathbf{v} \cdot \mathbf{w} = -1$

15. $\mathbf{u}_j \cdot \mathbf{u}_k = 0$ when $j \neq k$, and $|\mathbf{u}_k| = 1$ for $k = 1, 2, 3, 4, 5$

17. $\mathbf{p} = (\mathbf{v} \cdot \mathbf{u}_1)\mathbf{u}_1 + (\mathbf{v} \cdot \mathbf{u}_2)\mathbf{u}_2 = \langle 2, -4, 0, 0, 0 \rangle$,

$|\mathbf{v} - \mathbf{p}| = \sqrt{21} \approx 4.58$, $(\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_1 = (\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_2 = 0$

19. $\mathbf{p} = (\mathbf{v} \cdot \mathbf{u}_1)\mathbf{u}_1 + (\mathbf{v} \cdot \mathbf{u}_2)\mathbf{u}_2 + (\mathbf{v} \cdot \mathbf{u}_3)\mathbf{u}_3 + (\mathbf{v} \cdot \mathbf{u}_4)\mathbf{u}_4$
 $= \langle 2, -4, 4, 2, 0 \rangle$, $|\mathbf{v} - \mathbf{p}| = 1$, $(\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_1 = (\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_2$
 $= (\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_3 = (\mathbf{v} - \mathbf{p}) \cdot \mathbf{u}_4 = 0$

21. $\mathbf{u} \cdot \mathbf{v} = \sum_{k=1}^d u_k v_k = \sum_{k=1}^d v_k u_k = \mathbf{v} \cdot \mathbf{u}$.

23. By the symmetry and distributive properties (Exercises 21 and 22),

$|\mathbf{u} + \mathbf{v}|^2 = (\mathbf{u} + \mathbf{v}) \cdot (\mathbf{u} + \mathbf{v})$

$= \mathbf{u} \cdot \mathbf{u} + \mathbf{v} \cdot \mathbf{u} + \mathbf{u} \cdot \mathbf{v} + \mathbf{v} \cdot \mathbf{v} = |\mathbf{u}|^2 + 2(\mathbf{u} \cdot \mathbf{v}) + |\mathbf{v}|^2$.

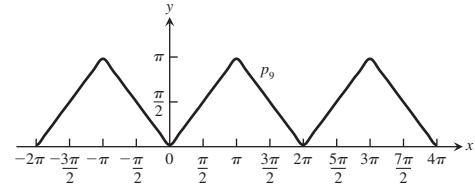

SECTION 19.4, p. 19-23

1. $\sqrt{2/3} \pi^{3/2}$ 3. $\sqrt{2/5} \pi^{5/2}$ 5. $\sqrt{(e^{4\pi} - 1)/2}$

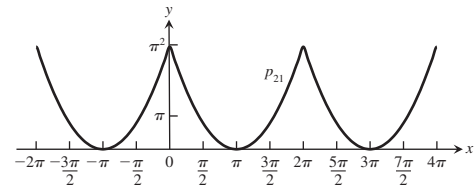

7. $7\pi^3/24$, no 9. $2\pi^3/3$, no 11. 0, yes

13. $a_0 = \frac{\pi}{2}$, $a_{2k-1} = -\frac{4}{(2k-1)^2 \pi}$, $a_{2k} = 0$, $b_k = 0$,

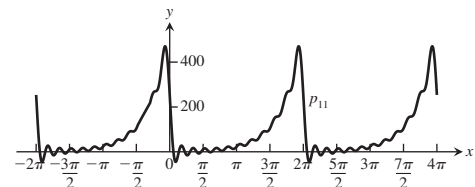

$p_{2n}(x) = p_{2n-1}(x) = \frac{\pi}{2} - \sum_{k=1}^n \frac{4}{(2k-1)^2 \pi} \cos(2k-1)x$

15. $a_0 = \frac{\pi^2}{3}$, $a_k = \frac{4}{k^2}$, $b_k = 0$, $p_n(x) = \frac{\pi^2}{3} + \sum_{k=1}^n \frac{4}{k^2} \cos kx$

17. $a_0 = \frac{e^{2\pi} - 1}{2\pi}$, $a_k = \frac{e^{2\pi} - 1}{(k^2 + 1)\pi}$, $b_k = -\frac{k(e^{2\pi} - 1)}{(k^2 + 1)\pi}$,
 $p_n(x) = \frac{e^{2\pi} - 1}{2\pi} + \sum_{k=1}^n \frac{e^{2\pi} - 1}{(k^2 + 1)\pi} \cos kx - \sum_{k=1}^n \frac{k(e^{2\pi} - 1)}{(k^2 + 1)\pi} \sin kx$

23. $\langle f, g \rangle = \int_0^{2\pi} f(x)g(x) dx = \int_0^{2\pi} g(x)f(x) dx = \langle g, f \rangle$
29. $a_0 = a_1 = b_1 = 1$, and $a_k = b_k = 0$ for all $k \geq 2$ so $p_n = 1 + \cos(x) + \sin(x) = f(x)$ for all n .
31. Assume that $m \neq n$ are positive integers. The integral of $\cos kx$ over $[0, 2\pi]$ is zero when k is a nonzero integer. Therefore, since $m - n \neq 0$ and $m + n \neq 0$, we have

$$\int_0^{2\pi} \cos(m-n)x dx = 0 \quad \text{and} \quad \int_0^{2\pi} \cos(m+n)x dx = 0.$$

Applying the trigonometric identity given in the hint, it follows that

$$\begin{aligned} \int_0^{2\pi} \sin mx \sin nx dx &= \frac{1}{2} \int_0^{2\pi} \cos(m-n)x dx \\ &\quad - \frac{1}{2} \int_0^{2\pi} \cos(m+n)x dx = 0 - 0 = 0. \end{aligned}$$

33. Assume that m and n are positive integers. The integral of $\sin kx$ over $[0, 2\pi]$ is zero for every integer k . Applying the trigonometric identity given in the hint, it follows that

$$\begin{aligned} \int_0^{2\pi} \sin mx \cos nx dx &= \frac{1}{2} \int_0^{2\pi} \sin(m+n)x dx \\ &\quad + \frac{1}{2} \int_0^{2\pi} \sin(m-n)x dx = 0 + 0 = 0. \end{aligned}$$

SECTION 19.5, p. 19-34

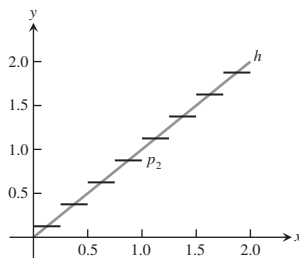

1. $\sqrt{26}$ 3. $2\sqrt{2/3}$ 5. $\sqrt{3/2}$
 7. $-11/6$, no 9. 4, no 11. 1, no
13. $a_0 = 5$, $a_1 = 1$, and all other Haar coefficients are zero.
15. If $k < 0$ or $k > 1$, then $a_k = 0$. For $k = 0$ or $k = 1$,

$$a_k = \int_k^{k+1} x dx = k + \frac{1}{2}.$$

Given $n \geq 0$, if $k < 0$ or $k \geq 2^{n+1}$, then the support of $\psi_{n,k}$ does not intersect $[0, 2]$, and therefore $b_{n,k} = 0$ for those k . For all other k ,

$$b_{n,k} = 2^{n/2} \int_{2^{-n}k}^{2^{-n}(k+1/2)} x dx - 2^{n/2} \int_{2^{-n}(k+1/2)}^{2^{-n}(k+1)} x dx = -\frac{1}{4 \cdot 2^{3n/2}}.$$

This graph shows h and p_2 :

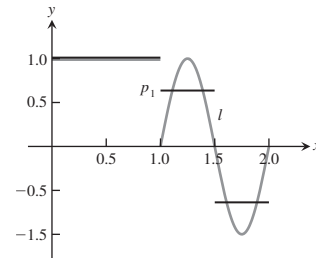

17. $a_0 = 1$, $a_1 = 0$. For $n \geq 0$, if $2^n \leq k < 2^{n+1}$, then the support of $\psi_{n,k}$ intersects the interval $[1, 2]$. For these k ,

$$\begin{aligned} b_{n,k} &= 2^{n/2} \int_{2^{-n}k}^{2^{-n}(k+1/2)} \sin 2\pi x dx - 2^{n/2} \int_{2^{-n}(k+1/2)}^{2^{-n}(k+1)} \sin 2\pi x dx \\ &= -\frac{2^{n/2}}{2\pi} \left(2 \cos 2\pi 2^{-n}(k+1/2) - \cos 2\pi 2^{-n}k \right. \\ &\quad \left. - \cos 2\pi 2^{-n}(k+1) \right) \end{aligned}$$

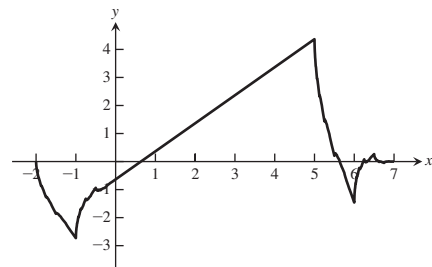

All other Haar coefficients are zero.

This graph shows ℓ and p_1 ; they are equal on $[0, 1]$:

A.1 Real Numbers and the Real Line

This section reviews real numbers, inequalities, intervals, and absolute values.

Real Numbers

Much of calculus is based on properties of the real number system. **Real numbers** are numbers that can be expressed as decimals, such as

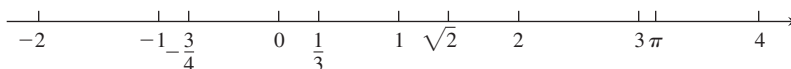

$$-\frac{3}{4} = -0.75000 \dots$$

$$\frac{1}{3} = 0.33333 \dots$$

$$\sqrt{2} = 1.4142 \dots$$

The dots ... in each case indicate that the sequence of decimal digits goes on forever. Every conceivable decimal expansion represents a real number; although, some numbers have two representations. For instance, the infinite decimals .999 ... and 1.000 ... represent the same real number 1. A similar statement holds for any number with an infinite tail of 9's.

The real numbers can be represented geometrically as points on a number line called the **real line**.

RULES FOR INEQUALITIES

If a , b , and c are real numbers, then:

- $a < b \Rightarrow a + c < b + c$
- $a < b \Rightarrow a - c < b - c$
- $a < b$ and $c > 0 \Rightarrow ac < bc$
- $a < b$ and $c < 0 \Rightarrow bc < ac$
Special case: $a < b \Rightarrow -b < -a$
- $a > 0 \Rightarrow \frac{1}{a} > 0$
- If a and b are both positive or both negative, then $a < b \Rightarrow \frac{1}{b} < \frac{1}{a}$.

The symbol \mathbb{R} denotes either the real number system or, equivalently, the real line.

The properties of the real number system fall into three categories: algebraic properties, order properties, and completeness. The **algebraic properties** say that the real numbers can be added, subtracted, multiplied, and divided (except by 0) to produce more real numbers under the usual rules of arithmetic. *You can never divide by 0.*

The **order properties** of real numbers are given in Appendix A.7. The useful rules at the left can be derived from them, where the symbol \Rightarrow means “implies.”

Notice the rules for multiplying an inequality by a number. Multiplying by a positive number preserves the inequality; multiplying by a negative number reverses the inequality. Also, reciprocation reverses the inequality for numbers of the same sign. For example, $2 < 5$ but $-2 > -5$ and $1/2 > 1/5$.

The **completeness property** of the real number system is deeper and harder to define precisely. However, the property is essential to the idea of a limit (Chapter 2). Roughly speaking, it says that there are enough real numbers to “complete” the real number line, in

the sense that there are no “holes” or “gaps” in it. Many theorems of calculus would fail if the real number system were not complete. Appendix A.7 introduces the ideas involved and discusses how the real numbers are constructed.

We distinguish three special subsets of real numbers.

1. The **natural numbers**, namely 1, 2, 3, 4, ...
2. The **integers**, namely 0, ± 1 , ± 2 , ± 3 , ...
3. The **rational numbers**, namely the numbers that can be expressed in the form of a fraction m/n , where m and n are integers and $n \neq 0$. Examples are

$$\frac{1}{3}, \quad -\frac{4}{9} = \frac{-4}{9} = \frac{4}{-9}, \quad \frac{200}{13}, \quad \text{and} \quad 57 = \frac{57}{1}.$$

The rational numbers are precisely the real numbers with decimal expansions that are either

- a. terminating (ending in an infinite string of zeros), for example,

$$\frac{3}{4} = 0.75000 \dots = 0.75 \quad \text{or}$$

- b. eventually repeating (ending with a block of digits that repeats over and over), for example,

$$\frac{23}{11} = 2.090909 \dots = 2.\overline{09} \quad \text{The bar indicates the block of repeating digits.}$$

A terminating decimal expansion is a special type of repeating decimal, since the ending zeros repeat.

The set of rational numbers has all the algebraic and order properties of the real numbers but lacks the completeness property. For example, there is no rational number whose square is 2; there is a “hole” in the rational line where $\sqrt{2}$ should be.

Real numbers that are not rational are called **irrational numbers**. They are characterized by having nonterminating and nonrepeating decimal expansions. Examples are π , $\sqrt{2}$, $\sqrt[3]{5}$, and $\log_{10} 3$. Since every decimal expansion represents a real number, there are infinitely many irrational numbers. Both rational and irrational numbers are found arbitrarily close to any given point on the real line.

Set notation is very useful for specifying sets of real numbers. A **set** is a collection of objects, and these objects are the **elements** of the set. If S is a set, the notation $a \in S$ means that a is an element of S , and $a \notin S$ means that a is not an element of S . If S and T are sets, then $S \cup T$ is their **union** and consists of all elements belonging to either S or T (or to both S and T). The **intersection** $S \cap T$ consists of all elements belonging to both S and T . The **empty set** \emptyset is the set that contains no elements. For example, the intersection of the rational numbers and the irrational numbers is the empty set.

Some sets can be described by *listing* their elements in braces. For instance, the set A consisting of the natural numbers (or positive integers) less than 6 can be expressed as

$$A = \{1, 2, 3, 4, 5\}.$$

The entire set of integers is written as

$$\{0, \pm 1, \pm 2, \pm 3, \dots\}.$$

Another way to describe a set is to enclose in braces a rule that generates all the elements of the set. For instance, the set

$$A = \{x \mid x \text{ is an integer and } 0 < x < 6\}$$

is the set of positive integers less than 6.

Intervals

A subset of the real line is called an **interval** if it contains at least two numbers and contains all the real numbers lying between any two of its elements. For example, the set of all real numbers x such that $x > 6$ is an interval, as is the set of all x such that $-2 \leq x \leq 5$. The set of all nonzero real numbers is not an interval; since 0 is absent, the set fails to contain every real number between -1 and 1 (for example).

Geometrically, intervals correspond to rays and line segments on the real line, along with the real line itself. Intervals of numbers corresponding to line segments are **finite intervals**; intervals corresponding to rays and the real line are **infinite intervals**.

A finite interval is said to be **closed** if it contains both of its endpoints, **half-open** if it contains one endpoint but not the other, and **open** if it contains neither endpoint. The endpoints are also called **boundary points**; they make up the interval's **boundary**. The remaining points of the interval are **interior points** and together compose the interval's **interior**. Infinite intervals are closed if they contain a finite endpoint, and open otherwise. The entire real line \mathbb{R} is an infinite interval that is both open and closed. Table A.1 summarizes the various types of intervals.

TABLE A.1 Types of intervals

Notation	Set description	Type	Picture
(a, b)	$\{x \mid a < x < b\}$	Open	
$[a, b]$	$\{x \mid a \leq x \leq b\}$	Closed	
$[a, b)$	$\{x \mid a \leq x < b\}$	Half-open	
$(a, b]$	$\{x \mid a < x \leq b\}$	Half-open	
(a, ∞)	$\{x \mid x > a\}$	Open	
$[a, \infty)$	$\{x \mid x \geq a\}$	Closed	
$(-\infty, b)$	$\{x \mid x < b\}$	Open	
$(-\infty, b]$	$\{x \mid x \leq b\}$	Closed	
$(-\infty, \infty)$	\mathbb{R} (set of all real numbers)	Both open and closed	

Solving Inequalities

The process of finding the interval or intervals of numbers that satisfy an inequality in x is called **solving** the inequality.

EXAMPLE 1 Solve the following inequalities and show their solution sets on the real line.

(a) $2x - 1 < x + 3$

(b) $\frac{6}{x-1} \geq 5$

AP-4 Appendix A

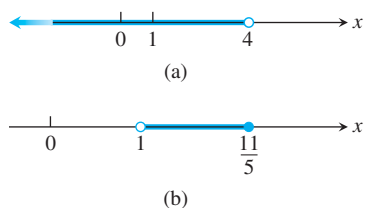

FIGURE A.1 Solution sets for the inequalities in Example 1. Hollow circles indicate endpoints that are not included in the interval, and solid dots indicate included endpoints.

Solution

$$\begin{aligned}
 \text{(a)} \quad 2x - 1 &< x + 3 \\
 2x &< x + 4 && \text{Add 1 to both sides.} \\
 x &< 4 && \text{Subtract } x \text{ from both sides.}
 \end{aligned}$$

The solution set is the open interval $(-\infty, 4)$ (Figure A.1a).

(b) The inequality $6/(x - 1) \geq 5$ can hold only if $x > 1$ because otherwise $6/(x - 1)$ is undefined or negative. Therefore, $(x - 1)$ is positive, and the inequality will be preserved if we multiply both sides by $(x - 1)$:

$$\begin{aligned}
 \frac{6}{x - 1} &\geq 5 \\
 6 &\geq 5x - 5 && \text{Multiply both sides by } (x - 1). \\
 11 &\geq 5x && \text{Add 5 to both sides.} \\
 \frac{11}{5} &\geq x. && \text{Or } x \leq \frac{11}{5}.
 \end{aligned}$$

The solution set is the half-open interval $(1, 11/5]$ (Figure A.1b). ■

Absolute Value

The **absolute value** of a number x , denoted by $|x|$, is defined by the formula

$$|x| = \begin{cases} x, & x \geq 0 \\ -x, & x < 0. \end{cases}$$

EXAMPLE 2 $|3| = 3$, $|0| = 0$, $|-5| = -(-5) = 5$, $|-|a|| = |a|$ ■

Geometrically, the absolute value of x is the distance from x to 0 on the real number line. Since distances are always positive or 0, we see that $|x| \geq 0$ for every real number x , and $|x| = 0$ if and only if $x = 0$. Also,

$$|x - y| = \text{the distance between } x \text{ and } y$$

on the real line (Figure A.2).

Since the symbol \sqrt{a} always denotes the *nonnegative* square root of a , an alternate definition of $|x|$ is

$$|x| = \sqrt{x^2}.$$

It is important to remember that $\sqrt{a^2} = |a|$. Do not write $\sqrt{a^2} = a$ unless you already know that $a \geq 0$.

The absolute value function has the following properties. (You are asked to prove these properties in the exercises.)

Absolute Value Properties

1. $|-a| = |a|$ A number and its negative have the same absolute value.
2. $|ab| = |a||b|$ The absolute value of a product is the product of the absolute values.
3. $\left|\frac{a}{b}\right| = \frac{|a|}{|b|}$ The absolute value of a quotient is the quotient of the absolute values.
4. $|a + b| \leq |a| + |b|$ The **triangle inequality**. The absolute value of the sum of two numbers is less than or equal to the sum of their absolute values.

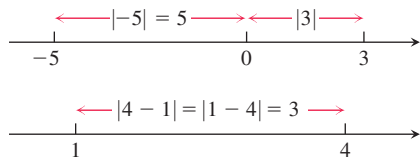

FIGURE A.2 Absolute values give distances between points on the number line.

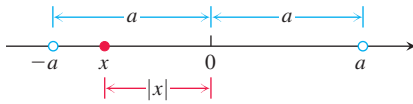

FIGURE A.3 $|x| < a$ means x lies between $-a$ and a .

Note that $|-a| \neq -|a|$. For example, $|-3| = 3$, whereas $-|3| = -3$. If a and b differ in sign, then $|a + b|$ is less than $|a| + |b|$. In all other cases, $|a + b|$ equals $|a| + |b|$. Absolute value bars in expressions like $|-3 + 5|$ work like parentheses: We do the arithmetic inside *before* taking the absolute value.

EXAMPLE 3

$$|-3 + 5| = |2| = 2 < |-3| + |5| = 8$$

$$|3 + 5| = |8| = |3| + |5|$$

$$|-3 - 5| = |-8| = 8 = |-3| + |-5|$$

FURTHER PROPERTIES: ABSOLUTE VALUES AND INTERVALS

If a is any positive number, then:

5. $|x| = a \Leftrightarrow x = \pm a$
6. $|x| < a \Leftrightarrow -a < x < a$
7. $|x| > a \Leftrightarrow x > a \text{ or } x < -a$
8. $|x| \leq a \Leftrightarrow -a \leq x \leq a$
9. $|x| \geq a \Leftrightarrow x \geq a \text{ or } x \leq -a$

The inequality $|x| < a$ says that the distance from x to 0 is less than the positive number a . This means that x must lie between $-a$ and a , as we can see from Figure A.3.

Statements 5–9 in the table at left are all consequences of the definition of absolute value and are often helpful when solving equations or inequalities involving absolute values. The symbol \Leftrightarrow that appears in the table is often used by mathematicians to denote the “if and only if” logical relationship. It also means “implies and is implied by.”

EXAMPLE 4 Solve the equation $|2x - 3| = 7$.

Solution By Property 5, $2x - 3 = \pm 7$, so there are two possibilities:

$$\begin{array}{lll} 2x - 3 = 7 & 2x - 3 = -7 & \text{Equivalent equations without absolute values} \\ 2x = 10 & 2x = -4 & \text{Solve as usual.} \\ x = 5 & x = -2 & \end{array}$$

The solutions of $|2x - 3| = 7$ are $x = 5$ and $x = -2$.

EXAMPLE 5 Solve the inequality $\left|5 - \frac{2}{x}\right| < 1$.

Solution We have

$$\begin{aligned} \left|5 - \frac{2}{x}\right| < 1 &\Leftrightarrow -1 < 5 - \frac{2}{x} < 1 && \text{Property 6} \\ &\Leftrightarrow -6 < -\frac{2}{x} < -4 && \text{Subtract 5.} \\ &\Leftrightarrow 3 > \frac{1}{x} > 2 && \text{Multiply by } -\frac{1}{2}. \\ &\Leftrightarrow \frac{1}{3} < x < \frac{1}{2}. && \text{Take reciprocals.} \end{aligned}$$

Notice how the various rules for inequalities were used here. Multiplying by a negative number reverses the inequality. So does taking reciprocals in an inequality in which both sides are positive. The original inequality holds if and only if $(1/3) < x < (1/2)$. The solution set is the open interval $(1/3, 1/2)$.

EXERCISES A.1

- Express $1/9$ as a repeating decimal, using a bar to indicate the repeating digits. What are the decimal representations of $2/9$? $3/9$? $8/9$? $9/9$?
- If $2 < x < 6$, which of the following statements about x are necessarily true, and which are not necessarily true?
 - $0 < x < 4$
 - $0 < x - 2 < 4$
 - $1 < \frac{x}{2} < 3$
 - $\frac{1}{6} < \frac{1}{x} < \frac{1}{2}$
 - $1 < \frac{6}{x} < 3$
 - $|x - 4| < 2$
 - $-6 < -x < 2$
 - $-6 < -x < -2$

In Exercises 3–6, solve the inequalities and show the solution sets on the real line.

- $-2x > 4$
- $5x - 3 \leq 7 - 3x$
- $2x - \frac{1}{2} \geq 7x + \frac{7}{6}$
- $\frac{4}{5}(x - 2) < \frac{1}{3}(x - 6)$

Solve the equations in Exercises 7–9.

- $|y| = 3$
- $|2t + 5| = 4$
- $|8 - 3s| = \frac{9}{2}$

Solve the inequalities in Exercises 10–17, expressing the solution sets as intervals or unions of intervals. Also, show each solution set on the real line.

- $|x| < 2$
- $|t - 1| \leq 3$
- $|3y - 7| < 4$
- $\left| \frac{z}{5} - 1 \right| \leq 1$
- $\left| 3 - \frac{1}{x} \right| < \frac{1}{2}$
- $|2s| \geq 4$
- $|1 - x| > 1$
- $\left| \frac{r+1}{2} \right| \geq 1$

Solve the inequalities in Exercises 18–21. Express the solution sets as intervals or unions of intervals and show them on the real line. Use the result $\sqrt{a^2} = |a|$ as appropriate.

- $x^2 < 2$
- $4 < x^2 < 9$
- $(x - 1)^2 < 4$
- $x^2 - x < 0$
- Do not fall into the trap of thinking $|-a| = a$. For what real numbers a is this equation true? For what real numbers is it false?
- Solve the equation $|x - 1| = 1 - x$.
- A proof of the triangle inequality** Give the reason justifying each of the numbered steps in the following proof of the triangle inequality.

$$|a + b|^2 = (a + b)^2 \quad (1)$$

$$= a^2 + 2ab + b^2$$

$$\leq a^2 + 2|a||b| + b^2 \quad (2)$$

$$= |a|^2 + 2|a||b| + |b|^2 \quad (3)$$

$$= (|a| + |b|)^2$$

$$|a + b| \leq |a| + |b| \quad (4)$$

- Prove that $|ab| = |a||b|$ for any numbers a and b .
- If $|x| \leq 3$ and $x > -1/2$, what can you say about x ?
- Graph the inequality $|x| + |y| \leq 1$.
- For any number a , prove that $|-a| = |a|$.
- Let a be any positive number. Prove that $|x| > a$ if and only if $x > a$ or $x < -a$.
- a.** If b is any nonzero real number, prove that $|1/b| = 1/|b|$.
b. Prove that $\left| \frac{a}{b} \right| = \frac{|a|}{|b|}$ for any numbers a and $b \neq 0$.

A.2 Graphing with Software

Many computers, calculators, and smartphones have graphing applications that enable us to graph very complicated functions with high precision. Many of these functions could not otherwise be easily graphed. However, some care must be taken when using such graphing software, and in this section we address some of the issues that can arise. In Chapter 4 we will see how calculus helps us determine that we are accurately viewing the important features of a function's graph.

Graphing Windows

When software is used for graphing, a portion of the graph is visible in a **display** or **viewing window**. Depending on the software, the default window may give an incomplete or misleading picture of the graph. We use the term *square window* when the units or scales used on both axes are the same. This term does not mean that the display window itself is square (usually it is rectangular), but instead it means that the x -unit is the same length as the y -unit.

When a graph is displayed in the default mode, the x -unit may differ from the y -unit of scaling in order to capture essential features of the graph. This difference in scaling can cause visual distortions that may lead to erroneous interpretations of the function's behavior. Some graphing software enables us to set the viewing window by specifying one or both of the intervals, $a \leq x \leq b$ and $c \leq y \leq d$, and it may allow for equalizing the scales used for the axes as well. The software selects equally spaced x -values in $[a, b]$ and then plots the points $(x, f(x))$. A point is plotted if and only if x lies in the domain of the function and $f(x)$ lies within the interval $[c, d]$. A short line segment is then drawn between each plotted point and its next neighboring point. We now give illustrative examples of some common problems that may occur with this procedure.

EXAMPLE 1 Graph the function $f(x) = x^3 - 7x^2 + 28$ in each of the following display or viewing windows:

- (a) $[-10, 10]$ by $[-10, 10]$ (b) $[-4, 4]$ by $[-50, 10]$ (c) $[-4, 10]$ by $[-60, 60]$

Solution

- (a) We select $a = -10$, $b = 10$, $c = -10$, and $d = 10$ to specify the interval of x -values and the range of y -values for the window. The resulting graph is shown in Figure A.4a. It appears that the window is cutting off the bottom and top parts of the graph and that the interval of x -values is too large. Let's try the next window.
- (b) We see some new features of the graph (Figure A.4b), but the top is still missing and we need to view more to the right of $x = 4$ as well. The next window should help.

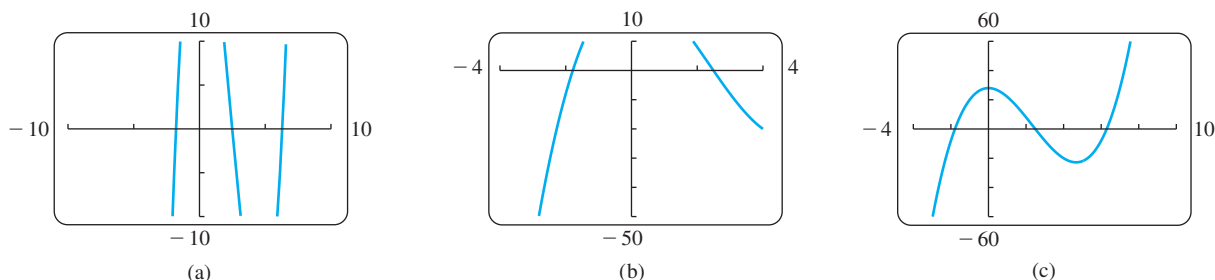

FIGURE A.4 The graph of $f(x) = x^3 - 7x^2 + 28$ in different viewing windows. Selecting a window that gives a clear picture of a graph is often a trial-and-error process (Example 1). The default window used by the software may automatically display the graph in (c).

- (c) Figure A.4c shows the graph in this new viewing window. Observe that we get a more complete picture of the graph in this window, and it is a reasonable graph of a third-degree polynomial. ■

EXAMPLE 2 When a graph is displayed, the x -unit may differ from the y -unit, as in the graphs shown in Figure A.4. The result is distortion in the picture, which may be misleading. The display window can be made square by compressing or stretching the units on one axis to match the scale on the other, giving the true graph. Many software systems have built-in options to make the window “square.” If yours does not, you may have to bring to your viewing some foreknowledge of the true picture.

Figure A.5a shows the graphs of the perpendicular lines $y = x$ and $y = -x + 3\sqrt{2}$, together with the semicircle $y = \sqrt{9 - x^2}$, in a nonsquare $[-4, 4]$ by $[-6, 8]$ display window. Notice the distortion. The lines do not appear to be perpendicular, and the semicircle appears to be elliptical in shape.

Figure A.5b shows the graphs of the same functions in a square window in which the x -units are scaled to be the same as the y -units. Notice that the scaling on the x -axis for Figure A.5a has been compressed in Figure A.5b to make the window square. Figure A.5c gives an enlarged view of Figure A.5b with a square $[-3, 3]$ by $[0, 4]$ window. ■

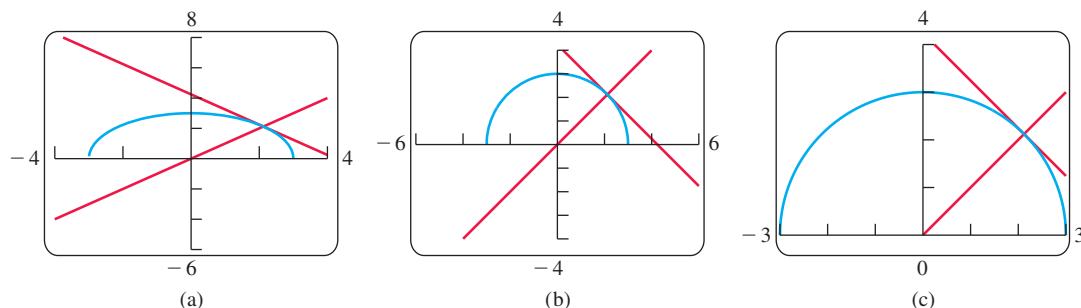

FIGURE A.5 Graphs of the perpendicular lines $y = x$ and $y = -x + 3\sqrt{2}$ and of the semicircle $y = \sqrt{9 - x^2}$ appear distorted (a) in a nonsquare window, but clear (b) and (c) in square windows (Example 2). Some software may not provide options for the views in (b) or (c).

If the denominator of a rational function is zero at some x -value within the viewing window, graphing software may produce a steep, near-vertical line segment from the top to the bottom of the window. Example 3 illustrates steep line segments.

Sometimes the graph of a trigonometric function oscillates very rapidly. When graphing software plots the points of the graph and connects them, many of the maximum and minimum points are actually missed. The resulting graph is then very misleading.

EXAMPLE 3 Graph the function $f(x) = \sin 100x$.

Solution Figure A.6a shows the graph of f in the viewing window $[-12, 12]$ by $[-1, 1]$. We see that the graph looks very strange because the sine curve should oscillate periodically between -1 and 1 . This behavior is not exhibited in Figure A.6a. We might experiment with a smaller viewing window, say $[-6, 6]$ by $[-1, 1]$, but the graph is not better (Figure A.6b). The difficulty is that the period of the trigonometric function $y = \sin 100x$ is very small ($2\pi/100 \approx 0.063$). If we choose the much smaller viewing window $[-0.1, 0.1]$ by $[-1, 1]$ we get the graph shown in Figure A.6c. This graph reveals the expected oscillations of a sine curve. ■

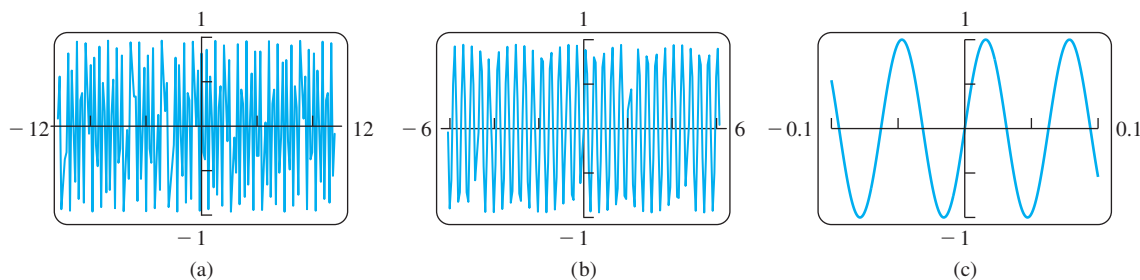

FIGURE A.6 Graphs of the function $y = \sin 100x$ in three viewing windows. Because the period is $2\pi/100 \approx 0.063$, the smaller window in (c) best displays the true aspects of this rapidly oscillating function (Example 3).

EXAMPLE 4 Graph the function $y = \cos x + \frac{1}{200}\sin 200x$.

Solution In the viewing window $[-6, 6]$ by $[-1, 1]$ the graph appears much like the cosine function with some very small sharp wiggles on it (Figure A.7a). We get a better

look when we significantly reduce the window to $[-0.2, 0.2]$ by $[0.97, 1.01]$, obtaining the graph in Figure A.7b. We now see the small but rapid oscillations of the second term, $(1/200) \sin 200x$, added to the comparatively larger values of the cosine curve. ■

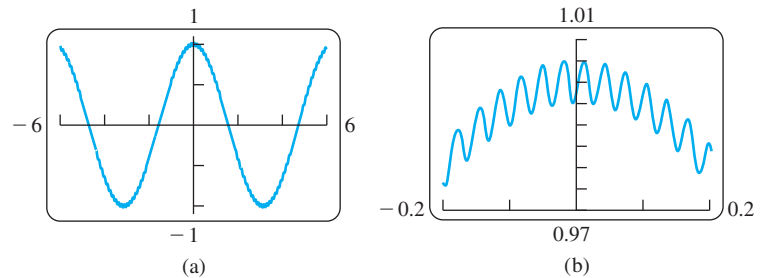

FIGURE A.7 (a) The function $y = \cos x + \frac{1}{200} \sin 200x$. (b) A close-up view, blown up near the y -axis. The term $\cos x$ clearly dominates the second term, $\frac{1}{200} \sin 200x$, which produces the rapid oscillations along the cosine curve. Both views are needed for a clear idea of the graph (Example 4).

Obtaining a Complete Graph

Some graphing software will not display the portion of a graph for $f(x)$ when $x < 0$. Usually that happens because of the algorithm the software is using to calculate the function values. Sometimes we can obtain the complete graph by defining the formula for the function in a different way, as illustrated in the next example.

EXAMPLE 5 Graph the function $y = x^{1/3}$.

Solution Some graphing software displays the graph shown in Figure A.8a. When we compare it with the graph of $y = x^{1/3} = \sqrt[3]{x}$ in Figure 1.17, we see that the left branch for $x < 0$ is missing. The reason the graphs differ is that the software algorithm calculates $x^{1/3}$ as $e^{(1/3)\ln x}$. Since the logarithmic function is not defined for negative values of x , the software can produce only the right branch, where $x > 0$. (Logarithmic and exponential functions are introduced in the next two sections.)

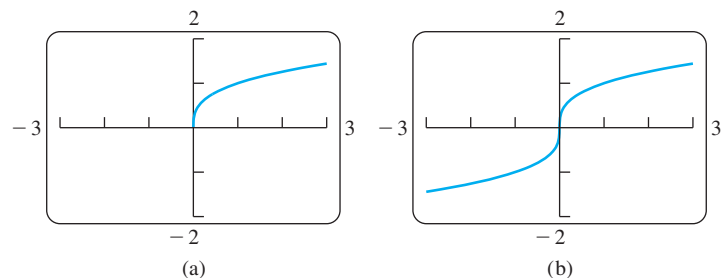

FIGURE A.8 The graph of $y = x^{1/3}$ is missing the left branch in (a). In (b) we graph the function $f(x) = \frac{x}{|x|} \cdot |x|^{1/3}$, obtaining both branches. (See Example 5.)

To obtain the full picture showing both branches, we can graph the function

$$f(x) = \frac{x}{|x|} \cdot |x|^{1/3}.$$

This function equals $x^{1/3}$ except at $x = 0$ (where f is undefined, although $0^{1/3} = 0$). A graph of f is displayed in Figure A.8b. ■

EXERCISES A.2

Choosing a Viewing Window

T In Exercises 1–4, use graphing software to determine which of the given viewing windows displays the most appropriate graph of the specified function.

- $f(x) = x^4 - 7x^2 + 6x$
 - $[-1, 1]$ by $[-1, 1]$
 - $[-2, 2]$ by $[-5, 5]$
 - $[-10, 10]$ by $[-10, 10]$
 - $[-5, 5]$ by $[-25, 15]$
- $f(x) = x^3 - 4x^2 - 4x + 16$
 - $[-1, 1]$ by $[-5, 5]$
 - $[-3, 3]$ by $[-10, 10]$
 - $[-5, 5]$ by $[-10, 20]$
 - $[-20, 20]$ by $[-100, 100]$
- $f(x) = 5 + 12x - x^3$
 - $[-1, 1]$ by $[-1, 1]$
 - $[-5, 5]$ by $[-10, 10]$
 - $[-4, 4]$ by $[-20, 20]$
 - $[-4, 5]$ by $[-15, 25]$
- $f(x) = \sqrt{5 + 4x - x^2}$
 - $[-2, 2]$ by $[-2, 2]$
 - $[-2, 6]$ by $[-1, 4]$
 - $[-3, 7]$ by $[0, 10]$
 - $[-10, 10]$ by $[-10, 10]$

Finding a Viewing Window

T In Exercises 5–30, find an appropriate graphing software viewing window for the given function and use it to display that function's graph. The window should give a picture of the overall behavior of the function. There is more than one choice, but incorrect choices can miss important aspects of the function.

- $f(x) = x^4 - 4x^3 + 15$
- $f(x) = \frac{x^3}{3} - \frac{x^2}{2} - 2x + 1$
- $f(x) = x^5 - 5x^4 + 10$
- $f(x) = 4x^3 - x^4$
- $f(x) = x\sqrt{9 - x^2}$
- $f(x) = x^2(6 - x^3)$

- $y = 2x - 3x^{2/3}$
- $y = x^{1/3}(x^2 - 8)$
- $y = 5x^{2/5} - 2x$
- $y = x^{2/3}(5 - x)$
- $y = |x^2 - 1|$
- $y = |x^2 - x|$
- $y = \frac{x + 3}{x + 2}$
- $y = 1 - \frac{1}{x + 3}$
- $f(x) = \frac{x^2 + 2}{x^2 + 1}$
- $f(x) = \frac{x^2 - 1}{x^2 + 1}$
- $f(x) = \frac{x - 1}{x^2 - x - 6}$
- $f(x) = \frac{8}{x^2 - 9}$
- $f(x) = \frac{6x^2 - 15x + 6}{4x^2 - 10x}$
- $f(x) = \frac{x^2 - 3}{x - 2}$
- $y = \sin 250x$
- $y = 3 \cos 60x$
- $y = \cos\left(\frac{x}{50}\right)$
- $y = \frac{1}{10} \sin\left(\frac{x}{10}\right)$
- $y = x + \frac{1}{10} \sin 30x$
- $y = x^2 + \frac{1}{50} \cos 100x$

Use graphing software to graph the functions specified in Exercises 31–36. Select a viewing window that reveals the key features of the function.

- Graph the lower half of the circle defined by the equation $x^2 + 2x = 4 + 4y - y^2$.
- Graph the upper branch of the hyperbola $y^2 - 16x^2 = 1$.
- Graph four periods of the function $f(x) = -\tan 2x$.
- Graph two periods of the function $f(x) = 3 \cot \frac{x}{2} + 1$.
- Graph the function $f(x) = \sin 2x + \cos 3x$.
- Graph the function $f(x) = \sin^3 x$.

A.3 Mathematical Induction

Many formulas, like

$$1 + 2 + \cdots + n = \frac{n(n+1)}{2},$$

can be shown to hold for every positive integer n by applying an axiom called the *mathematical induction principle*. A proof that uses this axiom is called a *proof by mathematical induction* or a *proof by induction*.

The steps in proving a formula by induction are the following:

- Check that the formula holds for $n = 1$.
- Prove that *if* the formula holds for any positive integer $n = k$, *then* it also holds for the next integer, $n = k + 1$.

The induction axiom says that once these steps are completed, the formula holds for all positive integers n . By Step 1 it holds for $n = 1$. By Step 2 it holds for $n = 2$, and therefore by Step 2 also for $n = 3$, and by Step 2 again for $n = 4$, and so on. If the first domino

falls, and if the k th domino always knocks over the $(k + 1)$ st when it falls, then all the dominoes fall.

EXAMPLE 1 Use mathematical induction to prove that for every positive integer n ,

$$1 + 2 + \cdots + n = \frac{n(n + 1)}{2}.$$

Solution We accomplish the proof by carrying out the two steps above.

1. The formula holds for $n = 1$ because

$$1 = \frac{1(1 + 1)}{2}.$$

2. If the formula holds for $n = k$, does it also hold for $n = k + 1$? The answer is yes, as we now show. If it is the case that

$$1 + 2 + \cdots + k = \frac{k(k + 1)}{2},$$

then it follows that

$$\begin{aligned} 1 + 2 + \cdots + k + (k + 1) &= \frac{k(k + 1)}{2} + (k + 1) = \frac{k^2 + k + 2k + 2}{2} \\ &= \frac{(k + 1)(k + 2)}{2} = \frac{(k + 1)((k + 1) + 1)}{2}. \end{aligned}$$

The last expression in this string of equalities is the expression $n(n + 1)/2$ for $n = (k + 1)$.

The mathematical induction principle now guarantees the original formula for all positive integers n . ■

In Example 4 of Section 5.2 we gave another proof for the formula giving the sum of the first n positive integers. However, proofs by mathematical induction can also be used to find the sums of the squares and cubes of the first n positive integers (Exercises 9 and 10). Here is another example of a proof by induction.

EXAMPLE 2 Show by mathematical induction that for all positive integers n ,

$$\frac{1}{2^1} + \frac{1}{2^2} + \cdots + \frac{1}{2^n} = 1 - \frac{1}{2^n}.$$

Solution We accomplish the proof by carrying out the two steps of mathematical induction.

1. The formula holds for $n = 1$ because

$$\frac{1}{2^1} = 1 - \frac{1}{2^1}.$$

2. If it is the case that

$$\frac{1}{2^1} + \frac{1}{2^2} + \cdots + \frac{1}{2^k} = 1 - \frac{1}{2^k},$$

then it follows that

$$\begin{aligned}\frac{1}{2^1} + \frac{1}{2^2} + \cdots + \frac{1}{2^k} + \frac{1}{2^{k+1}} &= 1 - \frac{1}{2^k} + \frac{1}{2^{k+1}} = 1 - \frac{1 \cdot 2}{2^k \cdot 2} + \frac{1}{2^{k+1}} \\ &= 1 - \frac{2}{2^{k+1}} + \frac{1}{2^{k+1}} = 1 - \frac{1}{2^{k+1}}.\end{aligned}$$

Thus, the original formula holds for $n = (k + 1)$ whenever it holds for $n = k$.

With these steps verified, the mathematical induction principle now guarantees the formula for every positive integer n . ■

Other Starting Integers

Instead of starting at $n = 1$, some induction arguments start at another integer. The steps for such an argument are as follows.

1. Check that the formula holds for $n = n_1$ (the first appropriate integer).
2. Prove that if the formula holds for any integer $n = k \geq n_1$, then it also holds for $n = (k + 1)$.

Once these steps are completed, the mathematical induction principle guarantees the formula for all $n \geq n_1$.

EXAMPLE 3 Show that $n! > 3^n$ if n is large enough.

Solution How large is large enough? We experiment:

n	1	2	3	4	5	6	7
$n!$	1	2	6	24	120	720	5040
3^n	3	9	27	81	243	729	2187

It looks as if $n! > 3^n$ for $n \geq 7$. To be sure, we apply mathematical induction. We take $n_1 = 7$ in Step 1 and complete Step 2.

Suppose $k! > 3^k$ for some $k \geq 7$. Then

$$(k + 1)! = (k + 1)(k!) > (k + 1)3^k > 7 \cdot 3^k > 3^{k+1}.$$

Thus, for $k \geq 7$,

$$k! > 3^k \quad \text{implies} \quad (k + 1)! > 3^{k+1}.$$

The mathematical induction principle now guarantees $n! \geq 3^n$ for all $n \geq 7$. ■

Proof of the Derivative Sum Rule for Sums of Finitely Many Functions

We prove the statement

$$\frac{d}{dx}(u_1 + u_2 + \cdots + u_n) = \frac{du_1}{dx} + \frac{du_2}{dx} + \cdots + \frac{du_n}{dx}$$

by mathematical induction. The statement is true for $n = 2$, as was proved in Section 3.3. This is Step 1 of the induction proof.

Step 2 is to show that if the statement is true for any positive integer $n = k$, where $k \geq n_0 = 2$, then it is also true for $n = k + 1$. So suppose that

$$\frac{d}{dx}(u_1 + u_2 + \cdots + u_k) = \frac{du_1}{dx} + \frac{du_2}{dx} + \cdots + \frac{du_k}{dx}. \quad (1)$$

Then

$$\begin{aligned} & \frac{d}{dx}(\underbrace{u_1 + u_2 + \cdots + u_k}_{\text{Call the function defined by this sum } u.} + \underbrace{u_{k+1}}_{\text{Call this function } v.}) \\ &= \frac{d}{dx}(u_1 + u_2 + \cdots + u_k) + \frac{du_{k+1}}{dx} \quad \text{Sum Rule for } \frac{d}{dx}(u + v) \\ &= \frac{du_1}{dx} + \frac{du_2}{dx} + \cdots + \frac{du_k}{dx} + \frac{du_{k+1}}{dx}. \quad \text{Eq. (1)} \end{aligned}$$

With these steps verified, the mathematical induction principle now guarantees the Sum Rule for every integer $n \geq 2$.

EXERCISES A.3

1. Assuming that the triangle inequality $|a + b| \leq |a| + |b|$ holds for any two numbers a and b , show that

$$|x_1 + x_2 + \cdots + x_n| \leq |x_1| + |x_2| + \cdots + |x_n|$$

for any n numbers.

2. Show that if $r \neq 1$, then

$$1 + r + r^2 + \cdots + r^n = \frac{1 - r^{n+1}}{1 - r}$$

for every positive integer n .

3. Use the Product Rule, $\frac{d}{dx}(uv) = u\frac{dv}{dx} + v\frac{du}{dx}$, and the fact that $\frac{d}{dx}(x) = 1$ to show that $\frac{d}{dx}(x^n) = nx^{n-1}$ for every positive integer n .

4. Suppose that a function $f(x)$ has the property that $f(x_1x_2) = f(x_1) + f(x_2)$ for any two positive numbers x_1 and x_2 . Show that

$$f(x_1x_2 \cdots x_n) = f(x_1) + f(x_2) + \cdots + f(x_n)$$

for the product of any n positive numbers x_1, x_2, \dots, x_n .

5. Show that

$$\frac{2}{3^1} + \frac{2}{3^2} + \cdots + \frac{2}{3^n} = 1 - \frac{1}{3^n}$$

for all positive integers n .

6. Show that $n! > n^3$ if n is large enough.

7. Show that $2^n > n^2$ if n is large enough.

8. Show that $2^n \geq 1/8$ for $n \geq -3$.

9. **Sums of squares** Show that the sum of the squares of the first n positive integers is

$$\frac{n\left(n + \frac{1}{2}\right)(n + 1)}{3}.$$

10. **Sums of cubes** Show that the sum of the cubes of the first n positive integers is $(n(n + 1)/2)^2$.

11. **Rules for finite sums** Show that the following finite sum rules hold for every positive integer n . (See Section 5.2.)

a. $\sum_{k=1}^n (a_k + b_k) = \sum_{k=1}^n a_k + \sum_{k=1}^n b_k$

b. $\sum_{k=1}^n (a_k - b_k) = \sum_{k=1}^n a_k - \sum_{k=1}^n b_k$

c. $\sum_{k=1}^n ca_k = c \cdot \sum_{k=1}^n a_k$ (any number c)

d. $\sum_{k=1}^n a_k = n \cdot c$ (if a_k has the constant value c)

12. Show that $|x^n| = |x|^n$ for every positive integer n and every real number x .

A.4 Lines, Circles, and Parabolas

This section reviews coordinates, lines, distance, circles, and parabolas in the plane. The notion of increment is also discussed.

Cartesian Coordinates in the Plane

In Appendix A.1 we identified the points on the line with real numbers by assigning them coordinates. Points in the plane can be identified with ordered pairs of real numbers. To begin, we draw two perpendicular coordinate lines that intersect at the 0-point of each line.

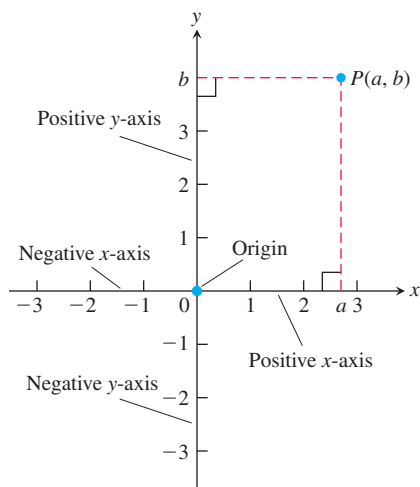

FIGURE A.9 Cartesian coordinates in the plane are based on two perpendicular axes intersecting at the origin.

HISTORICAL BIOGRAPHY

René Descartes (1596–1650)

The Cartesian coordinate system is named in honor of Descartes. Legend tells us that he thought of this coordinate system while watching a fly crawl around on the ceiling. He noticed that the path of the fly could be described by the fly's distances from each of the walls. His discovery of analytic geometry was hailed as one of the most remarkable feats in mathematical history.

To know more, visit the companion Website.

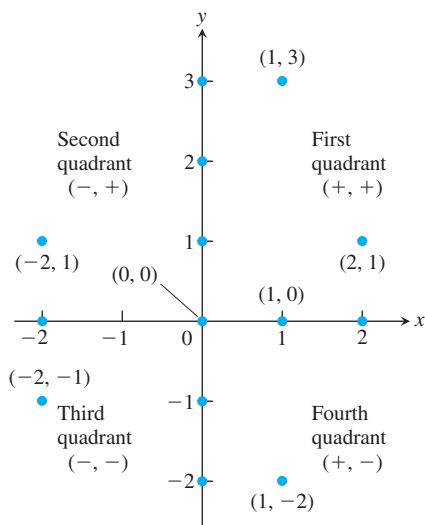

FIGURE A.10 Points labeled in the xy -coordinate or Cartesian plane. The points on the axes all have coordinate pairs but are usually labeled with single real numbers, (so $(1, 0)$ on the x -axis is labeled as 1). Notice the coordinate sign patterns of the quadrants.

These lines are called **coordinate axes**. On the horizontal x -axis, numbers are denoted by x and increase to the right. On the vertical y -axis, numbers are denoted by y and increase upward (Figure A.9). Thus “upward” and “to the right” are positive directions, whereas “downward” and “to the left” are considered negative. The **origin** O , also labeled 0, of the coordinate system is the point in the plane where x and y are both zero.

If P is any point in the plane, it can be located by exactly one ordered pair of real numbers in the following way. Draw lines through P perpendicular to the two coordinate axes. These lines intersect the axes at points with coordinates a and b (Figure A.9). The ordered pair (a, b) is assigned to the point P and is called its **coordinate pair**. The first number a is the **x -coordinate** (or **abscissa**) of P ; the second number b is the **y -coordinate** (or **ordinate**) of P . The x -coordinate of every point on the y -axis is 0. The y -coordinate of every point on the x -axis is 0. The origin is the point $(0, 0)$.

Starting with an ordered pair (a, b) , we can reverse the process and arrive at a corresponding point P in the plane. Often we identify P with the ordered pair and write $P(a, b)$. We sometimes also refer to “the point (a, b) ” and it will be clear from the context when (a, b) refers to a point in the plane and not to an open interval on the real line. Several points labeled by their coordinates are shown in Figure A.10.

This coordinate system is called the **rectangular coordinate system** or **Cartesian coordinate system** (after the sixteenth-century French mathematician René Descartes). The coordinate axes of this coordinate or Cartesian plane divide the plane into four regions called **quadrants**, numbered counterclockwise as shown in Figure A.10.

The **graph** of an equation or inequality in the variables x and y is the set of all points $P(x, y)$ in the plane whose coordinates satisfy the equation or inequality. When we plot data in the coordinate plane or graph formulas whose variables have different units of measure, we do not need to use the same scale on the two axes. If we plot time vs. thrust for a rocket motor, for example, there is no reason to place the mark that shows 1 s on the time axis the same distance from the origin as the mark that shows 1 N on the thrust axis.

Usually when we graph functions whose variables do not represent physical measurements and when we draw figures in the coordinate plane to study their geometry and trigonometry, we make the scales on the axes identical. A vertical unit of distance then looks the same as a horizontal unit. As on a surveyor's map or a scale drawing, line segments that are supposed to have the same length will look as if they do, and angles that are supposed to be congruent will look congruent.

Computer displays and calculator displays are another matter. The vertical and horizontal scales on machine-generated graphs usually differ, and there are corresponding distortions in distances, slopes, and angles. Circles may look like ellipses, rectangles may look like squares, right angles may appear to be acute or obtuse, and so on. We discuss these displays and distortions in greater detail in Appendix A.2.

Increments and Straight Lines

When a particle moves from one point in the plane to another, the net changes in its coordinates are called **increments**. They are calculated by subtracting the coordinates of the starting point from the coordinates of the ending point. If x changes from x_1 to x_2 , the **increment** in x is

$$\Delta x = x_2 - x_1.$$

EXAMPLE 1 As shown in Figure A.11, in going from the point $A(4, -3)$ to the point $B(2, 5)$, the increments in the x - and y -coordinates are

$$\Delta x = 2 - 4 = -2, \quad \Delta y = 5 - (-3) = 8.$$

From $C(5, 6)$ to $D(5, 1)$ the coordinate increments are

$$\Delta x = 5 - 5 = 0, \quad \Delta y = 1 - 6 = -5. \quad \blacksquare$$

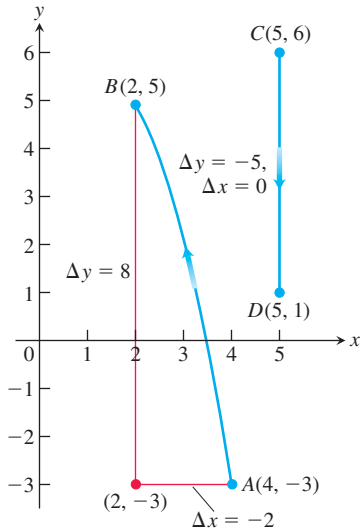

FIGURE A.11 Coordinate increments may be positive, negative, or zero (Example 1).

Given two points $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$ in the plane, we call the increments $\Delta x = x_2 - x_1$ and $\Delta y = y_2 - y_1$ the **run** and the **rise**, respectively, between P_1 and P_2 . Two such points always determine a unique straight line (usually called simply a line) passing through them both. We call the line P_1P_2 .

Any nonvertical line in the plane has the property that the ratio

$$m = \frac{\text{rise}}{\text{run}} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

has the same value for every choice of the two points $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$ on the line (Figure A.12). This is because the ratios of corresponding sides for similar triangles are equal.

DEFINITION The constant ratio

$$m = \frac{\text{rise}}{\text{run}} = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

is the **slope** of the nonvertical line P_1P_2 .

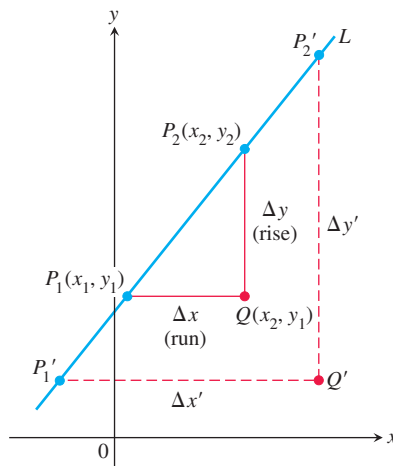

FIGURE A.12 Triangles P_1QP_2 and $P_1'Q'P_2'$ are similar, so the ratio of their sides has the same value for any two points on the line. This common value is the line's slope.

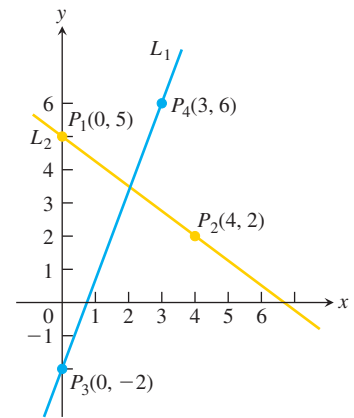

FIGURE A.13 The slope of L_1 is

$$m = \frac{\Delta y}{\Delta x} = \frac{6 - (-2)}{3 - 0} = \frac{8}{3}$$

That is, y increases 8 units every time x increases 3 units. The slope of L_2 is

$$m = \frac{\Delta y}{\Delta x} = \frac{2 - 5}{4 - 0} = \frac{-3}{4}$$

That is, y decreases 3 units every time x increases 4 units.

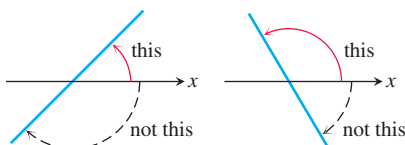

FIGURE A.14 Angles of inclination are measured counterclockwise from the x -axis.

The slope tells us the direction (uphill, downhill) and steepness of a line. A line with positive slope rises uphill to the right; one with negative slope falls downhill to the right (Figure A.13). The greater the absolute value of the slope, the more rapid the rise or fall. The slope of a vertical line is *undefined*. Since the run Δx is zero for a vertical line, we cannot form the slope ratio m .

The direction and steepness of a line can also be measured with an angle. The **angle of inclination** of a line that crosses the x -axis is the smallest counterclockwise angle from the x -axis to the line (Figure A.14). The inclination of a horizontal line is 0° . The inclination of a vertical line is 90° . If ϕ (the Greek letter phi) is the inclination of a line, then $0 \leq \phi < 180^\circ$.

The relationship between the slope m of a nonvertical line and the line's angle of inclination ϕ is shown in Figure A.15:

$$m = \tan \phi.$$

Straight lines have relatively simple equations. All points on the *vertical line* through the point a on the x -axis have x -coordinates equal to a . Thus, $x = a$ is an equation for the vertical line. Similarly, $y = b$ is an equation for the *horizontal line* meeting the y -axis at b . (See Figure A.16.)

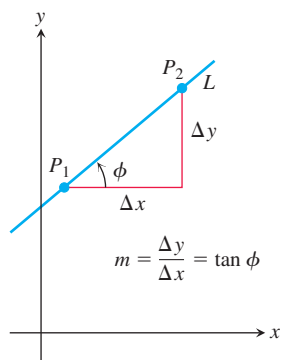

FIGURE A.15 The slope of a nonvertical line is the tangent of its angle of inclination.

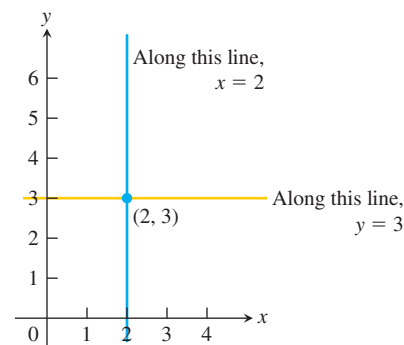

FIGURE A.16 The standard equations for the vertical and horizontal lines through $(2, 3)$ are $x = 2$ and $y = 3$.

We can write an equation for a nonvertical straight line L if we know its slope m and the coordinates of one point $P_1(x_1, y_1)$ on it. If $P(x, y)$ is *any* other point on L , then we can use the two points P_1 and P to compute the slope,

$$m = \frac{y - y_1}{x - x_1}$$

so that

$$y - y_1 = m(x - x_1), \quad \text{or} \quad y = y_1 + m(x - x_1).$$

The equation

$$y = y_1 + m(x - x_1)$$

is the **point-slope equation** of the line that passes through the point (x_1, y_1) and has slope m .

EXAMPLE 2 Write an equation for the line through the point $(2, 3)$ with slope $-3/2$.

Solution We substitute $x_1 = 2$, $y_1 = 3$, and $m = -3/2$ into the point-slope equation and obtain

$$y = 3 - \frac{3}{2}(x - 2), \quad \text{or} \quad y = -\frac{3}{2}x + 6. \quad \blacksquare$$

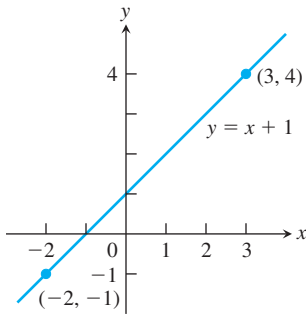

FIGURE A.17 The line in Example 3.

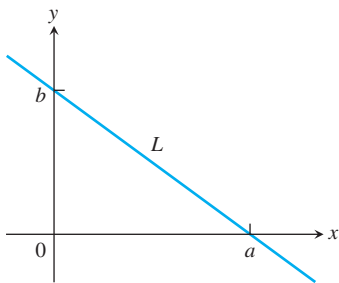

FIGURE A.18 Line L has x -intercept a and y -intercept b .

EXAMPLE 3 Write an equation for the line through $(-2, -1)$ and $(3, 4)$.

Solution The line's slope is

$$m = \frac{-1 - 4}{-2 - 3} = \frac{-5}{-5} = 1.$$

We can use this slope with either of the two given points in the point-slope equation:

With $(x_1, y_1) = (-2, -1)$

$$y = -1 + 1 \cdot (x - (-2))$$

$$y = -1 + x + 2$$

$$y = x + 1$$

With $(x_1, y_1) = (3, 4)$

$$y = 4 + 1 \cdot (x - 3)$$

$$y = 4 + x - 3$$

$$y = x + 1$$

Same result

Either way, we see that $y = x + 1$ is an equation for the line (Figure A.17). ■

The y -coordinate of the point where a nonvertical line intersects the y -axis is called the **y -intercept** of the line. Similarly, the **x -intercept** of a nonhorizontal line is the x -coordinate of the point where it crosses the x -axis (Figure A.18). A line with slope m and y -intercept b passes through the point $(0, b)$, so it has equation

$$y = b + m(x - 0), \quad \text{or, more simply,} \quad y = mx + b.$$

The equation

$$y = mx + b$$

is called the **slope-intercept equation** of the line with slope m and y -intercept b .

Lines with equations of the form $y = mx$ have y -intercept 0 and so pass through the origin. Equations of lines are called **linear** equations.

The equation

$$Ax + By = C \quad (A \text{ and } B \text{ not both } 0)$$

is called the **general linear equation** in x and y because its graph always represents a line and every line has an equation in this form (including lines with undefined slope).

Parallel and Perpendicular Lines

Lines that are parallel have equal angles of inclination, so they have the same slope (if they are not vertical). Conversely, lines with equal slopes have equal angles of inclination and so are parallel.

If two nonvertical lines L_1 and L_2 are perpendicular, their slopes m_1 and m_2 satisfy $m_1 m_2 = -1$, so each slope is the *negative reciprocal* of the other:

$$m_1 = -\frac{1}{m_2}, \quad m_2 = -\frac{1}{m_1}.$$

To see this, notice by inspecting similar triangles in Figure A.19 that $m_1 = a/h$, and $m_2 = -h/a$. Hence, $m_1 m_2 = (a/h)(-h/a) = -1$.

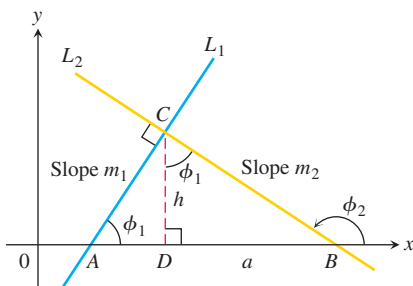

FIGURE A.19 $\triangle ADC$ is similar to $\triangle CDB$. Hence ϕ_1 is also the upper angle in $\triangle CDB$. From the sides of $\triangle CDB$, we read $\tan \phi_1 = a/h$.

Distance and Circles in the Plane

The distance between points in the plane is calculated with a formula that comes from the Pythagorean theorem (Figure A.20).

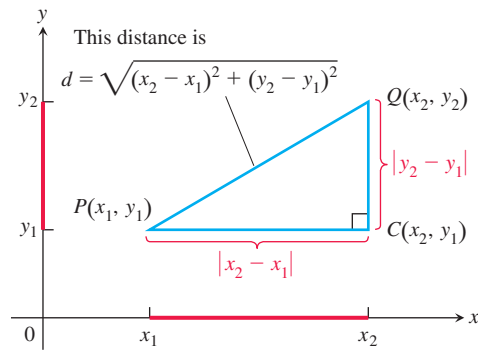

FIGURE A.20 To calculate the distance between $P(x_1, y_1)$ and $Q(x_2, y_2)$, apply the Pythagorean theorem to triangle PCQ .

Distance Formula for Points in the Plane

The distance between $P(x_1, y_1)$ and $Q(x_2, y_2)$ is

$$d = \sqrt{(\Delta x)^2 + (\Delta y)^2} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}.$$

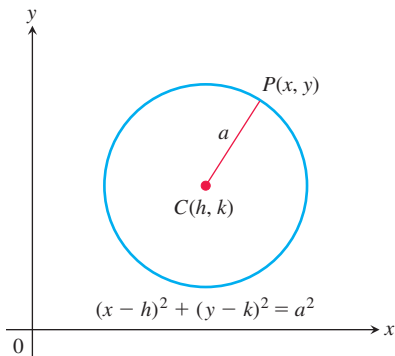

FIGURE A.21 A circle of radius a in the xy -plane, with center at (h, k) .

By definition, a **circle** of radius a is the set of all points $P(x, y)$ whose distance from some center $C(h, k)$ equals a (Figure A.21). From the distance formula, P lies on the circle if and only if

$$\sqrt{(x - h)^2 + (y - k)^2} = a,$$

so

$$(x - h)^2 + (y - k)^2 = a^2. \quad (1)$$

Equation (1) is the **standard equation** of a circle with center (h, k) and radius a . The circle of radius $a = 1$ and centered at the origin is the **unit circle** with equation

$$x^2 + y^2 = 1.$$

EXAMPLE 4

(a) The standard equation for the circle of radius 2 centered at $(3, 4)$ is

$$(x - 3)^2 + (y - 4)^2 = 2^2 = 4.$$

(b) The circle

$$(x - 1)^2 + (y + 5)^2 = 3$$

has $h = 1$, $k = -5$, and $a = \sqrt{3}$. The center is the point $(h, k) = (1, -5)$ and the radius is $a = \sqrt{3}$. ■

If an equation for a circle is not in standard form, we can find the circle's center and radius by first converting the equation to standard form. The algebraic technique for doing so is *completing the square*.

EXAMPLE 5 Find the center and radius of the circle

$$x^2 + y^2 + 4x - 6y - 3 = 0.$$

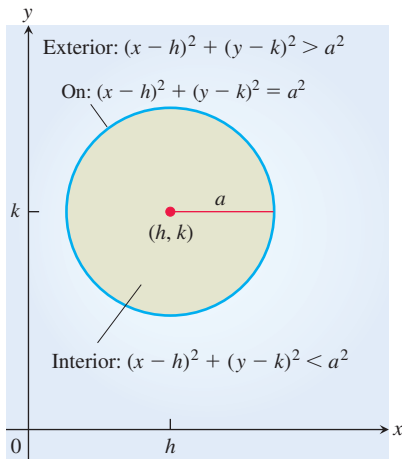

FIGURE A.22 The interior and exterior of the circle $(x - h)^2 + (y - k)^2 = a^2$.

Solution We convert the equation to standard form by completing the squares in x and y :

$$x^2 + y^2 + 4x - 6y - 3 = 0$$

$$(x^2 + 4x) + (y^2 - 6y) = 3$$

$$\left(x^2 + 4x + \left(\frac{4}{2}\right)^2\right) + \left(y^2 - 6y + \left(\frac{-6}{2}\right)^2\right)$$

$$= 3 + \left(\frac{4}{2}\right)^2 + \left(\frac{-6}{2}\right)^2$$

$$(x^2 + 4x + 4) + (y^2 - 6y + 9) = 3 + 4 + 9$$

$$(x + 2)^2 + (y - 3)^2 = 16$$

The center is $(-2, 3)$ and the radius is $a = 4$. ■

Start with the given equation.
Gather terms. Move the constant to the right-hand side.

Add the square of half the coefficient of x to each side of the equation. Do the same for y . The parenthetical expressions on the left-hand side are now perfect squares.

Write each quadratic as a squared linear expression.

The points (x, y) satisfying the inequality

$$(x - h)^2 + (y - k)^2 < a^2$$

make up the **interior** region of the circle with center (h, k) and radius a (Figure A.22). The circle's **exterior** consists of the points (x, y) satisfying

$$(x - h)^2 + (y - k)^2 > a^2.$$

Parabolas

The geometric definition and properties of general parabolas are reviewed in Chapter 10. Here we look at parabolas arising as the graphs of equations of the form $y = ax^2 + bx + c$.

EXAMPLE 6 Consider the equation $y = x^2$. Some points whose coordinates satisfy this equation are $(0, 0)$, $(1, 1)$, $(\frac{3}{2}, \frac{9}{4})$, $(-1, 1)$, $(2, 4)$, and $(-2, 4)$. These points (and all others satisfying the equation) make up a smooth curve called a parabola (Figure A.23). ■

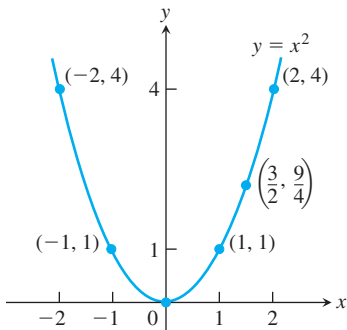

FIGURE A.23 The parabola $y = x^2$ (Example 6).

The graph of an equation of the form

$$y = ax^2$$

is a **parabola** whose **axis** (axis of symmetry) is the y -axis. The parabola's **vertex** (point where the parabola and axis cross) lies at the origin. The parabola opens upward if $a > 0$ and downward if $a < 0$. The larger the value of $|a|$, the narrower the parabola (Figure A.24).

Generally, the graph of $y = ax^2 + bx + c$ is a shifted and scaled version of the parabola $y = x^2$. We discuss shifting and scaling of graphs in more detail in Section 1.2.

The Graph of $y = ax^2 + bx + c$, $a \neq 0$

The graph of the equation $y = ax^2 + bx + c$, $a \neq 0$, is a parabola. The parabola opens upward if $a > 0$ and downward if $a < 0$. The **axis** is the line

$$x = -\frac{b}{2a}. \quad (2)$$

The **vertex** of the parabola is the point where the axis and parabola intersect. Its x -coordinate is $x = -b/2a$; its y -coordinate is found by substituting $x = -b/2a$ in the parabola's equation.

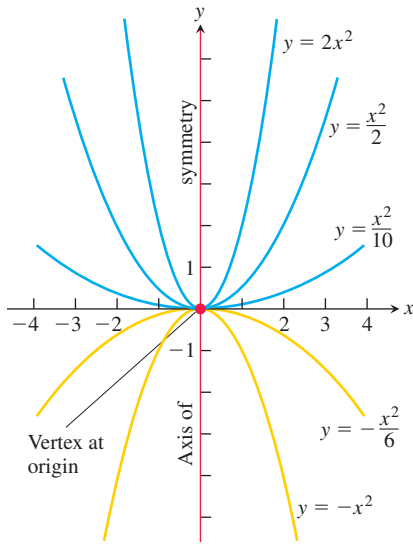

FIGURE A.24 Besides determining the direction in which the parabola $y = ax^2$ opens, the number a is a scaling factor. The parabola widens as a approaches zero and narrows as $|a|$ becomes large.

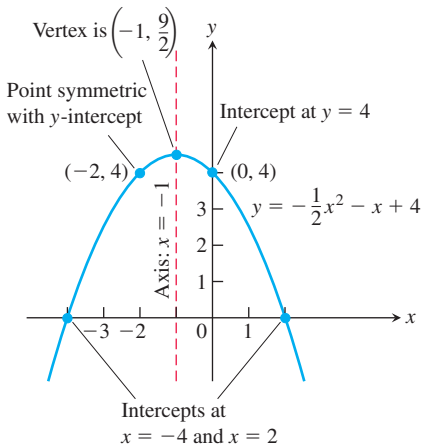

FIGURE A.25 The parabola in Example 7.

Notice that if $a = 0$, then we have $y = bx + c$, which is an equation for a line. The axis, given by Equation (2), can be found by completing the square.

EXAMPLE 7 Graph the equation $y = -\frac{1}{2}x^2 - x + 4$.

Solution Comparing the equation with $y = ax^2 + bx + c$ we see that

$$a = -\frac{1}{2}, \quad b = -1, \quad c = 4.$$

Since $a < 0$, the parabola opens downward. From Equation (2) the axis is the vertical line

$$x = -\frac{b}{2a} = -\frac{(-1)}{2(-1/2)} = -1.$$

When $x = -1$, we have

$$y = -\frac{1}{2}(-1)^2 - (-1) + 4 = \frac{9}{2}.$$

The vertex is $(-1, 9/2)$.

The x -intercepts are where $y = 0$:

$$\begin{aligned} -\frac{1}{2}x^2 - x + 4 &= 0 \\ x^2 + 2x - 8 &= 0 \\ (x - 2)(x + 4) &= 0 \\ x &= 2, \quad x = -4 \end{aligned}$$

We plot some points, sketch the axis, and use the direction of opening to complete the graph in Figure A.25. ■

Ellipses

The geometric definition and properties of general ellipses are reviewed in Chapter 10. Here we relate them to circles. Although they are not the graphs of functions, circles can be stretched horizontally or vertically in the same way as the graphs of functions. The standard equation for a circle of radius r centered at the origin is

$$x^2 + y^2 = r^2.$$

Substituting cx for x in the standard equation for a circle (Figure A.26) gives

$$c^2x^2 + y^2 = r^2. \tag{3}$$

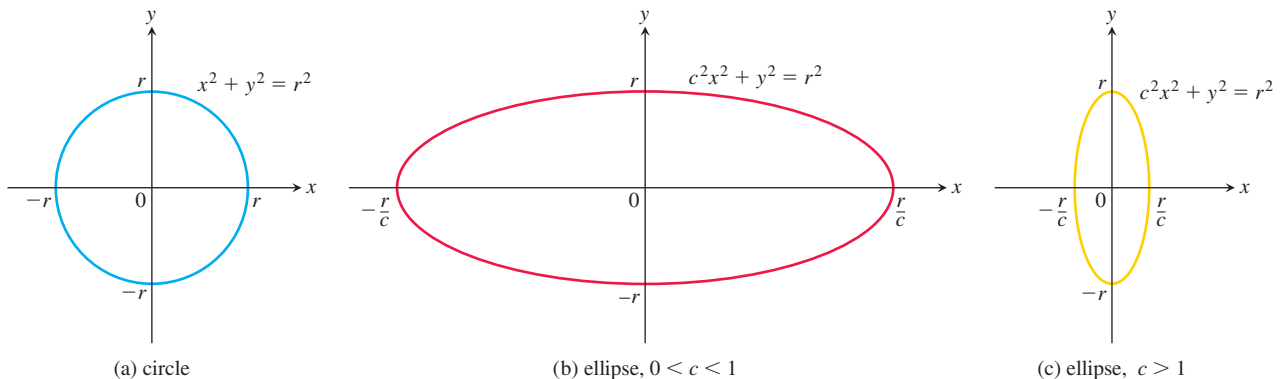

FIGURE A.26 Horizontal stretching or compression of a circle produces graphs of ellipses.

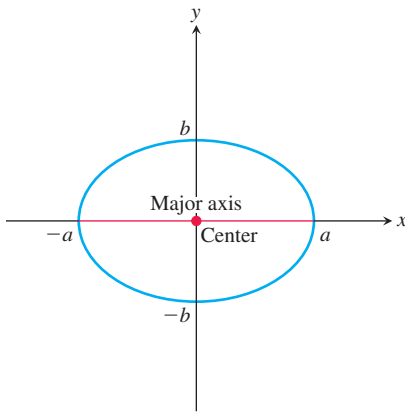

FIGURE A.27 Graph of the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, $a > b$, where the major axis is horizontal.

If $0 < c < 1$, the graph of Equation (3) horizontally stretches the circle; if $c > 1$ the circle is compressed horizontally. In either case, the graph of Equation (3) is an ellipse (Figure A.26). Notice in Figure A.26 that the y -intercepts of all three graphs are always $-r$ and r . In Figure A.26b, the line segment joining the points $(\pm r/c, 0)$ is called the **major axis** of the ellipse; the **minor axis** is the line segment joining $(0, \pm r)$. The axes of the ellipse are reversed in Figure A.26c: The major axis is the line segment joining the points $(0, \pm r)$, and the minor axis is the line segment joining the points $(\pm r/c, 0)$. In both cases, the major axis is the longer line segment.

If we divide both sides of Equation (3) by r^2 , we obtain

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad (4)$$

where $a = r/c$ and $b = r$. If $a > b$, the major axis is horizontal; if $a < b$, the major axis is vertical. The **center** of the ellipse given by Equation (4) is the origin (Figure A.27).

Substituting $x - h$ for x , and $y - k$ for y , in Equation (4) results in

$$\frac{(x - h)^2}{a^2} + \frac{(y - k)^2}{b^2} = 1. \quad (5)$$

Equation (5) is the **standard equation of an ellipse** with center at (h, k) .

EXERCISES A.4

Distance, Slopes, and Lines

In Exercises 1 and 2, a particle moves from A to B in the coordinate plane. Find the increments Δx and Δy in the particle's coordinates. Also find the distance from A to B .

1. $A(-3, 2)$, $B(-1, -2)$ 2. $A(-3.2, -2)$, $B(-8.1, -2)$

Describe the graphs of the equations in Exercises 3 and 4.

3. $x^2 + y^2 = 1$ 4. $x^2 + y^2 \leq 3$

Plot the points in Exercises 5 and 6 and find the slope (if any) of the line they determine. Also find the common slope (if any) of the lines perpendicular to line AB .

5. $A(-1, 2)$, $B(-2, -1)$ 6. $A(2, 3)$, $B(-1, 3)$

In Exercises 7 and 8, find an equation for (a) the vertical line and (b) the horizontal line through the given point.

7. $(-1, 4/3)$ 8. $(0, -\sqrt{2})$

In Exercises 9–15, write an equation for each line described.

9. Passes through $(-1, 1)$ with slope -1
 10. Passes through $(3, 4)$ and $(-2, 5)$
 11. Has slope $-5/4$ and y -intercept 6
 12. Passes through $(-12, -9)$ and has slope 0
 13. Has y -intercept 4 and x -intercept -1
 14. Passes through $(5, -1)$ and is parallel to the line $2x + 5y = 15$
 15. Passes through $(4, 10)$ and is perpendicular to the line $6x - 3y = 5$

In Exercises 16 and 17, find the line's x - and y -intercepts and use this information to graph the line.

16. $3x + 4y = 12$ 17. $\sqrt{2}x - \sqrt{3}y = \sqrt{6}$

18. Is there anything special about the relationship between the lines $Ax + By = C_1$ and $Bx - Ay = C_2$ ($A \neq 0$, $B \neq 0$)? Give reasons for your answer.

19. A particle starts at $A(-2, 3)$ and its coordinates change by increments $\Delta x = 5$, $\Delta y = -6$. Find its new position.

20. The coordinates of a particle change by $\Delta x = 5$ and $\Delta y = 6$ as it moves from $A(x, y)$ to $B(3, -3)$. Find x and y .

Circles

In Exercises 21–23, find an equation for the circle with the given center $C(h, k)$ and radius a . Then sketch the circle in the xy -plane. Include the circle's center in your sketch. Also, label the circle's x - and y -intercepts, if any, with their coordinate pairs.

21. $C(0, 2)$, $a = 2$ 22. $C(-1, 5)$, $a = \sqrt{10}$
 23. $C(-\sqrt{3}, -2)$, $a = 2$

Graph the circles whose equations are given in Exercises 24–26. Label each circle's center and intercepts (if any) with their coordinate pairs.

24. $x^2 + y^2 + 4x - 4y + 4 = 0$
 25. $x^2 + y^2 - 3y - 4 = 0$ 26. $x^2 + y^2 - 4x + 4y = 0$

Parabolas

Graph the parabolas in Exercises 27–30. Label the vertex, axis, and intercepts in each case.

27. $y = x^2 - 2x - 3$ 28. $y = -x^2 + 4x$
 29. $y = -x^2 - 6x - 5$ 30. $y = \frac{1}{2}x^2 + x + 4$

Inequalities

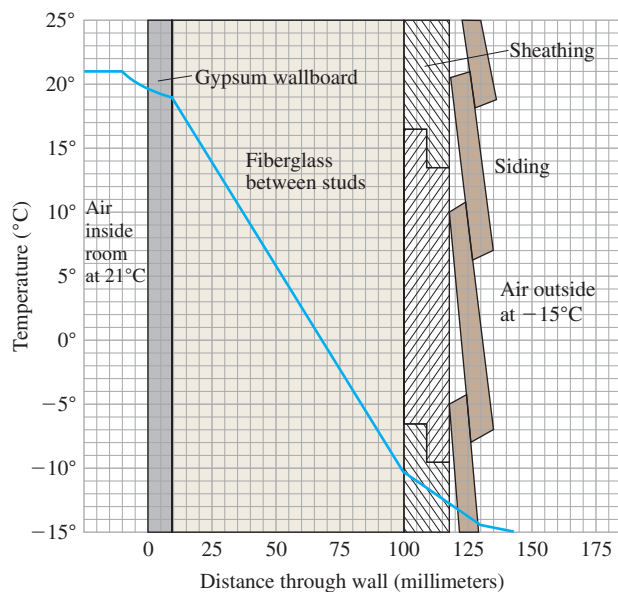

Describe the regions defined by the inequalities and pairs of inequalities in Exercises 31–34.

31. $x^2 + y^2 > 7$ 32. $(x - 1)^2 + y^2 \leq 4$
 33. $x^2 + y^2 > 1$, $x^2 + y^2 < 4$
 34. $x^2 + y^2 + 6y < 0$, $y > -3$
 35. Write an inequality that describes the points that lie inside the circle with center $(-2, 1)$ and radius $\sqrt{6}$.
 36. Write a pair of inequalities that describe the points that lie inside or on the circle with center $(0, 0)$ and radius $\sqrt{2}$, and on or to the right of the vertical line through $(1, 0)$.

Theory and Examples

In Exercises 37–40, graph the two equations and find the points at which the graphs intersect.

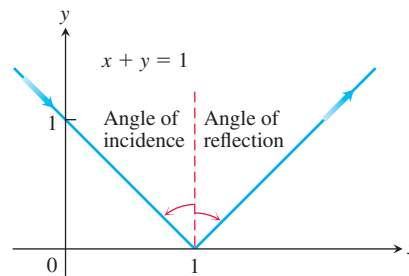

37. $y = 2x$, $x^2 + y^2 = 1$ 38. $y - x = 1$, $y = x^2$
 39. $y = -x^2$, $y = 2x^2 - 1$
 40. $x^2 + y^2 = 1$, $(x - 1)^2 + y^2 = 1$
 41. **Insulation** By measuring slopes in the figure, estimate the temperature change in degrees per centimeter for (a) the gypsum wallboard; (b) the fiberglass insulation; (c) the wood sheathing.

The temperature changes in the wall in Exercises 41 and 42.

42. **Insulation** According to the figure in Exercise 41, which of the materials is the best insulator? The poorest? Explain.
 43. **Pressure under water** The pressure p experienced by a diver under water is related to the diver's depth d by an equation of the form $p = kd + 1$ (k a constant). At the surface, the pressure is 1 atmosphere. The pressure at 100 meters is about 10.94 atmospheres. Find the pressure at 50 meters.
 44. **Reflected light** A ray of light comes in along the line $x + y = 1$ from the second quadrant and reflects off the x -axis (see the accompanying figure). The angle of incidence is equal to the

angle of reflection. Write an equation for the line along which the departing light travels.

The path of the light ray in Exercise 44.

Angles of incidence and reflection are measured from the perpendicular.

45. **Fahrenheit vs. Celsius** In the FC -plane, sketch the graph of the equation

$$C = \frac{5}{9}(F - 32)$$

linking Fahrenheit and Celsius temperatures. On the same graph sketch the line $C = F$. Is there a temperature at which a Celsius thermometer gives the same numerical reading as a Fahrenheit thermometer? If so, find it.

46. **The Mt. Washington Cog Railway** Civil engineers calculate the slope of roadbed as the ratio of the distance it rises or falls to the distance it runs horizontally. They call this ratio the **grade** of the roadbed, usually written as a percentage. Along the coast, commercial railroad grades are usually less than 2%. In the mountains, they may go as high as 4%. Highway grades are usually less than 5%.

The steepest part of the Mt. Washington Cog Railway in New Hampshire has an exceptional 37.1% grade. Along this part of the track, the seats in the front of the car are 4 m above those in the rear. About how far apart are the front and rear rows of seats?

47. By calculating the lengths of its sides, show that the triangle with vertices at the points $A(1, 2)$, $B(5, 5)$, and $C(4, -2)$ is isosceles but not equilateral.
 48. Show that the triangle with vertices $A(0, 0)$, $B(1, \sqrt{3})$, and $C(2, 0)$ is equilateral.
 49. Show that the points $A(2, -1)$, $B(1, 3)$, and $C(-3, 2)$ are vertices of a square, and find the fourth vertex.
 50. Three different parallelograms have vertices at $(-1, 1)$, $(2, 0)$, and $(2, 3)$. Sketch them and find the coordinates of the fourth vertex of each.
 51. For what value of k is the line $2x + ky = 3$ perpendicular to the line $4x + y = 1$? For what value of k are the lines parallel?
 52. **Midpoint of a line segment** Show that the point with coordinates

$$\left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2} \right)$$

is the midpoint of the line segment joining $P(x_1, y_1)$ to $Q(x_2, y_2)$.

A.5 Proofs of Limit Theorems

This appendix proves Theorem 1, Parts 2–5, and Theorem 4 from Section 2.2.

THEOREM 1—Limit Laws

If L , M , c , and k are real numbers and

$$\lim_{x \rightarrow c} f(x) = L \quad \text{and} \quad \lim_{x \rightarrow c} g(x) = M, \quad \text{then}$$

- | | |
|-----------------------------------|---|
| 1. <i>Sum Rule:</i> | $\lim_{x \rightarrow c} (f(x) + g(x)) = L + M$ |
| 2. <i>Difference Rule:</i> | $\lim_{x \rightarrow c} (f(x) - g(x)) = L - M$ |
| 3. <i>Constant Multiple Rule:</i> | $\lim_{x \rightarrow c} (kf(x)) = kL$ |
| 4. <i>Product Rule:</i> | $\lim_{x \rightarrow c} (f(x)g(x)) = LM$ |
| 5. <i>Quotient Rule:</i> | $\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \frac{L}{M}, \quad M \neq 0$ |
| 6. <i>Power Rule:</i> | $\lim_{x \rightarrow c} [f(x)]^n = L^n, n \text{ a positive integer}$ |
| 7. <i>Root Rule:</i> | $\lim_{x \rightarrow c} \sqrt[n]{f(x)} = \sqrt[n]{L} = L^{1/n}, n \text{ a positive integer}$ |
- (If n is even, we assume that $\lim_{x \rightarrow c} f(x) = L > 0$.)

We proved the Sum Rule in Section 2.3, and the Power and Root Rules are proved in more advanced texts. We obtain the Difference Rule by replacing $g(x)$ by $-g(x)$ and M by $-M$ in the Sum Rule. The Constant Multiple Rule is the special case $g(x) = k$ of the Product Rule. This leaves only the Product and Quotient Rules.

Proof of the Limit Product Rule We show that for any $\varepsilon > 0$ there exists a $\delta > 0$ such that for all x in the intersection D of the domains of f and g ,

$$|f(x)g(x) - LM| < \varepsilon \quad \text{whenever} \quad 0 < |x - c| < \delta.$$

Suppose then that ε is a positive number, and write $f(x)$ and $g(x)$ as

$$f(x) = L + (f(x) - L), \quad g(x) = M + (g(x) - M).$$

Multiply these expressions together and subtract LM :

$$\begin{aligned} f(x)g(x) - LM &= (L + (f(x) - L))(M + (g(x) - M)) - LM \\ &= LM + L(g(x) - M) + M(f(x) - L) \\ &\quad + (f(x) - L)(g(x) - M) - LM \\ &= L(g(x) - M) + M(f(x) - L) + (f(x) - L)(g(x) - M). \end{aligned} \quad (1)$$

Since f and g have limits L and M as $x \rightarrow c$, there exist positive numbers δ_1 , δ_2 , δ_3 , and δ_4 such that

$$\begin{aligned} |f(x) - L| &< \sqrt{\varepsilon/3} && \text{whenever} && 0 < |x - c| < \delta_1 \\ |g(x) - M| &< \sqrt{\varepsilon/3} && \text{whenever} && 0 < |x - c| < \delta_2 \\ |f(x) - L| &< \varepsilon/(3(1 + |M|)) && \text{whenever} && 0 < |x - c| < \delta_3 \\ |g(x) - M| &< \varepsilon/(3(1 + |L|)) && \text{whenever} && 0 < |x - c| < \delta_4. \end{aligned} \quad (2)$$

If we take δ to be the smallest of the numbers δ_1 through δ_4 , the inequalities on the right-hand side of the Implications (2) will hold simultaneously for $0 < |x - c| < \delta$. Therefore, for all x in D , if $0 < |x - c| < \delta$ then

$$\begin{aligned} & |f(x)g(x) - LM| && \text{Triangle inequality applied to Eq. (1)} \\ & \leq |L||g(x) - M| + |M||f(x) - L| + |f(x) - L||g(x) - M| \\ & \leq (1 + |L|)|g(x) - M| + (1 + |M|)|f(x) - L| + |f(x) - L||g(x) - M| \\ & < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \sqrt{\frac{\varepsilon}{3}}\sqrt{\frac{\varepsilon}{3}} = \varepsilon. && \text{Values from (2)} \end{aligned}$$

This completes the proof of the Limit Product Rule. ■

Proof of the Limit Quotient Rule We show that $\lim_{x \rightarrow c} (1/g(x)) = 1/M$. We can then conclude that

$$\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \lim_{x \rightarrow c} \left(f(x) \cdot \frac{1}{g(x)} \right) = \lim_{x \rightarrow c} f(x) \cdot \lim_{x \rightarrow c} \frac{1}{g(x)} = L \cdot \frac{1}{M} = \frac{L}{M}$$

by the Limit Product Rule.

Let $\varepsilon > 0$ be given. To show that $\lim_{x \rightarrow c} (1/g(x)) = 1/M$, we need to show that there exists a $\delta > 0$ such that

$$\left| \frac{1}{g(x)} - \frac{1}{M} \right| < \varepsilon \quad \text{whenever} \quad 0 < |x - c| < \delta.$$

Since g has the limit M as $x \rightarrow c$ and since $|M| > 0$, there exists a positive number δ_1 such that

$$|g(x) - M| < \frac{M}{2} \quad \text{whenever} \quad 0 < |x - c| < \delta_1. \quad (3)$$

For any numbers A and B , the triangle inequality implies that $|A| - |B| \leq |A - B|$ and $|B| - |A| \leq |A - B|$, from which it follows that $||A| - |B|| \leq |A - B|$. With $A = g(x)$ and $B = M$, this becomes

$$||g(x)| - |M|| \leq |g(x) - M|,$$

which can be combined with the inequality on the right in Implication (3) to get, in turn,

$$\begin{aligned} & ||g(x)| - |M|| < \frac{|M|}{2} \\ & -\frac{|M|}{2} < |g(x)| - |M| < \frac{|M|}{2} \\ & \frac{|M|}{2} < |g(x)| < \frac{3|M|}{2} \\ & |M| < 2|g(x)| < 3|M| \\ & \frac{1}{|g(x)|} < \frac{2}{|M|} < \frac{3}{|g(x)|}. \end{aligned} \quad (4)$$

Therefore, $0 < |x - c| < \delta_1$ implies that

$$\begin{aligned} \left| \frac{1}{g(x)} - \frac{1}{M} \right| &= \left| \frac{M - g(x)}{Mg(x)} \right| \leq \frac{1}{|M|} \cdot \frac{1}{|g(x)|} \cdot |M - g(x)| \\ &< \frac{1}{|M|} \cdot \frac{2}{|M|} \cdot |M - g(x)|. && \text{Inequality (4)} \end{aligned} \quad (5)$$

Since $(1/2)|M|^2\varepsilon > 0$, there exists a number $\delta_2 > 0$ such that

$$|M - g(x)| < \frac{\varepsilon}{2}|M|^2 \quad \text{whenever} \quad 0 < |x - c| < \delta_2. \quad (6)$$

If we take δ to be the smaller of δ_1 and δ_2 , the conclusions in (5) and (6) both hold whenever $0 < |x - c| < \delta$. Combining these conclusions gives

$$\left| \frac{1}{g(x)} - \frac{1}{M} \right| < \varepsilon \quad \text{whenever} \quad 0 < |x - c| < \delta.$$

This concludes the proof of the Limit Quotient Rule. ■

THEOREM 4—The Sandwich Theorem

Suppose that $g(x) \leq f(x) \leq h(x)$ for all x in some open interval I containing c , except possibly at $x = c$ itself. Suppose also that $\lim_{x \rightarrow c} g(x) = \lim_{x \rightarrow c} h(x) = L$. Then $\lim_{x \rightarrow c} f(x) = L$.

Proof for Right-Hand Limits Suppose $\lim_{x \rightarrow c^+} g(x) = \lim_{x \rightarrow c^+} h(x) = L$. Then for any $\varepsilon > 0$ there exists a $\delta > 0$ such that the interval $(c, c + \delta)$ is contained in I , and

$$L - \varepsilon < g(x) < L + \varepsilon \quad \text{and} \quad L - \varepsilon < h(x) < L + \varepsilon$$

whenever $c < x < c + \delta$. Since we always have $g(x) \leq f(x) \leq h(x)$ it follows that if $c < x < c + \delta$, then

$$\begin{aligned} L - \varepsilon < g(x) &\leq f(x) \leq h(x) < L + \varepsilon, \\ L - \varepsilon < f(x) &< L + \varepsilon, \\ -\varepsilon < f(x) - L &< \varepsilon. \end{aligned}$$

Therefore, $|f(x) - L| < \varepsilon$ whenever $c < x < c + \delta$.

Proof for Left-Hand Limits Suppose $\lim_{x \rightarrow c^-} g(x) = \lim_{x \rightarrow c^-} h(x) = L$. Then for any $\varepsilon > 0$ there exists a $\delta > 0$ such that the interval $(c - \delta, c)$ is contained in I , and

$$L - \varepsilon < g(x) < L + \varepsilon \quad \text{and} \quad L - \varepsilon < h(x) < L + \varepsilon$$

whenever $c - \delta < x < c$. We conclude as before that $|f(x) - L| < \varepsilon$ whenever $c - \delta < x < c$.

Proof for Two-Sided Limits If $\lim_{x \rightarrow c} g(x) = \lim_{x \rightarrow c} h(x) = L$, then $g(x)$ and $h(x)$ both approach L as $x \rightarrow c^+$ and as $x \rightarrow c^-$; so $\lim_{x \rightarrow c^+} f(x) = L$ and $\lim_{x \rightarrow c^-} f(x) = L$. Hence $\lim_{x \rightarrow c} f(x)$ exists and equals L . ■

EXERCISES A.5

- Suppose that functions $f_1(x)$, $f_2(x)$, and $f_3(x)$ have limits L_1 , L_2 , and L_3 , respectively, as $x \rightarrow c$. Show that their sum has limit $L_1 + L_2 + L_3$. Use mathematical induction (Appendix A.3) to generalize this result to the sum of any finite number of functions.
- Use mathematical induction and the Limit Product Rule in Theorem 1 to show that if functions $f_1(x)$, $f_2(x)$, \dots , $f_n(x)$ have limits L_1 , L_2 , \dots , L_n as $x \rightarrow c$, then

$$\lim_{x \rightarrow c} f_1(x) \cdot f_2(x) \cdot \dots \cdot f_n(x) = L_1 \cdot L_2 \cdot \dots \cdot L_n.$$

3. Use the fact that $\lim_{x \rightarrow c} x = c$ and the result of Exercise 2 to show that $\lim_{x \rightarrow c} x^n = c^n$ for any integer $n > 1$.

4. **Limits of polynomials** Use the fact that $\lim_{x \rightarrow c} k = k$ for any number k , together with the results of Exercises 1 and 3, to show that $\lim_{x \rightarrow c} f(x) = f(c)$ for any polynomial function

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0.$$

5. **Limits of rational functions** Use Theorem 1 and the result of Exercise 4 to show that if $f(x)$ and $g(x)$ are polynomial functions and $g(c) \neq 0$, then

$$\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \frac{f(c)}{g(c)}.$$

6. **Composites of continuous functions** Figure A.28 gives the diagram for a proof that the composite of two continuous functions is continuous. Reconstruct the proof from the diagram. The statement to be proved is this: If f is continuous at $x = c$ and g is continuous at $f(c)$, then $g \circ f$ is continuous at c .

Assume that c is an interior point of the domain of f and that $f(c)$ is an interior point of the domain of g . This will make the limits involved two-sided. (The arguments for the cases that involve one-sided limits are similar.)

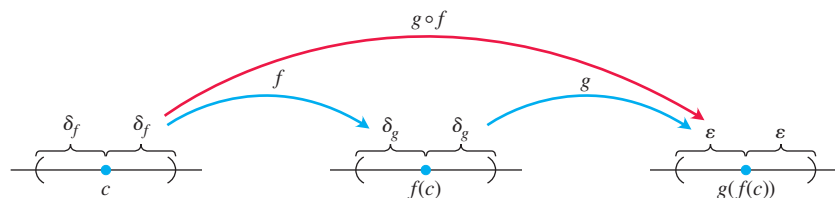

FIGURE A.28 The diagram for a proof that the composite of two continuous functions is continuous.

A.6 Commonly Occurring Limits

This appendix verifies limits (4)–(6) in Theorem 5 of Section 9.1.

Limit 4: If $|x| < 1$, $\lim_{n \rightarrow \infty} x^n = 0$ We need to show that to each $\varepsilon > 0$ there corresponds an integer N so large that $|x^n| < \varepsilon$ for all n greater than N . Since $\varepsilon^{1/n} \rightarrow 1$, while $|x| < 1$, there exists an integer N for which $\varepsilon^{1/N} > |x|$. In other words,

$$|x^N| = |x|^N < \varepsilon. \quad (1)$$

This is the integer we seek because, if $|x| < 1$, then

$$|x^n| < |x^N| \quad \text{for all } n > N. \quad (2)$$

Combining (1) and (2) produces $|x^n| < \varepsilon$ for all $n > N$, concluding the proof. ■

Limit 5: For any number x , $\lim_{n \rightarrow \infty} \left(1 + \frac{x}{n}\right)^n = e^x$ Let

$$a_n = \left(1 + \frac{x}{n}\right)^n.$$

Then

$$\ln a_n = \ln \left(1 + \frac{x}{n}\right)^n = n \ln \left(1 + \frac{x}{n}\right) \rightarrow x,$$

as we can see by the following application of L'Hôpital's Rule, in which we differentiate with respect to n :

$$\begin{aligned} \lim_{n \rightarrow \infty} n \ln \left(1 + \frac{x}{n}\right) &= \lim_{n \rightarrow \infty} \frac{\ln(1 + x/n)}{1/n} \\ &= \lim_{n \rightarrow \infty} \frac{\left(\frac{1}{1 + x/n}\right) \cdot \left(-\frac{x}{n^2}\right)}{-1/n^2} = \lim_{n \rightarrow \infty} \frac{x}{1 + x/n} = x. \end{aligned}$$

Apply Theorem 3, Section 9.1, with $f(x) = e^x$ to conclude that

$$\left(1 + \frac{x}{n}\right)^n = a_n = e^{\ln a_n} \rightarrow e^x. \quad \blacksquare$$

Limit 6: For any number x , $\lim_{n \rightarrow \infty} \frac{x^n}{n!} = 0$ Since

$$-\frac{|x|^n}{n!} \leq \frac{x^n}{n!} \leq \frac{|x|^n}{n!},$$

all we need to show is that $|x|^n/n! \rightarrow 0$. We can then apply the Sandwich Theorem for Sequences (Section 9.1, Theorem 2) to conclude that $x^n/n! \rightarrow 0$.

The first step in showing that $|x|^n/n! \rightarrow 0$ is to choose an integer $M > |x|$, so that $(|x|/M) < 1$. By Limit 4, just proved, we then have $(|x|/M)^n \rightarrow 0$. We then restrict our attention to values of $n > M$. For these values of n , we can write

$$\begin{aligned} \frac{|x|^n}{n!} &= \frac{|x|^n}{1 \cdot 2 \cdot \cdots \cdot M \cdot \underbrace{(M+1) \cdot (M+2) \cdot \cdots \cdot n}_{(n-M) \text{ factors}}} \\ &\leq \frac{|x|^n}{M! M^{n-M}} = \frac{|x|^n M^M}{M! M^n} = \frac{M^M}{M!} \left(\frac{|x|}{M}\right)^n. \end{aligned}$$

Thus,

$$0 \leq \frac{|x|^n}{n!} \leq \frac{M^M}{M!} \left(\frac{|x|}{M}\right)^n.$$

Now, the constant $M^M/M!$ does not change as n increases. Thus the Sandwich Theorem tells us that $|x|^n/n! \rightarrow 0$ because $(|x|/M)^n \rightarrow 0$. \blacksquare

A.7 Theory of the Real Numbers

A rigorous development of calculus is based on properties of the real numbers. Many results about functions, derivatives, and integrals would be false if stated for functions defined only on the rational numbers. In this appendix we briefly examine some basic concepts of the theory of the reals that hint at what might be learned in a deeper, more theoretical study of calculus.

Three types of properties make the real numbers what they are. These are the **algebraic**, **order**, and **completeness** properties. The algebraic properties involve addition and multiplication, subtraction and division. They apply to rational or complex numbers (discussed in Chapter 18) as well as to the reals.

The structure of numbers is built around a set with addition and multiplication operations. The following properties are required of addition and multiplication.

- A1** $a + (b + c) = (a + b) + c$ for all a, b, c .
- A2** $a + b = b + a$ for all a, b .
- A3** There is a number called "0" such that $a + 0 = a$ for all a .
- A4** For each number a , there is a number b such that $a + b = 0$.
- M1** $a(bc) = (ab)c$ for all a, b, c .
- M2** $ab = ba$ for all a, b .
- M3** There is a number called "1" such that $a \cdot 1 = a$ for all a .
- M4** For each nonzero number a , there is a number b such that $ab = 1$.
- D** $a(b + c) = ab + ac$ for all a, b, c .

A1 and M1 are *associative laws*, A2 and M2 are *commutativity laws*, A3 and M3 are *identity laws*, and D is the *distributive law*. Sets that have these algebraic properties are examples of **fields**; they are studied in depth in the area of theoretical mathematics called abstract algebra.

The **order** properties enable us to compare the sizes of any two numbers. The order properties are

- O1** For any a and b , either $a \leq b$ or $b \leq a$ or both.
- O2** If $a \leq b$ and $b \leq a$ then $a = b$.
- O3** If $a \leq b$ and $b \leq c$ then $a \leq c$.
- O4** If $a \leq b$ then $a + c \leq b + c$.
- O5** If $a \leq b$ and $0 \leq c$ then $ac \leq bc$.

O3 is the *transitivity law*, and O4 and O5 relate ordering to addition and multiplication.

We can order the reals, the integers, and the rational numbers, but we cannot order the complex numbers (there is no reasonable way to decide whether a number like $i = \sqrt{-1}$ is bigger or smaller than zero). A field in which the size of any two elements can be compared as above is called an **ordered field**. Both the rational numbers and the real numbers are ordered fields, and there are many others.

We can think of real numbers geometrically, lining them up as points on a line. The **completeness property** says that the real numbers correspond to all points on the line, with no “holes” or “gaps.” The rationals, in contrast, omit points such as $\sqrt{2}$ and π , and the integers even leave out fractions like $1/2$. The reals, having the completeness property, omit no points.

What exactly do we mean by this vague idea of missing holes? To answer this we must give a more precise description of completeness. A number M is an **upper bound** for a set of numbers if all numbers in the set are smaller than or equal to M . M is a **least upper bound** if it is the smallest upper bound. For example, $M = 2$ is an upper bound for the negative numbers. So is $M = 1$, showing that 2 is not a least upper bound. The least upper bound for the set of negative numbers is $M = 0$. We define a **complete** ordered field to be one in which every nonempty set bounded above has a least upper bound.

If we work with just the rational numbers, the set of numbers less than $\sqrt{2}$ is bounded, but it does not have a rational least upper bound, since any rational upper bound M must be larger than $\sqrt{2}$ and can be replaced by a slightly smaller rational number that is still larger than $\sqrt{2}$. So the rationals are not complete. In the real numbers, a set that is bounded above always has a least upper bound. The reals are a complete ordered field.

The completeness property is at the heart of many results in calculus. One example occurs when we search for a maximum value for a function on a closed interval $[a, b]$, as in Section 4.1. The function $y = x - x^3$ has a maximum value on $[0, 1]$ at the point x satisfying $1 - 3x^2 = 0$, or $x = \sqrt{1/3}$. If we limited our consideration to functions defined only on rational numbers, we would have to conclude that the function has no maximum, since $\sqrt{1/3}$ is irrational (Figure A.29). The Extreme Value Theorem (Section 4.1), which implies that continuous functions on closed intervals $[a, b]$ have a maximum value, is not true for functions defined only on the rationals.

The Intermediate Value Theorem implies that a continuous function f on an interval $[a, b]$ with $f(a) < 0$ and $f(b) > 0$ must be zero somewhere in $[a, b]$. The function values cannot jump from negative to positive without there being some point x in $[a, b]$ where $f(x) = 0$. The Intermediate Value Theorem also relies on the completeness of the real numbers and is false for continuous functions defined only on the rationals. The function $f(x) = 3x^2 - 1$ has $f(0) = -1$ and $f(1) = 2$, but if we consider f only on the rational numbers, it never equals zero. The only value of x for which $f(x) = 0$ is $x = \sqrt{1/3}$, an irrational number.

We have captured the desired properties of the reals by saying that the real numbers are a complete ordered field. But we’re not quite finished. Greek mathematicians in the

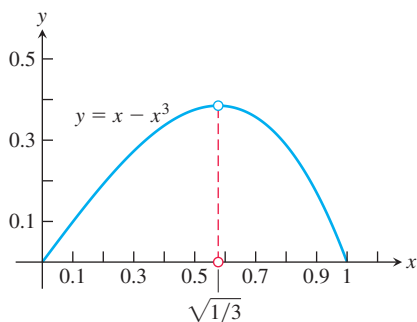

FIGURE A.29 The maximum value of $y = x - x^3$ on $[0, 1]$ occurs at the irrational number $x = \sqrt{1/3}$.

school of Pythagoras tried to impose another property on the numbers of the real line, the condition that all numbers are ratios of integers. They learned that their effort was doomed when they discovered irrational numbers such as $\sqrt{2}$. How do we know that our efforts to specify the real numbers are not also flawed, for some unseen reason? The artist Escher drew optical illusions of spiral staircases that went up and up until they rejoined themselves at the bottom. An engineer trying to build such a staircase would find that no structure realized the plans the architect had drawn. Could it be that our design for the reals contains some subtle contradiction, and that no construction of such a number system can be made?

We resolve this issue by giving a specific description of the real numbers and verifying that the algebraic, order, and completeness properties are satisfied in this model. This is called a **construction** of the reals, and just as stairs can be built with wood, stone, or steel, there are several approaches to constructing the reals. One construction treats the reals as all the infinite decimals,

$$a.d_1d_2d_3d_4 \dots$$

In this approach a real number is an integer a followed by a sequence of decimal digits d_1, d_2, d_3, \dots , each between 0 and 9. This sequence may stop, or repeat in a periodic pattern, or keep going forever with no pattern. In this form, 2.00, 0.3333333 ... and 3.1415926535898 ... represent three familiar real numbers. The real meaning of the dots “...” following these digits requires development of the theory of sequences and series, as in Chapter 9. Each real number is constructed as the limit of a sequence of rational numbers given by its finite decimal approximations. An infinite decimal is then the same as a series

$$a + \frac{d_1}{10} + \frac{d_2}{100} + \dots$$

This decimal construction of the real numbers is not entirely straightforward. It's easy enough to check that it gives numbers that satisfy the completeness and order properties, but verifying the algebraic properties is rather involved. Even adding or multiplying two numbers requires an infinite number of operations. Making sense of division requires a careful argument involving limits of rational approximations to infinite decimals.

A different approach was taken by Richard Dedekind (1831–1916), a German mathematician, who gave the first rigorous construction of the real numbers in 1872. Given any real number x , we can divide the rational numbers into two sets: those less than or equal to x and those greater. Dedekind cleverly reversed this reasoning and defined a real number to be a division of the rational numbers into two such sets. This seems like a strange approach, but such indirect methods of constructing new structures from old are powerful tools in theoretical mathematics.

These and other approaches can be used to construct a system of numbers having the desired algebraic, order, and completeness properties. A final issue that arises is whether all the constructions give the same thing. Is it possible that different constructions result in different number systems satisfying all the required properties? If yes, which of these comprises the real numbers? Fortunately, the answer turns out to be no. The reals are the only number system satisfying the algebraic, order, and completeness properties.

Confusion about the nature of the numbers and about limits caused considerable controversy in the early development of calculus. Calculus pioneers such as Newton, Leibniz, and their successors, when looking at what happens to the difference quotient

$$\frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

as each of Δy and Δx approach zero, talked about the resulting derivative being a quotient of two infinitely small quantities. These “infinitesimals,” written dx and dy , were thought to be some new kind of number, smaller than any fixed number but not zero. Similarly, a definite integral was thought of as a sum of an infinite number of infinitesimals

$$f(x) \cdot dx$$

as x varied over a closed interval. The approximating difference quotients $\Delta y/\Delta x$ were understood much as today, but it was the quotient of infinitesimal quantities, rather than a limit, that was thought to encapsulate the meaning of the derivative. This way of thinking led to logical difficulties, as attempted definitions and manipulations of infinitesimals ran into contradictions and inconsistencies. The more concrete and computable difference quotients did not cause such trouble, but they were thought of merely as useful calculation tools. Difference quotients were used to work out the numerical value of the derivative and to derive general formulas for calculation, but they were not considered to be at the heart of what the derivative actually was. Today we realize that the logical problems associated with infinitesimals can be avoided by *defining* the derivative to be the limit of its approximating difference quotients. The ambiguities of the old approach are no longer present, and in the standard theory of calculus, infinitesimals are neither needed nor used.

A.8 Probability

The outcome of some events, such as a heavy rock falling from a great height, can be modeled so that we can predict with high accuracy what will happen. On the other hand, many events have more than one possible outcome and which one of them will occur is uncertain. If we toss a coin, a head or a tail will result with each outcome being equally likely, but we do not know in advance which one it will be. If we randomly select and then weigh a person from a large population, there are many possible weights the person might have, and it is not certain whether the weight will be between 80 and 85 kg. We are told it is highly likely, but not known for sure, that an earthquake of magnitude 6.0 or greater on the Richter scale will occur near a major population area in California within the next one hundred years. Events having more than one possible outcome are *probabilistic* in nature, and when modeling them we assign a *probability* to the likelihood that a particular outcome may occur. In this section we show how calculus plays a central role in making predictions with probabilistic models.

Random Variables

We begin our discussion with some familiar examples of uncertain events for which the collection of all possible outcomes is finite.

EXAMPLE 1

- (a) If we toss a coin once, there are two possible outcomes $\{H, T\}$, where H represents the coin landing head face up and T a tail landing face up. If we toss a coin three times, there are eight possible outcomes, taking into account the order in which a head or tail occurs. The set of outcomes is $\{HHH, HHT, HTH, THH, HTT, THT, TTH, TTT\}$.
- (b) If we roll a six-sided die once, the set of possible outcomes is $\{1, 2, 3, 4, 5, 6\}$ representing the six faces of the die.
- (c) If we select at random two cards from a 52-card deck, there are 52 possible outcomes for the first card drawn and then 51 possibilities for the second card. Since the order of the cards does not matter, there are $(52 \cdot 51)/2 = 1,326$ possible outcomes altogether. ■

It is customary to refer to the set of all possible outcomes as the *sample space* for an event. With an uncertain event we are usually interested in which outcomes, if any, are more likely to occur than others, and to how large an extent. In tossing a coin three times, is it more likely that two heads or that one head will result? To answer such questions, we need a way to quantify the outcomes.

DEFINITION A **random variable** is a function X that assigns a numerical value to each outcome in a sample space.

Random variables that have only finitely many values are called **discrete** random variables. A **continuous random variable** can take on values in an entire interval, and it is associated with a *distribution function*, which we explain later.

EXAMPLE 2

- (a) Suppose we toss a coin three times giving the possible outcomes $\{HHH, HHT, HTH, THH, HTT, THT, TTH, TTT\}$. Define the random variable X to be the number of heads that appear. So $X(HHT) = 2$, $X(THT) = 1$, and so forth. Since X can only assume the values 0, 1, 2, or 3, it is a discrete random variable.
- (b) We spin an arrow anchored by a pin located at the origin. The arrow can wind up pointing in any possible direction, and we define the random variable X as the radian angle the arrow makes with the positive x -axis, measured counterclockwise. In this case, X is a continuous random variable that can take on any value in the interval $[0, 2\pi)$.
- (c) The weight of a randomly selected person in a given population is a continuous random variable W . The cholesterol level of a randomly chosen person, and the waiting time for service of a person in a queue at a bank, are also continuous random variables.
- (d) The scores on the national ACT Examination for college admissions in a particular year are described by a discrete random variable S taking on integer values between 1 and 36. If the number of outcomes is large, or for reasons involving statistical analysis, discrete random variables such as test scores are often modeled as continuous random variables (Example 13).
- (e) We roll a pair of dice and define the random variable X to be the sum of the numbers on the top faces. This sum can only assume the integer values from 2 through 12, so X is a discrete random variable.
- (f) A tire company produces tires for mid-sized sedans. The tires are guaranteed to last for 50,000 kilometers, but some will fail sooner, and some will last many more kilometers beyond 50,000 kilometers. The lifetime in kilometers of a tire is described by a continuous random variable L . ■

Probability Distributions

A *probability distribution* describes the probabilistic behavior of a random variable. Our chief interest is in probability distributions associated with continuous random variables, but to gain some perspective we first consider a distribution for a discrete random variable.

Suppose we toss a coin three times, with each side H or T equally likely to occur on a given toss. We define the discrete random variable X that assigns the number of heads appearing in each outcome, giving the following.

	{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT}							
X	↓	↓	↓	↓	↓	↓	↓	↓
	3	2	2	1	2	1	1	0

Next we count the *frequency* or number of times a specific value of X occurs. Because each of the eight outcomes is equally likely to occur, we can calculate the probability of the random variable X by dividing the frequency of each value by the total number of outcomes. We summarize our results as follows:

Value of X	0	1	2	3
Frequency	1	3	3	1
$P(X)$	1/8	3/8	3/8	1/8

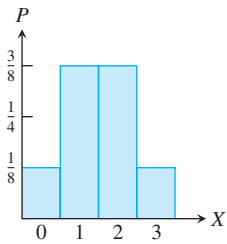

FIGURE A.30 Probability bar graph for the random variable X when tossing a fair coin three times.

We display this information in a probability bar graph of the discrete random variable X , as shown in Figure A.30. The values of X are portrayed by intervals of length 1 on the x -axis so the area of each bar in the graph is the probability of the corresponding outcome. For instance, the probability that exactly two heads occurs in the three tosses of the coin is the area of the bar associated with the value $X = 2$, which is $3/8$. Similarly, the probability that two or more heads occurs is the sum of areas of the bars associated with the values $X = 2$ and $X = 3$, or $4/8$. The probability that either zero or three heads occurs is $\frac{1}{8} + \frac{1}{8} = \frac{1}{4}$, and so forth. Note that the total area of all the bars in the graph is 1, which is the sum of all the probabilities for X .

With a continuous random variable, even when the outcomes are equally likely, we cannot simply count the number of outcomes in the sample space or the frequencies of outcomes that lead to a specific value of X . In fact, the probability that X takes on any particular one of its values is zero. What *is* meaningful to ask is how probable it is that the random variable takes on a value within some specified *interval* of values.

We capture the information we need about the probabilities of X in a function whose graph behaves much like the bar graph in Figure A.30. That is, we take a nonnegative function f defined over the range of the random variable with the property that the total area beneath the graph of f is 1. The probability that a value of the random variable X lies within some specified interval $[c, d]$ is then the area under the graph of f over that interval. The following definition assumes the range of the continuous random variable X is any real value, but the definition is general enough to account for random variables having a range of finite length.

DEFINITIONS A **probability density function** for a continuous random variable is a function f defined over $(-\infty, \infty)$ and having the following properties:

1. f is continuous, except possibly at a finite number of points.
2. f is nonnegative, so $f \geq 0$.
3. $\int_{-\infty}^{\infty} f(x) dx = 1$.

If X is a continuous random variable with probability density function f , the **probability** that X assumes a value in the interval between $X = c$ and $X = d$ is given by the integral

$$P(c \leq X \leq d) = \int_c^d f(x) dx.$$

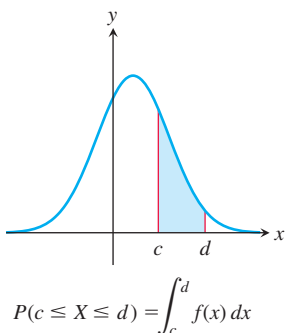

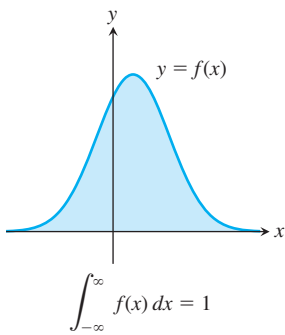

FIGURE A.31 A probability density function for the continuous random variable X .

The probability that a continuous random variable X assumes a particular real value c is $P(X = c) = \int_c^c f(x) dx = 0$, consistent with our previous assertion. Since the area under the graph of f over the interval $[c, d]$ is only a portion of the total area beneath the graph, the probability $P(c \leq X \leq d)$ is always a number between zero and one. Figure A.31 illustrates a probability density function.

A probability density function for a random variable X resembles the density function for a wire of varying density. To obtain the mass of a segment of the wire, we integrate the density of the wire over an interval. To obtain the probability that a random variable has values in a particular interval, we integrate the probability density function over that interval.

EXAMPLE 3 Let $f(x) = 2e^{-2x}$ if $0 \leq x < \infty$ and $f(x) = 0$ for all negative values of x .

- (a) Verify that f is a probability density function.
- (b) The time T in hours until a car passes a spot on a remote road is described by the probability density function f . Find the probability $P(T \leq 1)$ that a hitchhiker at that spot will see a car within one hour.
- (c) Find the probability $P(T = 1)$ that a car passes by the spot after precisely one hour.

Solution

(a) The function f is continuous except at $x = 0$, and is everywhere nonnegative. Moreover,

$$\int_{-\infty}^{\infty} f(x) dx = \int_0^{\infty} 2e^{-2x} dx = \lim_{b \rightarrow \infty} \int_0^b 2e^{-2x} dx = \lim_{b \rightarrow \infty} (1 - e^{-2b}) = 1.$$

So all of the conditions are satisfied and we have shown that f is a probability density function.

(b) The probability that a car comes after a time lapse between zero and one hour is given by integrating the probability density function over the interval $[0, 1]$. So

$$P(T \leq 1) = \int_0^1 2e^{-2t} dt = -e^{-2t} \Big|_0^1 = 1 - e^{-2} \approx 0.865.$$

This result can be interpreted to mean that if 100 people were to hitchhike at that spot, about 87 of them can expect to see a car within one hour.

(c) This probability is the integral $\int_1^1 f(t) dt$, which equals zero. We interpret this to mean that a sufficiently accurate measurement of the time until a car comes by the spot would have no possibility of being precisely equal to one hour. It might be very close, perhaps, but it would not be exactly one hour. ■

We can extend the definition to finite intervals. If f is a nonnegative function with at most finitely many discontinuities over the interval $[a, b]$, and its extension F to $(-\infty, \infty)$, obtained by defining F to be 0 outside of $[a, b]$, satisfies the definition for a probability density function, then f is a **probability density function for $[a, b]$** . This means that $\int_a^b f(x) dx = 1$. Similar definitions can be made for the intervals (a, b) , $(a, b]$, and $[a, b)$.

EXAMPLE 4 Show that $f(x) = \frac{4}{27}x^2(3 - x)$ is a probability density function over the interval $[0, 3]$.

Solution The function f is continuous and nonnegative over $[0, 3]$. Also,

$$\int_0^3 \frac{4}{27}x^2(3 - x) dx = \frac{4}{27} \left[x^3 - \frac{1}{4}x^4 \right]_0^3 = \frac{4}{27} \left(27 - \frac{81}{4} \right) = 1.$$

We conclude that f is a probability density function over $[0, 3]$. ■

Exponentially Decreasing Distributions

The distribution in Example 3 is called an *exponentially decreasing probability density function*. These probability density functions always take on the form

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ ce^{-cx} & \text{if } x \geq 0 \end{cases}$$

(see Exercise 23). Exponential density functions can provide models for describing random variables such as the lifetimes of light bulbs, radioactive particles, tooth crowns, and many kinds of electronic components. They also model the amount of time until some specific event occurs, such as the time until a pollinator arrives at a flower, the arrival times of a bus at a stop, the time between individuals joining a queue, the waiting time between phone calls at a help desk, and even the lengths of the phone calls themselves. A graph of an exponential density function is shown in Figure A.32.

Random variables with exponential distributions are *memoryless*. If we think of X as describing the lifetime of some object, then the probability that the object survives for at least $s + t$ hours, given that it has survived t hours, is the same as the initial probability that it survives for at least s hours. For instance, the current age t of a radioactive particle does not change the probability that it will survive for at least another time period of length s . Sometimes the exponential distribution is used as a model when the memoryless

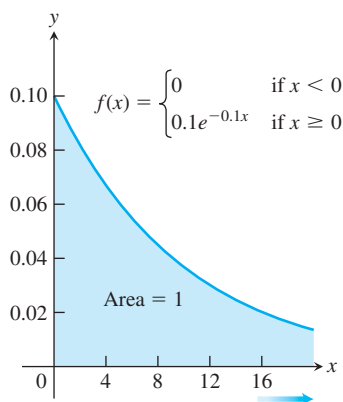

FIGURE A.32 An exponentially decreasing probability density function.

principle is violated because it provides reasonable approximations that are good enough for their intended use. For instance, this might be the case when predicting the lifetime of an artificial hip replacement or heart valve for a particular patient. Here is an application illustrating the exponential distribution.

EXAMPLE 5 An electronics company models the lifetime T in years of a chip they manufacture with the exponential density function

$$f(t) = \begin{cases} 0 & \text{if } t < 0 \\ 0.1e^{-0.1t} & \text{if } t \geq 0. \end{cases}$$

Using this model,

- (a) Find the probability $P(T > 2)$ that a chip will last for more than two years.
- (b) Find the probability $P(4 \leq T \leq 5)$ that a chip will fail in the fifth year.
- (c) If 1000 chips are shipped to a customer, how many can be expected to fail within three years?

Solution

- (a) The probability that a chip lasts at least two years is

$$\begin{aligned} P(T > 2) &= \int_2^{\infty} 0.1e^{-0.1t} dt = \lim_{b \rightarrow \infty} \int_2^b 0.1e^{-0.1t} dt \\ &= \lim_{b \rightarrow \infty} [e^{-0.2} - e^{-0.1b}] = e^{-0.2} \approx 0.819. \end{aligned}$$

That is, about 82% of the chips last more than two years.

- (b) The probability is

$$P(4 \leq T \leq 5) = \int_4^5 0.1e^{-0.1t} dt = -e^{-0.1t} \Big|_4^5 = e^{-0.4} - e^{-0.5} \approx 0.064$$

which means that about 6% of the chips fail during the fifth year.

- (c) We want the probability

$$P(0 \leq T \leq 3) = \int_0^3 0.1e^{-0.1t} dt = -e^{-0.1t} \Big|_0^3 = 1 - e^{-0.3} \approx 0.259.$$

We can expect that about 259 of the 1000 chips will fail within three years. ■

Expected Values, Means, and Medians

Suppose the weight in lbs of a steer raised on a cattle ranch is described by a continuous random variable W with probability density function $f(w)$ and that the rancher can sell a steer of weight w for $g(w)$ dollars. How much can the rancher expect to earn for a randomly chosen steer on the ranch?

To answer this question, we consider a small interval $[w_i, w_{i+1}]$ of width Δw_i and note that the probability a steer has weight in this interval is

$$\int_{w_i}^{w_{i+1}} f(w) dw \approx f(w_i) \Delta w_i.$$

The earning on a steer in this interval is approximately $g(w_i)$. The Riemann sum

$$\sum g(w_i) f(w_i) \Delta w_i$$

then approximates the amount the rancher would receive for a steer. We assume that steers have a maximum weight, so f is zero outside some finite interval $[0, b]$. Then taking the limit of the Riemann sum as the width of each interval approaches zero gives the integral

$$\int_{-\infty}^{\infty} g(w) f(w) dw.$$

This integral estimates how much the rancher can expect to earn for a typical steer on the ranch and is the *expected value of the function* g .

The expected values of certain functions of a random variable X have particular importance in probability and statistics. One of the most important of these functions is the expected value of the function $g(x) = x$.

DEFINITION The **expected value** or **mean** of a continuous random variable X with probability density function f is the number

$$\mu = E(X) = \int_{-\infty}^{\infty} xf(x) dx.$$

The expected value $E(X)$ can be thought of as a weighted average of the random variable X , where each value of X is weighted by $f(X)$. The mean can also be interpreted as the long-run average value of the random variable X , and it is one measure of the centrality of the random variable X .

EXAMPLE 6 Find the mean of the random variable X with exponential probability density function

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ ce^{-cx} & \text{if } x \geq 0. \end{cases}$$

Solution From the definition we have

$$\begin{aligned} \mu &= \int_{-\infty}^{\infty} xf(x) dx = \int_0^{\infty} xce^{-cx} dx \\ &= \lim_{b \rightarrow \infty} \int_0^b xce^{-cx} dx = \lim_{b \rightarrow \infty} \left(-xe^{-cx} \Big|_0^b + \int_0^b e^{-cx} dx \right) \\ &= \lim_{b \rightarrow \infty} \left(-be^{-cb} - \frac{1}{c}e^{-cb} + \frac{1}{c} \right) = \frac{1}{c}. \end{aligned}$$

l'Hôpital's Rule on first term

Therefore, the mean is $\mu = 1/c$. ■

From the result in Example 6, knowing the mean or expected value μ of a random variable X having an exponential density function allows us to write its entire formula.

Exponential Density Function for a Random Variable X with Mean μ

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ \mu^{-1}e^{-x/\mu} & \text{if } x \geq 0 \end{cases}$$

EXAMPLE 7 Suppose the time T before a chip fails in Example 5 is modeled instead by the exponential density function with a mean of eight years. Find the probability that a chip will fail within five years.

Solution The exponential density function with mean $\mu = 8$ is

$$f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{8}e^{-t/8} & \text{if } t \geq 0 \end{cases}$$

Then the probability a chip will fail within five years is the definite integral

$$P(0 \leq T \leq 5) = \int_0^5 0.125e^{-0.125t} dt = -e^{-0.125t} \Big|_0^5 = 1 - e^{-0.625} \approx 0.465$$

so about 47% of the chips can be expected to fail within five years. ■

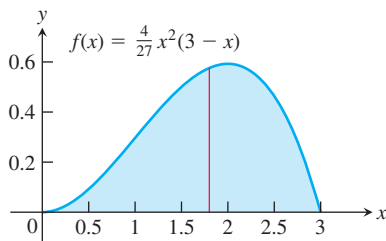

FIGURE A.33 The expected value of a random variable with this probability density function is $\mu = 1.8$ (Example 8).

EXAMPLE 8 Find the expected value for the random variable X with probability density function given by Example 4.

Solution The expected value is

$$\begin{aligned} \mu = E(X) &= \int_0^3 \frac{4}{27}x^3(3-x) dx = \frac{4}{27} \left[\frac{3}{4}x^4 - \frac{1}{5}x^5 \right]_0^3 \\ &= \frac{4}{27} \left(\frac{243}{4} - \frac{243}{5} \right) = 1.8 \end{aligned}$$

From Figure A.33, you can see that this expected value is reasonable because the region beneath the probability density function appears to be balanced about the vertical line $x = 1.8$. That is, the horizontal coordinate of the centroid of a plate described by the region is $\bar{x} = 1.8$. ■

There are other ways to measure the centrality of a random variable with a given probability density function.

DEFINITION The **median** of a continuous random variable X with probability density function f is the number m for which

$$\int_{-\infty}^m f(x) dx = \frac{1}{2} \quad \text{and} \quad \int_m^{\infty} f(x) dx = \frac{1}{2}.$$

The definition of the median means that there is an equal likelihood that the random variable X will be smaller than m or larger than m .

EXAMPLE 9 Find the median of a random variable X with exponential probability density function

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ ce^{-cx} & \text{if } x \geq 0. \end{cases}$$

Solution The median m must satisfy

$$\frac{1}{2} = \int_0^m ce^{-cx} dx = -e^{-cx} \Big|_0^m = 1 - e^{-cm}.$$

It follows that

$$e^{-cm} = \frac{1}{2} \quad \text{or} \quad m = \frac{1}{c} \ln 2.$$

Also,

$$\frac{1}{2} = \lim_{b \rightarrow \infty} \int_m^b ce^{-cx} dx = \lim_{b \rightarrow \infty} \left[-e^{-cx} \right]_m^b = \lim_{b \rightarrow \infty} (e^{-cm} - e^{-cb}) = e^{-cm}$$

giving the same value for m . Since $1/c$ is the mean μ of X with an exponential distribution, we conclude that the median is $m = \mu \ln 2$. The mean and median differ because the probability density function is skewed and spreads toward the right. ■

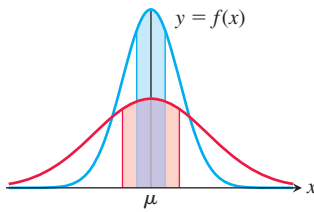

FIGURE A.34 Probability density functions with the same mean can have different spreads in relation to the mean. The blue and red regions under the curves have equal area.

Variance and Standard Deviation

Random variables with exactly the same mean μ but different distributions can behave very differently (see Figure A.34). The *variance* of a random variable X measures how spread out the values of X are in relation to the mean, and we measure this dispersion by the expected value of $(X - \mu)^2$. Since the variance measures the expected square of the difference from the mean, we often work instead with its square root.

DEFINITIONS The **variance** of a random variable X with probability density function f is the expected value of $(X - \mu)^2$:

$$\text{Var}(X) = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx$$

The **standard deviation** of X is

$$\sigma_X = \sqrt{\text{Var}(X)} = \sqrt{\int_{-\infty}^{\infty} (x - \mu)^2 f(x) dx}.$$

EXAMPLE 10 Find the standard deviation of the random variable T in Example 5, and find the probability that T lies within one standard deviation of the mean.

Solution The probability density function is the exponential density function with mean $\mu = 10$ by Example 6. To find the standard deviation we first calculate the variance integral:

$$\begin{aligned} \int_{-\infty}^{\infty} (t - \mu)^2 f(t) dt &= \int_0^{\infty} (t - 10)^2 (0.1e^{-0.1t}) dt \\ &= \lim_{b \rightarrow \infty} \int_0^b (t - 10)^2 (0.1e^{-0.1t}) dt \\ &= \lim_{b \rightarrow \infty} \left[(-t - 10)^2 - 20(t - 10) \right] e^{-0.1t} \Big|_0^b \\ &\quad + \lim_{b \rightarrow \infty} \int_0^b 20e^{-0.1t} dt \qquad \text{Integrating by parts} \\ &= [0 + (-10)^2 + 20(-10)] - 20 \lim_{b \rightarrow \infty} (10e^{-0.1t}) \Big|_0^b \\ &= -100 - 200 \lim_{b \rightarrow \infty} (e^{-0.1b} - 1) = 100. \end{aligned}$$

The standard deviation is the square root of the variance, so $\sigma = 10.0$.

To find the probability that T lies within one standard deviation of the mean, we find the probability $P(\mu - \sigma \leq T \leq \mu + \sigma)$. For this example, we have

$$P(10 - 10 \leq T \leq 10 + 10) = \int_0^{20} 0.1e^{-0.1t} dt = -e^{-0.1t} \Big|_0^{20} = 1 - e^{-2} \approx 0.865$$

This means that about 87% of the chips will fail within twenty years. ■

Uniform Distributions

The **uniform distribution** is very simple, but it occurs commonly in applications. The probability density function for this distribution on the interval $[a, b]$ is

$$f(x) = \frac{1}{b - a}, \quad a \leq x \leq b.$$

If each outcome in the sample space is equally likely to occur, then the random variable X has a uniform distribution. Since f is constant on $[a, b]$, a random variable with a uniform

distribution is just as likely to be in one subinterval of a fixed length as in any other of the same length. The probability that X assumes a value in a subinterval of $[a, b]$ is the length of that subinterval divided by $(b - a)$.

EXAMPLE 11 An anchored arrow is spun around the origin, and the random variable X is the radian angle the arrow makes with the positive x -axis, measured within the interval $[0, 2\pi)$. Assuming there is equal probability for the arrow pointing in any direction, find the probability density function and the probability that the arrow ends up pointing between North and East.

Solution We model the probability density function with the uniform distribution $f(x) = 1/2\pi$, $0 \leq x < 2\pi$, and $f(x) = 0$ elsewhere.

The probability that the arrow ends up pointing between North and East is given by

$$P\left(0 \leq X \leq \frac{\pi}{2}\right) = \int_0^{\pi/2} \frac{1}{2\pi} dx = \frac{1}{4}. \quad \blacksquare$$

Normal Distributions

Numerous applications use the **normal distribution**, which is defined by the probability density function

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2}.$$

It can be shown that the mean of a random variable X with this probability density function is μ and its standard deviation is σ . In applications the values of μ and σ are often estimated using large sets of data. The function is graphed in Figure A.35, and the graph is sometimes called a *bell curve* because of its shape. Since the curve is symmetric about the mean, the median for X is the same as its mean. It is often observed in practice that many random variables have approximately a normal distribution. Some examples illustrating this phenomenon are the height of a man, the annual rainfall in a certain region, an individual's blood pressure, the serum cholesterol level in the blood, the brain weights in a certain population of adults, and the amount of growth in a given period for a population of sunflower seeds.

The normal probability density function does not have an antiderivative expressible in terms of familiar functions. Once μ and σ are fixed, however, an integral involving the normal probability density function can be computed using numerical integration methods. Usually we use the numerical integration capability of a computer or calculator to estimate the values of these integrals. Such computations show that for any normal distribution, we get the following values for the probability that the random variable X lies within $k = 1, 2, 3,$ or 4 standard deviations of the mean:

$$P(\mu - \sigma < X < \mu + \sigma) \approx 0.68269$$

$$P(\mu - 2\sigma < X < \mu + 2\sigma) \approx 0.95450$$

$$P(\mu - 3\sigma < X < \mu + 3\sigma) \approx 0.99730$$

$$P(\mu - 4\sigma < X < \mu + 4\sigma) \approx 0.99994$$

This means, for instance, that the random variable X will take on a value within two standard deviations of the mean about 95% of the time. About 68% of the time, X will lie within one standard deviation of the mean (see Figure A.36).

EXAMPLE 12 An individual's blood pressure is an important indicator of overall health. A medical study of healthy individuals between 14 and 70 years of age modeled

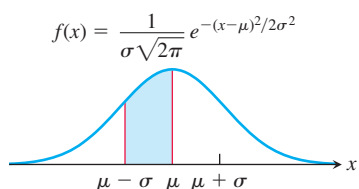

FIGURE A.35 The normal probability density function with mean μ and standard deviation σ .

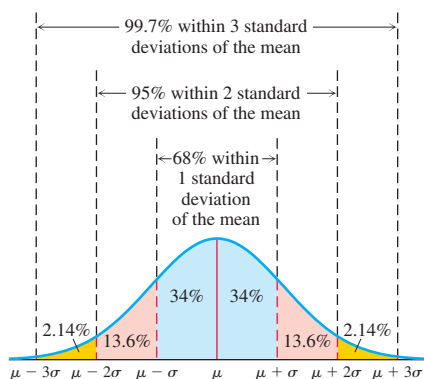

FIGURE A.36 Probabilities of the normal distribution within its standard deviation bands.

their systolic blood pressure using a normal distribution with mean 119.7 mm Hg and standard deviation 10.9 mm Hg.

- Using this model, what percentage of the population has a systolic blood pressure between 140 and 160 mm Hg, the levels set by the American Heart Association for Stage 1 hypertension?
- What percentage has a blood pressure between 160 and 180 mm Hg, the levels set by the American Heart Association for Stage 2 hypertension?
- What percentage has a blood pressure in the normal range of 90–120, as set by the American Heart Association?

Solution

- Since we cannot find an antiderivative, we use a computer to evaluate the probability integral of the normal probability density function with $\mu = 119.7$ and $\sigma = 10.9$:

$$P(140 \leq X \leq 160) = \int_{140}^{160} \frac{1}{10.9\sqrt{2\pi}} e^{-(x-119.7)^2/2(10.9)^2} dx \approx 0.03117.$$

This means that about 3% of the population in the studied age range have Stage 1 hypertension.

- Again we use a computer to calculate the probability that the blood pressure is between 160 and 180 mm Hg:

$$P(160 \leq X \leq 180) = \int_{160}^{180} \frac{1}{10.9\sqrt{2\pi}} e^{-(x-119.7)^2/2(10.9)^2} dx \approx 0.00011.$$

We conclude that about 0.011% of the population has Stage 2 hypertension.

- The probability that the blood pressure falls in the normal range is

$$P(90 \leq X \leq 120) = \int_{90}^{120} \frac{1}{10.9\sqrt{2\pi}} e^{-(x-119.7)^2/2(10.9)^2} dx \approx 0.50776.$$

That is, about 51% of the population has a normal systolic blood pressure. ■

Many national tests are standardized using the normal distribution. The following example illustrates modeling the discrete random variable for scores on a test using the normal distribution function for a continuous random variable.

EXAMPLE 13 The ACT is a standardized test taken by high school students seeking admission to many colleges and universities. The test measures knowledge, skills, and proficiency in the areas of English, math, and science, with scores ranging over the interval $[1, 36]$. Nearly 1.5 million high school students took the test in 2009, and the composite mean score across the academic areas was $\mu = 21.1$ with standard deviation $\sigma = 5.1$.

- What percentage of the population had an ACT score between 18 and 24?
- What is the ranking of a student who scored 27 on the test?
- What is the minimal integer score a student needed to get in order to be in the top 8% of the scoring population?

Solution

- We use a computer to evaluate the probability integral of the normal probability density function with $\mu = 21.1$ and $\sigma = 5.1$:

$$P(18 \leq X \leq 24) = \int_{18}^{24} \frac{1}{5.1\sqrt{2\pi}} e^{-(x-21.1)^2/2(5.1)^2} dx \approx 0.44355.$$

This means that about 44% of the students had an ACT score between 18 and 24.

- (b) Again we use a computer to calculate the probability of a student getting a score lower than 27 on the test:

$$P(1 \leq X < 27) = \int_1^{27} \frac{1}{5.1\sqrt{2\pi}} e^{-(x-21.1)^2/2(5.1)^2} dx \approx 0.87630.$$

We conclude that about 88% of the students scored below a score of 27, so the student ranked in the top 12% of the population.

- (c) We look at how many students had a mark higher than 28:

$$P(28 < X \leq 36) = \int_{28}^{36} \frac{1}{5.1\sqrt{2\pi}} e^{-(x-21.1)^2/2(5.1)^2} dx \approx 0.0863.$$

Since this number gives more than 8% of the students, we look at the next higher integer score:

$$P(29 < X \leq 36) = \int_{29}^{36} \frac{1}{5.1\sqrt{2\pi}} e^{-(x-21.1)^2/2(5.1)^2} dx \approx 0.0595.$$

Therefore, 29 is the lowest integer score a student could get in order to score in the top 8% of the population (and actually scoring here in the top 6%). ■

The simplest form for a normal distribution of X occurs when its mean is zero and its standard deviation is one. The *standard normal probability density function* f giving mean $\mu = 0$ and standard deviation $\sigma = 1$ is

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}.$$

Note that the substitution $z = (x - \mu)/\sigma$ gives the equivalent integrals

$$\int_a^b \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)/\sigma^2/2} dx = \int_\alpha^\beta \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz,$$

where $\alpha = (a - \mu)/\sigma$ and $\beta = (b - \mu)/\sigma$. So we can convert random variable values to the “z-values” to standardize a normal distribution, and then use the integral on the right-hand side of the last equation to calculate probabilities for the original random variable normal distribution with mean μ and standard deviation σ . In a normal distribution, we know that 95.5% of the population lies within two standard deviations of the mean, so a random variable X converted to a z-value has more than a 95% chance of occurring in the interval $[-2, 2]$.

EXERCISES A.8

Probability Density Functions

In Exercises 1–8, determine which are probability density functions and justify your answer.

1. $f(x) = \frac{1}{18}x$ over $[4, 8]$

2. $f(x) = \frac{1}{2}(2 - x)$ over $[0, 2]$

3. $f(x) = 2^x$ over $\left[0, \frac{\ln(1 + \ln 2)}{\ln 2}\right]$

4. $f(x) = x - 1$ over $[0, 1 + \sqrt{3}]$

5. $f(x) = \begin{cases} \frac{1}{x^2} & x \geq 1 \\ 0 & x < 1 \end{cases}$

6. $f(x) = \begin{cases} \frac{8}{\pi(4 + x^2)}, & x \geq 0 \\ 0, & x < 0 \end{cases}$

7. $f(x) = 2 \cos 2x$ over $\left[0, \frac{\pi}{4}\right]$

8. $f(x) = \frac{1}{x}$ over $(0, e]$

9. Let f be the probability density function for the random variable L in Example 2f. Explain the meaning of each integral.

a. $\int_{25,000}^{32,000} f(l) dl$

b. $\int_{30,000}^{\infty} f(l) dl$

c. $\int_0^{20,000} f(l) dl$

d. $\int_{-\infty}^{15,000} f(l) dl$

10. Let $f(x)$ be the uniform distribution for the random variable X in Example 11. Express the following probabilities as integrals.
- The probability that the arrow points either between South and West or between North and West.
 - The probability that the arrow makes an angle of at least 2 radians.

Verify that the functions in Exercises 11–16 are probability density functions for a continuous random variable X over the given interval. Determine the specified probability.

11. $f(x) = xe^{-x}$ over $[0, \infty)$, $P(1 \leq X \leq 3)$

T 12. $f(x) = \frac{\ln x}{x^2}$ over $[1, \infty)$, $P(2 < X < 15)$

13. $f(x) = \frac{3}{2}x(2 - x)$ over $[0, 1]$, $P(0.5 > X)$

T 14. $f(x) = \frac{\sin^2 \pi x}{\pi x^2}$ over $\left[\frac{200}{1059}, \infty\right)$, $P(X < \pi/6)$

15. $f(x) = \begin{cases} \frac{2}{x^3} & x > 1 \\ 0 & x \leq 1 \end{cases}$ over $(-\infty, \infty)$, $P(4 \leq X < 9)$

16. $f(x) = \sin x$ over $[0, \pi/2]$, $P\left(\frac{\pi}{6} < X \leq \frac{\pi}{4}\right)$

In Exercises 17–20, find the value of the constant c so that the given function is a probability density function for a random variable over the specified interval.

17. $f(x) = \frac{1}{6}x$ over $[3, c]$ 18. $f(x) = \frac{1}{x}$ over $[c, c + 1]$

19. $f(x) = 4e^{-2x}$ over $[0, c]$

20. $f(x) = cx\sqrt{25 - x^2}$ over $[0, 5]$

21. Let $f(x) = \frac{c}{1 + x^2}$. Find the value of c so that f is a probability density function. If f is a probability density function for the random variable X , find the probability $P(1 \leq X < 2)$.

22. Find the value of c so that $f(x) = c\sqrt{x}(1 - x)$ is a probability density function for the random variable X over $[0, 1]$, and find the probability $P(0.25 \leq X \leq 0.5)$.

23. Show that if the exponentially decreasing function

$$f(x) = \begin{cases} 0 & \text{if } x < 0 \\ Ae^{-cx} & \text{if } x \geq 0 \end{cases}$$

is a probability density function, then $A = c$.

24. Suppose f is a probability density function for the random variable X with mean μ . Show that its variance satisfies

$$\text{Var}(X) = \int_{-\infty}^{\infty} x^2 f(x) dx - \mu^2.$$

Compute the mean and median for a random variable with the probability density functions in Exercises 25–28.

25. $f(x) = \frac{1}{8}x$ over $[0, 4]$ 26. $f(x) = \frac{1}{9}x^2$ over $[0, 3]$

27. $f(x) = \begin{cases} \frac{2}{x^3} & x \geq 1 \\ 0 & x < 1 \end{cases}$ 28. $f(x) = \begin{cases} \frac{1}{x} & 1 \leq x \leq e \\ 0 & \text{Otherwise} \end{cases}$

Exponential Distributions

29. **Digestion time** The digestion time in hours of a fixed amount of food is exponentially distributed with a mean of 1 hour. What is the probability that the food is digested in less than 30 minutes?
30. **Pollinating flowers** A biologist models the time in minutes until a bee arrives at a flowering plant with an exponential distribution having a mean of 4 minutes. If 1000 flowers are in a field, how many can be expected to be pollinated within 5 minutes?
31. **Lifetime of light bulbs** A manufacturer of light bulbs finds that the mean lifetime of a bulb is 1200 hours. Assume the life of a bulb is exponentially distributed.
- Find the probability that a bulb will last less than its guaranteed lifetime of 1000 hours.
 - In a batch of light bulbs, what is the expected time until half the light bulbs in the batch fail?
32. **Lifetime of an electronic component** The life expectancy in years of a component in a microcomputer is exponentially distributed, and 1/3 of the components fail in the first 3 years. The company that manufactures the component offers a 1 year warranty. What is the probability that a component will fail during the warranty period?
33. **Lifetime of an organism** A *hydra* is a small fresh-water animal, and studies have shown that its probability of dying does not increase with the passage of time. The lack of influence of age on mortality rates for this species indicates that an exponential distribution is an appropriate model for the mortality of hydra. A biologist studies a population of 500 hydra and observes that 200 of them die within the first 2 years. How many of the hydra would you expect to die within the first six months?
34. **Car accidents** The number of days that elapse between the beginning of a calendar year and the moment a high-risk driver is involved in an accident is exponentially distributed. Based on historical data, an insurance company expects that 30% of high-risk drivers will be involved in an accident during the first 50 days of the calendar year. In a group of 100 high-risk drivers, how many do you expect to be involved in an accident during the first 80 days of the calendar year?
35. **Customer service time** The mean waiting time to get served after walking into a bakery is 30 seconds. Assume that an exponential density function describes the waiting times.
- What is the probability a customer waits 15 seconds or less?
 - What is the probability a customer waits longer than one minute?
 - What is the probability a customer waits exactly 5 minutes?
 - If 200 customers come to the bakery in a day, how many are likely to be served within three minutes?
36. **Airport waiting time** According to the U.S. Customs and Border Protection Agency, the average airport wait time at Chicago's O'Hare International airport is 16 minutes for a traveler arriving during the hours 7–8 A.M., and 32 minutes for arrival during the hours 4–5 P.M. The wait time is defined as the total processing time from arrival at the airport until the completion of a passenger's security screening. Assume the wait time is exponentially distributed.
- What is the probability of waiting between 10 and 30 minutes for a traveler arriving during the 7–8 A.M. hour?
 - What is the probability of waiting more than 25 minutes for a traveler arriving during the 7–8 P.M. hour?

- c. What is the probability of waiting between 35 and 50 minutes for a traveler arriving during the 4–5 P.M. hour?
- d. What is the probability of waiting less than 20 minutes for a traveler arriving during the 4–5 P.M. hour?
- 37. Printer lifetime** The lifetime of a \$200 printer is exponentially distributed with a mean of 2 years. The manufacturer agrees to pay a full refund to a buyer if the printer fails during the first year following its purchase, and a one-half refund if it fails during the second year. If the manufacturer sells 100 printers, how much should it expect to pay in refunds?
- 38. Failure time** The time between failures of a photocopier is exponentially distributed. Half of the copiers at a university require service during the first 2 years of operations. If the university purchased 150 copiers, how many do you expect to require service during the first year of their operation?
- T Normal Distributions**
- 39. Cholesterol levels** The serum cholesterol levels of children aged 12 to 14 years follows a normal distribution with mean $\mu = 162$ mg/dl and standard deviation $\sigma = 28$ mg/dl. In a population of 1000 of these children, how many would you expect to have serum cholesterol levels between 165 and 193? between 148 and 167?
- 40. Annual rainfall** The annual rainfall in millimeters for San Francisco, California, is approximately a normal random variable with mean 510 mm and standard deviation 120 mm. What is the probability that next year's rainfall will exceed 444 mm?
- 41. Manufacturing time** The assembly time in minutes for a component at an electronic manufacturing plant is normally distributed with a mean of $\mu = 55$ and standard deviation $\sigma = 4$. What is the probability that a component will be made in less than one hour?
- 42. Lifetime of a tire** Assume the random variable L in Example 2f is normally distributed with mean $\mu = 35,000$ kilometers and $\sigma = 6,000$ kilometers.
- a. In a batch of 4000 tires, how many can be expected to last for at least 29,000 kilometers?
- b. What is the minimum number of kilometers you would expect to find as the lifetime for 90% of the tires?
- 43. Height** The average height of American women aged 18–24 is normally distributed with mean $\mu = 166$ cm and $\sigma = 6$ cm.
- a. What percentage of women are taller than 172 cm?
- b. What is the probability a woman is between 155 cm and 163 cm tall?
- 44. Life expectancy** At birth, a French citizen has an average life expectancy of 82 years with a standard deviation of 7 years. If 100 newly born French babies are selected at random, how many would you expect to live between 75 and 85 years? Assume life expectancy is normally distributed.
- 45. Length of pregnancy** A team of medical practitioners determines that in a population of 1000 women with ages ranging from 20 to 35 years, the length of pregnancy from conception to birth is approximately normally distributed with a mean of 266 days and a standard deviation of 16 days. How many of these women would you expect to have a pregnancy lasting from 36 weeks to 40 weeks?
- 46. Brain weights** In a population of 500 adult Swedish men, medical researchers find their brain weights to be approximately normally distributed with mean $\mu = 1400$ gm and standard deviation $\sigma = 100$ gm.
- a. What percentage of brain weights are between 1325 and 1450 gm?
- b. How many men in the population would you expect to have a brain weight exceeding 1480 gm?
- 47. Blood pressure** Diastolic blood pressure in adults is normally distributed with $\mu = 80$ mm Hg and $\sigma = 12$ mm Hg. In a random sample of 300 adults, how many would be expected to have a diastolic blood pressure below 70 mm Hg?
- 48. Albumin levels** Serum albumin in healthy 20-year-old men is normally distributed with $\mu = 4.4$ and $\sigma = 0.2$. How likely is it for a healthy 20-year-old man to have a level in the range 4.3 to 4.45?
- 49. Quality control** A manufacturer of generator shafts finds that it needs to add additional weight to its shafts in order to achieve proper static and dynamic balance. Based on experimental tests, the average weight it needs to add is $\mu = 35$ gm with $\sigma = 9$ gm. Assuming a normal distribution, from 1000 randomly selected shafts, how many would be expected to need an added weight in excess of 40 gm?
- 50. Kilometers driven** A taxicab company in New York City analyzed the daily number of kilometers driven by each of its drivers. It found the average distance was 300 km with a standard deviation of 50 km. Assuming a normal distribution, what prediction can we make about the percentage of drivers who will log in either more than 400 km or less than 250 km?
- 51. Germination of sunflower seeds** The germination rate of a particular seed is the percentage of seeds in the batch which successfully emerge as plants. Assume that the germination rate for a batch of sunflower seeds is 80%, and that among a large population of n seeds the number of successful germinations is normally distributed with mean $\mu = 0.8n$ and $\sigma = 0.4\sqrt{n}$.
- a. In a batch of $n = 2500$ seeds, what is the probability that at least 1960 will successfully germinate?
- b. In a batch of $n = 2500$ seeds, what is the probability that at most 1980 will successfully germinate?
- c. In a batch of $n = 2500$ seeds, what is the probability that between 1940 and 2020 will successfully germinate?
- 52.** Suppose you toss a fair coin n times and record the number of heads that land. Assume that n is large and approximate the discrete random variable X with a continuous random variable that is normally distributed with $\mu = n/2$ and $\sigma = \sqrt{n}/2$. If $n = 400$, find the given probabilities.
- a. $P(190 \leq X < 210)$ b. $P(X < 170)$
c. $P(X > 220)$ d. $P(X = 300)$
- Discrete Random Variables**
- 53.** A fair coin is tossed four times and the random variable X assigns the number of tails that appear in each outcome.
- a. Determine the set of possible outcomes.
b. Find the value of X for each outcome.

- c. Create a probability bar graph for X , as in Figure A.30. What is the probability that at least two heads appear in the four tosses of the coin?
54. You roll a pair of six-sided dice, and the random variable X assigns to each outcome the sum of the number of dots showing on each face, as in Example 2e.
- Find the set of possible outcomes.
 - Create a probability bar graph for X .
 - What is the probability that $X = 8$?
 - What is the probability that $X \leq 5$? $X > 9$?
55. Three people are asked their opinion in a poll about a particular brand of a common product found in grocery stores. They can answer in one of three ways: “Like the product brand” (L), “Dislike the product brand” (D), or “Undecided” (U). For each outcome, the random variable X assigns the number of L’s that appear.
- Find the set of possible outcomes and the range of X .
 - Create a probability bar graph for X .
 - What is the probability that at least two people like the product brand?
 - What is the probability that no more than one person dislikes the product brand?
56. **Spacecraft components** A component of a spacecraft has both a main system and a backup system operating throughout a flight. The probability that both systems fail sometime during the flight is 0.0148. Assuming that each system separately has the same failure rate, what is the probability that the main system fails during the flight?

A.9 The Distributive Law for Vector Cross Products

In this appendix we prove the Distributive Law

$$\mathbf{u} \times (\mathbf{v} + \mathbf{w}) = \mathbf{u} \times \mathbf{v} + \mathbf{u} \times \mathbf{w},$$

which is Property 2 in Section 11.4.

Proof To derive the Distributive Law, we construct $\mathbf{u} \times \mathbf{v}$ a new way. We draw \mathbf{u} and \mathbf{v} from the common point O and construct a plane M perpendicular to \mathbf{u} at O (Figure A.37). We then project \mathbf{v} orthogonally onto M , yielding a vector \mathbf{v}_1 with length $|\mathbf{v}|\sin\theta$. We rotate \mathbf{v}_1 by 90° about \mathbf{u} in the positive sense to produce a vector \mathbf{v}_2 . Finally, we multiply \mathbf{v}_2 by the length of \mathbf{u} . The resulting vector $|\mathbf{u}|\mathbf{v}_2$ is equal to $\mathbf{u} \times \mathbf{v}$ since \mathbf{v}_2 has the same direction as $\mathbf{u} \times \mathbf{v}$ by its construction (Figure A.37) and

$$|\mathbf{u}|\mathbf{v}_2 = |\mathbf{u}|\mathbf{v}_1 = |\mathbf{u}|\mathbf{v}\sin\theta = |\mathbf{u} \times \mathbf{v}|.$$

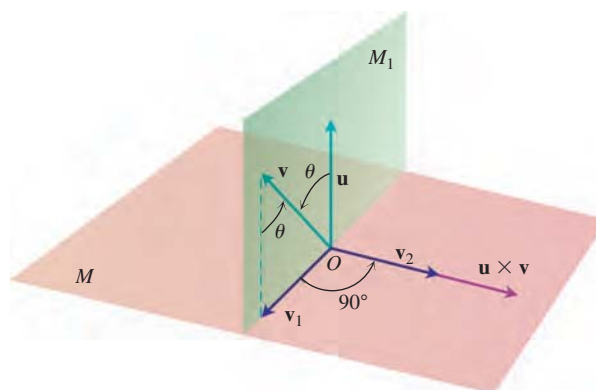

FIGURE A.37 As explained in the text, $\mathbf{u} \times \mathbf{v} = |\mathbf{u}|\mathbf{v}_2$.

Now each of these three operations, namely,

- projection onto M
- rotation about \mathbf{u} through 90°
- multiplication by the scalar $|\mathbf{u}|$,

when applied to a triangle whose plane is not parallel to \mathbf{u} , will produce another triangle. If we start with the triangle whose sides are \mathbf{v} , \mathbf{w} , and $\mathbf{s} = \mathbf{v} + \mathbf{w}$ (Figure A.38) and apply these three steps, we successively obtain the following:

- A triangle whose sides are \mathbf{v}_1 , \mathbf{w}_1 , and \mathbf{s}_1 satisfying the vector equation

$$\mathbf{v}_1 + \mathbf{w}_1 = \mathbf{s}_1$$

2. A triangle whose sides are \mathbf{v}_2 , \mathbf{w}_2 , and \mathbf{s}_2 satisfying the vector equation

$$\mathbf{v}_2 + \mathbf{w}_2 = \mathbf{s}_2$$

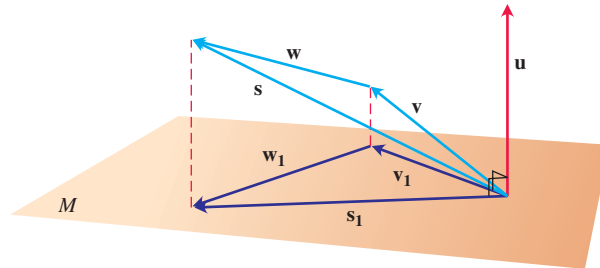

FIGURE A.38 The vectors \mathbf{v} , \mathbf{w} , and $\mathbf{v} + \mathbf{w}$ and their projections onto a plane perpendicular to \mathbf{u} .

3. A triangle whose sides are $|\mathbf{u}|\mathbf{v}_2$, $|\mathbf{u}|\mathbf{w}_2$, and $|\mathbf{u}|\mathbf{s}_2$ satisfying the vector equation

$$|\mathbf{u}|\mathbf{v}_2 + |\mathbf{u}|\mathbf{w}_2 = |\mathbf{u}|\mathbf{s}_2.$$

Substituting $|\mathbf{u}|\mathbf{v}_2 = \mathbf{u} \times \mathbf{v}$, $|\mathbf{u}|\mathbf{w}_2 = \mathbf{u} \times \mathbf{w}$, and $|\mathbf{u}|\mathbf{s}_2 = \mathbf{u} \times (\mathbf{v} + \mathbf{w})$ from our discussion above into this last equation gives

$$\mathbf{u} \times \mathbf{v} + \mathbf{u} \times \mathbf{w} = \mathbf{u} \times (\mathbf{v} + \mathbf{w}),$$

which is the law we wanted to establish. ■

A.10 The Mixed Derivative Theorem and the Increment Theorem

This appendix derives the Mixed Derivative Theorem (Theorem 2, Section 13.3) and the Increment Theorem for Functions of Two Variables (Theorem 3, Section 13.3). Euler first published the Mixed Derivative Theorem in 1734, in a series of papers he wrote on hydrodynamics.

THEOREM 2—The Mixed Derivative Theorem

If $f(x, y)$ and its partial derivatives f_x , f_y , f_{xy} , and f_{yx} are defined throughout an open region containing a point (a, b) and are all continuous at (a, b) , then

$$f_{xy}(a, b) = f_{yx}(a, b).$$

Proof The equality of $f_{xy}(a, b)$ and $f_{yx}(a, b)$ can be established by four applications of the Mean Value Theorem (Theorem 4, Section 4.2). By hypothesis, the point (a, b) lies in the interior of a rectangle R in the xy -plane on which f , f_x , f_y , f_{xy} , and f_{yx} are all defined. We let h and k be the numbers such that the point $(a + h, b + k)$ also lies in R , and we consider the difference

$$\Delta = F(a + h) - F(a), \quad (1)$$

where

$$F(x) = f(x, b + k) - f(x, b). \quad (2)$$

We apply the Mean Value Theorem to F , which is continuous because it is differentiable. Then Equation (1) becomes

$$\Delta = hF'(c_1), \quad (3)$$

where c_1 lies between a and $a + h$. From Equation (2),

$$F'(x) = f_x(x, b + k) - f_x(x, b),$$

so Equation (3) becomes

$$\Delta = h[f_x(c_1, b + k) - f_x(c_1, b)]. \quad (4)$$

Now we apply the Mean Value Theorem to the function $g(y) = f_x(c_1, y)$ and have

$$g(b + k) - g(b) = kg'(d_1),$$

or

$$f_x(c_1, b + k) - f_x(c_1, b) = kf_{xy}(c_1, d_1)$$

for some d_1 between b and $b + k$. By substituting this into Equation (4), we get

$$\Delta = hkf_{xy}(c_1, d_1) \quad (5)$$

for some point (c_1, d_1) in the rectangle R' whose vertices are the four points (a, b) , $(a + h, b)$, $(a + h, b + k)$, and $(a, b + k)$. (See Figure A.39.)

By substituting from Equation (2) into Equation (1), we may also write

$$\begin{aligned} \Delta &= f(a + h, b + k) - f(a + h, b) - f(a, b + k) + f(a, b) \\ &= [f(a + h, b + k) - f(a, b + k)] - [f(a + h, b) - f(a, b)] \\ &= \phi(b + k) - \phi(b), \end{aligned} \quad (6)$$

where

$$\phi(y) = f(a + h, y) - f(a, y). \quad (7)$$

The Mean Value Theorem applied to Equation (6) now gives

$$\Delta = k\phi'(d_2) \quad (8)$$

for some d_2 between b and $b + k$. By Equation (7),

$$\phi'(y) = f_y(a + h, y) - f_y(a, y). \quad (9)$$

Substituting from Equation (9) into Equation (8) gives

$$\Delta = k[f_y(a + h, d_2) - f_y(a, d_2)].$$

Finally, we apply the Mean Value Theorem to the expression in brackets and get

$$\Delta = khf_{yx}(c_2, d_2) \quad (10)$$

for some c_2 between a and $a + h$.

Together, Equations (5) and (10) show that

$$f_{xy}(c_1, d_1) = f_{yx}(c_2, d_2), \quad (11)$$

where (c_1, d_1) and (c_2, d_2) both lie in the rectangle R' (Figure A.39). Equation (11) is not quite the result we want, since it says only that f_{xy} has the same value at (c_1, d_1) that f_{yx} has at (c_2, d_2) . The numbers h and k in our discussion, however, may be made as small as we wish. The hypothesis that f_{xy} and f_{yx} are both continuous at (a, b) means that $f_{xy}(c_1, d_1) = f_{xy}(a, b) + \varepsilon_1$ and $f_{yx}(c_2, d_2) = f_{yx}(a, b) + \varepsilon_2$, where each of $\varepsilon_1, \varepsilon_2 \rightarrow 0$ as both $h, k \rightarrow 0$. Hence, if we let h and $k \rightarrow 0$, we have $f_{xy}(a, b) = f_{yx}(a, b)$. ■

The equality of $f_{xy}(a, b)$ and $f_{yx}(a, b)$ can be proved with hypotheses weaker than the ones we assumed. For example, it is enough for f , f_x , and f_y to exist in R and for f_{xy} to be continuous at (a, b) . Then f_{yx} will exist at (a, b) and will equal f_{xy} at that point.

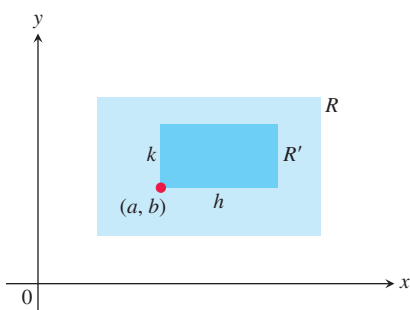

FIGURE A.39 The key to proving $f_{xy}(a, b) = f_{yx}(a, b)$ is that no matter how small R' is, f_{xy} and f_{yx} take on equal values somewhere inside R' (though not necessarily at the same point).

THEOREM 3—The Increment Theorem for Functions of Two Variables

Suppose that the first partial derivatives of $f(x, y)$ are defined throughout an open region R containing the point (x_0, y_0) and that f_x and f_y are continuous at (x_0, y_0) . Then the change

$$\Delta z = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0, y_0)$$

in the value of f that results from moving from (x_0, y_0) to another point $(x_0 + \Delta x, y_0 + \Delta y)$ in R satisfies an equation of the form

$$\Delta z = f_x(x_0, y_0) \Delta x + f_y(x_0, y_0) \Delta y + \varepsilon_1 \Delta x + \varepsilon_2 \Delta y$$

in which each of $\varepsilon_1, \varepsilon_2 \rightarrow 0$ as both $\Delta x, \Delta y \rightarrow 0$.

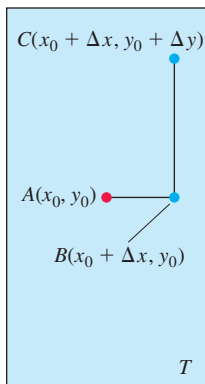

FIGURE A.40 The rectangular region T in the proof of the Increment Theorem. The figure is drawn for Δx and Δy positive, but either increment might be zero or negative.

Proof We work within a rectangle T centered at $A(x_0, y_0)$ and lying within R , and we assume that Δx and Δy are already so small that the line segment joining A to $B(x_0 + \Delta x, y_0)$ and the line segment joining B to $C(x_0 + \Delta x, y_0 + \Delta y)$ lie in the interior of T (Figure A.40).

We may think of Δz as the sum $\Delta z = \Delta z_1 + \Delta z_2$ of two increments, where

$$\Delta z_1 = f(x_0 + \Delta x, y_0) - f(x_0, y_0)$$

is the change in the value of f from A to B and

$$\Delta z_2 = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0 + \Delta x, y_0)$$

is the change in the value of f from B to C (Figure A.41).

On the closed interval of x -values joining x_0 to $x_0 + \Delta x$, the function $F(x) = f(x, y_0)$ is a differentiable (and hence continuous) function of x , with derivative

$$F'(x) = f_x(x, y_0).$$

By the Mean Value Theorem (Theorem 4, Section 4.2), there is an x -value c between x_0 and $x_0 + \Delta x$ at which

$$F(x_0 + \Delta x) - F(x_0) = F'(c) \Delta x$$

or

$$f(x_0 + \Delta x, y_0) - f(x_0, y_0) = f_x(c, y_0) \Delta x$$

or

$$\Delta z_1 = f_x(c, y_0) \Delta x. \quad (12)$$

Similarly, $G(y) = f(x_0 + \Delta x, y)$ is a differentiable (and hence continuous) function of y on the closed y -interval joining y_0 and $y_0 + \Delta y$, with derivative

$$G'(y) = f_y(x_0 + \Delta x, y).$$

Hence, there is a y -value d between y_0 and $y_0 + \Delta y$ at which

$$G(y_0 + \Delta y) - G(y_0) = G'(d) \Delta y$$

or

$$f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0 + \Delta x, y_0) = f_y(x_0 + \Delta x, d) \Delta y$$

or

$$\Delta z_2 = f_y(x_0 + \Delta x, d) \Delta y. \quad (13)$$

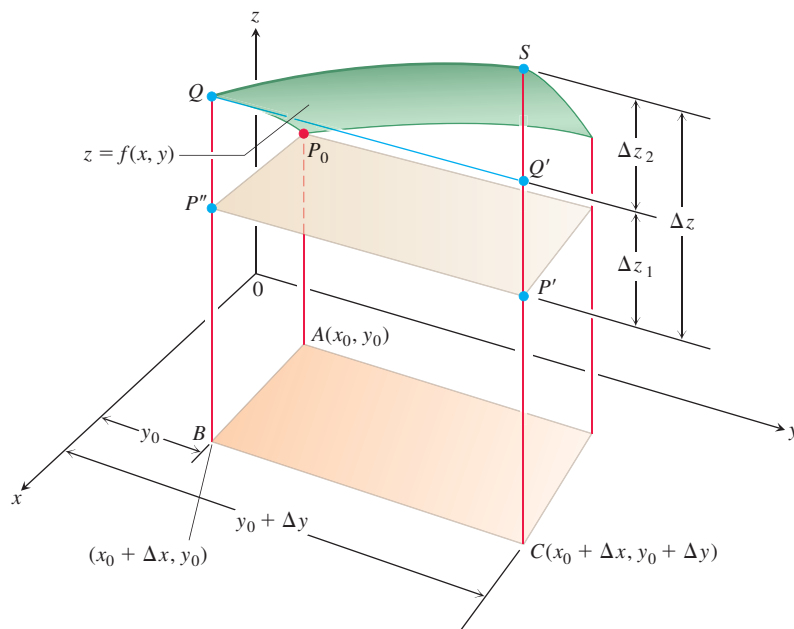

FIGURE A.41 Part of the surface $z = f(x, y)$ near $P_0(x_0, y_0, f(x_0, y_0))$. The points P_0 , P' , and P'' have the same height $z_0 = f(x_0, y_0)$ above the xy -plane. The change in z is $\Delta z = P'S$. The change

$$\Delta z_1 = f(x_0 + \Delta x, y_0) - f(x_0, y_0),$$

shown as $P''Q = P'Q'$, is caused by changing x from x_0 to $x_0 + \Delta x$ while holding y equal to y_0 . Then, with x held equal to $x_0 + \Delta x$,

$$\Delta z_2 = f(x_0 + \Delta x, y_0 + \Delta y) - f(x_0 + \Delta x, y_0)$$

is the change in z caused by changing y_0 from $y_0 + \Delta y$, which is represented by $Q'S$. The total change in z is the sum of Δz_1 and Δz_2 .

Now, as both Δx and $\Delta y \rightarrow 0$, we know that $c \rightarrow x_0$ and $d \rightarrow y_0$. Therefore, since f_x and f_y are continuous at (x_0, y_0) , the quantities

$$\begin{aligned} \varepsilon_1 &= f_x(c, y_0) - f_x(x_0, y_0), \\ \varepsilon_2 &= f_y(x_0 + \Delta x, d) - f_y(x_0, y_0) \end{aligned} \quad (14)$$

both approach zero as both Δx and $\Delta y \rightarrow 0$.

Finally,

$$\begin{aligned} \Delta z &= \Delta z_1 + \Delta z_2 \\ &= f_x(c, y_0) \Delta x + f_y(x_0 + \Delta x, d) \Delta y && \text{From Eqs. (12) and (13)} \\ &= [f_x(x_0, y_0) + \varepsilon_1] \Delta x + [f_y(x_0, y_0) + \varepsilon_2] \Delta y && \text{From Eq. (14)} \\ &= f_x(x_0, y_0) \Delta x + f_y(x_0, y_0) \Delta y + \varepsilon_1 \Delta x + \varepsilon_2 \Delta y, \end{aligned}$$

where both ε_1 and $\varepsilon_2 \rightarrow 0$ as both Δx and $\Delta y \rightarrow 0$, which is what we set out to prove. ■

Analogous results hold for functions of any finite number of independent variables. Suppose that the first partial derivatives of $w = f(x, y, z)$ are defined throughout an open region containing the point (x_0, y_0, z_0) and that $f_x, f_y,$ and f_z are continuous at (x_0, y_0, z_0) . Then

$$\begin{aligned}\Delta w &= f(x_0 + \Delta x, y_0 + \Delta y, z_0 + \Delta z) - f(x_0, y_0, z_0) \\ &= f_x \Delta x + f_y \Delta y + f_z \Delta z + \varepsilon_1 \Delta x + \varepsilon_2 \Delta y + \varepsilon_3 \Delta z,\end{aligned}\quad (15)$$

where $\varepsilon_1, \varepsilon_2,$ and $\varepsilon_3 \rightarrow 0$ as $\Delta x, \Delta y,$ and $\Delta z \rightarrow 0$.

The partial derivatives f_x, f_y, f_z in Equation (15) are to be evaluated at the point (x_0, y_0, z_0) .

Equation (15) can be proved by treating Δw as the sum of three increments,

$$\Delta w_1 = f(x_0 + \Delta x, y_0, z_0) - f(x_0, y_0, z_0) \quad (16)$$

$$\Delta w_2 = f(x_0 + \Delta x, y_0 + \Delta y, z_0) - f(x_0 + \Delta x, y_0, z_0) \quad (17)$$

$$\Delta w_3 = f(x_0 + \Delta x, y_0 + \Delta y, z_0 + \Delta z) - f(x_0 + \Delta x, y_0 + \Delta y, z_0), \quad (18)$$

and applying the Mean Value Theorem to each of these separately. Two coordinates remain constant and only one varies in each of these partial increments $\Delta w_1, \Delta w_2, \Delta w_3$. In Equation (17), for example, only y varies, since x is held equal to $x_0 + \Delta x$ and z is held equal to z_0 . Since $f(x_0 + \Delta x, y, z_0)$ is a continuous function of y with a derivative f_y , it is subject to the Mean Value Theorem, and we have

$$\Delta w_2 = f_y(x_0 + \Delta x, y_1, z_0) \Delta y$$

for some y_1 between y_0 and $y_0 + \Delta y$.

Appendix B

B.1 Determinants

A **matrix** is a rectangular array of numbers. For example,

$$A = \begin{bmatrix} 2 & 1 & 3 \\ 1 & 0 & -2 \end{bmatrix}$$

is a matrix with two rows and three columns. We call A a “2 by 3” matrix. More generally, an “ m by n matrix” is one that has m rows and n columns.

The element in the i th row and j th column of a matrix is represented by a_{ij} . In the example above, we have

$$\begin{aligned} a_{11} &= 2, & a_{12} &= 1, & a_{13} &= 3, \\ a_{21} &= 1, & a_{22} &= 0, & a_{23} &= -2. \end{aligned}$$

If A is an n by n matrix, then we associate A with a number called the **determinant** of A , written sometimes as $\det A$ and sometimes as $|A|$ with vertical bars (which do not mean absolute value). For $n = 1$ and $n = 2$ we have these definitions:

$$\det [a] = a, \quad \det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc. \quad (1)$$

For a 3 by 3 matrix, we define

$$\begin{aligned} \det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} &= a_{11} \begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{12} \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} + a_{13} \begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix} \\ &= a_{11}(a_{22}a_{33} - a_{23}a_{32}) - a_{12}(a_{21}a_{33} - a_{23}a_{31}) + a_{13}(a_{21}a_{32} - a_{22}a_{31}). \end{aligned} \quad (2)$$

In Equation (2) there are some determinants of 2 by 2 matrices – each of those matrices is obtained by deleting one row and one column of the original 3 by 3 matrix.

For an n by n matrix A , we define the **minor** of the element a_{ij} to be the determinant of the $(n - 1)$ by $(n - 1)$ matrix that remains when the row and the column that contain a_{ij} are deleted from A .

In particular, deleting the row and the column that contain the element a_{11} in the matrix

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}, \text{ and then taking the determinant of the resulting matrix yields}$$

$$\begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix},$$

There is a simple checkerboard pattern for the signs that correspond to $(-1)^{i+j}$. This pattern can be applied to convert the minor of an element in a matrix to the cofactor of the element. For a determinant of a 3 by 3 matrix the sign pattern is

$$\begin{array}{ccc} + & - & + \\ - & + & - \\ + & - & + \end{array}$$

In the upper left corner, $i = 1, j = 1$, and $(-1)^{1+1} = +1$. In going from any element to an adjacent element in the same row or column, we change i by 1 or j by 1, but not both, so we change the exponent from even to odd or from odd to even, which changes the sign from $+$ to $-$ or from $-$ to $+$.

which is the minor of a_{11} . Similarly, $\begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix}$ and $\begin{vmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{vmatrix}$ are the minors of a_{12} and a_{13} , respectively.

Given an n by n matrix A , the **cofactor** of a_{ij} is defined as $(-1)^{i+j}$ times the minor of a_{ij} . We denote the cofactor of a_{ij} by A_{ij} .

We can express Equation (2) using cofactors:

$$\det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13}. \quad (3)$$

EXAMPLE 1 Given the matrix

$$A = \begin{bmatrix} 2 & 1 & 3 \\ 3 & -1 & -2 \\ 2 & 3 & 0 \end{bmatrix},$$

- find the minors of a_{11} , a_{12} , and a_{13} .
- find the cofactors A_{11} , A_{12} , and A_{13} .
- use Equation (3) to evaluate $\det A$.

Solution

- To obtain the minor of a_{11} , we delete row 1 and column 1 from the matrix, and then compute the determinant by using Equation (1):

$$\text{minor of } a_{11} = \begin{vmatrix} -1 & -2 \\ 3 & 0 \end{vmatrix} = (-1)(0) - (-2)(3) = 6.$$

Likewise, we obtain

$$\text{minor of } a_{12} = \begin{vmatrix} 3 & -2 \\ 2 & 0 \end{vmatrix} = (3)(0) - (-2)(2) = 4$$

and

$$\text{minor of } a_{13} = \begin{vmatrix} 3 & -1 \\ 2 & 3 \end{vmatrix} = (3)(3) - (-1)(2) = 11.$$

- The cofactor of a_{11} is $(-1)^{1+1} = 1$ times the minor of a_{11} :

$$A_{11} = (-1)^{1+1}(\text{minor of } a_{11}) = (1)(6) = 6.$$

The cofactor of a_{12} is $(-1)^{1+2} = -1$ times the minor of a_{12} :

$$A_{12} = (-1)^{1+2}(\text{minor of } a_{12}) = (-1)(4) = -4$$

and the cofactor of a_{13} is $(-1)^{1+3} = 1$ times the minor of a_{13} :

$$A_{13} = (-1)^{1+3}(\text{minor of } a_{13}) = (1)(11) = 11.$$

(c) To find $\det A$ by using Equation (3), we multiply each element of the first row of A by its cofactor and add:

$$\begin{aligned}\det A &= a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} \\ &= (2)(6) + (1)(-4) + (3)(11) \\ &= 12 - 4 + 33 \\ &= 41.\end{aligned}$$

For any integer $n > 3$, the determinant of an n by n matrix is defined to be the sum of the products of the elements in the first row by their cofactors:

$$\det \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nn} \end{bmatrix} = a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} + \cdots + a_{1n}A_{1n}. \quad (4)$$

EXAMPLE 2 Use the cofactors of the elements in the first row of the matrix

$$A = \begin{bmatrix} 1 & -2 & 3 & 1 \\ 2 & 1 & 0 & 2 \\ -1 & 2 & 1 & -2 \\ 0 & 1 & 2 & 1 \end{bmatrix}$$

to evaluate $\det A$.

Solution The cofactors are

$$\begin{aligned}A_{11} &= (-1)^{1+1} \begin{vmatrix} 1 & 0 & 2 \\ 2 & 1 & -2 \\ 1 & 2 & 1 \end{vmatrix}, & A_{12} &= (-1)^{1+2} \begin{vmatrix} 2 & 0 & 2 \\ -1 & 1 & -2 \\ 0 & 2 & 1 \end{vmatrix}, \\ A_{13} &= (-1)^{1+3} \begin{vmatrix} 2 & 1 & 2 \\ -1 & 2 & -2 \\ 0 & 1 & 1 \end{vmatrix}, & A_{14} &= (-1)^{1+4} \begin{vmatrix} 2 & 1 & 0 \\ -1 & 2 & 1 \\ 0 & 1 & 2 \end{vmatrix}.\end{aligned}$$

These are multiplied by the corresponding elements of A , and then the determinant is obtained by using Equation (4):

$$\begin{aligned}\det A &= a_{11}A_{11} + a_{12}A_{12} + a_{13}A_{13} + a_{14}A_{14} \\ &= 1 \begin{vmatrix} 1 & 0 & 2 \\ 2 & 1 & -2 \\ 1 & 2 & 1 \end{vmatrix} - 2(-1) \begin{vmatrix} 2 & 0 & 2 \\ -1 & 1 & -2 \\ 0 & 2 & 1 \end{vmatrix} + 3 \begin{vmatrix} 2 & 1 & 2 \\ -1 & 2 & -2 \\ 0 & 1 & 1 \end{vmatrix} + 1(-1) \begin{vmatrix} 2 & 1 & 0 \\ -1 & 2 & 1 \\ 0 & 1 & 2 \end{vmatrix}.\end{aligned}$$

Each of the determinants on the right side can now be evaluated using Equation (2):

$$\begin{aligned}\det A &= 1[1(1 + 4) - 0 + 2(4 - 1)] \\ &\quad + 2[2(1 + 4) - 0 + 2(-2 - 0)] \\ &\quad + 3[2(2 + 2) - 1(-1 - 0) + 2(-1 - 0)] \\ &\quad - 1[2(4 - 1) - 1(-2 - 0) + 0] \\ &= 11 + 12 + 21 - 8 = 36.\end{aligned}$$

It becomes very lengthy to compute determinants of large matrices by using the definition. In the mathematical field called **linear algebra**, additional methods are developed to speed up this process. We present a few of those results without proofs.

THEOREM 1—Cofactor Expansion Suppose that A is an n by n matrix, where $n > 2$. For any i , the determinant of A is the sum of the products of the elements in the i th row (or column) with their cofactors.

EXAMPLE 3 Apply Theorem 1 to evaluate the determinant from Example 1 by a cofactor expansion along the third column.

Solution

$$\begin{aligned}
 \det \begin{bmatrix} 2 & 1 & 3 \\ 3 & -1 & -2 \\ 2 & 3 & 0 \end{bmatrix} &= a_{13}A_{13} + a_{23}A_{23} + a_{33}A_{33} && \text{Expand by cofactors of the} \\
 &= 3 \begin{vmatrix} 2 & 1 \\ 3 & -1 \end{vmatrix} - 2(-1) \begin{vmatrix} 2 & 1 \\ 2 & 3 \end{vmatrix} + 0 \begin{vmatrix} 2 & 1 \\ 3 & -1 \end{vmatrix} && \text{Cofactor of } a_{ij} \text{ is } (-1)^{i+j} \\
 &= 3(9 + 2) + 2(6 - 2) + 0(-2 - 3) && \text{Equation (1)} \\
 &= 33 + 8 - 0 = 41 && \blacksquare
 \end{aligned}$$

According to Theorem 1, it is no accident that the answers in Examples 1 and 3 are the same. If we were to multiply the elements of any row (or column) by the cofactors of the corresponding elements and add the products, we would get the same answer: the value of the determinant.

In Example 3, we do not actually need to compute the cofactor A_{33} since it is multiplied by $a_{33} = 0$. Generally, when calculating the determinant of a matrix containing some zero elements, we may want to choose to expand along a row or column with as many zeros as possible.

In an n by n matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nn} \end{bmatrix}$$

we refer to the elements $a_{11}, a_{22}, a_{33}, \dots, a_{nn}$ as the **main diagonal** of the matrix.

If an n by n matrix has all elements below the main diagonal (or all elements above the main diagonal) equal to zero, then its determinant is easy to calculate as illustrated in our next example.

EXAMPLE 4 Evaluate the determinant of the matrix

$$A = \begin{bmatrix} 7 & -4 & 0 & -1 \\ 0 & -3 & 16 & 8 \\ 0 & 0 & -2 & 12 \\ 0 & 0 & 0 & 2 \end{bmatrix}$$

Solution

$$\det \begin{bmatrix} 7 & -4 & 0 & -1 \\ 0 & -3 & 16 & 8 \\ 0 & 0 & -2 & 12 \\ 0 & 0 & 0 & 2 \end{bmatrix}$$

$$= a_{11}A_{11} + a_{21}A_{21} + a_{31}A_{31} + a_{41}A_{41}$$

Expand by cofactors of the first column (Theorem 1).

$$= (7) \begin{vmatrix} -3 & 16 & 8 \\ 0 & -2 & 12 \\ 0 & 0 & 2 \end{vmatrix} + 0 + 0 + 0$$

We do not need the values of the cofactors A_{21} , A_{31} , and A_{41} since each of them is multiplied by 0.

$$= (7) \left(-3 \begin{vmatrix} -2 & 12 \\ 0 & 2 \end{vmatrix} + 0 + 0 \right)$$

Expand the 3 by 3 determinant by cofactors of the first column (Theorem 1).

$$= (7)(-3)(-2)(2)$$

Equation (1)

$$= 84$$

The first part of the following theorem generalizes this result. The remaining parts give other methods that can simplify the computation of a determinant. ■

THEOREM 2—Properties of Determinants

Suppose that A is an n by n matrix, where $n > 2$.

1. If all elements of A below the main diagonal (or all above it) are zero, the determinant of A is the product of the elements on the main diagonal.
2. If each element of a row (or column) of A is multiplied by a constant c and the results are added to a different row (or column), the determinant is not changed.
3. If each element of a row (or column) of A is multiplied by a constant c , the determinant is multiplied by c .
4. If two rows (or columns) of A are interchanged, the determinant just changes its sign.

EXAMPLE 5 We can apply Theorems 1 and 2 to make the evaluation of the determinant from Example 2 easier.

$$\begin{vmatrix} 1 & -2 & 3 & 1 \\ 2 & 1 & 0 & 2 \\ -1 & 2 & 1 & -2 \\ 0 & 1 & 2 & 1 \end{vmatrix} = \begin{vmatrix} 1 & -2 & 3 & 1 \\ 0 & 5 & -6 & 0 \\ -1 & 2 & 1 & -2 \\ 0 & 1 & 2 & 1 \end{vmatrix}$$

We add -2 times row 1 to row 2. By part 2 of Theorem 2 the determinant does not change.

$$= \begin{vmatrix} 1 & -2 & 3 & 1 \\ 0 & 5 & -6 & 0 \\ 0 & 0 & 4 & -1 \\ 0 & 1 & 2 & 1 \end{vmatrix}$$

We add 1 times row 1 to row 3. By part 2 of Theorem 2 the determinant does not change.

$$= 1 \begin{vmatrix} 5 & -6 & 0 \\ 0 & 4 & -1 \\ 1 & 2 & 1 \end{vmatrix} + 0 + 0 + 0$$

Expand by cofactors of the first column (Theorem 1).

$$= 5(4 + 2) - (-6)(0 + 1) + 0 = 36 \quad \text{Equation (2)} \quad \blacksquare$$

The determinant has several important applications, which are studied in a course in linear algebra.

- The absolute value of the determinant gives the volume of the region spanned by the vectors that form the columns (or rows) of the matrix. We saw this in Section 11.4, where we encountered the box product.
- A determinant can be used to indicate whether a system of n linear equations in n unknowns has a unique solution. The answer is yes when the determinant is not equal to zero, and in this case determinants can be used to solve the system.
- We saw in Section 13.7 that the determinant of the Hessian matrix of a function of two variables can help us decide whether a critical point is a saddle point or a local extremum. In Appendix B.2, we will use determinants to extend this to functions of more than two variables.

EXERCISES B.1

Evaluating Determinants

Evaluate the determinants in Exercises 1–14.

$$1. \begin{vmatrix} 2 & 3 & 1 \\ 4 & 5 & 2 \\ 1 & 2 & 3 \end{vmatrix}$$

$$2. \begin{vmatrix} 2 & -1 & -2 \\ -1 & 2 & 1 \\ 3 & 0 & -3 \end{vmatrix}$$

$$3. \begin{vmatrix} 5 & 2 & 0 \\ 2 & -1 & 1 \\ 3 & 3 & -1 \end{vmatrix}$$

$$4. \begin{vmatrix} 4 & 0 & -3 \\ 3 & -2 & 2 \\ 1 & 2 & -1 \end{vmatrix}$$

$$5. \begin{vmatrix} 5 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -5 \end{vmatrix}$$

$$6. \begin{vmatrix} 0 & 0 & 0 & 4 \\ 0 & 0 & 3 & 0 \\ 0 & 2 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{vmatrix}$$

$$7. \begin{vmatrix} 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 3 & 2 \end{vmatrix}$$

$$8. \begin{vmatrix} 1 & -1 & 2 & 3 \\ 2 & 1 & 2 & 6 \\ 1 & 0 & 2 & 3 \\ -2 & 2 & 0 & -5 \end{vmatrix}$$

$$9. \begin{vmatrix} 0 & -2 & 1 & 0 \\ 3 & 0 & 2 & 1 \\ 1 & 2 & 2 & 3 \\ -1 & 0 & 0 & 2 \end{vmatrix}$$

$$10. \begin{vmatrix} -1 & -1 & 3 & 3 \\ 2 & -2 & 1 & -1 \\ 0 & 1 & 2 & 0 \\ 2 & -1 & -1 & 0 \end{vmatrix}$$

$$11. \begin{vmatrix} -3 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 4 & 1 & -5 & 0 & 0 \\ 0 & 2 & -1 & 4 & 0 \\ 6 & 8 & 3 & 2 & -1 \end{vmatrix}$$

$$12. \begin{vmatrix} -4 & 5 & 6 & 7 & 8 \\ 0 & 2 & 5 & 6 & 7 \\ 0 & 0 & -2 & 5 & 6 \\ 0 & 0 & 0 & 2 & 5 \\ 0 & 0 & 0 & 0 & -2 \end{vmatrix}$$

$$13. \begin{vmatrix} 1 & 2 & 0 & 0 & 1 \\ 0 & 2 & 1 & 2 & 0 \\ 0 & 0 & 3 & 1 & 0 \\ 0 & 2 & 0 & 2 & 2 \\ 1 & 0 & 0 & 0 & 1 \end{vmatrix}$$

$$14. \begin{vmatrix} -2 & 0 & 0 & 1 & 2 \\ 1 & 2 & 1 & 0 & 1 \\ 0 & -2 & 2 & 1 & 0 \\ 1 & 0 & 1 & 1 & -1 \\ 1 & 0 & -2 & 0 & 0 \end{vmatrix}$$

B.2 Extreme Values and Saddle Points for Functions of More than Two Variables

Many applications involve functions of multiple independent variables. For instance, to predict energy trends in the United States, an econometric model may use a function $f(p_1, p_2, \dots, p_{50})$ of fifty independent variables representing average prices of gasoline in the fifty states.

It is often important to determine extreme values of such functions. In Section 13.1 we defined a function of n variables whose domain is a set of n -tuples of real numbers (x_1, x_2, \dots, x_n) . The domain is a region in n -dimensional space.

We will use open balls to define some important concepts, such as interior and boundary points. An n -dimensional open ball (or open n -ball) of radius r centered at (a_1, a_2, \dots, a_n) is the set consisting of the points (x_1, x_2, \dots, x_n) that satisfy $(x_1 - a_1)^2 + (x_2 - a_2)^2 + \dots + (x_n - a_n)^2 < r^2$.

EXAMPLE 1 Determine whether the following points in 4-dimensional space are in the open 4-ball with radius 5 and center at $(-2, 0, 3, 1)$.

(a) $(1, -2, 1, 0)$

(b) $(0, 1, -1, 5)$

Solution

(a) $(1 - (-2))^2 + (-2 - 0)^2 + (1 - 3)^2 + (0 - 1)^2 = 9 + 4 + 4 + 1 = 18 < 25 = 5^2$; therefore, $(1, -2, 1, 0)$ is in the open 4-ball.

(b) $(0 - (-2))^2 + (1 - 0)^2 + (-1 - 3)^2 + (5 - 1)^2 = 4 + 1 + 16 + 16 = 37 \geq 25 = 5^2$; therefore, $(0, 1, -1, 5)$ is not in the open 4-ball. ■

Using open n -balls we can extend definitions from Section 13.1 to regions in n -dimensional spaces.

DEFINITIONS A point (x_1, x_2, \dots, x_n) in a region D in n -dimensional space is an **interior point** of D if it is the center of an open n -ball of positive radius that lies entirely in D . A point (x_1, x_2, \dots, x_n) is a **boundary point** of D if every open n -ball centered at (x_1, x_2, \dots, x_n) contains points that lie outside D as well as points that lie inside D .

The **interior** of D is the set of interior points of D . The **boundary** of D is the set of boundary points of D .

A region is **open** if it consists entirely of interior points. A region is **closed** if it contains its entire boundary.

A region is **bounded** if it lies inside an open n -ball of finite radius. A region is **unbounded** if it is not bounded.

Extreme Values and Saddle Points of Functions of More than Two Variables

While Section 13.7 discussed extreme values and saddle points for functions of two variables, here we extend this treatment to functions of three or more variables.

DEFINITIONS Let $f(x_1, x_2, \dots, x_n)$ be defined on a set D of n -tuples of real numbers (x_1, x_2, \dots, x_n) including a point (a_1, a_2, \dots, a_n) .

$f(a_1, a_2, \dots, a_n)$ is a **local maximum** value of f if $f(a_1, a_2, \dots, a_n) \geq f(x_1, x_2, \dots, x_n)$ for all domain points (x_1, x_2, \dots, x_n) that lie in an open n -ball centered at (a_1, a_2, \dots, a_n) .

$f(a_1, a_2, \dots, a_n)$ is a **local minimum** value of f if $f(a_1, a_2, \dots, a_n) \leq f(x_1, x_2, \dots, x_n)$ for all domain points (x_1, x_2, \dots, x_n) that lie in an open n -ball centered at (a_1, a_2, \dots, a_n) .

EXAMPLE 2 The function $f(x, y, z) = 10 - x^2 - y^2 - z^2$ is defined on all of three-dimensional space. Figure B.1 shows an assortment of level surfaces of this function. The level set $f(x, y, z) = 10$ is a single point, the origin. At every point (x, y, z) we have $f(x, y, z) = 10 - x^2 - y^2 - z^2 \leq 10 = f(0, 0, 0)$; therefore, f has a local (and absolute) maximum value of 10 at $(0, 0, 0)$. This function has no local minimum values. ■

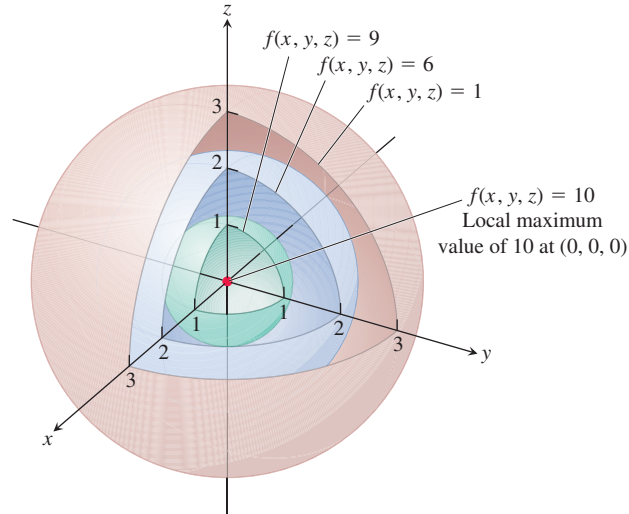

FIGURE B.1 Level surfaces of the function $f(x, y, z) = 10 - x^2 - y^2 - z^2$ in Example 2.

Suppose $f(x_1, x_2, \dots, x_n)$ has a local maximum or minimum value at an interior point (a_1, a_2, \dots, a_n) of its domain and all of its first-order partial derivatives are defined there. The function $g_1(t) = f(t, a_2, \dots, a_n)$ must then have a local extremum at $t = a_1$. Therefore, $g_1'(a_1) = 0$ and consequently

$$\frac{\partial f}{\partial x_1}(a_1, a_2, \dots, a_n) = 0.$$

Likewise, we can use the function $g_2(t) = f(a_1, t, a_3, \dots, a_n)$ to show that

$$\frac{\partial f}{\partial x_2}(a_1, a_2, \dots, a_n) = 0,$$

and continue in the same manner to conclude that

$$\frac{\partial f}{\partial x_i}(a_1, a_2, \dots, a_n) = 0$$

for all $i = 1, 2, \dots, n$.

The above discussion extends Theorem 10 of Section 13.7 to functions of n variables. We present this in a more succinct form by using the gradient notation

$$\nabla f = \left\langle \frac{\partial f}{\partial x_1}, \frac{\partial f}{\partial x_2}, \dots, \frac{\partial f}{\partial x_n} \right\rangle.$$

THEOREM 3—First Derivative Theorem for Local Extreme Values (General Version) If $f(x_1, x_2, \dots, x_n)$ has a local maximum or minimum value at an interior point (a_1, a_2, \dots, a_n) of its domain and if ∇f exists at that point, then $\nabla f(a_1, a_2, \dots, a_n) = \mathbf{0}$, where $\mathbf{0} = \langle 0, 0, \dots, 0 \rangle$ denotes the zero vector in n -dimensional space.

The following definition of a critical point uses the gradient notation.

DEFINITION An interior point of the domain of f where either $\nabla f = \mathbf{0}$ or ∇f does not exist is called a **critical point** of f .

Note that a vector does not exist whenever one or more of its components does not exist.

The notion of a saddle point generalizes to functions f of n variables.

DEFINITION A critical point (a_1, a_2, \dots, a_n) of a differentiable function $f(x_1, x_2, \dots, x_n)$ is a **saddle point** if every open n -ball centered at the point (a_1, a_2, \dots, a_n) contains points (x_1, x_2, \dots, x_n) with $f(a_1, a_2, \dots, a_n) > f(x_1, x_2, \dots, x_n)$ as well as points (y_1, y_2, \dots, y_n) with $f(a_1, a_2, \dots, a_n) < f(y_1, y_2, \dots, y_n)$.

The Hessian matrix of a function of two variables was introduced in Section 13.7. We now generalize this concept for functions of n variables.

DEFINITIONS The **Hessian matrix** of $f(x_1, x_2, \dots, x_n)$ is the $n \times n$ matrix (containing n rows and n columns)

$$Hf = \begin{bmatrix} f_{x_1x_1} & f_{x_1x_2} & \cdots & f_{x_1x_n} \\ f_{x_2x_1} & f_{x_2x_2} & \cdots & f_{x_2x_n} \\ \vdots & \vdots & \ddots & \vdots \\ f_{x_nx_1} & f_{x_nx_2} & \cdots & f_{x_nx_n} \end{bmatrix}.$$

The **principal minor determinants** of the Hessian matrix are

$$\Delta_1 = f_{x_1x_1},$$

$$\Delta_2 = \begin{vmatrix} f_{x_1x_1} & f_{x_1x_2} \\ f_{x_2x_1} & f_{x_2x_2} \end{vmatrix},$$

$$\Delta_3 = \begin{vmatrix} f_{x_1x_1} & f_{x_1x_2} & f_{x_1x_3} \\ f_{x_2x_1} & f_{x_2x_2} & f_{x_2x_3} \\ f_{x_3x_1} & f_{x_3x_2} & f_{x_3x_3} \end{vmatrix},$$

...

$$\Delta_n = |Hf| = \begin{vmatrix} f_{x_1x_1} & f_{x_1x_2} & \cdots & f_{x_1x_n} \\ f_{x_2x_1} & f_{x_2x_2} & \cdots & f_{x_2x_n} \\ \vdots & \vdots & \ddots & \vdots \\ f_{x_nx_1} & f_{x_nx_2} & \cdots & f_{x_nx_n} \end{vmatrix}.$$

Theorem 11 in Section 13.7 gave us tools to decide whether a critical point of a function $f(x_1, x_2)$ is a local maximum, local minimum, or a saddle point. The nature of a critical point of a function of more than two variables can be similarly determined using the principal minor determinants of the Hessian matrix.

THEOREM 4—Second Derivative Test for Local Extreme Values (General Version) Suppose that $f(x_1, x_2, \dots, x_n)$ and its first and second partial derivatives are continuous throughout an open n -ball centered at (a_1, a_2, \dots, a_n) and suppose that $\nabla f(a_1, a_2, \dots, a_n) = \mathbf{0}$. Then

- i)** f has a local maximum at (a_1, a_2, \dots, a_n) if $(-1)^i \Delta_i > 0$ at the point (a_1, a_2, \dots, a_n) for $i = 1, 2, \dots, n$.
- ii)** f has a local minimum at (a_1, a_2, \dots, a_n) if $\Delta_i > 0$ at (a_1, a_2, \dots, a_n) for $i = 1, 2, \dots, n$.
- iii)** f has a saddle point at (a_1, a_2, \dots, a_n) if $\Delta_n \neq 0$ at (a_1, a_2, \dots, a_n) and neither of conditions (i) or (ii) hold.
- iv)** the test is inconclusive if $\Delta_n = 0$ at (a_1, a_2, \dots, a_n) .

For $n = 2$, Theorem 4 reduces to Theorem 11 of Section 13.7 (see Exercise 11).

The principal minor determinants Δ_i keep track of directions along which f has a local maximum and directions along which f has a local minimum. If it has a local maximum (or local minimum) when traveling along each of the n possible axis directions, then f has a local maximum (or local minimum) in an open n -ball.

Applying Theorem 4 to the function $f(x, y, z) = 10 - x^2 - y^2 - z^2$ of Example 2, we get the Hessian matrix $Hf = \begin{bmatrix} -2 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{bmatrix}$. Its principal minor determinants are

$$\Delta_1 = -2,$$

$$\Delta_2 = \begin{vmatrix} -2 & 0 \\ 0 & -2 \end{vmatrix} = 4, \text{ and}$$

$$\Delta_3 = \begin{vmatrix} -2 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & -2 \end{vmatrix} = -2 \begin{vmatrix} -2 & 0 \\ 0 & -2 \end{vmatrix} - 0 \begin{vmatrix} 0 & 0 \\ 0 & -2 \end{vmatrix} + 0 \begin{vmatrix} 0 & -2 \\ 0 & 0 \end{vmatrix} = -8.$$

At the critical point $(0, 0, 0)$, we have $\Delta_1 < 0$, $\Delta_2 > 0$, and $\Delta_3 < 0$, so Theorem 4 confirms the conclusion we reached in Example 2: f has a local maximum at $(0, 0, 0)$.

EXAMPLE 3 Find the local extreme values and saddle points of the function

$$f(x, y, z) = 2x^3y + 3y^2 + 6yz + 6z^2 - 6xy.$$

Solution The function f is differentiable, therefore its critical points are points at which $\nabla f = \mathbf{0}$. Setting each component of the gradient equal to zero yields the following equations:

$$f_x = 6x^2y - 6y = 6y(x^2 - 1) = 0$$

$$f_y = 2x^3 + 6y + 6z - 6x = 0$$

$$f_z = 6y + 12z = 0.$$

The equation $f_x = 0$ can be satisfied in three possible ways: (i) if $y = 0$, (ii) if $x = 1$, or (iii) if $x = -1$. Let's consider these possibilities one at a time.

(i) If $y = 0$, then the equation $f_z = 0$ yields $z = 0$, and then the equation $f_y = 0$ leads to

$$2x^3 - 6x = 2x(x^2 - 3) = 0.$$

This equation has three solutions: $x = 0, \pm\sqrt{3}$, so we obtain critical points $(0, 0, 0)$, $(\sqrt{3}, 0, 0)$, and $(-\sqrt{3}, 0, 0)$.

(ii) If $x = 1$, then the equation $f_y = 0$ becomes $6y + 6z - 4 = 0$. Together with the equation $f_z = 6y + 12z = 0$, this forms a system of two linear equations, which can be solved to obtain $y = 4/3$ and $z = -2/3$. The resulting critical point is $(1, 4/3, -2/3)$.

(iii) If $x = -1$, then similarly to case (ii) we solve the remaining two equations, which yields $y = -4/3$ and $z = 2/3$ and the final critical point is $(-1, -4/3, 2/3)$.

The Hessian matrix of f is

$$Hf = \begin{bmatrix} f_{xx} & f_{xy} & f_{xz} \\ f_{yx} & f_{yy} & f_{yz} \\ f_{zx} & f_{zy} & f_{zz} \end{bmatrix} = \begin{bmatrix} 12xy & 6x^2 - 6 & 0 \\ 6x^2 - 6 & 6 & 6 \\ 0 & 6 & 12 \end{bmatrix},$$

and the principal minor determinants are

$$\Delta_1 = 12xy$$

$$\Delta_2 = \begin{vmatrix} 12xy & 6x^2 - 6 \\ 6x^2 - 6 & 6 \end{vmatrix} = 72xy - (6x^2 - 6)^2$$

$$\begin{aligned} \Delta_3 &= \begin{vmatrix} 12xy & 6x^2 - 6 & 0 \\ 6x^2 - 6 & 6 & 6 \\ 0 & 6 & 12 \end{vmatrix} = 12xy \begin{vmatrix} 6 & 6 \\ 6 & 12 \end{vmatrix} - (6x^2 - 6) \begin{vmatrix} 6x^2 - 6 & 6 \\ 0 & 12 \end{vmatrix} + 0 \\ &= 12xy \cdot 36 - (6x^2 - 6)^2(12). \end{aligned}$$

We list the values of these determinants at the critical points in the following table.

Critical Point	Δ_1	Δ_2	Δ_3
$(0, 0, 0)$	0	-36	-432
$(\sqrt{3}, 0, 0)$	0	-144	-1728
$(-\sqrt{3}, 0, 0)$	0	-144	-1728
$(1, \frac{4}{3}, -\frac{2}{3})$	16	96	576
$(-1, -\frac{4}{3}, \frac{2}{3})$	16	96	576

According to Theorem 4,

- (i) f has a local maximum at a critical point if $\Delta_1 < 0$, $\Delta_2 > 0$, and $\Delta_3 < 0$. This pattern is not observed at any of our critical points; therefore, f has no local maximum values.
- (ii) f has a local minimum at a critical point if $\Delta_1 > 0$, $\Delta_2 > 0$, and $\Delta_3 > 0$. The signs of the principal minor determinants listed in the table follow this pattern for the last two critical points, so f has local minimum values at $(1, 4/3, -2/3)$ and at $(-1, -4/3, 2/3)$.
- (iii) f has a saddle point at a critical point if $\Delta_3 \neq 0$, but neither of the conditions (i) or (ii) hold. Based on our table, this is the case at each of the first three critical points. We conclude that f has saddle points at $(0, 0, 0)$, $(\sqrt{3}, 0, 0)$, and $(-\sqrt{3}, 0, 0)$.

EXERCISES B.2

Finding Local Extrema and Saddle Points

Find all the local maxima, local minima, and saddle points of the functions in Exercises 1–10.

1. $f(x, y, z) = x^3y - 3xy + 3yz - 3y + 6z$

2. $f(x, y, z) = xy + x^2z^2 + x^2 + y^2 + z^2$

3. $f(x, y, z) = x^3 - 3x + y^2 + 2y + 2z^2 - 8z + 6$

4. $f(x, y, z) = \frac{x^3}{8} - \frac{x}{2} + xy - y^2 - z^2$

5. $f(x, y, z) = \frac{12z}{x^2 + y^2 + z^2 + 4}$

6. $f(x, y, z) = x^2 + 4y^2 + xz - yz + 4$

7. $f(x, y, z, w) = x^2 + y^2 + z^2 + w^2 + xy + zw - y + 2z$

8. $f(x, y, z, w) = 3x + yz - 4z - w - x^2 - y^2 - z^2 - w^2$

9. $f(x, y, z, v, w) = x^2 + 2y^2 - z^2 + v^2 + w^2 + x - 3v + xv$

10. $f(x, y, z, v, w) = x + z + yv - 4w - 3x^2 - 2y^2 - z^2 - v^2 - w^2$

Theory

11. Show that for $n = 2$ Theorem 4 reduces to Theorem 11 of Section 13.7.

B.3 The Method of Gradient Descent

In Section 13.7 and in Appendix B.2 we discussed methods allowing us to analytically determine local maxima, local minima, and saddle points of a differentiable function f of n variables. While these methods apply for any integer $n \geq 2$, they may not be practical when n is very large. Furthermore, there are important applications where we can evaluate (or approximate) f and its partial derivative values without having an explicit formula for f . These are among the reasons to numerically search for local extrema of a function of n variables.

In this appendix, we will refer to values of a function of n variables $f(x_1, x_2, \dots, x_n)$ using the notation $f(\mathbf{x})$ where $\mathbf{x} = \langle x_1, x_2, \dots, x_n \rangle$ is the position vector of the point (x_1, x_2, \dots, x_n) . The directional derivative of f at that point in the direction of a unit vector \mathbf{u} can be expressed as

$$D_{\mathbf{u}}f(\mathbf{x}) = \nabla f(\mathbf{x}) \cdot \mathbf{u}.$$

In Section 13.5, where the notion of the directional derivative was introduced, we noticed that the function f increases most rapidly in the direction of ∇f while it decreases most rapidly in the direction of $-\nabla f$. This leads to the **method of gradient descent** (also known as the **method of steepest descent**) for numerically approximating a local minimum for a function f of n variables.

The initial approximation \mathbf{x}_0 can be chosen to be the best guess for where a minimum might be. (Alternatively a randomly chosen point can be used for \mathbf{x}_0 .) We then take a step in the direction of $-\nabla f(\mathbf{x}_0)$ to yield the next approximation

$$\mathbf{x}_1 = \mathbf{x}_0 - h_0 \nabla f(\mathbf{x}_0),$$

where the positive quantity h_0 controls the size of the step. We obtain subsequent approximations $\mathbf{x}_2, \mathbf{x}_3, \dots$ in the same manner.

Method of Gradient Descent

1. Start with a first approximation to a local minimum of $f(\mathbf{x}_0)$.
2. Use the first approximation to obtain a second, the second to obtain a third, and so on, using the formula

$$\mathbf{x}_{k+1} = \mathbf{x}_k - h_k \nabla f(\mathbf{x}_k) \quad (1)$$

with $h_k > 0$.

In applications, including those in the field of machine learning, the method of gradient descent can be applied to approximate a local minimum of a function involving a large number of independent variables. To gain insight into this method, consider Figure B.2, where we show the method being applied to a function of two variables $f(\mathbf{x}) = f(x, y)$ (we take $\mathbf{x} = \langle x, y \rangle$ to be the position vector of the point (x, y)). Notice that the vector $-\nabla f(\mathbf{x}_0)$ is perpendicular to the level curve of f passing through the point \mathbf{x}_0 , which consists of all points \mathbf{x} in the plane that satisfy the equation $f(\mathbf{x}) = f(\mathbf{x}_0)$. Adding $-\nabla f(\mathbf{x}_0)$ to \mathbf{x}_0 gives us our next approximation, \mathbf{x}_1 . Once again, $-\nabla f(\mathbf{x}_1)$ is perpendicular to the level curve through that point. The process then continues in a similar manner. In addition to level curves, Figure B.2 shows the surface $z = f(\mathbf{x})$, which helps visualize the descent of the values $f(\mathbf{x}_0), f(\mathbf{x}_1), f(\mathbf{x}_2), \dots$. These values appear to be approaching a minimum value of f .

In Figure B.2, we used a constant value $h = 1$ for all h_k . Figure B.3 illustrates how different choices of h value could affect the method's performance. When h is small (Figure B.3a), the method is forced to take more steps. It is often more efficient to take larger steps (Figure B.3b, same h as in Figure B.2). If the value of h is too large (Figure B.3c),

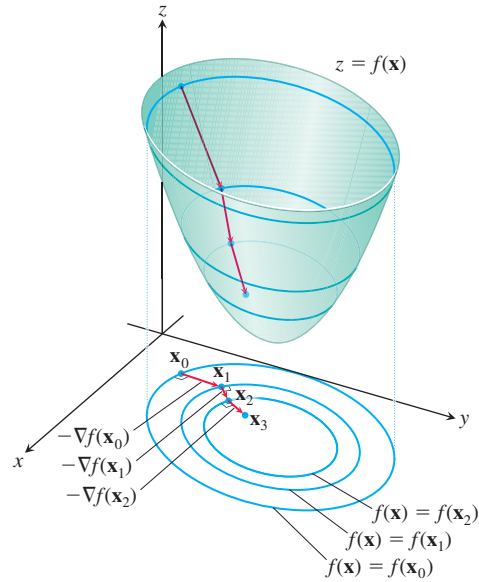

FIGURE B.2 The method of gradient descent is applied to a function f of two variables using a constant $h = 1$. The level curves and the corresponding surface plot show how the value of f decreases at each step.

then the method may not converge. To understand why the method may fail when h is too large, recall that while at \mathbf{x}_k the function f decreases most rapidly in the direction of $-\nabla f(\mathbf{x}_k)$, the function may start increasing if we continue in this direction and go too far from \mathbf{x}_k .

Choosing a desirable value for the quantity h (which in machine learning is sometimes called the *learning rate*) that is neither too small nor too large could be challenging. We consider here only the case where the gradient descent method uses a constant, pre-chosen value $h_k = h$. More advanced methods focus on identifying desirable h_k values (which may not be constant) – one of those would involve performing a *line search* (see Exercise 5).

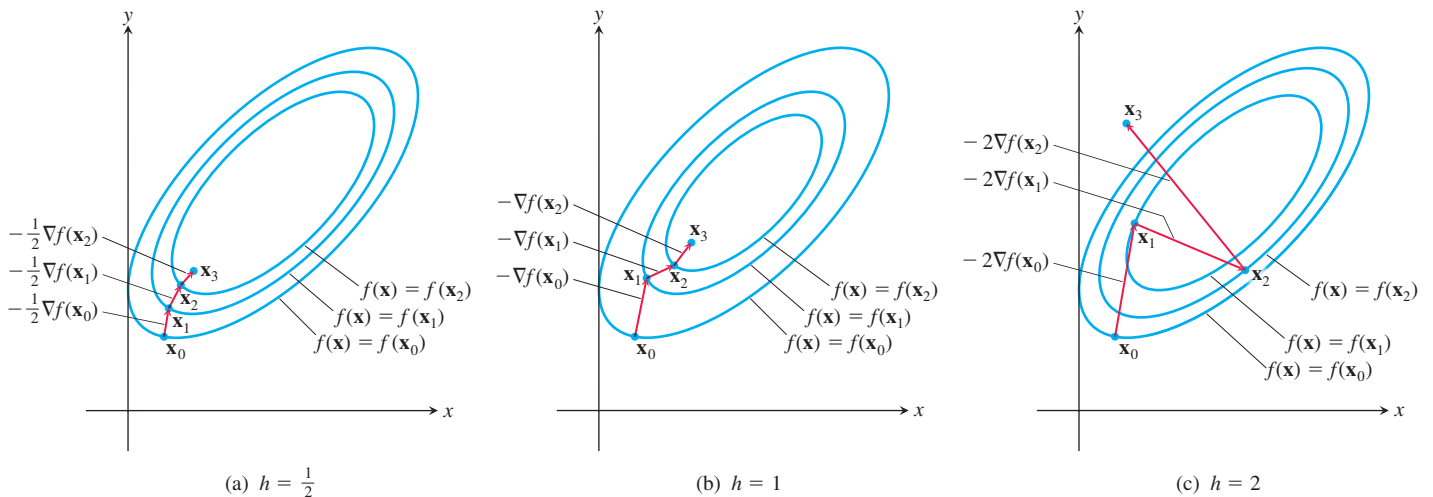

FIGURE B.3 Different choices of h affect the performance of the method of gradient descent.

EXAMPLE 1 Apply the method of gradient descent to $f(x, y, z) = 2x^3y + 3y^2 + 6yz + 6z^2 - 6xy$ using the initial approximation $\mathbf{x}_0 = \langle 2, 1, -1 \rangle$ and taking $h_k = h = 0.1$. List the components of \mathbf{x}_k and $f(\mathbf{x}_k)$ for $k = 0, 1, 2, \dots, 10$.

Solution At the initial approximation $\mathbf{x}_0 = \langle 2, 1, -1 \rangle$, we have $f(\mathbf{x}_0) = f(2, 1, -1) = 7$.

The gradient of the function f is

$$\nabla f = \langle 6x^2y - 6y, 2x^3 + 6y + 6z - 6x, 6y + 12z \rangle.$$

Evaluating the gradient at the initial approximation yields $\nabla f(\mathbf{x}_0) = \langle 18, 4, -6 \rangle$.

We now apply Equation (1) to obtain the second approximation

$$\begin{aligned} \mathbf{x}_1 &= \mathbf{x}_0 - h_0 \nabla f(\mathbf{x}_0) \\ &= \langle 2, 1, -1 \rangle - (0.1)\langle 18, 4, -6 \rangle \\ &= \langle 0.2, 0.6, -0.4 \rangle. \end{aligned}$$

At this point, $f(\mathbf{x}_1) \approx -0.11$.

Subsequent approximations $\mathbf{x}_2, \mathbf{x}_3, \dots$ are then obtained using technology by repeatedly applying Equation (1). These approximations, along with the corresponding f values, are listed in the table below.

k	x component of \mathbf{x}_k	y component of \mathbf{x}_k	z component of \mathbf{x}_k	$f(\mathbf{x}_k)$

The function f in Example 1 was analyzed in Example 3 of Appendix B.2 and was shown to have a local minimum $f(1, 4/3, -2/3) = -8/3$. The sequence of approximations generated in Example 1 appears to converge to this local minimum.

The method of gradient descent is designed to approximate a local minimum of a function of many variables. If we are interested in approximating a local *maximum* instead, then we apply the **method of gradient ascent**

$$\mathbf{x}_{k+1} = \mathbf{x}_k + h_k \nabla f(\mathbf{x}_k),$$

in which we follow the direction of the gradient ∇f , rather than $-\nabla f$.

EXERCISES B.3

You may need to use appropriate technology (such as a calculator or a computer).

Gradient Descent

- Apply the method of gradient descent to $f(x, y, z) = \frac{12z}{x^2 + y^2 + z^2 + 4}$ using the initial approximation $\mathbf{x}_0 = \langle 1, 1, -1 \rangle$ and the given constant value $h_k = h = 1$. List the components of \mathbf{x}_k and $f(\mathbf{x}_k)$ for $k = 0, 1, 2, \dots, 5$.
- Apply the method of gradient descent to $f(x, y, z) = x^3 - 3x + y^2 + 2y + 2z^2 - 8z + 6$ using the initial approximation $\mathbf{x}_0 = \langle 0, 0, 1 \rangle$ and the given constant value $h_k = h = 0.2$. List the components of \mathbf{x}_k and $f(\mathbf{x}_k)$ for $k = 0, 1, 2, \dots, 5$.
- Apply the method of gradient descent to $f(x, y, z, w) = x^2 + y^2 + z^2 + w^2 + xy + zw - y + 2z$ using the initial approximation $\mathbf{x}_0 = \langle -1, 1, -1, 1 \rangle$ and the given constant value $h_k = h = 0.5$. List the components of \mathbf{x}_k and $f(\mathbf{x}_k)$ for $k = 0, 1, 2, \dots, 5$.

- Apply the method of gradient descent to $f(x, y, z, v, w) = -x - z - yv + 4w + 3x^2 + 2y^2 + z^2 + v^2 + w^2$ using the initial approximation $\mathbf{x}_0 = \langle 1, 1, 1, 1, 1 \rangle$ and the given constant value $h_k = h = 0.2$. List the components of \mathbf{x}_k and $f(\mathbf{x}_k)$ for $k = 0, 1, 2, \dots, 5$.

Line Search

- In Example 1, we applied the method of gradient descent to the function $f(x, y, z) = 2x^3y + 3y^2 + 6yz + 6z^2 - 6xy$ with the initial approximation $\mathbf{x}_0 = \langle 2, 1, -1 \rangle$. Plot the function $g(h_0) = f(\mathbf{x}_0 - h_0 \nabla f(\mathbf{x}_0))$ to approximate a positive value of h_0 that minimizes $g(h_0)$. (This process, known as the line search, can then be repeatedly used at subsequent steps of the gradient descent method to obtain the values h_1, h_2, \dots . Using these values, rather than a constant h , can lead to a faster convergence to a minimum.)

 81. $x \approx 3.5156$ 83. $x \approx 0.7391$

PRACTICE EXERCISES, pp. 133-134

1. At $x = -1$: $\lim_{x \rightarrow -1^-} f(x) = \lim_{x \rightarrow -1^+} f(x) = 1$, so $\lim_{x \rightarrow -1} f(x) = 1 = f(-1)$; continuous at $x = -1$
 At $x = 0$: $\lim_{x \rightarrow 0^-} f(x) = \lim_{x \rightarrow 0^+} f(x) = 0$, so $\lim_{x \rightarrow 0} f(x) = 0$. However, $f(0) \neq 0$, so f is discontinuous at $x = 0$. The discontinuity can be removed by redefining $f(0)$ to be 0.
 At $x = 1$: $\lim_{x \rightarrow 1^-} f(x) = -1$ and $\lim_{x \rightarrow 1^+} f(x) = 1$, so $\lim_{x \rightarrow 1} f(x)$ does not exist. The function is discontinuous at $x = 1$, and the discontinuity is not removable.

 (b) $\cos 2\theta = \cos^2 \theta - \sin^2 \theta$; $-2 \sin 2\theta = 2 \cos \theta(-\sin \theta) - 2 \sin \theta(\cos \theta)$; $\sin 2\theta = \cos \theta \sin \theta + \sin \theta \cos \theta$; $\sin 2\theta = 2 \sin \theta \cos \theta$

3. (a) $a = 1, b = 0, c = -\frac{1}{2}$ (b) $b = \cos a, c = \sin a$

5. $h = -4, k = \frac{9}{2}, a = \frac{5\sqrt{5}}{2}$

7. (a) 0.09y (b) Increasing at 1% per year

9. Answers will vary. Here is one possibility.

11. (a) 2 s, 19.6 m/s (b) 12.25 s, 120 m

15. $y' = \frac{x^{y-1}y^2 - ye^x(x^y + 1)\ln y}{e^x(x^y + 1) - x^y y \ln x}$

17. (a) $m = -\frac{b}{\pi}$ (b) $m = -1, b = \pi$

19. (a) $a = \frac{3}{4}, b = \frac{9}{4}$ 21. f odd $\Rightarrow f'$ is even

25. h' is defined but not continuous at $x = 0$; k' is defined and continuous at $x = 0$.

27. $\frac{-7}{75}$ rad/s

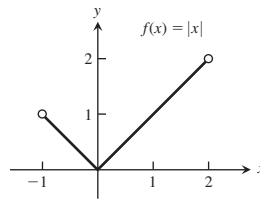

31. (a) 0.248 m (b) 0.02015 s
 (c) It will lose about 28.3 min/day.

Chapter 4

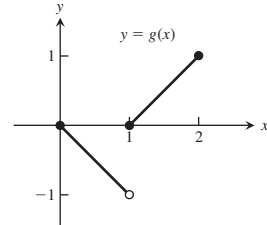

SECTION 4.1, pp. 241–243

1. Absolute minimum at $x = c_2$; absolute maximum at $x = b$
 3. Absolute maximum at $x = c$; no absolute minimum
 5. Absolute minimum at $x = a$; absolute maximum at $x = c$
 7. No absolute minimum; no absolute maximum
 9. Absolute maximum at $(0, 5)$ 11. (c) 13. (d)

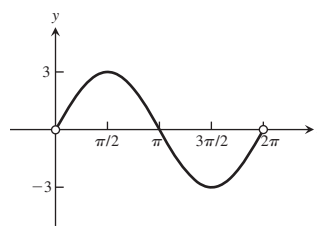

15. Absolute minimum at $x = 0$; no absolute maximum

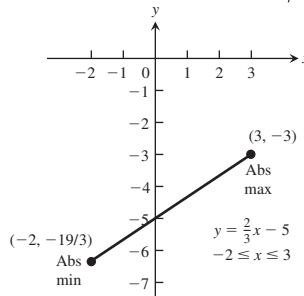

17. Absolute maximum at $x = 2$; no absolute minimum

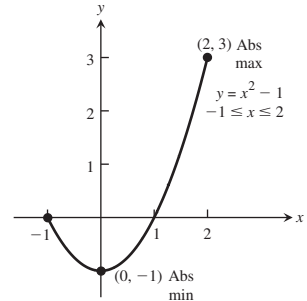

19. Absolute maximum at $x = \pi/2$; absolute minimum at $x = 3\pi/2$

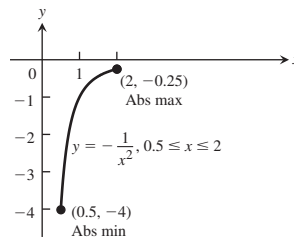

21. Absolute maximum: -3 ; absolute minimum: $-19/3$

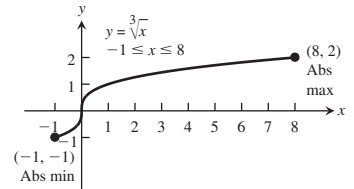

23. Absolute maximum: 3; absolute minimum: -1

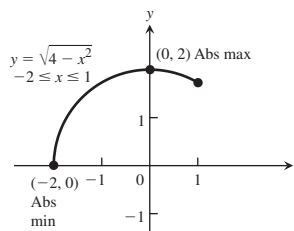

25. Absolute maximum: -0.25 ; absolute minimum: -4

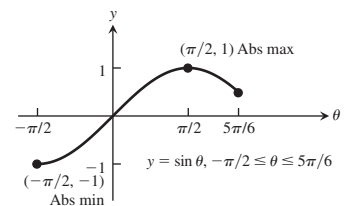

27. Absolute maximum: 2; absolute minimum: -1

29. Absolute maximum: 2; absolute minimum: 0

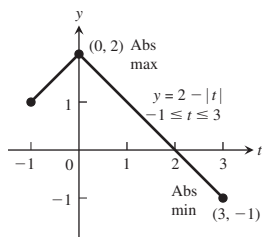

31. Absolute maximum: 1; absolute minimum: -1

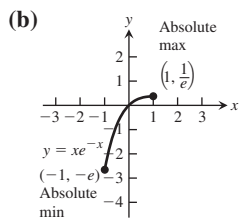

33. Absolute maximum: $2/\sqrt{3}$; absolute minimum: 1

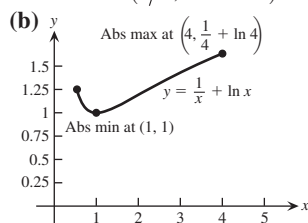

35. Absolute maximum: 2; absolute minimum: -1

37. (a) Absolute maximum is $1/e$ at $x = 1$; absolute minimum is $-e$ at $x = -1$.

39. (a) Absolute maximum value is $(1/4) + \ln 4$ at $x = 4$; absolute minimum value is 1 at $x = 1$; local maximum at $(1/2, 2 - \ln 2)$.

41. Increasing on $(0, 8)$, decreasing on $(-1, 0)$; absolute maximum: 16 at $x = 8$; absolute minimum: 0 at $x = 0$

43. Increasing on $(-32, 1)$; absolute maximum: 1 at $\theta = 1$; absolute minimum: -8 at $\theta = -32$

45. $x = 3$

47. $x = 1, x = 4$

49. $x = 1$

51. $x = 0, x = 4$

53. $x = 0, x = 1$

55. $x = 2, x = -4$

57. (a) No

(b) The derivative is defined and nonzero for $x \neq 2$. Also, $f(2) = 0$ and $f(x) > 0$ for all $x \neq 2$.

(c) No, because $(-\infty, \infty)$ is not a closed interval.

(d) The answers are the same as parts (a) and (b), with 2 replaced by a .

59. y is increasing on $(-\infty, \infty)$ so has no extrema.

61. y is decreasing on $(-\infty, \infty)$ so has no extrema.

63. Yes

65. g assumes a local maximum at $-c$.

67. (a) Maximum value is 144 at $x = 2$.

(b) The largest volume of the box is 144 cubic units, and it occurs when $x = 2$.

69. $\frac{v_0^2}{2g} + s_0$

71. Maximum value is 11 at $x = 5$; minimum value is 5 on the interval $[-3, 2]$; local maximum at $(-5, 9)$.

73. Maximum value is 5 on the interval $[3, \infty)$; minimum value is -5 on the interval $(-\infty, -2]$.

SECTION 4.2, pp. 248-249

1. $1/2$ 3. 1 5. $\pm\sqrt{1 - \frac{4}{\pi^2}} \approx \pm 0.771$

7. $\frac{1}{3}(1 + \sqrt{7}) \approx 1.22, \frac{1}{3}(1 - \sqrt{7}) \approx -0.549$

9. Does not; f is not differentiable at the interior domain point $x = 0$.

11. Does

13. Does not; f is not differentiable at $x = -1$.

17. (a)

29. Yes 31. (a) 4 (b) 3 (c) 3

33. (a) $\frac{x^2}{2} + C$ (b) $\frac{x^3}{3} + C$ (c) $\frac{x^4}{4} + C$

35. (a) $\frac{1}{x} + C$ (b) $x + \frac{1}{x} + C$ (c) $5x - \frac{1}{x} + C$

37. (a) $-\frac{1}{2}\cos 2t + C$ (b) $2\sin \frac{t}{2} + C$

(c) $-\frac{1}{2}\cos 2t + 2\sin \frac{t}{2} + C$

39. $f(x) = x^2 - x$ 41. $f(x) = 1 + \frac{e^{2x}}{2}$

43. $s = 4.9t^2 + 5t + 10$ 45. $s = \frac{1 - \cos(\pi t)}{\pi}$

47. $s = e^t + 19t + 4$ 49. $s = \sin(2t) - 3$

51. If $T(t)$ is the temperature of the thermometer at time t , then $T(0) = -19^\circ\text{C}$ and $T(14) = 100^\circ\text{C}$. From the Mean Value Theorem, there exists a $0 < t_0 < 14$ such that $\frac{T(14) - T(0)}{14 - 0} = 8.5^\circ\text{C/s} = T'(t_0)$, the rate at which the

temperature was changing at $t = t_0$ as measured by the rising mercury on the thermometer.

53. Because its average speed was approximately 7.667 knots, and by the Mean Value Theorem, it must have been going that speed at least once during the trip.

57. The conclusion of the Mean Value Theorem yields

$$\frac{\frac{1}{b} - \frac{1}{a}}{\frac{b}{b-a} - \frac{1}{a}} = -\frac{1}{c^2} \Rightarrow c^2 \left(\frac{a-b}{ab} \right) = a-b \Rightarrow c = \sqrt{ab}.$$

61. $f(x)$ must be zero at least once between a and b by the Intermediate Value Theorem. Now suppose that $f(x)$ is zero twice between a and b . Then, by the Mean Value Theorem, $f'(x)$ would have to be zero at least once between the two zeros of $f(x)$, but this can't be true since we are given that $f'(x) \neq 0$ on this interval. Therefore, $f(x)$ is zero once and only once between a and b .

71. $1.09999 \leq f(0.1) \leq 1.1$

SECTION 4.3, pp. 253-255

1. (a) 0, 1

(b) Increasing on $(-\infty, 0)$ and $(1, \infty)$; decreasing on $(0, 1)$

(c) Local maximum at $x = 0$; local minimum at $x = 1$

3. (a) $-2, 1$

(b) Increasing on $(-2, 1)$ and $(1, \infty)$; decreasing on $(-\infty, -2)$

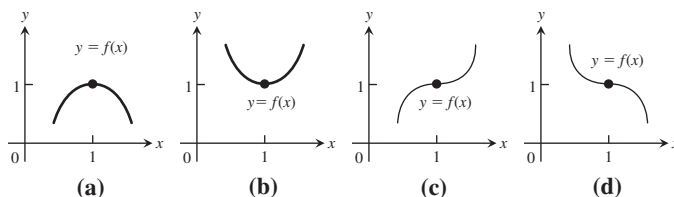

(c) No local maximum; local minimum at $x = -2$

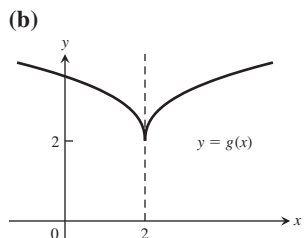

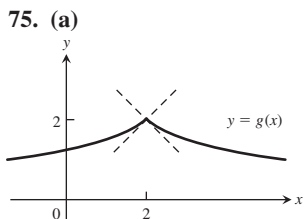

5. (a) Critical point at $x = 1$

(b) Decreasing on $(-\infty, 1)$, increasing on $(1, \infty)$

(c) Local (and absolute) minimum at $x = 1$

7. (a) 0, 1
 (b) Increasing on $(-\infty, -2)$ and $(1, \infty)$; decreasing on $(-2, 0)$ and $(0, 1)$
 (c) Local minimum at $x = 1$
9. (a) $-2, 2$
 (b) Increasing on $(-\infty, -2)$ and $(2, \infty)$; decreasing on $(-2, 0)$ and $(0, 2)$
 (c) Local maximum at $x = -2$; local minimum at $x = 2$
11. (a) $-2, 0$
 (b) Increasing on $(-\infty, -2)$ and $(0, \infty)$; decreasing on $(-2, 0)$
 (c) Local maximum at $x = -2$; local minimum at $x = 0$
13. (a) $\frac{\pi}{2}, \frac{2\pi}{3}, \frac{4\pi}{3}$
 (b) Increasing on $(\frac{2\pi}{3}, \frac{4\pi}{3})$; decreasing on $(0, \frac{\pi}{2}), (\frac{\pi}{2}, \frac{2\pi}{3})$, and $(\frac{4\pi}{3}, 2\pi)$
 (c) Local maximum at $x = 0$ and $x = \frac{4\pi}{3}$; local minimum at $x = \frac{2\pi}{3}$ and $x = 2\pi$
15. (a) Increasing on $(-2, 0)$ and $(2, 4)$; decreasing on $(-4, -2)$ and $(0, 2)$
 (b) Absolute maximum at $(-4, 2)$; local maximum at $(0, 1)$ and $(4, -1)$; absolute minimum at $(2, -3)$; local minimum at $(-2, 0)$
17. (a) Increasing on $(-4, -1), (1/2, 2)$, and $(2, 4)$; decreasing on $(-1, 1/2)$
 (b) Absolute maximum at $(4, 3)$; local maximum at $(-1, 2)$ and $(2, 1)$; no absolute minimum; local minimum at $(-4, -1)$ and $(1/2, -1)$
19. (a) Increasing on $(-\infty, -1.5)$; decreasing on $(-1.5, \infty)$
 (b) Local maximum: 5.25 at $t = -1.5$
21. (a) Decreasing on $(-\infty, 0)$; increasing on $(0, 4/3)$; decreasing on $(4/3, \infty)$
 (b) Local minimum at $x = 0(0, 0)$; local maximum at $x = 4/3(4/3, 32/27)$
23. (a) Decreasing on $(-\infty, 0)$; increasing on $(0, 1/2)$; decreasing on $(1/2, \infty)$
 (b) Local minimum at $\theta = 0(0, 0)$; local maximum at $\theta = 1/2(1/2, 1/4)$
25. (a) Increasing on $(-\infty, \infty)$; never decreasing
 (b) No local extrema
27. (a) Increasing on $(-2, 0)$ and $(2, \infty)$; decreasing on $(-\infty, -2)$ and $(0, 2)$
 (b) Local maximum: 16 at $x = 0$; local minimum: 0 at $x = \pm 2$
29. (a) Increasing on $(-\infty, -1)$; decreasing on $(-1, 0)$; increasing on $(0, 1)$; decreasing on $(1, \infty)$
 (b) Local maximum: 0.5 at $x = \pm 1$; local minimum: 0 at $x = 0$
31. (a) Increasing on $(10, \infty)$; decreasing on $(1, 10)$
 (b) Local maximum: 1 at $x = 1$; local minimum: -8 at $x = 10$
33. (a) Decreasing on $(-2\sqrt{2}, -2)$; increasing on $(-2, 2)$; decreasing on $(2, 2\sqrt{2})$
 (b) Local minima: $g(-2) = -4, g(2\sqrt{2}) = 0$; local maxima: $g(-2\sqrt{2}) = 0, g(2) = 4$
35. (a) Increasing on $(-\infty, 1)$; decreasing when $1 < x < 2$; decreasing when $2 < x < 3$; discontinuous at $x = 2$; increasing on $(3, \infty)$
 (b) Local minimum at $x = 3(3, 6)$; local maximum at $x = 1(1, 2)$
37. (a) Increasing on $(-2, 0)$ and $(0, \infty)$; decreasing on $(-\infty, -2)$
 (b) Local minimum: $-6\sqrt[3]{2}$ at $x = -2$
39. (a) Increasing on $(-\infty, -2/\sqrt{7})$ and $(2/\sqrt{7}, \infty)$; decreasing on $(-2/\sqrt{7}, 0)$ and $(0, 2/\sqrt{7})$
 (b) Local maximum: $24\sqrt[3]{2}/7^{7/6} \approx 3.12$ at $x = -2/\sqrt{7}$; local minimum: $-24\sqrt[3]{2}/7^{7/6} \approx -3.12$ at $x = 2/\sqrt{7}$
41. (a) Increasing on $((1/3)\ln(1/2), \infty)$, decreasing on $(-\infty, (1/3)\ln(1/2))$
 (b) Local minimum is $\frac{3}{2^{2/3}}$ at $x = (1/3)\ln(1/2)$; no local maximum
43. (a) Increasing on (e^{-1}, ∞) ; decreasing on $(0, e^{-1})$
 (b) A local minimum is $-e^{-1}$ at $x = e^{-1}$; no local maximum
45. (a) Increasing on $(0, e^{-2})$ and $(1, \infty)$; decreasing on $(e^{-2}, 1)$
 (b) Local maximum is $4/e^2$ at $x = e^{-2}$
47. (a) Local maximum: 1 at $x = 1$; local minimum: 0 at $x = 2$
 (b) Absolute maximum: 1 at $x = 1$; no absolute minimum
49. (a) Local maximum: 1 at $x = 1$; local minimum: 0 at $x = 2$
 (b) No absolute maximum; absolute minimum: 0 at $x = 2$
51. (a) Local maxima: -9 at $t = -3$ and 16 at $t = 2$; local minimum: -16 at $t = -2$
 (b) Absolute maximum: 16 at $t = 2$; no absolute minimum
53. (a) Local minimum: 0 at $x = 0$
 (b) No absolute maximum; absolute minimum: 0 at $x = 0$
55. (a) Local maximum: 5 at $x = 0$; local minimum: 0 at $x = -5$ and $x = 5$
 (b) Absolute maximum: 5 at $x = 0$; absolute minimum: 0 at $x = -5$ and $x = 5$
57. (a) Local maximum: 2 at $x = 0$;
 local minimum: $\frac{\sqrt{3}}{4\sqrt{3}-6}$ at $x = 2 - \sqrt{3}$
 (b) No absolute maximum; absolute minimum at $x = 2 - \sqrt{3}$
59. (a) Local maximum: 1 at $x = \pi/4$;
 local maximum: 0 at $x = \pi$;
 local minimum: 0 at $x = 0$;
 local minimum: -1 at $x = 3\pi/4$
61. (a) Local maximum: 2 at $x = \pi/6$;
 local maximum: $\sqrt{3}$ at $x = 2\pi$;
 local minimum: -2 at $x = 7\pi/6$;
 local minimum: $\sqrt{3}$ at $x = 0$
63. (a) Local minimum: $(\pi/3) - \sqrt{3}$ at $x = 2\pi/3$;
 local maximum: 0 at $x = 0$;
 local maximum: π at $x = 2\pi$
65. (a) Local minimum: 0 at $x = \pi/4$
67. Local minimum at $x = 1$; no local maximum
69. (a) Increasing on $(-1, 2)$;
 decreasing on $(-2, -1)$
 (b) The sign of f cannot be determined solely from the graph of f' .
71. Local maximum: 3 at $\theta = 0$;
 local minimum: -3 at $\theta = 2\pi$
- 73.

79. $a = -2, b = 4$

81. (a) Absolute minimum occurs at $x = \pi/3$ with $f(\pi/3) = -\ln 2$, and the absolute maximum occurs at $x = 0$ with $f(0) = 0$.

(b) Absolute minimum occurs at $x = 1/2$ and $x = 2$ with $f(1/2) = f(2) = \cos(\ln 2)$, and the absolute maximum occurs at $x = 1$ with $f(1) = 1$.

83. Minimum of $2 - 2 \ln 2 \approx 0.613706$ at $x = \ln 2$; maximum of 1 at $x = 0$

85. Absolute maximum value of $1/2e$ assumed at $x = 1/\sqrt{e}$

89. Increasing; $\frac{df^{-1}}{dx} = \frac{1}{9}x^{-2/3}$

91. Decreasing; $\frac{df^{-1}}{dx} = -\frac{1}{3}x^{-2/3}$

SECTION 4.4, pp. 264–268

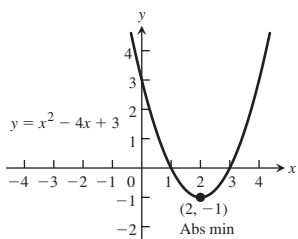

1. Local maximum: $3/2$ at $x = -1$; local minimum: -3 at $x = 2$; point of inflection at $(1/2, -3/4)$; rising on $(-\infty, -1)$ and $(2, \infty)$; falling on $(-1, 2)$; concave up on $(1/2, \infty)$; concave down on $(-\infty, 1/2)$

3. Local maximum: $3/4$ at $x = 0$; local minimum: 0 at $x = \pm 1$; points of inflection at $(-\sqrt{3}, \frac{3\sqrt{3}}{4})$ and $(\sqrt{3}, \frac{3\sqrt{3}}{4})$; rising on $(-1, 0)$ and $(1, \infty)$; falling on $(-\infty, -1)$ and $(0, 1)$; concave up on $(-\infty, -\sqrt{3})$ and $(\sqrt{3}, \infty)$; concave down on $(-\sqrt{3}, -1), (-1, 1)$, and $(1, \sqrt{3})$

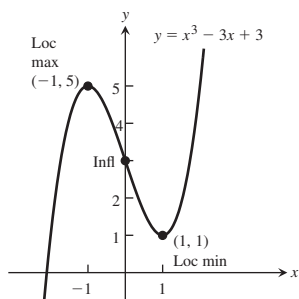

5. Local maxima: $\frac{-2\pi}{3} + \frac{\sqrt{3}}{2}$ at $x = -2\pi/3, \frac{\pi}{3} + \frac{\sqrt{3}}{2}$ at $x = \pi/3$; local minima: $-\frac{\pi}{3} - \frac{\sqrt{3}}{2}$ at $x = -\pi/3, \frac{2\pi}{3} - \frac{\sqrt{3}}{2}$ at $x = 2\pi/3$; points of inflection at $(-\pi/2, -\pi/2), (0, 0)$, and $(\pi/2, \pi/2)$; rising on $(-\pi/3, \pi/3)$; falling on $(-2\pi/3, -\pi/3)$ and $(\pi/3, 2\pi/3)$; concave up on $(-\pi/2, 0)$ and $(\pi/2, 2\pi/3)$; concave down on $(-2\pi/3, -\pi/2)$ and $(0, \pi/2)$

7. Local maxima: 1 at $x = -\pi/2$ and $x = \pi/2, 0$ at $x = -2\pi$ and $x = 2\pi$; local minima: -1 at $x = -3\pi/2$ and $x = 3\pi/2, 0$ at $x = 0$; points of inflection at $(-\pi, 0)$ and $(\pi, 0)$; rising on $(-3\pi/2, -\pi/2), (0, \pi/2)$, and $(3\pi/2, 2\pi)$; falling on $(-2\pi, -3\pi/2), (-\pi/2, 0)$, and $(\pi/2, 3\pi/2)$; concave up on $(-2\pi, -\pi)$ and $(\pi, 2\pi)$; concave down on $(-\pi, 0)$ and $(0, \pi)$

49. (a) 4 m

51. (a) $10\sqrt{3} \times 10\sqrt{6}$ cm

53. (a) $10\pi \approx 31.42$ cm/s; when $t = 0.5$ s, 1.5 s, 2.5 s, 3.5 s; $s = 0$, acceleration is 0.

- (b) 10 cm from rest position; speed is 0.

55. (a) $s = ((12 - 12t)^2 + 64t^2)^{1/2}$

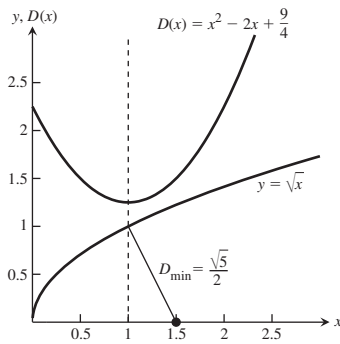

- (b) -12 knots; 8 knots (c) No

- (e) $4\sqrt{13}$; this limit is the square root of the sum of the squares of the individual speeds.

57. $x = \frac{a}{2}, v = \frac{ka^2}{4}$ 59. $\frac{c}{2} + 50$

61. (a) $\sqrt{\frac{2km}{h}}$ (b) $\sqrt{\frac{2km}{h}}$ 65. $2 \times 2 \times \frac{3}{2}$ m, \$720

67. $M = \frac{C}{2}$ 73. (a) $y = -1$

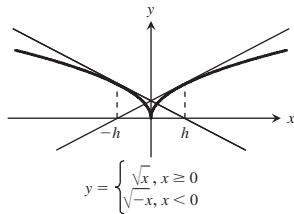

75. (a) The minimum distance is $\frac{\sqrt{5}}{2}$.(b) The minimum distance is from the point $(3/2, 0)$ to the point $(1, 1)$ on the graph of $y = \sqrt{x}$, and this occurs at the value $x = 1$, where $D(x)$, the distance squared, has its minimum value.

SECTION 4.7, pp. 292–294

1. $x_2 = -\frac{5}{3}, \frac{13}{21}$ 3. $x_2 = -\frac{51}{31}, \frac{5763}{4945}$ 5. $x_2 = \frac{2387}{2000}$

7. x_2 is approximately 2.20794 9. x_2 is approximately 0.6839411. x_1 , and all later approximations will equal x_0 .

13.

15. The points of intersection of $y = x^3$ and $y = 3x + 1$ or of $y = x^3 - 3x$ and $y = 1$ have the same x -values as the roots of part (i) or the solutions of part (iv).17. $x \approx 1.165561185, y \approx 2.33112237$ 19. (a) Two (b) 0.35003501505249 and -1.0261731615301 21. $\pm 1.3065629648764, \pm 0.5411961001462$ 23. $x \approx 0.45$

25. 0.8192 27. 0, 0.53485 29. The root is 1.17951.

31. (a) For $x_0 = -2$ or $x_0 = -0.8, x_i \rightarrow -1$ as i gets large.(b) For $x_0 = -0.5$ or $x_0 = 0.25, x_i \rightarrow 0$ as i gets large.(c) For $x_0 = 0.8$ or $x_0 = 2, x_i \rightarrow 1$ as i gets large.(d) For $x_0 = -\sqrt{21}/7$ or $x_0 = \sqrt{21}/7$, Newton's method does not converge. The values of x_i alternate between $-\sqrt{21}/7$ and $\sqrt{21}/7$ as i increases.

33. Answers will vary with machine speed.

SECTION 4.8, pp. 300–304

1. (a) x^2 (b) $\frac{x^3}{3}$ (c) $\frac{x^3}{3} - x^2 + x$

3. (a) x^{-3} (b) $-\frac{1}{3}x^{-3}$ (c) $-\frac{1}{3}x^{-3} + x^2 + 3x$

5. (a) $-\frac{1}{x}$ (b) $-\frac{5}{x}$ (c) $2x + \frac{5}{x}$

7. (a) $\sqrt{x^3}$ (b) \sqrt{x} (c) $\frac{2\sqrt{x^3}}{3} + 2\sqrt{x}$

9. (a) $x^{2/3}$ (b) $x^{1/3}$ (c) $x^{-1/3}$

11. (a) $\ln x$ (b) $7 \ln x$ (c) $x - 5 \ln x$

13. (a) $\cos(\pi x)$ (b) $-3 \cos x$ (c) $-\frac{1}{\pi} \cos(\pi x) + \cos(3x)$

15. (a) $\tan x$ (b) $2 \tan\left(\frac{x}{3}\right)$ (c) $-\frac{2}{3} \tan\left(\frac{3x}{2}\right)$

17. (a) $-\csc x$ (b) $\frac{1}{5} \csc(5x)$ (c) $2 \csc\left(\frac{\pi x}{2}\right)$

19. (a) $\frac{1}{3}e^{3x}$ (b) $-e^{-x}$ (c) $2e^{x/2}$

21. (a) $\frac{1}{\ln 3} 3^x$ (b) $\frac{-1}{\ln 2} 2^{-x}$ (c) $\frac{1}{\ln(5/3)} \left(\frac{5}{3}\right)^x$

23. (a) $2 \arcsin x$ (b) $\frac{1}{2} \arctan x$ (c) $\frac{1}{2} \arctan 2x$

25. $\frac{x^2}{2} + x + C$ 27. $t^3 + \frac{t^2}{4} + C$ 29. $\frac{x^4}{2} - \frac{5x^2}{2} + 7x + C$

31. $-\frac{1}{x} - \frac{x^3}{3} - \frac{x}{3} + C$ 33. $\frac{3}{2}x^{2/3} + C$

35. $\frac{2}{3}x^{3/2} + \frac{3}{4}x^{4/3} + C$ 37. $4y^2 - \frac{8}{3}y^{3/4} + C$

39. $x^2 + \frac{2}{x} + C$ 41. $2\sqrt{t} - \frac{2}{\sqrt{t}} + C$

43. $-2 \sin t + C$ 45. $-21 \cos \frac{\theta}{3} + C$

47. $3 \cot x + C$ 49. $-\frac{1}{2} \csc \theta + C$

51. $\frac{1}{3}e^{3x} - 5e^{-x} + C$ 53. $-e^{-x} + \frac{4^x}{\ln 4} + C$

55. $4 \sec x - 2 \tan x + C$ 57. $-\frac{1}{2} \cos 2x + \cot x + C$

59. $\frac{t}{2} + \frac{\sin 4t}{8} + C$ 61. $\ln|x| - 5 \arctan x + C$

63. $\frac{3x(\sqrt{3}+1)}{\sqrt{3}+1} + C$ 65. $\tan \theta + C$ 67. $-\cot x - x + C$

69. $-\cos \theta + \theta + C$

83. (a) Wrong: $\frac{d}{dx} \left(\frac{x^2}{2} \sin x + C \right) = \frac{2x}{2} \sin x + \frac{x^2}{2} \cos x = x \sin x + \frac{x^2}{2} \cos x$

(b) Wrong: $\frac{d}{dx} (-x \cos x + C) = -\cos x + x \sin x$

(c) Right: $\frac{d}{dx} (-x \cos x + \sin x + C) = -\cos x + x \sin x + \cos x = x \sin x$

85. (a) Wrong: $\frac{d}{dx} \left(\frac{(2x+1)^3}{3} + C \right) = \frac{3(2x+1)^2(2)}{3} = 2(2x+1)^2$

(b) Wrong: $\frac{d}{dx} ((2x+1)^3 + C) = 3(2x+1)^2(2) = 6(2x+1)^2$

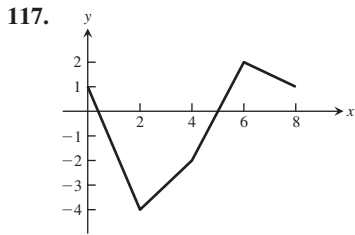

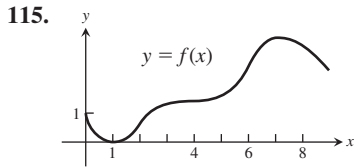

(c) Right: $\frac{d}{dx} ((2x+1)^3 + C) = 6(2x+1)^2$

87. Right 89. (b) 91. $y = x^2 - 7x + 10$

93. $y = -\frac{1}{x} + \frac{x^2}{2} - \frac{1}{2}$ 95. $y = 9x^{1/3} + 4$

AN-24 Chapter 4: Answers to Odd-Numbered Exercises

97. $s = t + \sin t + 4$ 99. $r = \cos(\pi\theta) - 1$
 101. $v = \frac{1}{2}\sec t + \frac{1}{2}$ 103. $v = 3\arcsin t - \pi$
 105. $y = x^2 - x^3 + 4x + 1$ 107. $r = \frac{1}{t} + 2t - 2$
 109. $y = x^3 - 4x^2 + 5$ 111. $y = -\sin t + \cos t + t^3 - 1$
 113. $y = 2x^{3/2} - 50$

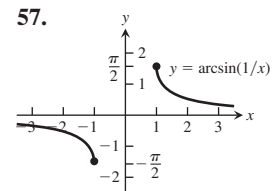

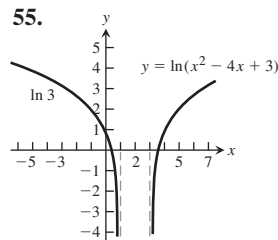

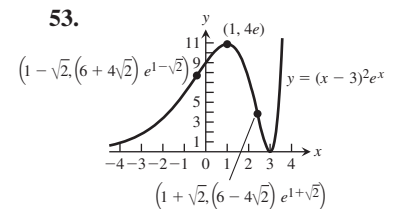

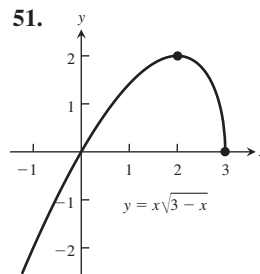

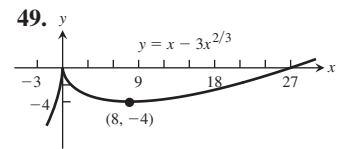

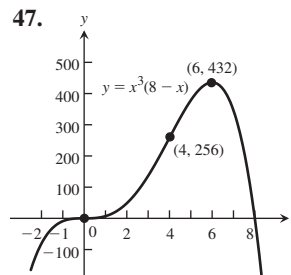

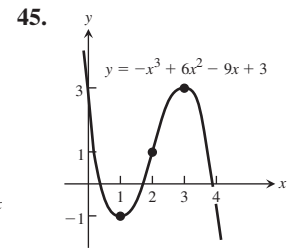

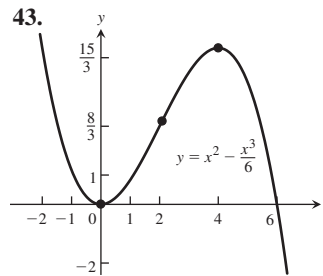

119. $y = x - x^{4/3} + \frac{1}{2}$
 121. $y = -\sin x - \cos x - 2$
 123. (a) (i) 33.2 units, (ii) 33.2 units, (iii) 33.2 units
 (b) True
 125. $t = 88/k, k = 16$
 127. (a) $v = 10t^{3/2} - 6t^{1/2}$ (b) $s = 4t^{5/2} - 4t^{3/2}$
 131. (a) $-\sqrt{x} + C$ (b) $x + C$ (c) $\sqrt{x} + C$
 (d) $-x + C$
 (e) $x - \sqrt{x} + C$
 (f) $-x - \sqrt{x} + C$

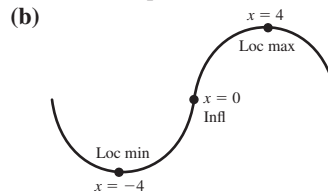

PRACTICE EXERCISES, pp. 305–308

1. Minimum value is 1 at $x = 2$.
 3. Local maximum at $(-2, 17)$; local minimum at $(\frac{4}{3}, -\frac{41}{27})$
 5. Minimum value is 0 at $x = -1$ and $x = 1$.
 7. There is a local minimum at $(0, 1)$.
 9. Maximum value is $\frac{1}{2}$ at $x = 1$; minimum value is $-\frac{1}{2}$ at $x = -1$.
 11. The minimum value is 2 at $x = 0$.
 13. The minimum value is $-\frac{1}{e}$ at $x = \frac{1}{e}$.
 15. The maximum value is $\frac{\pi}{2}$ at $x = 0$; an absolute minimum value is 0 at $x = 1$ and $x = -1$.
 17. No 19. No minimum; absolute maximum: $f(1) = 16$; critical points: $x = 1$ and $11/13$
 21. Absolute minimum: $g(0) = 1$; no absolute maximum; critical point: $x = 0$
 23. Absolute minimum: $2 - 2 \ln 2$ at $x = 2$; absolute maximum: 1 at $x = 1$
 25. Yes, except at $x = 0$ 27. No 31. (b) one
 33. (b) 0.8555 99677 2 35. NA
 39. Global minimum value of $\frac{1}{2}$ at $x = 2$

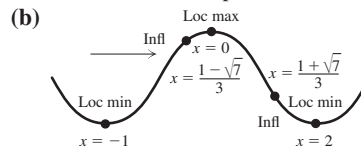

41. (a) $t = 0, 6, 12$ (b) $t = 3, 9$ (c) $6 < t < 12$
 (d) $0 < t < 6, 12 < t < 14$

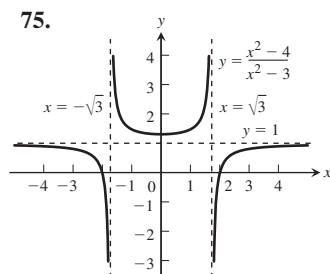

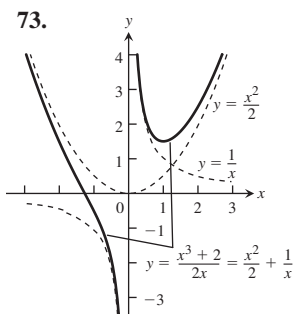

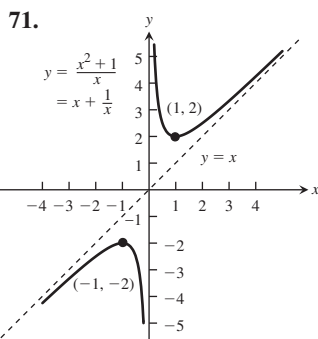

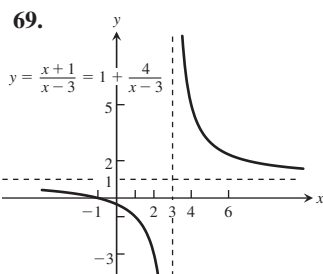

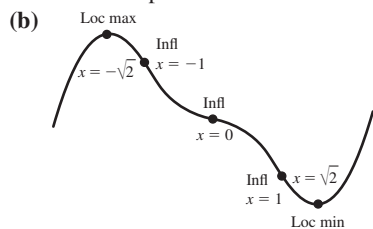

59. (a) Local maximum at $x = 4$, local minimum at $x = -4$, inflection point at $x = 0$

61. (a) Local maximum at $x = 0$, local minima at $x = -1$ and $x = 2$, inflection points at $x = (1 \pm \sqrt{7})/3$

63. (a) Local maximum at $x = -\sqrt{2}$, local minimum at $x = \sqrt{2}$, inflection points at $x = \pm 1$ and 0

77. 5 79. 0 81. 1 83. 3/7 85. 0 87. 1
 89. $\ln 10$ 91. $\ln 2$ 93. 5 95. $-\infty$ 97. 1 99. e^{bk}
 101. $-\infty$ 103. (a) 0, 36 (b) 18, 18 105. 54 square units
 107. height = 2, radius = $\sqrt{2}$
 109. $x = 5 - \sqrt{5}$ hundred ≈ 276 tires,
 $y = 2(5 - \sqrt{5})$ hundred ≈ 553 tires
 111. Dimensions: base is 15 cm by 30 cm,
 height = 5 cm; maximum volume = 2250 cm^3
 113. $x_5 = 2.195823345$ 115. $\frac{x^4}{4} + \frac{5}{2}x^2 - 7x + C$
 117. $2t^{3/2} - \frac{4}{t} + C$ 119. $-\frac{1}{r+5} + C$
 121. $(\theta^2 + 1)^{3/2} + C$ 123. $\frac{1}{3}(1 + x^4)^{3/4} + C$
 125. $10 \tan \frac{s}{10} + C$ 127. $-\frac{1}{\sqrt{2}} \csc \sqrt{2} \theta + C$
 129. $\frac{1}{2}x - \sin \frac{x}{2} + C$ 131. $3 \ln x - \frac{x^2}{2} + C$
 133. $\frac{1}{2}e^t + e^{-t} + C$ 135. $\frac{\theta^{2-\pi}}{2-\pi} + C$
 137. $\frac{3}{2} \operatorname{arcsec} |x| + C$ 139. $y = x - \frac{1}{x} - 1$

141. $r = 4t^{5/2} + 4t^{3/2} - 8t$
 143. Yes, $\arcsin x$ and $-\arccos x$ differ by the constant $\pi/2$.
 145. $1/\sqrt{2}$ units long by $1/\sqrt{e}$ units high,
 $A = 1/\sqrt{2e} \approx 0.43$ units²
 147. Absolute maximum = 0 at $x = e/2$,
 absolute minimum = -0.5 at $x = 0.5$
 149. $x = \pm 1$ are the critical points; $y = 1$ is a horizontal asymptote
 in both directions; absolute minimum value of the function
 is $e^{-\sqrt{2}/2}$ at $x = -1$, and absolute maximum value is $e^{\sqrt{2}/2}$
 at $x = 1$.
 151. (a) Absolute maximum of $2/e$ at $x = e^2$, inflection point
 $(e^{8/3}, (8/3)e^{-4/3})$, concave up on $(e^{8/3}, \infty)$, concave down
 on $(0, e^{8/3})$
 (b) Absolute maximum of 1 at $x = 0$, inflection
 points $(\pm 1/\sqrt{2}, 1/\sqrt{e})$, concave up on
 $(-\infty, -1/\sqrt{2}) \cup (1/\sqrt{2}, \infty)$, concave down on
 $(-1/\sqrt{2}, 1/\sqrt{2})$
 (c) Absolute maximum of 1 at $x = 0$, inflection point $(1, 2/e)$,
 concave up on $(1, \infty)$, concave down on $(-\infty, 1)$

ADDITIONAL AND ADVANCED EXERCISES, pp. 308–311

1. The function is constant on the interval.
 3. The extreme points will not be at the end of an open interval.
 5. NA
 9. No 11. $a = 1, b = 0, c = 1$ 13. Yes
 15. Drill the hole at $y = h/2$.
 17. $r = \frac{RH}{2(H-R)}$ for $H > 2R$, $r = R$ if $H \leq 2R$
 19. $\frac{12}{5}$ and 5
 21. (a) $\frac{10}{3}$ (b) $\frac{5}{3}$ (c) $\frac{1}{2}$ (d) 0 (e) $-\frac{1}{2}$ (f) 1

47. $\frac{5}{6} + \frac{6n+1}{6n^2}, \frac{5}{6}$

SECTION 5.3, pp. 338–341

1. $\int_0^2 x^2 dx$ 3. $\int_{-7}^5 (x^2 - 3x) dx$ 5. $\int_2^3 \frac{1}{1-x} dx$
 7. $\int_{-\pi/4}^0 \sec x dx$
 9. (a) 0 (b) -8 (c) -12 (d) 10 (e) -2 (f) 16
 11. (a) 5 (b) $5\sqrt{3}$ (c) -5 (d) -5
 13. (a) 4 (b) -4 15. Area = 21 square units
 17. Area = $9\pi/2$ square units 19. Area = 2.5 square units
 21. Area = 3 square units 23. $b^2/4$ 25. $b^2 - a^2$
 27. (a) 2π (b) π 29. $1/2$ 31. $3\pi^2/2$ 33. $7/3$
 35. $1/24$ 37. $3a^2/2$ 39. $b/3$ 41. -14
 43. -2 45. $-7/4$ 47. 7 49. 0
 51. Using n subintervals of length $\Delta x = b/n$ and right-endpoint values:

$$\text{Area} = \int_0^b 3x^2 dx = b^3$$

53. Using
- n
- subintervals of length
- $\Delta x = b/n$
- and right-endpoint values:

$$\text{Area} = \int_0^b 2x dx = b^2$$

55. $\text{av}(f) = 0$ 57. $\text{av}(f) = -2$ 59. $\text{av}(f) = 1$
 61. (a) $\text{av}(g) = -1/2$ (b) $\text{av}(g) = 1$ (c) $\text{av}(g) = 1/4$
 63. $c(b-a)$ 65. $b^3/3 - a^3/3$ 67. 9
 69. $b^4/4 - a^4/4$ 71. $a = 0$ and $b = 1$ maximize the integral.
 73. Upper bound = 1, lower bound = $1/2$

75. For example, $\int_0^1 \sin(x^2) dx \leq \int_0^1 dx = 1$

77. $\int_a^b f(x) dx \geq \int_a^b 0 dx = 0$ 79. Upper bound = $1/2$

89. Since f is continuous, the Extreme Value Theorem implies that the continuous function f has a maximum value M and a minimum value m (Chapter 4, Theorem 1). The values of f and g are equal except at a single point c where $g(c)$ differs from $f(c)$. The magnitude of the difference is some number between the two numbers $|g(c) - m|$ and $|g(c) - M|$. Call the larger of these two numbers D . In the formula for a Riemann sum given in Equation (1), for a given n , the difference between the Riemann sum for f and the

Riemann sum for g is at most $D(b - a)/n$. Taking the limit as $n \rightarrow \infty$, we see that the difference between the two Riemann sums approaches 0, so that the two limits are equal. A similar bound holds for a general partition, where $D\|P\| \rightarrow 0$.

SECTION 5.4, pp. 351–353

1. $-10/3$ 3. $124/3$ 5. $753/16$ 7. 1 9. $2\sqrt{3}$
 11. 0 13. $-\pi/4$ 15. $1 - \frac{\pi}{4}$ 17. $\frac{2 - \sqrt{2}}{4}$ 19. $-8/3$
 21. $-3/4$ 23. $\sqrt{2} - \sqrt[4]{8} + 1$ 25. $1/2$ 27. 16
 29. $7/3$ 31. $2\pi/3$ 33. $\frac{1}{\pi}(4\pi - 2\pi)$ 35. $\frac{1}{2}(e - 1)$
 37. $\sqrt{26} - \sqrt{5}$ 39. $(\cos \sqrt{x})\left(\frac{1}{2\sqrt{x}}\right)$ 41. $4t^5$
 43. $3x^2e^{-x^3}$ 45. $\sqrt{1 + x^2}$ 47. $-\frac{1}{2}x^{-1/2} \sin x$ 49. 0
 51. 1 53. $2xe^{(1/2)x^2}$ 55. 1 57. $28/3$ 59. $1/2$
 61. π 63. $\frac{\sqrt{2}\pi}{2}$
 65. d, since $y' = \frac{1}{x}$ and $y(\pi) = \int_{\pi}^{\pi} \frac{1}{t} dt - 3 = -3$
 67. b, since $y' = \sec x$ and $y(0) = \int_0^0 \sec t dt + 4 = 4$
 69. $y = \int_2^x \sec t dt + 3$ 71. $(1 + \ln t)^2$
 73. $\frac{2}{3}bh$ 75. \$9.00
 77. (a) $T(0) = 20^\circ\text{C}$, $T(16) = 24^\circ\text{C}$, $T(25) = 30^\circ\text{C}$
 (b) $\text{av}T = 23.33^\circ\text{C}$
 79. $2x - 2$ 81. $-3x + 5$
 83. (a) True. Since f is continuous, g is differentiable by Part 1 of the Fundamental Theorem of Calculus.
 (b) True: g is continuous because it is differentiable.
 (c) True, since $g'(1) = f(1) = 0$.
 (d) False, since $g''(1) = f'(1) > 0$.
 (e) True, since $g'(1) = 0$ and $g''(1) = f'(1) > 0$.
 (f) False: $g''(x) = f'(x) > 0$, so g'' never changes sign.
 (g) True, since $g'(1) = f(1) = 0$ and $g'(x) = f(x)$ is an increasing function of x (because $f'(x) > 0$).
 85. (a) $v = \frac{ds}{dt} = \frac{d}{dt} \int_0^t f(x) dx = f(t) \Rightarrow v(5) = f(5) = 2 \text{ m/s}$
 (b) $a = df/dt$ is negative, since the slope of the tangent line at $t = 5$ is negative.
 (c) $s = \int_0^3 f(x) dx = \frac{1}{2}(3)(3) = \frac{9}{2} \text{ m}$, since the integral is the area of the triangle formed by $y = f(x)$, the x -axis, and $x = 3$.
 (d) $t = 6$, since after $t = 6$ to $t = 9$, the region lies below the x -axis.
 (e) At $t = 4$ and $t = 7$, since there are horizontal tangents there.
 (f) Toward the origin between $t = 6$ and $t = 9$, since the velocity is negative on this interval. Away from the origin between $t = 0$ and $t = 6$, since the velocity is positive there.
 (g) Right or positive side, because the integral of f from 0 to 9 is positive, there being more area above the x -axis than below.

SECTION 5.5, pp. 360–361

 69. Yes 71. Converges absolutely

SECTION 9.6, pp. 583–585

1. Converges by Alternating Series Test
 3. Converges; Alternating Series Test
 5. Converges; Alternating Series Test
 7. Diverges; $a_n \not\rightarrow 0$
 9. Diverges; $a_n \not\rightarrow 0$
 11. Converges; Alternating Series Test
 13. Converges by Alternating Series Test
 15. Converges absolutely. Series of absolute values is a convergent geometric series.
 17. Converges conditionally; $1/\sqrt{n} \rightarrow 0$ but $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ diverges.
 19. Converges absolutely; compare with $\sum_{n=1}^{\infty} (1/n^2)$.
 21. Converges conditionally; $1/(n+3) \rightarrow 0$ but $\sum_{n=1}^{\infty} \frac{1}{n+3}$ diverges (compare with $\sum_{n=1}^{\infty} (1/n)$).
 23. Diverges; $\frac{3+n}{5+n} \rightarrow 1$
 25. Converges conditionally; $\left(\frac{1}{n^2} + \frac{1}{n}\right) \rightarrow 0$ but $(1+n)/n^2 > 1/n$
 27. Converges absolutely; Ratio Test
 29. Converges absolutely by Integral Test
 31. Diverges; $a_n \not\rightarrow 0$
 33. Converges absolutely by Ratio Test
 35. Converges absolutely, since $\left|\frac{\cos n\pi}{n\sqrt{n}}\right| = \left|\frac{(-1)^{n+1}}{n^{3/2}}\right| = \frac{1}{n^{3/2}}$ (convergent p -series)
 37. Converges absolutely by Root Test
 39. Diverges; $a_n \rightarrow \infty$
 41. Converges conditionally;
 $\sqrt{n+1} - \sqrt{n} = 1/(\sqrt{n} + \sqrt{n+1}) \rightarrow 0$, but series of absolute values diverges (compare with $\sum (1/\sqrt{n})$).
 43. Diverges, $a_n \rightarrow 1/2 \neq 0$
 45. Converges absolutely;
 $\operatorname{sech} n = \frac{2}{e^n + e^{-n}} = \frac{2e^n}{e^{2n} + 1} < \frac{2e^n}{e^{2n}} = \frac{2}{e^n}$, a term from a convergent geometric series.
 47. Converges conditionally; $\sum (-1)^{n+1} \frac{1}{2(n+1)}$ converges by Alternating Series Test; $\sum \frac{1}{2(n+1)}$ diverges by limit comparison with $\sum (1/n)$.
 49. |Error| < 0.2 51. |Error| < 2×10^{-11}
 53. $n \geq 31$ 55. $n \geq 4$ 57. Converges; Root Test

 $\mathbf{r}(t) = (x(t))\mathbf{i} + (y(t))\mathbf{j}$, where $x(t) = (12 \cos 27^\circ)t$ and
 $y(t) = 1.3 + (12 \sin 27^\circ)t - 4.9t^2$.

- (b) At $t \approx 0.556$ s, it reaches its maximum height of about 2.814 m.

- (c) Range ≈ 14 m; flight time ≈ 1.31 s

- (d) At $t \approx 0.232$ and $t \approx 0.880$ s, when it is ≈ 11.52 and ≈ 4.59 m from where it will land

- (e) Yes. It changes things because the ball won't clear the net.

39. Height is about 10.8 m.

47. (a) $\mathbf{r}(t) = (x(t))\mathbf{i} + (y(t))\mathbf{j}$; where

$$x(t) = \left(\frac{1}{0.08}\right)(1 - e^{-0.08t})(50 \cos 20^\circ - 5) \text{ and}$$

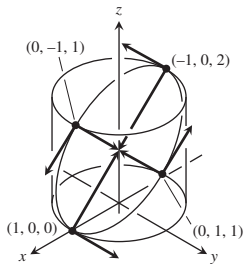

$$y(t) = 1 + \left(\frac{50}{0.08}\right)(1 - e^{-0.08t})(\sin 20^\circ)$$

$$+ \left(\frac{9.8}{0.08^2}\right)(1 - 0.08t - e^{-0.08t})$$

- (b) At $t \approx 1.633$ s, it reaches a maximum height of about 14.66 m.
 (c) Range ≈ 125.11 m; flight time ≈ 3.404 s
 (d) At $t \approx 0.670$ and 2.622 s, when it is about 27.39 and 99.30 m from home plate
 (e) No

101. $\frac{3M}{\pi R^3}$

103. The surface's equation $r = f(z)$ tells us that the point $(r, \theta, z) = (f(z), \theta, z)$ will lie on the surface for all θ . In particular, $(f(z), \theta + \pi, z)$ lies on the surface whenever $(f(z), \theta, z)$ lies on the surface, so the surface is symmetric with respect to the z -axis.

15. $y(\text{exact}) = -x^2, y_1 = -2, y_2 = -3.3333, y_3 = -5$
 17. $y(\text{exact}) = 3e^{x(x+2)}, y_1 = 4.2, y_2 = 6.216, y_3 = 9.697$
 19. $y(\text{exact}) = e^{x^2} + 1, y_1 = 2.0, y_2 = 2.0202, y_3 = 2.0618$
 21. $y \approx 2.48832$; exact value is e .
 23. $y \approx -0.2272$; exact value is $1/(1 - 2\sqrt{5}) \approx -0.2880$.
 27.

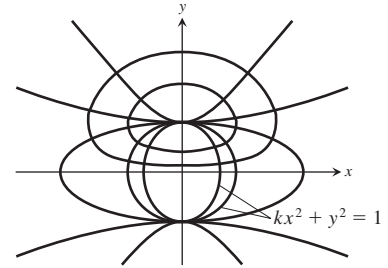

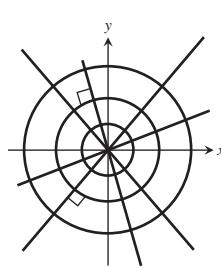

39. Euler's method gives $y \approx 3.45835$; the exact solution is $y = 1 + e \approx 3.71828$.
 41. $y \approx 1.5000$; exact value is 1.5275.

SECTION 16.2, pp. 1036-1038

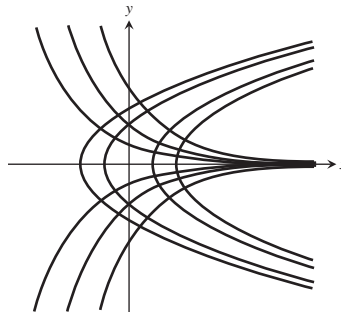

1. $y = \frac{e^x + C}{x}, x > 0$ 3. $y = \frac{C - \cos x}{x^3}, x > 0$
 5. $y = \frac{1}{2} - \frac{1}{x} + \frac{C}{x^2}, x > 0$ 7. $y = \frac{1}{2}xe^{x/2} + Ce^{x/2}$
 9. $y = x(\ln x)^2 + Cx$
 11. $s = \frac{t^3}{3(t-1)^4} - \frac{t}{(t-1)^4} + \frac{C}{(t-1)^4}$
 13. $r = (\csc \theta)(\ln|\sec \theta| + C), 0 < \theta < \pi/2$
 15. $y = \frac{3}{2} - \frac{1}{2}e^{-2t}$ 17. $y = -\frac{1}{\theta} \cos \theta + \frac{\pi}{2\theta}$
 19. $y = 6e^{x^2} - \frac{e^{x^2}}{x+1}$ 21. $y = y_0 e^{kt}$
 23. (b) is correct, but (a) is not. 25. $t = \frac{L}{R} \ln 2$ sec
 27. (a) $i = \frac{V}{R} - \frac{V}{R}e^{-3} = \frac{V}{R}(1 - e^{-3}) \approx 0.95 \frac{V}{R}$ amp (b) 86%
 29. $y = \frac{1}{1 + Ce^{-x}}$ 31. $y^3 = 1 + Cx^{-3}$

SECTION 16.3, pp. 1043-1044

1. (a) 168.5 m (b) 41.13 s
 3. $s(t) = 4.91(1 - e^{-(22.36/39.92)t})$
 5. $x^2 + y^2 = C$ 7. $\ln|y| - \frac{1}{2}y^2 = \frac{1}{2}x^2 + C$

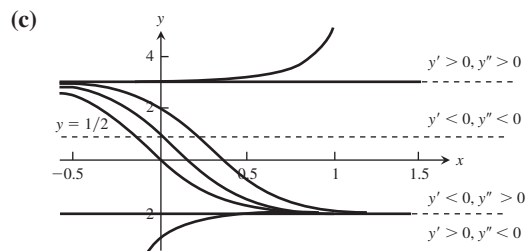

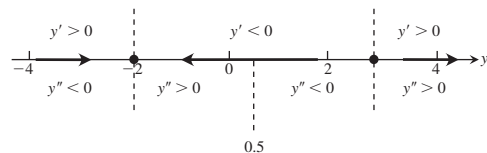

9. $y = \pm\sqrt{2x + C}$

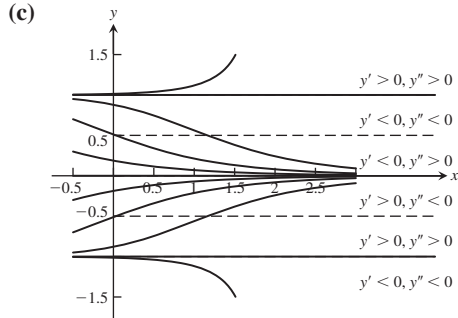

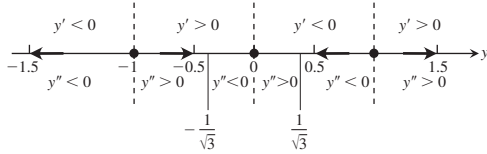

13. (a) 4 kg/min (b) $(400 + 4t)$ L (c) $4\left(\frac{y}{100 + t}\right)$ kg/min
 (d) $\frac{dy}{dt} = 4 - \frac{4y}{100 + t}, y(0) = 20,$
 $y = 0.8(100 + t) - \frac{60}{\left(1 + \frac{t}{100}\right)^4}$
 (e) Concentration = $\frac{y(25)}{\text{amt. brine in tank}}$
 $= \frac{75.424}{500} \approx 0.151$ kg/L
 15. $y(27.8) \approx 5.93$ kg, $t \approx 27.8$ min

SECTION 16.4, pp. 1052-1053

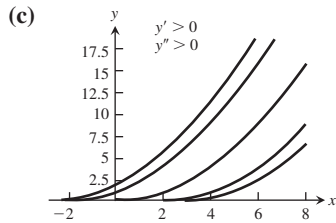

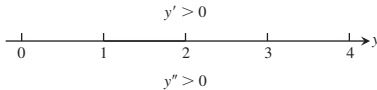

1. $y' = (y + 2)(y - 3)$
 (a) $y = -2$ is a stable equilibrium value, and $y = 3$ is an unstable equilibrium value.
 (b) $y'' = 2(y + 2)\left(y - \frac{1}{2}\right)(y - 3)$

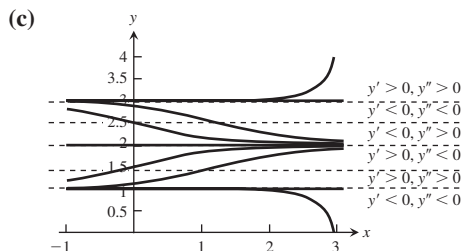

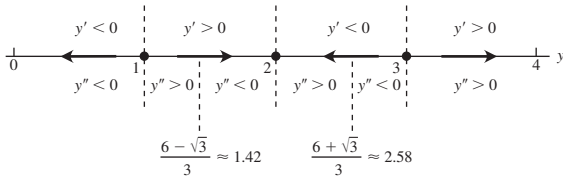

3. $y' = y^3 - y = (y + 1)y(y - 1)$
 (a) $y = -1$ and $y = 1$ are unstable equilibria, and $y = 0$ is a stable equilibrium.
 (b) $y'' = (3y^2 - 1)y'$
 $= 3(y + 1)(y + 1/\sqrt{3})y(y - 1/\sqrt{3})(y - 1)$

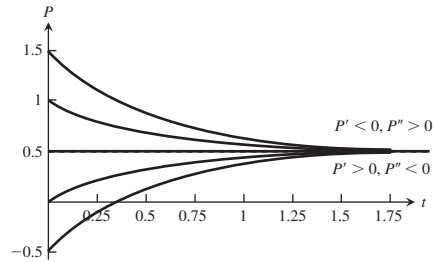

5. $y' = \sqrt{y}, y > 0$
 (a) There are no equilibrium values.
 (b) $y'' = \frac{1}{2}$

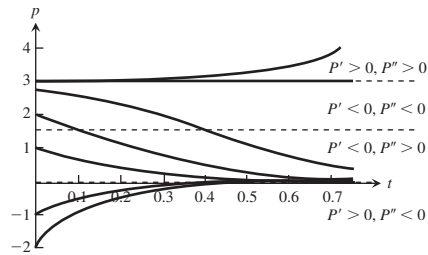

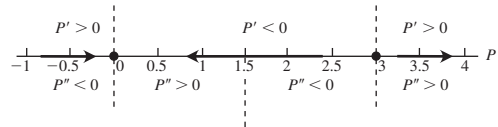

7. $y' = (y - 1)(y - 2)(y - 3)$
 (a) $y = 1$ and $y = 3$ are unstable equilibria, and $y = 2$ is a stable equilibrium.
 (b) $y'' = (3y^2 - 12y + 11)(y - 1)(y - 2)(y - 3) = 3(y - 1)\left(y - \frac{6 - \sqrt{3}}{3}\right)(y - 2)\left(y - \frac{6 + \sqrt{3}}{3}\right)(y - 3)$

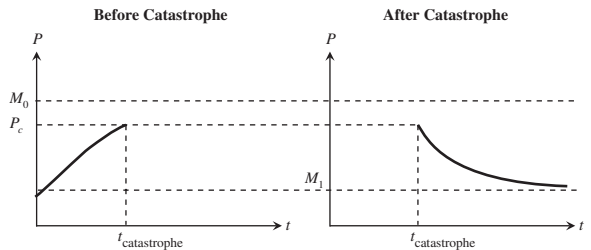

9. $\frac{dP}{dt} = 1 - 2P$ has a stable equilibrium at $P = \frac{1}{2}$;
 $\frac{d^2P}{dt^2} = -2\frac{dP}{dt} = -2(1 - 2P)$.

11. $\frac{dP}{dt} = 2P(P - 3)$ has a stable equilibrium at $P = 0$ and an unstable equilibrium at $P = 3$; $\frac{d^2P}{dt^2} = 2(2P - 3)\frac{dP}{dt} = 4P(2P - 3)(P - 3)$.

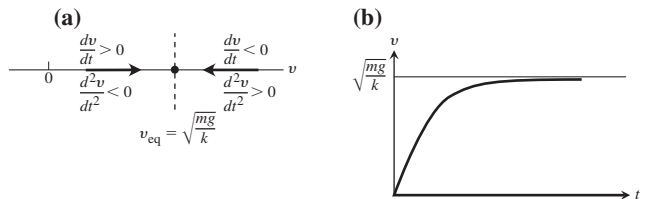

13. Before the catastrophe, the population exhibits logistic growth and $P(t)$ increases toward M_0 , the stable equilibrium. After the catastrophe, the population declines logistically and $P(t)$ decreases toward M_1 , the new stable equilibrium.

15. $\frac{dv}{dt} = g - \frac{k}{m}v^2$, $g, k, m > 0$ and $v(t) \geq 0$

Equilibrium: $\frac{dv}{dt} = g - \frac{k}{m}v^2 = 0 \Rightarrow v = \sqrt{\frac{mg}{k}}$

Concavity: $\frac{d^2v}{dt^2} = -2\left(\frac{k}{m}v\right)\frac{dv}{dt} = -2\left(\frac{k}{m}v\right)\left(g - \frac{k}{m}v^2\right)$

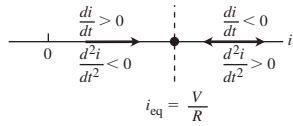

- (c) $v_{\text{terminal}} = \sqrt{\frac{441}{0.2}} = 46.96 \text{ m/s} = 169 \text{ km/h}$ for the 45-kg skydiver
 $v_{\text{terminal}} = \sqrt{\frac{7.84}{0.2}} = 62.6 \text{ m/s} = 225 \text{ km/h}$ for the 80-kg skydiver

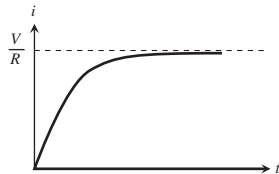

17. $F = F_p - F_f; ma = 50 - 5|v|; \frac{dv}{dt} = \frac{1}{m}(50 - 5|v|).$

The maximum velocity occurs when $\frac{dv}{dt} = 0$, or $v = 4$ m/s.

19. Phase line:

If the switch is closed at $t = 0$, then $i(0) = 0$, and the graph of the solution looks like this:

As $t \rightarrow \infty, i(t) \rightarrow i_{\text{steady state}} = \frac{V}{R}.$

21. $y = \frac{1}{1 + e^{-20x}}.$

SECTION 16.5, pp. 1056–1059

- Seasonal variations, nonconformity of the environments, effects of other interactions, unexpected disasters, etc.
- This model assumes that the number of interactions is proportional to the product of x and y :

$$\frac{dx}{dt} = (a - by)x, \quad a < 0,$$

$$\frac{dy}{dt} = m\left(1 - \frac{y}{M}\right)y - nxy = y\left(m - \frac{m}{M}y - nx\right).$$

Rest points are $(0, 0)$, unstable, and $(0, M)$, stable.

- (a) Logistic growth occurs in the absence of the competitor, and involves a simple interaction between the species. Growth dominates the competition when either population is small, so it is difficult to drive either species to extinction.

- a : per capita growth rate for trout
 - m : per capita growth rate for bass
 - b : intensity of competition to the trout
 - n : intensity of competition to the bass
 - k_1 : environmental carrying capacity for the trout
 - k_2 : environmental carrying capacity for the bass
 - $\frac{a}{b}$: growth versus competition or net growth of trout
 - $\frac{m}{n}$: relative survival of bass

(c) $\frac{dx}{dt} = 0$ when $x = 0$ or $y = \frac{a}{b} - \frac{a}{bk_1}x,$

$$\frac{dy}{dt} = 0 \text{ when } y = 0 \text{ or } y = k_2 - \frac{k_2n}{m}x.$$

By picking $a/b > k_2$ and $m/n > k_1$, we ensure that an equilibrium point exists inside the first quadrant.

PRACTICE EXERCISES, pp. 1059–1060

- $y = -\ln\left(C - \frac{2}{5}(x-2)^{5/2} - \frac{4}{3}(x-2)^{3/2}\right)$
- $\tan y = -x \sin x - \cos x + C$
- $(y+1)e^{-y} = -\ln|x| + C$

7. $y = C \frac{x-1}{x}$ 9. $y = \frac{x^2}{4}e^{x/2} + Ce^{x/2}$

11. $y = \frac{x^2 - 2x + C}{2x^2}$ 13. $y = \frac{e^{-x} + C}{1 + e^x}$ 15. $xy + y^3 = C$

17. $\tan y = -\cos x + (1/3)\cos^3 x + C$

19. $e^{x^2}y = (x-1)e^x + C$

21. $\ln|\ln y| = (1/2)x^2 \ln x - (1/4)x^2 + C$

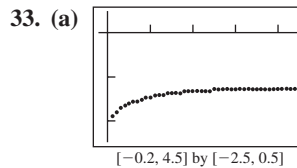

23. $y = \frac{2x^3 + 3x^2 + 6}{6(x+1)^2}$ 25. $y = \frac{1}{3}(1 - 4e^{-x^3})$

27. $y = e^{-x}(3x^3 - 3x^2)$

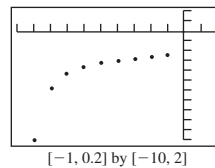

29.

x	y	x	y
0	0	1.1	1.6241
0.1	0.1000	1.2	1.8319
0.2	0.2095	1.3	2.0513
0.3	0.3285	1.4	2.2832
0.4	0.4568	1.5	2.5285
0.5	0.5946	1.6	2.7884
0.6	0.7418	1.7	3.0643
0.7	0.8986	1.8	3.3579
0.8	1.0649	1.9	3.6709
0.9	1.2411	2.0	4.0057
1.0	1.4273		

31. $y(3) \approx 0.9131$

- Note that we choose a small interval of x values because the y values decrease very rapidly and our calculator cannot handle the calculations for $x \leq -1$. (This occurs because the analytic solution is $y = -2 + \ln(2 - e^{-x})$, which has an asymptote at $x = -\ln 2 \approx -0.69$. Obviously, the Euler approximations are misleading for $x \leq -0.7$.)

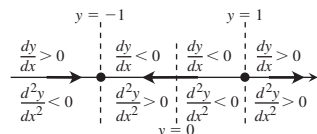

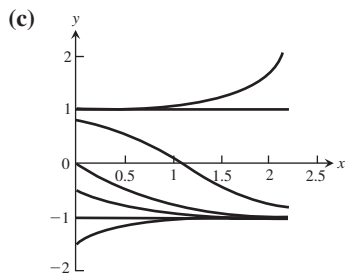

35. $y(\text{exact}) = \frac{1}{2}x^2 - \frac{3}{2}; y(2) \approx 0.4; \text{exact value is } \frac{1}{2}.$

37. $y(\text{exact}) = -e^{(x^2-1)/2}; y(2) \approx -3.4192; \text{exact value is } -e^{3/2} \approx -4.4817.$

39. (a) $y = -1$ is stable and $y = 1$ is unstable.

(b) $\frac{d^2y}{dx^2} = 2y \frac{dy}{dx} = 2y(y^2 - 1)$

43. (a) 1 min: 608 L; 10 min: 680 L; 60 min: 1080 L
 (b) $S(1) \approx 11.76$ kg, $S(10) \approx 57.89$ kg, $S(60) \approx 225.56$ kg

ADDITIONAL AND ADVANCED EXERCISES, p. 1061

1. (a) $y = c + (y_0 - c)e^{-k(A/V)t}$
 (b) Steady-state solution: $y_\infty = c$
 5. $x^2(x^2 + 2y^2) = C$
 7. $\ln|x| + e^{-y/x} = C$
 9. $\ln|x| - \ln|\sec(y/x - 1) + \tan(y/x - 1)| = C$

Appendices

 of a palm tree, 352
 of a paper clip shot into the air, 232
 of a pole, 69
 of a rocket, 1061
 of a weather balloon, 69
- Highway patrol plane, 214
- Impedance in a series circuit, 230
- Industrial costs, 33
- Inertia, moments of, 895–897
- Inflating balloon, 170, 206
- Inner product, 19–15–19–16
- Intensity of illumination, 286
- Kinetic energy
 and potential energy, 33
 and work, 417–418, 434
- Length
 of airplane gasoline tank, 518–519
 of an asteroid, 404
 of an object, 135
 of a beam, 843
 of curves, 400–401, 403–405, 433
 of a fish, 472
 of a graph, 401
 of a ladder carried around a corner, 307
 of a line segment, 404
 of a rocket, 135
- Lighthouse beam, 214
- Linearizations, 226, 231
- Locating a planet, 293
- Mass, 893–895
- Maximum volume
 of a box, 277, 307
 of a can, 278, 821
- Measuring cup stripes, 135
- Melting ice layer, 214
- Minimizing perimeter, 282
- Motion
 of an object along a line, 267
 of a beam, 214
 of a body along a line, 168, 169
 coasting battleship, 1043
 coasting bicycle, 1043
 with constant acceleration, 304
 damped, 17–17–17–18
- of a helicopter, 707–708
- of a model rocket, 168
- of a particle, 168, 169, 213, 230, 232, 286, 303, 307
- in the plane, 213
- of a projectile, 167, 286, 321, 740–742
- of a vehicle, 213
- Moving shadow, 213
- Norm of a function, 19–13–19–14
- Ohm's law for electrical circuits, 97
- Oil consumption rate, 519
- Oil slick spread, 214
- Orthogonal trajectory of curves, 1040–1041
- Osculating circle, 232
- Parametrization
 of a cone, 974
 of a cylinder, 974
 of a sphere, 974
- Particle motion, 167, 183, 209, 213, 303, 307
- Path
 of a ball, 738–739, 741
 of a baseball player, 214
 of a football, 309
 of a glider, 735–736, 743
 of a heat-seeking particle, 857
 of a javelin, 763
 of a projectile, 737–738, 740–741
 of a shot-put throw, 741
 of a water skier, 496
- Periodic functions, 19–1–19–2
- Planetary orbits, 669
- Pressure of fluid at bottom of dam, 414
- Pressure waves produced by tuning fork, 24
- Projectile motion, 167, 321, 698, 740–742, 763
- Pumping oil to the rim of the tank, 413
- Quadratic approximations, 225–226
- Quickest route, 286
- Radioactive decay rate, 53, 54, 66, 452–453, 456
- Radius
 increase of raindrop, 212
 of inflating balloon, 212
- Radon-238 decay, 66
- Reservoir water, 305
- Resistors connected in parallel, 230, 789
- Resultant force, 686–687
- Rolle's Theorem, 249
- Rotating spool speed, 230
- Satellite orbit, 418
- Searchlight beam motion, 231
- Shortest beam, 286
- Skaters stopping distances, 1039, 1043–1044, 1060
- Skylab 24 view, 764
- Sliding ladder, 211–212
- Sonobuoy submarine location, 294
- Specific heat of a gas, 375
- Speed
 of aircraft approaching island, 209–210
- of a frictionless cart, 286
- of a marathoner, 249
- of object dropped from tower, 141
- during parachute jump, 232
- of particle, 230, 232
- of a rocket, 141
- of rotating spool, 230
- of ships moving apart, 214
- underwater transmission cable, 308
- of a vehicle, 78, 208, 249
- velocity and, 162–163
- of warship, 249
- Speed of light, 279–280
- Spring's force constant, 416
- Standard unit vectors, 19–7, 19–11
- Stopping distance, 303
- Stream flow, 810
- Stretching a rubber band, 106, 416
- Submarine intercept, 722
- Surface area, 509
 of an asteroid, 410
 of an oil spill, 214
 of a cone, 230, 231, 409, 976
 cut from bottom of paraboloid, 979–980
 of an infinite paint can or Gabriel's horn, 530
 of a melting ice cube, 234
 of a right circular cylinder, 230
 of sliced bread, 410
 of a sphere, 211, 977
 of a torus, 429, 982
 of Weather Service dome, 409
 of a wok, 409
- Suspension bridge cables, 662
- Temperature
 air, 375
 below Earth's surface, 772
 in Fairbanks, Alaska, 183
 greatest, 939
 mean, 532
 and period of a pendulum, 183
 rate of change, 149, 249
 of a room, 352
- Thermal expansion in laboratory equipment, 135
- Tin pest, 287
- Tolerance, 225
- Torque, 702–704, 722
- Underwater transmission cable
 speed, 308
- Vectors, 19–7, 19–11
- Vehicular stopping distance, 169–170
- Velocity
 after ricochet, 858
 average and instantaneous, 233
 displacement from an antiderivative of, 303
 of falling meteorite, 183
 fields, fluid, 944–945, 966
 of moving object, 178
 of a particle, 233
 of particle moving along a horizontal line, 162–163, 168
 in a resisting medium, 1038–1039
- of a rocket, 168
- of a skydiver, 464
- of two particles, 232
- Velocity and acceleration, 164–165, 361
 of a piston, 182
 of weight on spring, 172–173, 175
- Vertical motion, 286
- Vertical spring with weight, 172–173
- Vibrating springs, 17–15–17–16
- Videotaping a moving car, 213
- Volcanic lava fountains, 170
- Voltage changes, 211, 455, 804–805
- Volume, 191, 464
 of an ice cream cone, 909–910
 of a ball, 141
 of a balloon, 39
 of a bowl, 390
 of a box, 33
 of a Bundt cake, 398
 of a football, 432
 of gasoline tanks, 509–510
 of a hemisphere, 390
 of material in a cylindrical shell, 225
 of noncircular right cylinder, 882
 of a pipeline, 855
 of a pyramid, 388
 of a right circular cone, 211
 of right prism, 866
 of a solid, 380–400
 of a solid region, 880
 of a solid sphere hole, 432
 of storage tank for molasses, 821
 of a swamp, 517
 of a tetrahedron, 888
 of a torus (doughnut), 390, 428
 of a trough, 284
 using cylindrical shells, 391–396
 of water in swimming pool, 518
 of a wedge, 434
 of a wedgelike solid beneath surface, 869–870
- Water flow, 135
- Water main, 697–698
- Wave equations, 795
- Weight on a pulley, 210
- Wind chill factor, 823
- Work
 along different paths, 960
 to carry water up mountain in a leaky tank, 433
 to compress a bathroom scale, 416
 done by a force field, 943–944
 done by a jack, 311
 done by a locomotive, 699
 done by the conservative field, 954
 done in lifting a bucket and rope, 412–413
 to fill a water tower, 418
 to haul up a rope, 416, 433
 and kinetic energy, 417–418, 434
 lifting a bag of sand, 416
 lifting an elevator cable, 416
 lifting water in a leaking bucket, 416
 to move electrons, 418
 to pump a reservoir, 433

- to pump a tank, 433
 - to pump liquids from containers, 416–417
 - to pump oil to the rim of a tank, 413
 - to put a satellite in orbit, 418
 - required to compress a spring, 412, 416
 - to stretch a spring, 416, 433
 - to suck milkshake through a straw, 417–418

 difference rules for (*See under* Differentiation)
- differentials and, 218–223
- directional (*See* Directional derivatives)
- in direction of vectors, 728–729
- Dot Product Rule, 730
- in economics, 165–167
- First Derivative Test for Local Extreme Values (General Version), B-8
- of functions, 139, 142–151
 cosecant, 173–174
 cosine, 171–172
 cotangent, 173–174
 definition of, 142–143
 differentiable (*See* Differentiable functions)
 exponential, 154–155
 extreme values of, on closed intervals, 235–243
 f at a point x_0 , 139
 graphical behavior of, 263–264
 hyperbolic, 458–462
 inverse, 189–191
 monotonic, and the first derivative test, 250–255
 natural exponential, 438, 440–441
 natural logarithm, 192
 negative, 153
 with no derivative at a point, 146
 reciprocal, 143
 recovering, from its derivative, 148
 secant, 173–174
 sine, 170–171
 trigonometric, 170–176, 200–206
 u and v for denoting, 153
 vector, 727–729
- General Power Rule for, 152, 195–197
 graphing, 144–145
 higher-order, 158
 history of, 142
 implicit differentiation and, 184–189
 as instantaneous rate of change, 140, 161–162
 intermediate forms and
 l'Hôpital's Rule, 268–276
 involving $\log_a x$, 444–445
 in irrational exponents and the Power Rule, 195–197
 left-hand, 145–146
 Leibniz's Rule, 233–234, 377
 linearization and, 214–217
 in logarithmic differentiation, 195
 Mean Value Theorem in, 245–249
- Mixed Derivative Theorem, AP-31–AP-32, 790–791
 motion and, 727–729
 Newton's dot notation for, 756
 Newton's method in, 289–294
 notations for, 144
 n th, 158
 number e expressed as a limit and, 197
 one-sided, 145–146
 partial (*See* Partial derivatives) at a point, 138–142
 rates of change and, 139–140
 of a positive integer power, 151
 of power series, 592
 as a rate of change, 161–170
 of related rates, 206–214
 right-hand, 145–146
 Rolle's Theorem in, 243–244
 second, 158
- Second Derivative Test for Local Extreme Values (General Version), B-9
 of the sine function, 170–171
 of the square root function, 144, 146, 191
 symbols for, 158
 of the tangent function, 173–174
 tangent lines and, 138–142
 definition of, 138
 finding, to graph a function, 138–139
 slope of, 138–139, 144
 of tangent vector, 748
 third, 158
 of trigonometric functions, 170–176
 as velocity, 162, 729
 of a^x and $\log_a x$, 193–194
- Derivative Sum Rule, AP-12–AP-13, 153–154, 171
- Descartes, René, AP-14, 184, 188
- Determinants, B-1–B-6
 absolute value of, 704
 calculating a cross product as, 701–702
 calculating the triple scalar product as, 703–704
 cofactors in, B-2–B-5
 definition of, B-1
 evaluating, 701
 formula, 701
 Jacobian, 916, 920
 matrix in, B-1–B-6
 method of, 17-12
 properties of, B-5
 vector as, 703–704
- Difference. *See* Subtraction
- Difference quotient, 139–140
 definition of, 139
 forms for, 143
 limit of, 143
- Difference Rule, 82–83, 153–154, 171
 for antiderivatives, 296–297, 299
 to calculate limits of sequences, 542
 definition of, 153

- Difference Rule (*continued*)
 for double and triple integrals, 869
 to find derivatives, 153–154, 171
 for finite sums, 324
 for gradients, 811
 for limits, AP-23
 for limits for functions of two variables, 777
 for series, 556–557
 for vector functions, 730
- Differentiability
 on an interval, 145–146
 definition of, 792–793
 for functions of several variables, 792–793
 partial derivatives and, 792–793
- Differentiable functions
 absolute maxima and minima, 239–240
 Cauchy's Mean Value Theorem, 273–274
 Chain Rule formula for
 functions of many variables, 803
 functions of three variables, 798–799
 functions of two variables, 796–798
 implicit differentiation, 802
 complex, 18–18–18-19
 continuous, 147, 407, 408, 429, 635, 638, 639
 with continuous first partial derivatives, 793
 continuously, 635
 definition of, 143, 792–793
 domain of, 810
 Extreme Value Theorem, 240
 First Derivative Test for Local Extrema, 251–253
 graphical behavior, 263–264
 increasing and decreasing functions, 250–251
 l'Hôpital's Rule, 268–274
 Mean Value Theorem, 245–246
 of more than two variables, 821–822
 negative, 153
 with no derivative at a point, 146
 on one-sided derivatives, 145–146
 optimization problems, 278, 280
 parametrized curves, 633–634
 plane tangent to the surface of, 815–817
 points of, 827
 Rolle's Theorem, 243
 rules for (*See under* Differentiation)
 Second Derivative Test for concavity, 256
 local extrema, 259–263
 twice-, 633–634
 vector functions, 728
- Differentiable Implies Continuous Theorem, 793
- Differential equations
 definition of, 297
 first-order, 1024–1061
 applications of, 1038–1043
 autonomous differential equations, 1044–1051, 1053
 autonomous systems of, 1053
 Bernoulli differential equation, 1038
 carrying capacity, 1049
 competitive-hunter model, 1054–1055
 curve, sigmoid shape of, 1050
 definition of, 1024–1025
 equilibrium values, 1044–1046
 Euler's method, 1027–1030
 Euler solution, 1029–1030
 exponential population growth model, inaccuracy of, 1039–1040
 falling body encountering resistance, 1047–1049
 first-order initial value problem, 1025–1026
 first-order linear equations, 1032–1036
 graphical solutions of
 autonomous, 1044–1051
 homogeneous, 1061
 initial value problems, 1025–1026
 integrating factor, 1033–1035
 Law of Exponential Change, 1039–1040
 limit cycle, 1056
 limiting population, 1049
 logistic equation in Neural Networks and Machine Learning, 1050–1051
 logistic growth, 1049
 logistic model for population growth, 1049–1050
 mixture problems, 1041–1043
 motion with resistance
 proportional to velocity, 1038–1039
 Newton's Law of Cooling, 1047
 Newton's second law of motion, 1038, 1048
 numerical method, 1027–1030
 numerical solution of the problem, 1027–1030
 orthogonal trajectories, 1038, 1040–1041
 particular solution, 1025–1026
 phase-plane analysis method, limitations of, 1056
 phase planes, 1053–1054
 predator-prey, 1058–1059
 resistance proportional to velocity, 1038–1039
 rest points, 1044–1046
 RL circuits, 1036
 slope fields, 1026–1027
 solution curves, 1026–1027
 solutions, 1024–1026
 standard form of linear equations, 1032–1033
 steady-state value, 1036
 systems of, 1053–1056
 terminal velocity, 355, 1049
 initial value problems and, 297
 second-order, 17-1–17-29
 applications, 17-15–17-20
 auxiliary equation, 17-3
 boundary value problems, 17-6
 boundary values, 17-6
 constant-coefficient
 homogeneous equations, 17-2–17-5
 damped motion, 17-17–17-18
 damped vibrations, 17-18
 definition of, 17-1
 electric circuits, 17-18–17-19
 Euler equations, 17-22–17-23
 general solution, 17-2
 homogeneous linear equations, 17-1
 initial conditions, 17-5
 initial value and boundary value problems, 17-5–17-6
 linear combination, 17-1
 linearly independent solutions, 17-2
 linear second-order constant-coefficient models, 17-20
 nonhomogeneous linear equations, 17-1, 17-7–17-14
 overdamping, 17-18
 power-series solutions, 17-24–17-29
 simple harmonic motion, 17-16–17-17
 superposition principle, 17-1
 trivial solution, 17-2
 underdamping, 17-18
 variation of parameters, 17-7, 17-12–17-14
 vibrations, 17-15–17-16
 separable, 448–450
 solution of, 449
 solving, 297
 for vector functions, 735–736, 740
- Differential formula for arc length, 402–403
- Differentials
 arc length, 638–639
 area change substituting, 916
 Chain Rule in, 219, 221–222
 definition of, 218, 820
 error in approximation of, 220–221
 estimating with, 219–220
 forms of, 943, 958–959
 geometric meaning of, 218
 of integration by parts formula, 479–482
 linearization and, 218–223
 for a parametrized surface, 976
 in partial derivatives, 820–821
 surface area, for a parametrized surface, 976
 tangent plane, 820–821
 total, 820–822
- Differentiation
 Chain Rule for implicit, 979
 coefficients determined by, 502
 definition of, 143
 implicit, 184–189
 integration and, relationship between, 349
 logarithmic, 195
 in related rates equations, 209
 rules, 151–160, 729–731
 Chain Rule, 176–184, 731
 choice of, in solving a differentiation problem, 157–158
 for constant function derivatives, 151
 Cross Product Rule, proof of, 730–731
 Derivative Constant Multiple Rule, 152–153, 155
 Derivative Power Rule (*See* Derivative Power Rule)
 Derivative Product Rule, 155–156, 171, 172, 174
 Derivative Quotient Rule, 157–158, 173, 180
 Derivative Sum Rule, 153–154, 171
 Difference Rule, 153–154, 171
 Dot Product Rule, proof of, 730
 for exponential function derivatives, 154–155
 for second-and higher-order derivatives, 158
 for vector functions, 729–731
- Diocles, 188
- Direct Comparison Test, 526–528, 568–569, 583
- Directed line segment to represent vectors, 680
- Direction
 along a path, 931
 cosines, 697
 downhill, 806
 estimating change in a specific, 818
 field, 1026–1027
 forward, 939
 rate of change in, 806
 scalar component in, 694–695
 of vectors, 684–685
- Directional derivatives, 806–814
 calculations of, 808–810
 definition of, 806
 as a dot product, 808–809
 estimating change in a specific direction, 818
 gradient vectors in, 808–814
 interpretation of, 807–808
 in a plane, 806–807
 properties of, 809–810
 zero, 814
- Directrices
 for ellipses, 664–665
 for hyperbolas, 664–665
 of parabolas, 656–657
- Dirichlet, Lejeune, 522
- Dirichlet ruler function, 136

- Discontinuity, 146, 402
 Discontinuous functions, 122–123
 Discriminant of local (relative)
 maxima or minima extrema,
 827–829
 Disk method, 382–385
 Displacement, 162
 definition of, 317
 versus distance traveled, 317–318
 work by force through, 696
 Distance
 formula for points in a plane,
 AP-18
 in a plane, AP-17–AP-19
 from a point to a line, 708
 from a point to a plane, 711
 spheres in space and, 677–678
 squares of, 897
 traveled, 315–318
 displacement *versus*, 317–318
 total distance traveled,
 317–318, 348
 velocity function, 315–318
 between two functions, 19-13
 between two points in the xy -
 plane, formula for, 677–679
 Distributive law for cross products,
 AP-30–AP-31
 Divergence
 curl and, 1009–1010
 Divergence Theorem, 1006–1014
 form of Green's Theorem,
 967–968, 1006
 partial sums in, 555–556
 of series, 552, 555–556
 tests to determine
 for alternating series, 579–583
 Alternating Series Estimation
 Theorem, 581
 Alternating Series Test,
 579–580
 Direct Comparison Test,
 568–569, 583
 geometric series, 553–555, 583
 Limit Comparison Test,
 569–571, 583
 n th-Term Test, 555–556, 583
 p -Series Test, 563, 583
 Ratio Test, 574–575, 583
 Root Test, 576–577, 583
 for series with some negative
 terms, 573, 581–583
 summary of, 583
 in three dimensions,
 1006–1007
 of a vector field, 964–966,
 1006–1007
 Divergence Theorem, 1006–1014
 corollary, 1007
 Green's Theorem compared to,
 1006–1007, 1014
 for other regions, 1011–1012
 proof of, for special regions,
 1010–1011
 for special regions, 1010–1011
 statement of, 1007
 Divergent improper integrals, 523,
 526–528
- Division
 of complex numbers, 18-4
 of functions, 34–35
 Domain
 assumptions on, 951
 connected, 951
 of differentiable functions, 810
 of functions, 21–22, 34
 of functions of several variables,
 767, 768
 natural, 22
 parameter, 973
 restrictions, applied to
 trigonometric functions,
 60–61
 simply connected, 951
 Dominant terms, 116–117
 Domination Rule
 for definite integrals, 334
 for double and triple integrals, 869
 Dot Product Rule, 730
 Dot products, 691–697
 Angle Between Two Vectors,
 691–693
 angles and, 692–693
 definition of, 691
 directional derivatives as, 808–809
 Dot Product Rule, 730
 of gradient vectors, 808–809
 inner product of functions, 19-12,
 19-14–19-15, 19-24
 orthogonal vectors and, 693
 properties of, 693–696
 of three-dimensional vectors,
 19-6
 of two n -dimensional vectors,
 696–697
 work by force through
 displacement, 696
 Double-angle formulas, 45
 Double integrals
 area by, 873–875
 definitions of, 860, 865
 Fubini's Theorem for calculating
 first form, 861–863
 stronger form, 865–868
 iterated or repeated, 861
 limits of integration, finding
 (See Limits of integration,
 finding)
 over general regions, 864–870
 over rectangles, 859–863
 partitions formed by, 859–860
 in polar form, 876–881
 properties of, 869–870
 Riemann sums for, 859–861,
 869, 873
 substitutions in, 915–919
 volumes
 over general regions, 865–868
 over rectangles, 860–861
 of a solid region in space,
 883–884
 Downhill direction, 806
 Drag coefficient, 742
 Drag force, 741–742
 D -tuple of numbers, 19-9
 Dummy variable, 331

- Force
constant, work done by, 410–411
drag, 741–742
fluid
centroids and, 427
on a constant-depth surface, 414–415
pressure and, 414–415
work and, 410–415
done by constant force, 410–411
done by variable force along a line, 411
Hooke's Law, 411–412
lifting objects and pumping liquids from containers, 412–413
work done by, through displacement, 696
- Force constant, 412
- Formula for Implicit Differentiation, 801–803
- Forward direction, 939
- Fourier, Jean-Baptiste Joseph, 19-1
- Fourier coefficients, 19-18–19-19
- Fourier series, 19-1
coefficients in, 19-18–19-19
convergence of, 19-19–19-21
Parseval Equality for, 19-21–19-22
- Fractions
method of partial, 497–502
partial, definition of, 497
- Free fall, 72
- Frenet, Jean-Frédéric, 753
- Frenet frame, 753
- Frequency
in periodic functions, 19-2
Frequency zero, 19-2
- Fubini, Guido, 862
- Fubini's Theorem
for calculating double integrals over general regions (stronger form), 865–868
for calculating double integrals over rectangles (first form), 861–863
- Functions, 21–71
absolute value, 25
adding, 34–35
approximation of, 19-16–19-19
arc length, 402–403, 744
arcsine and arccosine, 61–64
area under the graph of nonnegative, 336–337
arrow diagram of, 22
average value of
for approximating area of rectangles, 319–320
continuous, 337–338
nonnegative continuous, 318–320
in space, 890
- bounded, 81, 136
box, 19-25
circular, 458
on closed intervals, extreme values of, 235–243
combining, 34–41
common, 27–31 (*See also* individual functions)
algebraic, 29–30
exponential, 30, 49–54
inverse, 31, 55–57, 60–61
linear, 27
logarithmic, 31, 57–60
polynomials, 29
power, 27–28
rational, 29
transcendental, 31
trigonometric, 30, 41–49
complex differentiable, 18-18–18-19
of complex variables, 18-12–18-15
component, 725, 937
compositions of, 35–36, 125–126
constant, 27, 81
continuity and, 779–781
of compositions, 781
continuous, definition of, 779
continuous at the point, 779–780
continuous extension, 128–129, 783, 853
partial derivatives and, 789–790
continuously differentiable, 635
critical points of (*See* Critical points)
cube root, 28
cubic, 29
Daubechies scaling, 19-33–19-34
decreasing, 25–26, 250–251
defined by formulas, 34
defined on surfaces, 799–801
definition of, 21
dependent variable of, 21
derivative of, 139, 142–151
differentiable, 786, 792–793
discontinuous, 122–123
distance between two, 19-13
dividing, 34–35
domain of, 21–22, 34, 768
dominant terms in, 116–117
error, 530
even, symmetry properties of, 26–27
exponential (*See* Exponential functions)
extreme values
on closed intervals, 235–243
of continuous functions on closed, bounded sets, 781
saddle points and, 825–832
finitely many, sums of, AP-12–AP-13
Fourier series
convergence of, 19-19–19-21
Parseval Equality for, 19-21–19-22
general sine, 47

- gradient of, 811–813
 graphing with software, 772
 graphs of, 23
 of arcsine and arccosine functions, 62–63
 of catenary, 31
 exponential functions, 30
 logarithmic functions, 31
 reflecting, 36–38
 scaling, 36–38
 shifting, 36
 symmetric, 26–27
 transformations of
 trigonometric, 46–47
 trigonometric functions, 30, 44, 46–47, 62–63
 greatest integer, 25
 growth rates of, 465–469
 Hessian of, 827–829
 hyperbolic (*See* Hyperbolic functions)
 identity, 27, 57, 59, 80–81, 1003
 Implicit Function Theorem, 802–803
 implicitly defined, 184–186
 increasing, 25–26, 250–251
 Increment Theorem of, AP-33–AP-35
 independent variable of, 21
 infinitely many orthonormal, 19-20
 inner product of, 19-12, 19-14–19-15, 19-24
 input variable of, 21, 36
 integer ceiling, 25
 integer floor, 25
 integrable, 19-12–19-13, 331–332
 joint probability density, 899
 least integer, 25
 limits of, 72–137
 linearization of, 819–820
 definition of, 819
 function of two variables, 818–820
 functions of more than two variables, 821–822
 standard linear approximation and, 819–820
 logarithmic, 18-28–18-29
 as a machine, diagram of, 22
 of many variables, 803
 marginal cost, 165–166, 280–281
 maximum and minimum values of, 825–837
 monotonic, 250–255
 of more than two variables
 differential, 821–822
 linearization of, 821–822
 in tangent planes, 821–822
 multiplying, 34–35
 natural domain of, 22
 natural exponential, 52
 natural logarithm, 58
 nonintegrable, 331–332
 nonnegative area under graph of, 337–338
 norm of, 19-12–19-14
 numerical representation of, 24
 odd, symmetry properties of, 26–27
 one-to-one, 54–55
 orthogonal, 19-15, 19-24
 orthogonality of the trigonometric system, 19-15–19-16
 orthonormal, 19-12, 19-15–19-16, 19-20, 19-24, 19-27
 output variable of, 21, 36
 of partial derivatives, 784–793
 periodic, 19-1–19-2
 piecewise continuous, 331, 376
 piecewise-defined, 25
 piecewise-smooth, 728
 position, 25
 positive, area under graph of, 319
 potential, 951
 probability density (*See* Probability density functions)
 proportional relationship of, 27
 Pythagorean Theorem for, 19-15
 quadratic, 29
 range of, 21–22, 768
 real-valued, 22, 725–726, 767–768
 reciprocal, derivative of, 143
 representation as power series, 586–594
 root of, 289
 scalar, 725–726, 930–935, 943, 984
 scaling of, 36–38
 scatterplot of, 24
 of several variables, 767–772
 definitions of, 767
 dependent/independent variables, 767
 differentiability for, 792–793
 domain of, 767, 768
 input/output variables, 767
 partial derivatives of, 767–772
 range of, 767, 768
 real-valued function, 767
 shift formulas for, 36
 sine-integral, 530
 smooth, 399
 square root, 28
 subtracting, 34–35
 symmetric, 26–27, 363–364
 of three variables, 770–772
 boundary of, 771
 boundary points of, 771
 bounded/unbounded regions of, 771
 Chain Rule for, 798–799
 definitions of, 770–772
 gradient vectors in, 811–812
 interior points of, 771
 interior regions of, 771
 level surface of, 770
 open/closed regions of, 771–772
 torsion, of a smooth curve, 755
 total area under graph of, 349–350
 total cost, 166
 transcendental, 31, 445
 trigonometric (*See* Trigonometric functions)
 twice-differentiable, 633–634
 of two variables
 boundary of, 769
 boundary point of, 769
 Chain Rule for, 796–798
 Composition Rule for, 777
 Constant Multiple Rule for, 777
 contours of, 770
 definitions of, 769
 extreme values of, B-6–B-11
 graphs, level curves, and contours of, 770
 graphs/graphing, 770
 Increment Theorem for
 Functions of Two Variables, AP-33–AP-35, 793
 interior of the region of, 769
 interior point of, 769
 level curves of, 770
 limits for, 775–779
 linearization of, 818–820
 more than, 781, 788–789
 open/closed regions of, 769
 partial derivatives of, 784–786
 properties of limits of, 777
 saddle points of, B-6–B-11
 Sandwich Theorem for, 783
 Taylor's formula for, 846–847
 values of local extreme for, 825–829
 unit, 19-13, 19-24
 unit step, 81–82
 values, 22
 limits of, 79–80
 zero, 127
 vector (*See* Vector functions)
 velocity, 315–318, 738–739
 vertical line test for, 24
 Fundamental period, 19-1
 Fundamental Theorem of Algebra, 18-9
 Fundamental Theorem of Calculus, 342–350
 for arc length differential, 638–639
 for continuous vector functions, 735–736
 to define the natural logarithm function $\ln x$ as an integral, 436–438
 differential formula for arc length, 402–403
 Divergence Theorem and, 1014
 double integrals evaluated with, 862
 Fundamental Theorem of Line Integrals, 952–954
 Green's Theorem and, 967
 integration and differentiation in, relationship between, 349
 for line integrals, 930, 931, 952–954
 Part 1 (Mean Value Theorem), 342–345, 438
 proof of, 345
 Part 2 (Evaluation Theorem), 346–347
 Net Change Theorem, 347–348
 proof of, 346–348
 path independence and, 951
 total area and, 349–350
 Fundamental Theorem of Line Integrals, 952–954
 Galileo Galilei, 72
 free fall formula, 72, 164, 168
 law of, 72
 Gauss, Carl Friedrich, 324, 681
 Gauss's Law, 1013
 General exponential function, 443–444
 General linear equation, AP-17
 General quadric surfaces, 716, 718
 General sine function, 47
 General solution, 449
 General solution of differential equations, 297
 Generating curve, 714
 Genetic data and sensitivity to change, 167

 Parseval Equality, 19–21–19–22
 Partial derivatives, 784–793
 calculations of, 787–788
 Chain Rule for, 796–803
 with constrained variables, 848–851
 continuity and, 779–781, 789–790
 continuous, identity function with, 1003
 definitions of, 785–786
 differentiability and, 792–793
 Differentiable Implies Continuous Theorem, 793
 differentials in, 820–821
 directional derivatives and, 806–814
 extreme values and, 781, 825–832
 of a function of two variables, 784–786
 of functions of more than two variables, 788–789, 821–822
 of functions of several variables, 767–772
 gradient vectors and, 806–814
 Increment Theorem for Functions of Two Variables, 793
 Lagrange multipliers, 834–841
 limits for functions of two variables, 775–779
 linearization of a function of two variables, 818–820
 Mixed Derivative Theorem, 790–791
 normal lines and, 815–817
 notation for, 785
 second-order, 790
 of still higher order, 791
 tangent planes and, 815–822
 Partial fractions
 definition of, 497
 integration of rational functions by, 497–502
 method of, 497–502
 Partial sums
 in divergent series, 555–556
 nondecreasing, 561
 n th, 551–553
 of sequences, 551–552
 sequences of, 551–552
 Particles
 path of, 725
 position vector of, 725
 Particular solution, 17–8, 297, 1025–1026
 Partitions
 formed by double integrals over rectangles, 859–860
 k th subinterval of, 327
 norm of, 328, 860
 for Riemann sums, 326–328
 Parts, integration by, 478–483
 evaluating definite integrals, 482–483
 formula, 479–482
 Product Rule in integral form, 442–482
 Pascal, Blaise, 552
 Paths
 Chain Rule for, 813–814
 derivative along, 814
 direction along, 931
 independence, 951
 of particles, 725
 Percentage change, 222
 Perihelion, 669
 Period
 definition of, 19-1
 fundamental, 19-1
 Periodic functions, 19-1–19-2, 44
 Periodic trigonometric functions, 44

 Perpendicular lines, AP-17, 186
 Perpendicular vectors, 693
 Phase angle, 17-17
 Phase lines, 1044–1046
 Phase-plane analysis method, limitations of, 1056
 Phase planes, 1053–1054
 Φ , 907
 Φ -limits of integration, 909, 910
 Physics
 applied optimization in, 279–282
 vectors in, 686
 Piecewise continuous functions, 331, 376
 Piecewise-defined functions, 25
 Piecewise smooth curves, 728
 Pinching Theorem. *See* Sandwich Theorem
 Plane
 angles between, 711–712
 area in, 650–652
 Cartesian coordinates in, AP-13–AP-14
 circle of curvature for plane curves, 749–750
 circles in, AP-17–AP-19
 coordinate, 675–676
 curvature of, 747–749
 curve, flux across, 945–946
 determined by coordinate axes, 675
 determined by or spanned by r and s , 19-9
 distance from a point to, 711
 distance in, AP-17–AP-19
 equation for, 708–709
 flux across, 946
 line integrals in, 934–935
 origin of, 675–676
 points in, AP-18
 tangent (*See* Tangent planes)
 vector equation for, 709
 Plane region
 boundary of, 769
 boundary point of, 769
 bounded, 769
 closed, 769
 definitions of, 769
 interior of, 769
 interior point of, 769
 mass distributed over, 422
 open, 769
 unbounded, 769
 Planetary motion
 Kepler's first law (ellipse law), 760
 Kepler's second law (equal area law), 760–761
 Kepler's third law (time-distance law), 761–762
 Plates
 bounded by two curves, 425–426
 density of, 422
 integral for fluid force against a vertical, 415
 thin, flat, 422–425
 two-dimensional, formulas for, 894
 Points
 boundary, of a region
 closed bounded, absolute maxima and minima on, 829–832
 in Max-Min Tests, 831
 in a plane, 769
 in space, 771
 continuity at, 120–123
 continuous extension to, 128–129
 continuous functions at, 779–780
 critical (*See* Critical points)
 of differentiable functions, 827
 distance between two, in the xy -plane, formula for, 677–679
 distance from a line to, 708
 distance from a plane to, 711
 fixed, 106
 functions that are continuous at, 779
 of inflection, 239, 256–259
 initial, of vectors, 680
 interior, of a region
 closed bounded, absolute maxima and minima on, 829–832
 in a plane, 769
 in space, 771
 in a plane, distance formula for, AP-18
 saddle, 716, 825–832
 standard position for, 681
 Taylor's formula at, 846
 terminal, of vectors, 680
 Point-slope equation, AP-16–AP-17
 Poisson, Siméon-Denis, 825
 Polar coordinates
 acceleration in, 759–762
 area in, 878–879
 area of polar region, 650–652
 areas and lengths in, 650–653
 Cartesian coordinates related to, 643–645
 conic sections, 655–660
 conics in, 663–668
 definition of, 642–643
 equations (*See* Polar equations)
 initial ray in, 642
 integrals in, 876–878
 length of polar curve, 652–653
 of lines, 667
 motion in, 759
 pairs in, 642–643
 polar equations of, 643
 pole (origin) in, 642
 slope of polar curve, 647–648
 symmetry tests for, 647
 velocity in, 759–762
 Polar curve, length of, 652–653
 Polar equations
 for circles, 667–668
 for conics, 665–667
 for ellipses, 665–667
 graphs/graphing, 643–644, 646–649
 Archimedes spiral in, 672
 converting a graph from the $r\theta$ -plane to the xy -plane, 647–648
 lemniscate curves, 649
 limaçons, 650
 slope, 647–648
 symmetry, 647
 technology for, 647–648
 for hyperbolas, 665–667
 for lines, 667
 for parabolas, 665–667
 relating polar and cartesian coordinates, 644–645
 Polar form, double integrals in, 876–881
 Polar moment, 897
 Polar rectangles, 876
 Pole (origin), in polar coordinates, 642
 Polyhedral surfaces, 1002–1003
 Polynomials, 29

Rates of change, 72–77, 161–170
 average, 74, 76–77
 instantaneous, 76–77, 79, 102, 161–162
 marginals, 165–167
 secant lines and, 74
 sensitivity to, 167
 slope of a curve and, defining, 74–76
 in speed, 72–74
 tangent lines and, 76–77
 in velocity, 162–165
Ratio, in geometric series, 553
Rational functions, 29
 coefficients in, determining by differentiating, 502
 integration of, by partial fractions, 497–502
 method used in, general description of, 497–501
 limits at infinity of, 108
 limits of, evaluating, 83
Rational numbers, AP-2, 18-2
Ratio Test, 18-24, 574–575, 583
Real Analysis, 19-13
Real axis, 18-4
Real line, AP-1
Real numbers
 addition property of, AP-27
 algebraic properties of, AP-1, AP-27
 associative laws of, AP-28
 commutativity laws of, AP-28
 completeness property of, AP-1–AP-2, AP-27, AP-28, 547
 construction of reals and, AP-29–AP-30
 definition of, AP-1, AP-2
 irrational, AP-2
 multiplication property of, AP-27
 order properties of, AP-1, AP-28
 real line and, AP-1
 sets of, AP-2
 subsets of, AP-2
 theory of, AP-27–AP-30
Real parts of complex numbers, 18-3–18-4
Reals, construction of, AP-29–AP-30
Real-valued function, 22, 725–726, 767–768
Rearrangement Theorem for Absolutely Convergent Series, 582, 583
Reciprocal
 computing, 18-6
 derivative of, 143
 of sine function, 61
Reciprocal Rule, 58, 160
 for base a logarithm, 444
 for natural logarithms, 441–442
Rectangles, area of
 average value of the function for approximating, 319–320
 between curves, 364–367
 finite approximations, 315–320, 437
 finite sums for estimating, 313–315, 325–326
Fundamental Theorem of Calculus, 343
 under the graph of a nonnegative function, 336
 integration with respect to y , 366–367
 Mean Value Theorem, 342
 Riemann sums for approximating, 327–328, 349
 Riemann sums in defining, 328
 total, 349–350
Rectangles, polar, 876
Rectangular coordinates, 675, 883–890
 average value of a function in space, 890
 definition of, 883
 equations relating cylindrical coordinates to, 903–905
 iterated integrals, 884–890
 properties of, 890
 volume of a solid region in space, 883–884
Rectangular coordinates, triple integrals in, 883–890
 average value of a function in space, 890
 in cylindrical coordinates, 903–907
 definition of, 883
 iterated integrals, 884–890
 properties of, 890
 Riemann sums for, 904, 908
 in spherical coordinates, 907–911
 volume of a solid region in space, 883–884
Rectangular coordinate system, AP-10
Recursion formula, in sequences, 545
Recursive definitions, of sequences, 545–546
Reduction formula, 482, 505–506
Reflection of a graph, 36–38
Reflective property of parabolas, 663
Region
 connected, 951
 Divergence Theorem
 for other regions, 1011–1012
 for special regions, 1010–1011
 exterior of a circle, AP-19
 Green's Theorem for special, 969–970
 interior of a circle, AP-19
 open, 1003–1004
 simply connected, 951
Regression lines, 834
Reindexing series, 557–558
Related rates equations, 206–210.
See also Related rates problem
 Chain Rule in, 206, 208
 differentiation in, 209

- Related rates problem
 consistent units in solving, 210
 definition of, 206
 strategy, 207
 Relative change, 222
 Relative extrema, 826
 Relative (local) maxima or minima
 extrema. *See* Local
 (relative) maxima or
 minima extrema
 Remainder
 in Integral Test, 564–565
 of order n (or error term),
 603–604
 Remainder Estimation Theorem, 604
 Remainder Formula, 564
 Removable discontinuity, 120, 123
 Representations, series, 597–598
 Resistance
 definition of, 17-19
 falling body encountering,
 1047–1049
 proportional to velocity,
 1038–1039
 Resolution level zero
 adding details at, 19-30–19-31
 approximation at, 19-29
 Rest points, 1044–1046
 in graphical solutions of
 autonomous equations,
 1044–1046
 in systems of differential
 equations, 1054–1055
 unstable, 1055
 Resultant vectors, 682
 Revolution
 solids of, 382–387
 disk method, 382–385
 washer method, 385–387
 surface area of, 405–408
 Revolution, areas of surfaces of,
 639–640
 Riemann, Georg Friedrich Bernhard,
 326
 Riemann sums, 326–328
 for approximating area of
 rectangles, 327–328, 349
 for arc length, 400
 in calculus with parametric
 curves, 635
 convergence of, 331
 in defining area of rectangles, 328
 in defining the definite integral,
 329–330
 for double integrals, 859–861
 over area, 873
 over general regions, 869
 over rectangles, 860–861
 for integrals, 380, 422
 limits of, 326–328, 331, 394
 for mass of thin, flat plates, 422
 for mass of thin wires, 421
 notion of, 326–328
 for parametrically defined curves,
 635
 partitions for, 326–328
 in shell method, 394
 slicing by parallel lines, 381
 slicing with cylinders, 392–393
 for spherical coordinates, 904, 908
 total area of rectangles, 349–350
 for triple integrals, 904, 908
 for work done by a variable force,
 411, 413, 415
 Right-continuous function (or
 continuous from the right),
 120–122
 Right-hand derivatives, 145–146
 Right-hand limit (or limit from
 right), AP-25, 99–104,
 120, 122
 Right-hand rule for vectors, 699
 Rise, AP-15
 RL circuits, 1036
 R-limits of integration, 878, 904, 906
 Rolle, Michel, 236, 244
 Rolle's Theorem, 243–244
 Root finding, 127
 Root Rule, AP-23, 82–83, 777
 Roots
 binomial series for, 609–611
 in complex numbers, 18-7–18-9
 finding, 127
 Intermediate Value Theorem and,
 127–128
 linear approximation for, 217
 n th, 18-7–18-8
 principal n th, 18-8
 Root Test, 576–577, 583
 Rule of 70, 71
 Run, AP-15
 Saddle point, 825–832
 definition of, B-9
 of functions of two variables,
 B-6–B-11
 St. Vincent, Gregory, 655
 Sandwich Theorem, AP-25, 543
 Scalar, definition of, 682
 Scalar components of acceleration,
 753–754
 Scalar differential form, 943
 Scalar functions, 725–726
 line integrals of, 930–935
 surface integrals of, formulas
 for, 984
 Scalar Multiple Rules, 730
 Scalar multiplication of vectors,

 n th partial sums in, 551–552
 n th term of, 552
 n th-Term Test for divergent,
 555–556, 583
 p -, 563–565
 of partial sums, 551–553,
 555–556, 561
 power, 586–594
 p -Series Test, 563, 583
 rearranging, 582–583
 reindexing, 557–558
 representations, 597–598
 sigma notation to write, 552
 sum of, 552
 Sum Rule for, 556–557
 Taylor, 598–615
 test to verify convergence, 18-24
 Series Multiplication for Power
 Series, 591
 Sets of real numbers, AP-2, AP-28
 Shell method, 393–396
 Shift formulas, for functions, 36
 Shifting of a graph, 36
 Shift property for definite integrals,
 371
 Sigma notation, 322–325
 in trigonometric polynomials,
 19-5
 to write series, 552
 Σ , 323
 Sigmoid shape of curves, 1050
 Simple harmonic motion,
 17-16–17-17, 172–173
 derivatives of, 172–173
 Simply connected domains and
 regions, 951
 Simpson, Thomas, 501
 Simpson's Rule, 512–517
 approximations by, 512–514
 error analysis and, 514–517
 Sine
 limits involving, 102–104
 summing, 19-3–19-5
 values of, 43
 Sine function, 19-2, 42–43
 arcsine function and, 61–62
 derivatives of, 170–171
 general, 47
 graphs of, 30, 44, 62
 inequalities and, 46

I-18 Subject Index

- Sine function (*continued*)
 odd, 44
 one-to-one, 55, 60–61
 periodicity of, 44
 product of, 490
 products of powers of, 486–487
 reciprocal of, 61
- Sine-integral function, 530
- Sinusoid, 642
- Sinusoid formula, 47
- SI units (*Système International* or International System), 410–411
- Slant line asymptote, 111
- Slicing. *See* Method of slicing
- Slope fields, 1026–1027
- Slope-intercept equation, AP-17
- Slopes
 of the curve, definition of, 138
 negative reciprocal of, AP-17
 of a nonvertical line, AP-15
 of polar curve, 647–648
 on sine curves, 182
 of tangent lines, 138–139, 144
- Smooth curves, 728–729
 curvature of, 747–749
 length of, 743
 principal unit normal vector for, 748
 speed on, 729
 torsion of a, 755
- Smooth function, 399
- Smooth surface, 975–976, 984, 987
- Snell's Law, 280
- Snell van Royen, Willebrord, 279
- Snowflake curve, 560
- Solids, formulas for three-dimensional, 894
- Solids of revolution, 382–387
 Cavalieri's principle, 382
 definition of, 382
 disk method, 382–385
 washer method, 385–387
- Solution curves, 1026–1027
- Solutions
 of differential equations, 449
 of first-order differential equations, 1024–1026
 of first-order linear equations, 1033–1035
 general, 449
 for inequalities, AP-3–AP-4
 particular, 1025–1026
 steady-state, 1053
- Space
 arc length in, 743–745
 average value of a function in, 890
 curves, 725–731, 750–751
 motion in, 734–739
- Space regions
 boundary of, 771–772
 boundary point of, 771
 bounded, 771
 closed, 771–772
 interior point of a, 771
 open, 771–772
 unbounded, 771
- Speed, 162–163
 along smooth curves, 729
- average, 72–74
 initial, in ideal projectile motion, 737
 instantaneous, 73
- Spheres
 parametrization of, 974
 of radius and center, equations for, 678–679
 in space, 677–678
 surface area of, 977
- Spherical coordinates, 907–911
 algebra for finding, 908
 definition of, 907
 equations relating Cartesian and cylindrical coordinates to, 907–909
 geometry for finding, 908
 integration in, 907–911
 limits of integration in, finding, 909–911
 Riemann sums for, 904, 908
- Spin around axis, 961–964
- Spring constant, 412
- Square
 completing, AP-18–AP-19
 conformal maps of, 18–33–18–34
 of the distance, 897
- Square root functions
 definition of, 28
 derivatives of, 144, 146, 191
 linearization and, 216
- Square roots, eliminating, 488
- Square wavelet, 19–24–19–26, 19–31, 19–33–19–34
- Squeeze Theorem. *See* Sandwich Theorem
- Stable equilibria, 1046–1047
- Standard equation
 of an ellipse, AP-21
 of a circle, AP-18
- Standard form of linear equations, 1032–1033
- Standard linear approximations
 definition of, 215, 819
 error in, 820
 line, 215, 819
 linearization and, 215–217
 tangent-plane/tangent-line approximation, 819–820
- Standard position
 angles in, 42
 for a point, 681
- Standard unit vectors, 19–7, 684
- Starting integers, AP-12
- Steady-state solution, 1053
- Steady-state values, 1036
- Steepest descent, method of, B-12–B-14
- Step size, 511
- Still higher order, partial derivatives of, 791
- Stirling, James, 536–537
- Stirling's formula, 536–537
- Stokes' Theorem, 993–1004
 conservative fields and, 1003–1004
 definition of, 995
 Green's Theorem compared to, 995–996, 1002–1003, 1014
- identity arising in mathematics and physical sciences, 1003
 paddle wheel interpretation, 999–1002
 for polyhedral surfaces, proof outline of, 1002–1003
 for surfaces with holes, 1003
- Subsets of real numbers, AP-2
- Subspace, 19-11
- Substitution
 boundaries in, 917–919, 922
 differential area change, 916
 in double integrals, 915–919
 trigonometric, 492–495
 trigonometric, integration by, 492–495
 in triple integrals, 920–922
- Substitution, in integrals
 for definite integrals, 361–367
 areas between curves, 364–366
 integration with respect to y , 366–367
 Substitution Formula, 361–363
 for indefinite integrals, 354–359
 Chain Rule, 354–359
 Substitution Rule, 334, 355–356, 358
 of tangent, cotangent, secant, and cosecant functions, 359
 trying different substitutions, 359
- Substitution Formula, 361–363
- Substitution Rule
 for definite integrals, 334
 definition of, 916
 for indefinite integrals, 355–356, 358
 use of the variable u in, 356
- Subtraction
 derivatives of, 153–154
 of functions, 34–35
 of terms from series, 557
 of vectors, 683
- Sum Rule
 for antiderivatives, 296–297, 299
 to calculate limits of sequences, 542
 for definite integrals, 334
 derivative, AP-12–AP-13
 for derivatives, 153–154, 171
 for double and triple integrals, 869
 for finding complex derivatives, 18-19
 for finite sums, 324
 for gradients, 811
 for limits, AP-23, 82–83, 95
 for limits for functions of two variables, 777
 for series, 556–557
 for vector functions, 730
- Sums
 derivatives of, 153
 of series, 552
- Superposition principle, 17-1
- Surface area, 405–408, 973–981
 of an implicit surface, formula for, 979
 definition of, 405–407
- differential for a parametrized surface, 976
 element, 976
 of a graph, formula for, 981
 parametrization of, 974–978
 of revolution, 405–408
 for revolution about the x -axis, 407
 for revolution about the y -axis, 408
 of a smooth surface, 975–976
 of a sphere, 977
- Surface integrals, 983–991
 definitions of, 984
 for a level surface, computing, 989
 mass density of, 983, 985
 orientation of a surface, 987
 for a parametrized surface, computing, 988–989
 of a scalar function, formulas for, 984
 in Stokes' Theorem, 1003
 thin shells, moments and masses of, 989–991
 of vector fields, 987
- Surfaces
 area (*See* Surface area)
 functions defined on, 799–801
 with holes, in Stokes' Theorem, 1003
 integrals of (*See* Surface integrals)
 level, 770
 orientation of, 987
 parametrization of, 973–981
 of cones, 974
 of cylinders, 974
 by cylindrical coordinates, 974
 of implicit surfaces, 978–981
 of a sphere, 974
 of surface area, 974–978
 plane tangent to, 815–817
 polyhedral, 1002–1003
 saddle points of, 825–832
 smooth, 975–976, 984, 987
 of two-variable functions, 770
- Symmetric functions, definite integrals of, 363–364
- Symmetry tests for polar coordinates, 647
- Synchronous curves, 764
- System of first-order differential equations, 1053–1056
- System torque, 420–421
- Tangent function, 42–43
 derivatives of, 173–174
 graphs of, 44, 62
 integrals of, 359
 integrals of powers of, 488–489
 inverse of, 200–201
 odd, 44
 periodicity of, 44
- Tangential components of acceleration, 753–754
- Tangential form of Green's Theorem, 966–967, 1014
- Tangent lines
 to an ellipse, 810–811, 817

- approximating functions based on, 214 (*See also* Linearization)
- approximation, 819–820
- areas and, 633–634
- to a curve, 74–75
- to a level curve, 810
- to a parabola, 75–76
- rates of change and, 76–77
- vertical, 141–142, 146
- Tangent planes, 815–822
- approximation, 792, 819–820
- definition of, 815, 816
- differentials, 820–821
- estimating change in a specific direction, 818
- functions of more than two variables, 821–822
- linearization of a function of two variables, 818–820
- normal lines and, 815–817
- to a surface, 815–817
- Tangents
- area, 633–634
- to curves, 745
- of curves in space, 725–731
- definition of, 42–43
- unit vectors, 745, 757
- values of, 43
- Tautochrones, 628–629
- Taylor, Brook, 598
- Taylor polynomial, 19-1, 599–601
- Taylor series, 598–615
- applications of, 609–615
- arctangents, 612–613
- binomial series for powers and roots, 609–611
- Euler's identity, 614–615
- evaluating indeterminate forms, 613–614
- evaluating nonelementary integrals, 611–612
- Leibniz's formula, 613
- convergence of, 18-18, 602–607
- Remainder Estimation Theorem, 604
- remainder of order n (or error term), 603–604
- Taylor's Formula, 602–603
- Taylor's Theorem, 602, 607
- using Taylor series in, 605–606
- definition of, 598–599
- frequently used, 615
- Taylor polynomials in, 599–601
- Taylor's Formula, 844–847
- definition of, 602, 603
- to derive the Second Derivative Test, 844–845
- error formula for linear approximations, 845
- for functions of two variables, 846–847
- at the origin, 847
- at the point, 846
- Taylor's Theorem, 514–515
- definition of, 602
- Mean Value Theorem and, 602
- proof of, 607
- Remainder Estimation Theorem and, 604
- Term-by-Term Differentiation, 592–593
- Term-by-Term Integration, 593–594
- Terminal point in parametric equations, 624
- Terminal point of vectors, 680
- Terminal velocity, 355, 1049
- Terms, of sequences, 539
- Theorems
- absolute convergence of series, 18-24
- Absolute Convergence Test, 573
- Algebraic Properties of the Natural Logarithm, 58, 441–442

A Brief Table of Integrals

Basic Forms

1. $\int k dx = kx + C$, k any number
2. $\int x^n dx = \frac{x^{n+1}}{n+1} + C$, $n \neq -1$
3. $\int \frac{dx}{x} = \ln|x| + C$
4. $\int e^x dx = e^x + C$
5. $\int a^x dx = \frac{a^x}{\ln a} + C$ ($a > 0$, $a \neq 1$)
6. $\int \sin x dx = -\cos x + C$
7. $\int \cos x dx = \sin x + C$
8. $\int \sec^2 x dx = \tan x + C$
9. $\int \csc^2 x dx = -\cot x + C$
10. $\int \sec x \tan x dx = \sec x + C$
11. $\int \csc x \cot x dx = -\csc x + C$
12. $\int \tan x dx = \ln|\sec x| + C$
13. $\int \cot x dx = \ln|\sin x| + C$
14. $\int \sinh x dx = \cosh x + C$
15. $\int \cosh x dx = \sinh x + C$
16. $\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin \frac{x}{a} + C$
17. $\int \frac{dx}{a^2 + x^2} = \frac{1}{a} \arctan \frac{x}{a} + C$
18. $\int \frac{dx}{x\sqrt{x^2 - a^2}} = \frac{1}{a} \operatorname{arcsec} \left| \frac{x}{a} \right| + C$
19. $\int \frac{dx}{\sqrt{a^2 + x^2}} = \sinh^{-1} \frac{x}{a} + C$ ($a > 0$)
20. $\int \frac{dx}{\sqrt{x^2 - a^2}} = \cosh^{-1} \frac{x}{a} + C$ ($x > a > 0$)

Forms Involving $ax + b$

21. $\int (ax + b)^n dx = \frac{(ax + b)^{n+1}}{a(n+1)} + C$, $n \neq -1$
22. $\int x(ax + b)^n dx = \frac{(ax + b)^{n+1}}{a^2} \left[\frac{ax + b}{n+2} - \frac{b}{n+1} \right] + C$, $n \neq -1, -2$
23. $\int (ax + b)^{-1} dx = \frac{1}{a} \ln|ax + b| + C$
24. $\int x(ax + b)^{-1} dx = \frac{x}{a} - \frac{b}{a^2} \ln|ax + b| + C$
25. $\int x(ax + b)^{-2} dx = \frac{1}{a^2} \left[\ln|ax + b| + \frac{b}{ax + b} \right] + C$
26. $\int \frac{dx}{x(ax + b)} = \frac{1}{b} \ln \left| \frac{x}{ax + b} \right| + C$

Basic Algebra Formulas

Arithmetic Operations

$$a(b + c) = ab + ac, \quad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}$$

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}, \quad \frac{a/b}{c/d} = \frac{a}{b} \cdot \frac{d}{c}$$

Laws of Signs

$$-(-a) = a, \quad \frac{-a}{b} = -\frac{a}{b} = \frac{a}{-b}$$

Zero Division by zero is not defined.

$$\text{If } a \neq 0: \frac{0}{a} = 0, \quad a^0 = 1, \quad 0^a = 0$$

$$\text{For any number } a: a \cdot 0 = 0 \cdot a = 0$$

Laws of Exponents

$$a^m a^n = a^{m+n}, \quad (ab)^m = a^m b^m, \quad (a^m)^n = a^{mn}, \quad a^{m/n} = \sqrt[n]{a^m} = (\sqrt[n]{a})^m$$

If $a \neq 0$, then

$$\frac{a^m}{a^n} = a^{m-n}, \quad a^0 = 1, \quad a^{-m} = \frac{1}{a^m}.$$

The Binomial Theorem For any positive integer n ,

$$(a + b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{1 \cdot 2}a^{n-2}b^2 \\ + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}a^{n-3}b^3 + \dots + nab^{n-1} + b^n.$$

For instance,

$$(a + b)^2 = a^2 + 2ab + b^2, \quad (a - b)^2 = a^2 - 2ab + b^2 \\ (a + b)^3 = a^3 + 3a^2b + 3ab^2 + b^3, \quad (a - b)^3 = a^3 - 3a^2b + 3ab^2 - b^3.$$

Factoring the Difference of Like Integer Powers, $n > 1$

$$a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \dots + ab^{n-2} + b^{n-1})$$

For instance,

$$a^2 - b^2 = (a - b)(a + b), \\ a^3 - b^3 = (a - b)(a^2 + ab + b^2), \\ a^4 - b^4 = (a - b)(a^3 + a^2b + ab^2 + b^3).$$

Completing the Square If $a \neq 0$, then

$$ax^2 + bx + c = au^2 + C \quad \left(u = x + (b/2a), C = c - \frac{b^2}{4a} \right).$$

The Quadratic Formula

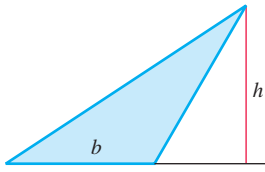

If $a \neq 0$ and $ax^2 + bx + c = 0$, then

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

Geometry Formulas

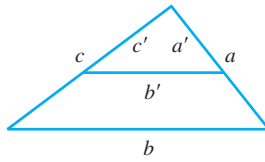

A = area, B = area of base, C = circumference, S = surface area, V = volume

Triangle

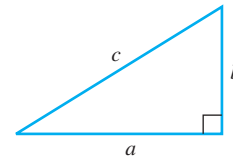

$$A = \frac{1}{2}bh$$

Similar Triangles

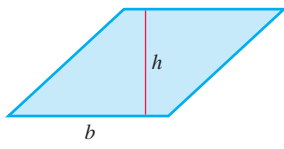

$$\frac{a'}{a} = \frac{b'}{b} = \frac{c'}{c}$$

Pythagorean Theorem

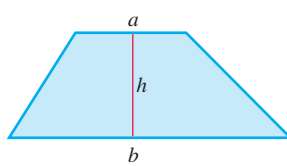

$$a^2 + b^2 = c^2$$

Parallelogram

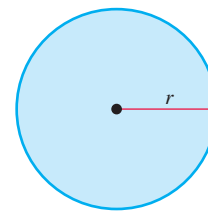

$$A = bh$$

Trapezoid

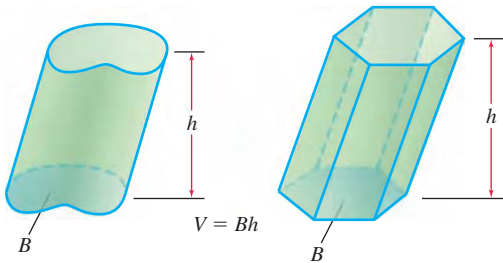

$$A = \frac{1}{2}(a + b)h$$

Circle

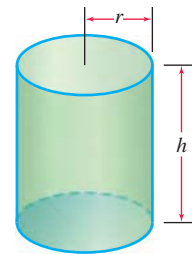

$$A = \pi r^2, \\ C = 2\pi r$$

Any Cylinder or Prism with Parallel Bases

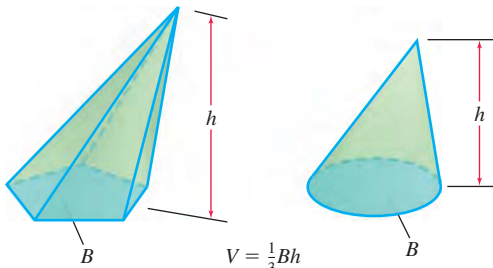

$$V = Bh$$

Right Circular Cylinder

$$V = \pi r^2 h \\ S = 2\pi r h = \text{Area of side}$$

Any Cone or Pyramid

$$V = \frac{1}{3}Bh$$

Right Circular Cone

$$V = \frac{1}{3}\pi r^2 h \\ S = \pi r s = \text{Area of side}$$

Sphere

$$V = \frac{4}{3}\pi r^3, S = 4\pi r^2$$

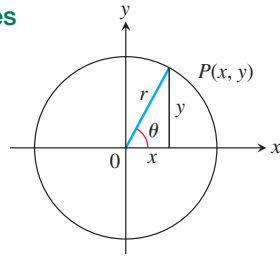

Trigonometry Formulas

Definitions and Fundamental Identities

Sine: $\sin \theta = \frac{y}{r} = \frac{1}{\csc \theta}$

Cosine: $\cos \theta = \frac{x}{r} = \frac{1}{\sec \theta}$

Tangent: $\tan \theta = \frac{y}{x} = \frac{1}{\cot \theta}$

Identities

$\sin(-\theta) = -\sin \theta, \cos(-\theta) = \cos \theta$

$\sin^2 \theta + \cos^2 \theta = 1, \sec^2 \theta = 1 + \tan^2 \theta, \csc^2 \theta = 1 + \cot^2 \theta$

$\sin 2\theta = 2 \sin \theta \cos \theta, \cos 2\theta = \cos^2 \theta - \sin^2 \theta$

$\cos^2 \theta = \frac{1 + \cos 2\theta}{2}, \sin^2 \theta = \frac{1 - \cos 2\theta}{2}$

$\sin(A + B) = \sin A \cos B + \cos A \sin B$

$\sin(A - B) = \sin A \cos B - \cos A \sin B$

$\cos(A + B) = \cos A \cos B - \sin A \sin B$

$\cos(A - B) = \cos A \cos B + \sin A \sin B$

$$\tan(A + B) = \frac{\tan A + \tan B}{1 - \tan A \tan B}$$

$$\tan(A - B) = \frac{\tan A - \tan B}{1 + \tan A \tan B}$$

$$\sin\left(A - \frac{\pi}{2}\right) = -\cos A, \quad \cos\left(A - \frac{\pi}{2}\right) = \sin A$$

$$\sin\left(A + \frac{\pi}{2}\right) = \cos A, \quad \cos\left(A + \frac{\pi}{2}\right) = -\sin A$$

$$\sin A \sin B = \frac{1}{2} \cos(A - B) - \frac{1}{2} \cos(A + B)$$

$$\cos A \cos B = \frac{1}{2} \cos(A - B) + \frac{1}{2} \cos(A + B)$$

$$\sin A \cos B = \frac{1}{2} \sin(A - B) + \frac{1}{2} \sin(A + B)$$

$$\sin A + \sin B = 2 \sin \frac{1}{2}(A + B) \cos \frac{1}{2}(A - B)$$

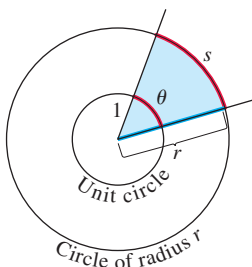

$$\sin A - \sin B = 2 \cos \frac{1}{2}(A + B) \sin \frac{1}{2}(A - B)$$

$$\cos A + \cos B = 2 \cos \frac{1}{2}(A + B) \cos \frac{1}{2}(A - B)$$

$$\cos A - \cos B = -2 \sin \frac{1}{2}(A + B) \sin \frac{1}{2}(A - B)$$

Trigonometric Functions

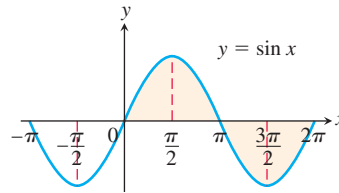

Radian Measure

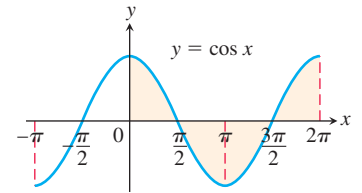

$\frac{s}{r} = \frac{\theta}{1} = \theta$ or $\theta = \frac{s}{r}$,
 $180^\circ = \pi$ radians.

Degrees	Radians

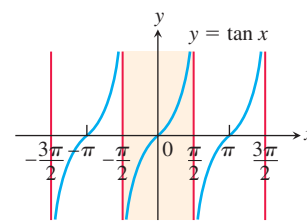

The angles of two common triangles, in degrees and radians.

 Range: $(-\infty, \infty)$

Series

Tests for Convergence of Infinite Series

- 1. The n th-Term Test:** Unless $a_n \rightarrow 0$, the series diverges.
- 2. Geometric series:** $\sum ar^n$ converges if $|r| < 1$; otherwise it diverges.
- 3. p -series:** $\sum 1/n^p$ converges if $p > 1$; otherwise it diverges.
- 4. Series with nonnegative terms:** Try the Integral Test, Ratio Test, or Root Test. Try comparing to a known series with the Comparison Test or the Limit Comparison Test.
- 5. Series with some negative terms:** Does $\sum |a_n|$ converge? If yes, so does $\sum a_n$ because absolute convergence implies convergence.
- 6. Alternating series:** $\sum a_n$ converges if the series satisfies the conditions of the Alternating Series Test.

Taylor Series

$$\frac{1}{1-x} = 1 + x + x^2 + \cdots + x^n + \cdots = \sum_{n=0}^{\infty} x^n, \quad |x| < 1$$

$$\frac{1}{1+x} = 1 - x + x^2 - \cdots + (-x)^n + \cdots = \sum_{n=0}^{\infty} (-1)^n x^n, \quad |x| < 1$$

$$e^x = 1 + x + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!} + \cdots = \sum_{n=0}^{\infty} \frac{x^n}{n!}, \quad |x| < \infty$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{(2n+1)!}, \quad |x| < \infty$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \cdots + (-1)^n \frac{x^{2n}}{(2n)!} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!}, \quad |x| < \infty$$

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \cdots + (-1)^{n-1} \frac{x^n}{n} + \cdots = \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^n}{n}, \quad -1 < x \leq 1$$

$$\ln \frac{1+x}{1-x} = 2 \tanh^{-1} x = 2 \left(x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots + \frac{x^{2n+1}}{2n+1} + \cdots \right) = 2 \sum_{n=0}^{\infty} \frac{x^{2n+1}}{2n+1}, \quad |x| < 1$$

$$\arctan x = x - \frac{x^3}{3} + \frac{x^5}{5} - \cdots + (-1)^n \frac{x^{2n+1}}{2n+1} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{2n+1}, \quad |x| \leq 1$$

Binomial Series

$$\begin{aligned} (1+x)^m &= 1 + mx + \frac{m(m-1)x^2}{2!} + \frac{m(m-1)(m-2)x^3}{3!} + \cdots + \frac{m(m-1)(m-2)\cdots(m-k+1)x^k}{k!} + \cdots \\ &= 1 + \sum_{k=1}^{\infty} \binom{m}{k} x^k, \quad |x| < 1, \end{aligned}$$

where

$$\binom{m}{1} = m, \quad \binom{m}{2} = \frac{m(m-1)}{2!}, \quad \binom{m}{k} = \frac{m(m-1)\cdots(m-k+1)}{k!} \quad \text{for } k \geq 3.$$

Vector Operator Formulas (Cartesian Form)

Formulas for Grad, Div, Curl, and the Laplacian

Cartesian (x, y, z) \mathbf{i} , \mathbf{j} , and \mathbf{k} are unit vectors in the directions of increasing x , y , and z . M , N , and P are the scalar components of $\mathbf{F}(x, y, z)$ in these directions.

Gradient $\nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} + \frac{\partial f}{\partial z} \mathbf{k}$

Divergence $\nabla \cdot \mathbf{F} = \frac{\partial M}{\partial x} + \frac{\partial N}{\partial y} + \frac{\partial P}{\partial z}$

Curl $\nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ M & N & P \end{vmatrix}$

Laplacian $\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$

Vector Triple Products

$$(\mathbf{u} \times \mathbf{v}) \cdot \mathbf{w} = (\mathbf{v} \times \mathbf{w}) \cdot \mathbf{u} = (\mathbf{w} \times \mathbf{u}) \cdot \mathbf{v}$$

$$\mathbf{u} \times (\mathbf{v} \times \mathbf{w}) = (\mathbf{u} \cdot \mathbf{w})\mathbf{v} - (\mathbf{u} \cdot \mathbf{v})\mathbf{w}$$

Vector Identities

In the identities here, f and g are differentiable scalar functions; \mathbf{F} , \mathbf{F}_1 , and \mathbf{F}_2 are differentiable vector fields; and a and b are real constants.

$$\nabla \times (\nabla f) = \mathbf{0}$$

$$\nabla(fg) = f\nabla g + g\nabla f$$

$$\nabla \cdot (g\mathbf{F}) = g\nabla \cdot \mathbf{F} + \nabla g \cdot \mathbf{F}$$

$$\nabla \times (g\mathbf{F}) = g\nabla \times \mathbf{F} + \nabla g \times \mathbf{F}$$

$$\nabla \cdot (a\mathbf{F}_1 + b\mathbf{F}_2) = a\nabla \cdot \mathbf{F}_1 + b\nabla \cdot \mathbf{F}_2$$

$$\nabla \times (a\mathbf{F}_1 + b\mathbf{F}_2) = a\nabla \times \mathbf{F}_1 + b\nabla \times \mathbf{F}_2$$

$$\nabla(\mathbf{F}_1 \cdot \mathbf{F}_2) = (\mathbf{F}_1 \cdot \nabla)\mathbf{F}_2 + (\mathbf{F}_2 \cdot \nabla)\mathbf{F}_1 +$$

$$\mathbf{F}_1 \times (\nabla \times \mathbf{F}_2) + \mathbf{F}_2 \times (\nabla \times \mathbf{F}_1)$$

The Fundamental Theorem of Line Integrals

Part 1 Let $\mathbf{F} = M\mathbf{i} + N\mathbf{j} + P\mathbf{k}$ be a vector field whose components are continuous throughout an open connected region D in space. Then there exists a differentiable function f such that

$$\mathbf{F} = \nabla f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} + \frac{\partial f}{\partial z} \mathbf{k}$$

if and only if, for all points A and B in D , the value of $\int_A^B \mathbf{F} \cdot d\mathbf{r}$ is independent of the path joining A to B in D .

Part 2 If the integral is independent of the path from A to B , its value is

$$\int_A^B \mathbf{F} \cdot d\mathbf{r} = f(B) - f(A).$$

Green's Theorem and Its Generalization to Three Dimensions

Tangential form of Green's Theorem: $\oint_C \mathbf{F} \cdot \mathbf{T} ds = \iint_R (\nabla \times \mathbf{F}) \cdot \mathbf{k} dA$

Stokes' Theorem: $\oint_C \mathbf{F} \cdot \mathbf{T} ds = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} d\sigma$

Normal form of Green's Theorem: $\oint_C \mathbf{F} \cdot \mathbf{n} ds = \iint_R (\nabla \cdot \mathbf{F}) dA$

Divergence Theorem: $\iint_S \mathbf{F} \cdot \mathbf{n} d\sigma = \iiint_D \nabla \cdot \mathbf{F} dV$

Limits

General Laws

If L, M, c , and k are real numbers and

$$\lim_{x \rightarrow c} f(x) = L \quad \text{and} \quad \lim_{x \rightarrow c} g(x) = M, \quad \text{then}$$

Sum Rule: $\lim_{x \rightarrow c} (f(x) + g(x)) = L + M$

Difference Rule: $\lim_{x \rightarrow c} (f(x) - g(x)) = L - M$

Product Rule: $\lim_{x \rightarrow c} (f(x) \cdot g(x)) = L \cdot M$

Constant Multiple Rule: $\lim_{x \rightarrow c} (k \cdot f(x)) = k \cdot L$

Quotient Rule: $\lim_{x \rightarrow c} \frac{f(x)}{g(x)} = \frac{L}{M}, \quad M \neq 0$

The Sandwich Theorem

If $g(x) \leq f(x) \leq h(x)$ in an open interval containing c , except possibly at $x = c$, and if

$$\lim_{x \rightarrow c} g(x) = \lim_{x \rightarrow c} h(x) = L,$$

then $\lim_{x \rightarrow c} f(x) = L$.

Inequalities

If $f(x) \leq g(x)$ in an open interval containing c , except possibly at $x = c$, and both limits exist, then

$$\lim_{x \rightarrow c} f(x) \leq \lim_{x \rightarrow c} g(x).$$

Continuity

If g is continuous at L and $\lim_{x \rightarrow c} f(x) = L$, then

$$\lim_{x \rightarrow c} g(f(x)) = g(L).$$

Specific Formulas

If $P(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_0$, then

$$\lim_{x \rightarrow c} P(x) = P(c) = a_n c^n + a_{n-1} c^{n-1} + \dots + a_0.$$

If $P(x)$ and $Q(x)$ are polynomials and $Q(c) \neq 0$, then

$$\lim_{x \rightarrow c} \frac{P(x)}{Q(x)} = \frac{P(c)}{Q(c)}.$$

If $f(x)$ is continuous at $x = c$, then

$$\lim_{x \rightarrow c} f(x) = f(c).$$

$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = 1 \quad \text{and} \quad \lim_{x \rightarrow 0} \frac{1 - \cos x}{x} = 0$$

L'Hôpital's Rule

If $f(a) = g(a) = 0$, both f' and g' exist in an open interval I containing a , and $g'(x) \neq 0$ on I if $x \neq a$, then

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \lim_{x \rightarrow a} \frac{f'(x)}{g'(x)},$$

assuming the limit on the right side exists.

Differentiation Rules

General Formulas

Assume u and v are differentiable functions of x .

Constant: $\frac{d}{dx}(c) = 0$

Sum: $\frac{d}{dx}(u + v) = \frac{du}{dx} + \frac{dv}{dx}$

Difference: $\frac{d}{dx}(u - v) = \frac{du}{dx} - \frac{dv}{dx}$

Constant Multiple: $\frac{d}{dx}(cu) = c \frac{du}{dx}$

Product: $\frac{d}{dx}(uv) = u \frac{dv}{dx} + \frac{du}{dx} v$

Quotient: $\frac{d}{dx}\left(\frac{u}{v}\right) = \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2}$

Power: $\frac{d}{dx} x^n = nx^{n-1}$

Chain Rule: $\frac{d}{dx}(f(g(x))) = f'(g(x)) \cdot g'(x)$

Trigonometric Functions

$$\frac{d}{dx}(\sin x) = \cos x \quad \frac{d}{dx}(\cos x) = -\sin x$$

$$\frac{d}{dx}(\tan x) = \sec^2 x \quad \frac{d}{dx}(\sec x) = \sec x \tan x$$

$$\frac{d}{dx}(\cot x) = -\csc^2 x \quad \frac{d}{dx}(\csc x) = -\csc x \cot x$$

Exponential and Logarithmic Functions

$$\frac{d}{dx} e^x = e^x \quad \frac{d}{dx} \ln x = \frac{1}{x}$$

$$\frac{d}{dx} a^x = a^x \ln a \quad \frac{d}{dx} (\log_a x) = \frac{1}{x \ln a}$$

Inverse Trigonometric Functions

$$\frac{d}{dx}(\arcsin x) = \frac{1}{\sqrt{1-x^2}} \quad \frac{d}{dx}(\arccos x) = -\frac{1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx}(\arctan x) = \frac{1}{1+x^2} \quad \frac{d}{dx}(\operatorname{arcsec} x) = \frac{1}{|x|\sqrt{x^2-1}}$$

$$\frac{d}{dx}(\operatorname{arccot} x) = -\frac{1}{1+x^2} \quad \frac{d}{dx}(\operatorname{arccsc} x) = -\frac{1}{|x|\sqrt{x^2-1}}$$

Hyperbolic Functions

$$\frac{d}{dx}(\sinh x) = \cosh x \quad \frac{d}{dx}(\cosh x) = \sinh x$$

$$\frac{d}{dx}(\tanh x) = \operatorname{sech}^2 x \quad \frac{d}{dx}(\operatorname{sech} x) = -\operatorname{sech} x \tanh x$$

$$\frac{d}{dx}(\operatorname{coth} x) = -\operatorname{csch}^2 x \quad \frac{d}{dx}(\operatorname{csch} x) = -\operatorname{csch} x \operatorname{coth} x$$

Inverse Hyperbolic Functions

$$\frac{d}{dx}(\sinh^{-1} x) = \frac{1}{\sqrt{1+x^2}} \quad \frac{d}{dx}(\cosh^{-1} x) = \frac{1}{\sqrt{x^2-1}}$$

$$\frac{d}{dx}(\tanh^{-1} x) = \frac{1}{1-x^2} \quad \frac{d}{dx}(\operatorname{sech}^{-1} x) = -\frac{1}{x\sqrt{1-x^2}}$$

$$\frac{d}{dx}(\operatorname{coth}^{-1} x) = \frac{1}{1-x^2} \quad \frac{d}{dx}(\operatorname{csch}^{-1} x) = -\frac{1}{|x|\sqrt{1+x^2}}$$

Parametric Equations

If $x = f(t)$ and $y = g(t)$ are differentiable, then

$$y' = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} \quad \text{and} \quad \frac{d^2y}{dx^2} = \frac{dy'/dt}{dx/dt}$$

Integration Rules

General Formulas

Zero:
$$\int_a^a f(x) dx = 0$$

Order of Integration:
$$\int_b^a f(x) dx = -\int_a^b f(x) dx$$

Constant Multiples:
$$\int_a^b kf(x) dx = k \int_a^b f(x) dx, \quad k \text{ any number}$$

$$\int_a^b -f(x) dx = -\int_a^b f(x) dx, \quad k = -1$$

Sums and Differences:
$$\int_a^b (f(x) \pm g(x)) dx = \int_a^b f(x) dx \pm \int_a^b g(x) dx$$

Additivity:
$$\int_a^b f(x) dx + \int_b^c f(x) dx = \int_a^c f(x) dx$$

Max-Min Inequality: If $\max f$ and $\min f$ are the maximum and minimum values of f on $[a, b]$, then

$$\min f \cdot (b - a) \leq \int_a^b f(x) dx \leq \max f \cdot (b - a).$$

Domination: $f(x) \geq g(x)$ on $[a, b]$ implies $\int_a^b f(x) dx \geq \int_a^b g(x) dx.$

$$f(x) \geq 0 \text{ on } [a, b] \text{ implies } \int_a^b f(x) dx \geq 0.$$

The Fundamental Theorem of Calculus

Part 1 If f is continuous on $[a, b]$, then $F(x) = \int_a^x f(t) dt$ is continuous on $[a, b]$ and differentiable on (a, b) , and its derivative is $f(x)$:

$$F'(x) = \frac{d}{dx} \int_a^x f(t) dt = f(x).$$

Part 2 If f is continuous at every point of $[a, b]$ and F is any antiderivative of f on $[a, b]$, then

$$\int_a^b f(x) dx = F(b) - F(a).$$

Substitution in Definite Integrals

$$\int_a^b f(g(x)) \cdot g'(x) dx = \int_{g(a)}^{g(b)} f(u) du$$

Integration by Parts

$$\int_a^b u(x)v'(x) dx = u(x)v(x) \Big|_a^b - \int_a^b v(x)u'(x) dx$$
